A two-region model of the turbulent boundary layer forms the basis for an analysis of equilibrium temperatures and heat transfer when helium injection is used as a method of cooling at high speeds. The fluid properties entering through the Prandtl number, Schmidt number and Lewis number are assumed to vary only with concentration. It is found that both equilibrium temperatures and heat transfer are reduced for all injection rates, and that the reduction in skin friction due to injection should be relatively greater than that for laminar flow. Final quantitative results will require a knowledge of the variation of skin friction and velocity at the sub-layer edge with injection. (Contractor's abstract)

PROPOSED COINCIDENCE METHOD FOR THE ELIMINATION OF THE DOPPLER EFFECT, by P. L. Sagalyn. [1956] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at Spectroscopy Symposium, Argonne National Labs., Lemont, Ill., Feb. 15-17, 1956.

Published in Spectrochimica Acta, v. 8: 188, Sept. 1956.

Brannen et al had recently shown that the coincidence rate between pairs of photons, emitted successively by the same atom, can be measured. A method is now devised using coincidence techniques, which in principle enables one to measure the wave-lengths of emission spectra with considerably greater resolution than would be allowed by the Doppler effect. Light from a very weakly excited source is passed through a spectrograph whose resolution is assumed high compared with Doppler width, thereby giving in the focal plane two lines with widths corresponding to the Doppler width. Two slits are used, a fixed reference slit in front of, say, line 1, and a movable scanning slit in front of line 2. Two photomultipliers are used, one behind each slit, and are connected to a coincidence counter through individual channel counters. The true coincidence rate is measured as a function of the position of the movable slit. The momentum of a photon is negligible with respect to that of an atom, and therefore, if the source is operated so that the atom is not perturbed during the lifetime of the intermediate level, the velocity of the atom will not change between the two transitions and the Doppler shifts of the two photons will be the same. The coincidence rate will then show a maximum when the two slits have the same relative positions on the two lines. The width of the response curve will depend on the slit-width and on the resolving power and aperture of the spectrograph, but not on the Doppler width. Estimated counting times for 0.1 Doppler width resolution are of the order of minutes.

RADIO FREQUENCY EXPERIMENTS IN MERCURY 3P_1 , by P. L. Sagalyn. [1956] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at Spectroscopy Symposium, Argonne National Labs., Lemont, Ill., Feb. 15-17, 1956.

Published in Spectrochimica Acta, v. 8: 188, Sept. 1956.

An apparatus has been constructed for studying radio frequency transitions in the 3P_1 state of the various mercury isotopes. The "double resonance" technique is used. Mercury atoms are excited by polarized light from a mercury arc, containing pure Hg¹⁹⁸, and placed in a magnetic field called the "scanning field." The mercury absorption cell is placed in a steady magnetic field, called the "splitting field," and subjected to an oscillating magnetic field at right angles to the splitting field. The re-emitted light is passed through a suitable polarizer to a photomultiplier and the photomultiplier current is amplified and displayed on a long persistence screen oscilloscope as a function of the splitting field. The splitting field is swept slowly by a low-frequency sinusoidal voltage applied to an auxiliary coil. The deflection of the oscilloscope trace at resonance is the "resonance amplitude." The splitting and scanning-field magnitudes are measured with a nuclear resonance magnetometer. With this apparatus one can study: (1) the g factors of the excited state; (2) if one plots the resonance amplitude as a function of the scanning field, the positions of the maxima provide a new method of measuring isotope shift, which eliminates the effects of overlapping lines whose g-factors differ; (3) at microwave frequencies, the splitting fields required for the odd isotope resonances provide a measurement of the magnetic hyperfine structure interaction. Results for the even isotopes taken at 3100 mc/sec are presented. (Contractor's abstract)

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 85, Jan. 30, 1957.

Also published in Phys. Rev., v. 106: 196-199, Apr. 15, 1957.

The conventional microwave method for measuring plasma electron densities is limited in its validity to relatively low concentrations ($\sim 10^9 \text{ cm}^{-3}$). Following a theoretical development by Persson, a method is presented whereby much higher densities can be measured. The method is based on eliminating the effect of ac space

MIT.12:149 - MIT.12:152

charge on the probing microwave field. This is accomplished by ensuring that the electric field be everywhere perpendicular to electron-density gradients. A discussion is presented on the effect of neighboring modes on the measuring mode in a microwave cavity. (Contractor's abstract)

OUTLINE OF LEBESGUE THEORY: A HEURISTIC INTRODUCTION, by R. E. Wernikoff. Jan. 11, 1957, 73p. incl. diags. refs. (Technical rept. no. 310) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 143098 Unclassified

A heuristic exposition is presented of measure theory and the theory of integration which derives from it. The aim is to acquaint communication engineers with terminology useful in probability and ergodic theories, statistics, and the theory of linear operators in function spaces. The Riemann definition of the integral is reviewed and some of the basic properties of the integral are derived. By means of an example, definite limitations to the class of functions to which the Riemann definition applies are pointed out. In finding an approach which makes these limitations irrelevant, a new point of view is presented which leads to a rudimentary form of Lebesgue's definition of the integral. The measure theory is discussed by answering 2 questions dealing with properties of a set function to make it correspond to the useful χ script (E) function, and with the domain over which such a set function can be defined. The integral is rigorously defined and some of its properties are derived. Convergence and limit are defined when a sequence of functions is given instead of a sequence of numbers. Conditions are established under which the order of a limit process and integration may be interchanged; some examples are given. Set functions, absolute continuity, and differentiation are discussed. (ASTIA abstract)

STARK EFFECT ON THE HYPERFINE STRUCTURE OF CESIUM¹³³, by R. D. Haun, Jr. Jan. 18, 1957, 64p. incl. diags. tables, refs. (Technical rept. no. 322) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 200290 Unclassified

Also published in *Phys. Rev.*, v. 107: 107-109, July 1, 1957.

The change of the hyperfine-structure separation energy caused by an electric field has been measured in cesium¹³³ by the atomic-beam magnetic-resonance method. The shift of the $(F = 4, m_F = 0) \rightarrow (F = 3, m_F = 0)$ transition frequency (9192.6 mc/sec) caused by electric field ξ is given by $\Delta(\xi) = -2.29 \times 10^{-6} (1 \pm .03) \xi^2$ cps, where ξ is in volt/cm. This number is 2.8 times the value predicted from the atomic polarizability measurements of H. Scheffers and J. Stark, if a simplified theory that neglects hyperfine-structure perturbations of the ground-state wave functions is used. A more precise theory which takes into account these wave-function differences has been outlined but the calculations have not been carried out in detail. A means has yet to be developed which will enable the difference between the $F = 4$ and the $F = 3$ wave functions to be taken into account.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 87, Jan. 30, 1957.

The method used by Gould and Brown for determining the electron collision probability for momentum transfer in helium by measuring the microwave conductivity of a decaying plasma as a function of the electron energy, controlled by a microwave heating field, has been used for determining the same parameter in neon. In this case, due to the smaller value of the electron collision probability and the larger atomic mass of neon as compared to helium, energy gradients produced by the heating field nonuniformities are very important in determining an energy redistribution inside the plasma. The conditions required for having a pressure independent ratio of the real to the imaginary part of the complex conductivity and for reaching steady-state electron energy conditions are theoretically investigated. From the measured microwave conductivity in neon contaminated with argon, the electron collision probability in neon has been computed as a function of the electron energy; the curve joins Ramsauer and Kollath's measurements for higher electron energies.

PLASMA OSCILLATIONS IN DC DISCHARGES (Abstract), by E. I. Gordon. [1957] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637])
Unclassified

Presented at the Ninth Annual Gaseous Electronics Conf., Pittsburgh, Pa., Oct. 31-Nov. 3, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 85-86, Jan. 30, 1957.

A general result for the conductivity of a plasma when the rf field exists in a region not necessarily large compared to a mean free path is shown to be

$$\sigma = -\frac{4\pi}{3} \frac{ne^2}{m} \int_0^\infty [(j\omega + \nu_c)^{-1} - (j\omega + \nu_3)^{-2} 3v/4d] v^3 f(v) dv,$$

where n is the electron density, ω the angular frequency, d the width of the region, $\nu_c(v)$ the collision frequency,

and $f(v)$ is the isotropic velocity distribution. In analogy with Margenau's result, this leads to an effective collision frequency $\nu(v) = \nu_c(v) + 3v/4d$, so that the damping

of plasma oscillations is pressure dependent only when the mean free path is comparable to d (order of a mm). It is shown that under conditions satisfied only in the sheath-plasma boundary region, a monoenergetic beam of electrons may have a conductivity whose real part is negative. Consequently, the beam could supply sufficient energy to maintain the oscillations if the beam current density is greater than a minimum value proportional to ω^2 . Results for double beam oscillations are also described and compared with experiment.

Presented at meeting of the Acoustical Soc. of Amer., Los Angeles, Calif., Nov. 15-17, 1956.

Published in Jour. Acoust. Soc. Amer., v. 29: 184, Jan. 1957.

When acoustic stimuli of duration longer than 0.1 sec are turned off, one frequently records electrical responses at cortical and cochlear locations. Several observations suggest that these "off"-responses are related to acoustic transients. Certain conditions under which cortical off-responses to transients occur have been determined. The stimuli were mostly bursts of tone (about 30 db above threshold) whose frequencies at each location of the recording electrode were specifically not those to which the cortical point was most sensitive. The large "off"-responses obtained are sensitive to decay-time, duration and intensity of the tonal stimulus; they can be masked by noise and they resemble in wave-forms the

MIT.12:156 - MIT.12:158

responses evoked by clicks at the same cortical location. When the stimuli were bursts of noise no "off"-responses were observed. These results may be interpreted in terms of the refractory characteristics of groups of neurones. Throughout the period of tonal stimulation, a large proportion of the available cortical neurones is inactive; stimulation with noise, on the other hand, activates many of these neurones. "Off"-responses become detectable when numerous non-refractory cortical neurones are available to fire synchronously. Recordings from cochlear locations support the interpretation.

PITCH JUDGEMENTS FOR REPEATED BURSTS OF TONE AND NOISE (Abstract), by M. H. Goldstein, Jr. [1957] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at the meeting of the Acoustical Soc. of Amer., Los Angeles, Calif., Nov. 15-17, 1956.

Published in Jour. Acoust. Soc. Amer., v. 29: 184, Jan. 1957.

Recently much interest has been shown in the study of pitch judgements for complex auditory stimuli. In the present investigation five subjects were instructed to judge which of a pair of stimuli sounded higher in pitch. One stimulus, the standard, of every pair had a repetition rate of 200/sec; the variable stimulus had a repetition rate that ranged from 175/sec to 225/sec. Within a given pair the stimuli differed thus with respect to modulation rate; the signal to be modulated remained the same. The results of three experiments are reported: in two experiments the stimuli were bursts of 2000 cps tones having different rise times while the third experiment involved bursts of wide-band noise. For repetition rates in the vicinity of 200/sec the difference limen for burst rate is smaller for bursts containing tonal stimuli than for bursts of wide-band noise. These data are discussed in relation to the findings of Miller and Taylor, Small, DeBoer, and Nowbray et al.

QUANTUM MECHANICAL AMPLIFIERS, by M. W. P. Strandberg. 1957 [2]p. incl. diagr. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 127598 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 45: 92-93, Jan. 1957.

The theoretical aspects of quantum mechanical amplifiers are presented. Recent work on these systems seems to have been restricted to the use of molecular beams and ammonia gas. The operation of a molecular amplifier is based on the principle of creating a nonequilibrium thermodynamic state which can be made to last long enough for net energy to be extracted. The two paramagnetic spin states of either a proton or an electron in a magnetic field are cited as the bases for systems offering marked advantages over the ammonia maser.

First, spin densities 10^5 larger may be achieved, and further, they are simply turnable by means of magnetic field. Other attributes of quantum mechanical amplifiers are considered, such as the possibility they offer of achieving essentially noise-free amplification, and their adaptability to the field of communications.

Neurophysiological representation of complex acoustic signals at the cochlea and cortex of the cat's auditory pathway was investigated. The signals were presented monaurally and included repetitive bursts of noise, clicks, and bursts of tone — signals which human listeners judge to be of low pitch, although the concentration of signal energy is not in the low audio-frequency range. For obtaining characteristic evoked responses from periphery (i.e., cochlea) and cortex, a certain degree of synchrony in the firing of the neural units that contribute to the potentials recorded by gross electrodes is required. By varying the rise time of the envelopes of bursts of noise, cortical responses were evoked for stimuli that did not give rise to the typical N_1 and N_2

spikes at the periphery. The representation of stimulus repetition rate was investigated. Thresholds of cortical responses to transient tonal stimuli vary with the tone frequency, so that tuning curves can be obtained for thresholds of a given cortical point as a function of frequency. Thresholds of cortical responses to repeated bursts of noise were obtained by this technique and were found to be independent of repetition rate. Thresholds could be raised by filtering from the noise the energy in the frequency range to which the point was most sensitive. We conclude that the tonotopic organization of the auditory cortex is related, primarily, to the distribution of stimulus energy in the spectrum. The temporal

representation of envelope repetition rate was studied for stimuli at low and moderate intensity levels. The synchrony of cortical potentials is difficult to study by visual inspection, since the ongoing activity tends to obscure small evoked responses. By using an electronic processing device that averages a large number of responses we detected synchrony to stimuli, with repetition rates up to 200/sec, in the cortical potentials from unanesthetized cats. In barbiturate-anesthetized cats evoked responses to stimuli, with repetition rates up to 100/sec, were detected. Some psychophysical data on the discrimination of envelope repetition rate of modulated stimuli are also presented. A mathematical representation of signals as a function of two variables—one related to spectral frequency, and the other related to envelope periodicity—is included. (Contractor's abstract)

Also published in Jour. Franklin Inst., v. 263: 213-223, Mar. 1957.

It is possible to compress the classical electromagnetic equations into three complex, four-dimensional quantities \bar{Q} , ${}^4\bar{I}$, and ${}^4\bar{\Psi}$. These quantities represent in order electromagnetic fields, currents and charges, and vector and scalar potentials. In addition to the four-dimensional quantities, a complex vector $\bar{Q} = a\bar{E} + jb\bar{B}$ is introduced, where \bar{E} = electric field-strength, \bar{B} = magnetic induction, $j = \sqrt{-1}$, and a and b are real or pure imaginary constants. The components of \bar{Q} represent two related modes, one electric and one magnetic. (Contractor's abstract)

Published in I.R.E. National Convention Record, Part 8: 176-202, 1957.

A new theory for the effect of feedback around the limiter upon interference rejection in FM receivers considers interference that results from superposition of two carriers differing in amplitude and frequency, and distinguishes between wideband and narrow-band feedback. The theory shows that wideband feedback cannot reduce the magnitude of the frequency spikes caused by the interference, regardless of the feedback angle. Inverse narrow-band feedback aggravates the disturbance and raises the limiting threshold. Positive narrow-band feedback, which causes self-oscillation in the absence of an input signal, results in pronounced capture improvement and automatic noise squelch, and lowers the limiting threshold.

A STUDY OF ASYNCHRONOUS LOGICAL FEEDBACK NETWORKS, by S. H. Unger. Apr. 26, 1957, 45p. incl. diagrs. refs. (Technical rept. no. 320) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 150502 Unclassified

The systems considered are asynchronous, dc-level, sequential switching circuits; that is, there are no clock pulses, and the signals are represented, not by pulses, but by variables that can assume values in either of two nonoverlapping ranges. The analysis of these circuits is discussed, with emphasis on the problem of choosing state variables. A relationship has been established between the number of rows of a reduced flow matrix and the feedback index of the associated circuit and, furthermore, the need for amplification around each feedback loop has been proved. The major portion of the research is devoted to a study of the effects of stray delays on the operation of sequential switching circuits. By inserting delay elements in all feedback loops, and using hazard-free combinational circuits, correct operation can be obtained despite the stray delays. It has been shown that, for a subset of all sequential functions, delay elements if the possibility of hazards (malfunctioning caused by stray delays) is to be averted, but methods are presented by means of which a single delay element is sufficient for the synthesis of any sequential function. These procedures usually entail more complex circuitry than would otherwise be needed, but several other techniques are presented that may, in certain cases, be useful in minimizing the number of delay elements at a relatively small cost in terms of other components. AN ANALOG PROBABILITY DENSITY ANALYZER, by H. E. White. Apr. 29, 1957, 28p. incl. illus. diagrs. table, refs. (Technical rept. no. 326) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 156601 Unclassified

The development and construction of an analog analyzer for determining the first-order probability density function of signal amplitudes of frequencies between 30 cps

and 20 kc is described. Values of probability density are determined by averaging a derived random variable that is unity when the signal is in the amplitude interval that is being analyzed and is zero at all other times. It is generated by a diode level-selector circuit that gates a 60-mc carrier to a bandpass amplifier. This level selector eliminates many of the problems of frequency response and drift that are associated with the amplitude discriminators of the conventional level selector. The amplitude range of the signal comprises 50 intervals that are analyzed sequentially and the complete probability density function is plotted by a pen recorder. The frequency response and drift stability of the analyzer are experimentally evaluated, and examples of experimental probability density functions are given. Block diagrams and descriptions of both digital and analog systems that have been previously developed for determining probability density functions are presented. Definitions and some properties of probability density functions are reviewed. (Contractor's abstract)

IMPEDANCE TRANSFORMATIONS BY EXTENSION OF THE ISOMETRIC CIRCLE METHOD TO THE THREE-DIMENSIONAL HYPERBOLIC SPACE, by E. F. Bolinder. [1957] [13]p. incl. diagrs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Published in Jour. Math. and Physics, v. 36: 49-61, Apr. 1957.

It is shown that for loxodromic transformations, corresponding to impedance transformations through lossy networks, the natural space to which the isometric circle method should be transferred is the three dimensional hyperbolic space which has the Riemann unit sphere as its absolute surface. Two important problems in network theory are studied in this space: (1) analysis or synthesis of a lossy two terminal-pair network from three measurements, and cascading of lossy two terminal-pair networks.

Published in Jour. Chem. Phys., v. 26: 787-793, Apr. 1957.

The lattice dynamics of hexagonal close-packed metals has been investigated, the assumption being made that the atoms interact with central forces. Atomic force constants are related to the elastic constants by the method of homogeneous deformation in which the contribution of the electron gas to the elastic constants is assumed to arise from an isotropic volume-dependent term in the energy. Relations are given for the propagation of acoustic waves in hexagonal crystals which permit calculation of the elastic constants from ultrasonic pulse velocity measurements. (Contractor's abstract)

A LOGICIAN'S REACTION TO RECENT THEORIZING ON INFORMATION SEARCH SYSTEMS, by Y. Bar-Hillel. [1957] [11]p. Incl. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 139565 unclassified

Also published in Amer. Documentation, v. 8: 103-113, Apr. 1957.

A clear understanding of the distinction between information retrieval systems, the function of which is to make detailed, factual information available, quickly, cheaply, and reliably, and literature search systems, the function of which is to provide a bibliography of documents for the use of the investigator of a specific problem, and of the related distinction between the information-condensing function of the abstract and the clue-providing function of an index, is necessary for progress in information searching. A thoroughly planned interplay of the modern methods of clue-providing by short-phrase index sets with streamlined and mechanizable tracing of leads through cross-references, appears to be definitely superior to any methods of literature searching currently used.

TRANSIENT CORRECTION BY MEANS OF ALL-PASS NETWORKS, by J. C. Pinson. May 13, 1957, 106p. Incl. diags. refs. (Technical rept. no. 324) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 143099 Unclassified

Phase correction, realized in the form of an all-pass network, is frequently used in order to improve the transient response of a system. An investigation is made here to determine the phase correction that should be used to achieve the optimum corrected response for a given system. In general, the ideally desired response cannot be obtained by means of phase correction. Then an error criterion must be used to define the corrected response that best approximates the desired response. The phase correction which gives the corrected response that approximates the desired response with minimum integral square error is determined. For the particular class of systems in which reproduction of the system input is desired, it is found that the correction should linearize the phase of the system in order to produce a corrected response with minimum integral square

MIT.12:175 - MIT.12:178

error. Phase correction is most commonly used to enable a system to reproduce better a step function input. It is found that the correction which yields the corrected response with minimum integral square error does not provide the step response with shortest rise time. By consideration of a suitably chosen weighted integral square error criterion, a phase correction is derived which yields a corrected step response with the shortest possible rise time. It is found, however, that the realization of this correction requires an all-pass network with an extremely large number of circuit elements. When correction to reduce the overshoot of the step response of a system is desired, it is found that correction for minimum integral square error provides the optimum response. If all available amplifying devices can be approximated by linear models with capacitive, terminal, energy storage, there are bounds on the allowed natural frequencies of circuits constructed from these devices. These bounds are readily determined from the eigenvalues of a frequency matrix and can be related to the maximum power that can be dissipated by the device per unit energy stored in the terminal capacity. Synthesis of unilateral and constant-k amplifiers is considered, and concepts such as the gain-bandwidth product and the maximum frequency of oscillation are related to the bounds on allowed natural frequencies.

INHERENT NOISE OF QUANTUM-MECHANICAL AMPLIFIERS, by M. W. P. Strandberg. [1957] [4]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637])
Unclassified

Published in Phys. Rev., v. 106: 617-620, May 15, 1957.

The noise figure or limiting sensitivity for both traveling-wave and resonant-cavity quantum-mechanical amplifiers, sensitive to one direction of propagation, is

derived with spontaneous emission as the limiting noise. The concept of effective temperature is introduced as an analytical parameter; thus negative temperatures appear in a natural fashion. It is pointed out that the results of this calculation can be considered the solution to the problem of linear counting of coherent particles. In this case the least count is one and the signal-to-noise ratio (for constant photon flux) increases as the reciprocal of the band width. The limiting temperature sensitivity of properly designed quantum-mechanical amplifiers is given as $h\nu/k$ degrees because of the drastic difference between negative and positive temperatures.

The idea of correlation functions is extended to higher-order correlation functions. A definition of n^{th} -order correlation functions is given, and the general nature of these functions is considered. The emphasis is placed on the case $n = 2$. A survey of the ideas of stochastic process is given, and it is shown how it serves as a model for messages in a communication system. The second-order autocorrelation functions of periodic, aperiodic, and random functions are computed and plotted. Properties of second-order autocorrelation functions concerning continuity, behavior at the origin, phase effects of harmonics, and so forth, are considered. For periodic and aperiodic functions, the relation between first- and second-order autocorrelation functions is given. The Fourier transform of second-order autocorrelation functions is investigated and a physical interpretation of this transform is given. Second-order crosscorrelation techniques are used to determine the location of random noise sources. (Contractor's abstract)

MIT.12:179 - MIT.12:182

An experiment designed to measure the spectral emissivity of tungsten at incandescent temperatures has been initiated. A direct comparison method is utilized in which the radiant intensity from a tungsten source is compared with the radiant intensity from an approximative black body, and the spectral emissivity is computed from the basic relation $E_{\lambda T} = S/B$, where $E_{\lambda T}$ is the spectral emissivity at temperature T and wavelength λ , S is the radiant intensity of the tungsten source, and B is the radiant intensity of the approximative black body. It is shown that the spectral emissivity of tungsten is caused by the classical electromagnetic reflection and refraction of black-body light incident upon the metal-vacuum interface from inside the metal. Equations for the spectral emissivity of tungsten as a function of the direction of polarization and the angle of viewing the tungsten surface are developed in terms of the optical constants of tungsten. The optical constants of tungsten are computed by comparing these equations with the experimental data. An attempt is made to explain the main features of these data in terms of a combination of the Lorentz elastically bound electron theory of insulators and the Drude-Zener-Kronig free-electron theory of metals. BIOLOGICAL COMPUTERS, by W. S. McCulloch. May 1957 [3]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Published in I.R.E. Trans. on Electronic Computers, v. EC-6: 190-192, Sept. 1957.

This review article describes the similarities between the central nervous system and the electro-mechanical computer devices. The principle function of the central nervous system is seen to be that of a computer for an enormously complex, multiple closed-loop servosystem with more than 10^3 but less than 10^6 distinguishable loops. The function of the reticular formation of the brain stem in the regulation of the firing of the neurons is discussed. The similarity of the parallel coding of the neurons in such a manner to preserve topological relations to the analog computer devices is given. The sequential coding of neurons is believed to have a reliability in distinguishing pulses by interval modulation of about 160 μ sec. At this time there appears to be no detailed understanding of the method of actual coding of information. Several modes of operation of the neuron system are given and it is concluded that the synapse acts as some sort of non-linear filter.

AN EXTENSION OF THE NOISE FIGURE DEFINITION, by H. A. Haus and R. B. Adler. [1957] [2]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Published in Proc. Inst. Radio Engineers, v. 45: 690-691, May 1957.

Generalized definitions are given for the available gain and noise figure of linear amplifiers which are applicable to those cases involving negative resistances and which reduce to the usual definitions except in those cases in which a negative output occurs somewhere in the cascade. The concept of exchangeable power is introduced in place of the concept available power. An example is given for the noise figure of a cascade of two amplifiers to illustrate the need and the applicability of the new definitions.

MICROWAVE GAS DISCHARGE BREAKDOWN IN AIR, NITROGEN, AND OXYGEN, by D. J. Rose and S. C. Brown. [1957] [3]p. incl. diags. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Published in Jour. Appl. Phys., v. 28: 561-563, May 1957.

The microwave breakdown electric field has been measured for pure air uncontaminated by discharge products (presumably oxides of nitrogen), and for nitrogen and oxygen separately. The breakdown field for pure air is significantly higher than that previously observed, in which cases such contamination could be suspected. The breakdown field for pure air lies between those for nitrogen and oxygen. A calculation of the high-frequency breakdown field in air is made from dc data, using the measured Townsend ionization coefficient, electron attachment coefficient, and average electron energy. The present data agree well with this calculation. (Contractor's abstract)

New methods are shown for the analysis of Langmuir probe data. Not only have the methods been explained, but the results are illustrated by relating the equations to the best experimental data available at present. The efficiency of the process by which excited atoms of Hg are converted into positive ions is discussed. It is proposed that this high efficiency results from the formation of an excited Hg molecule which is then ionized and dissociated.

An introductory investigation on the means by which modern (higher) geometry can be used for solving microwave problems is presented. It is based on the use of an elementary inversion method for the linear fractional transformation, called the "isometric circle method," and on the use of models of non-Euclidean hyperbolic geometry. After a description of the isometric circle method, the method is applied to numerous examples of impedance and reflection-coefficient transformations through bilateral two-port networks. The method is then transferred to, and generalized in, the Cayley-Klein model of two-dimensional hyperbolic space, the "Cayley-Klein diagram," for impedance transformations through lossless two-port networks. A similar transfer and generalization is performed in the Cayley-Klein model of three-dimensional hyperbolic space for impedance transformations through lossy two-port networks. In the Cayley-Klein models a bilateral two-port network is geometrically represented by a configuration consisting of an "inner axis" and two non-Euclidean perpendiculars to the inner axis. The position of the configuration in the models depends upon the fixed points and the multiplier of the linear fractional transformation. By using this geometric representation, an impedance transformation through a bilateral two-port network is performed by consecutive non-Euclidean reflections in the two perpendiculars. The Cayley-Klein model of three-dimensional hyperbolic space is used: (a) for creating a general method of analyzing bilateral two-port networks from three arbitrary impedance or reflection-coefficient measurements; (b) for creating a general method of cascading bilateral two-port networks by "the Schilling figure"; (c) for determining the efficiency of bilateral two-port networks; (d) for classifying two-port networks; (e) for splitting a two-port network into resistive and reactive parts; and (f) for comparing the iterative impedance method and the image impedance method. York, May 23-25, 1957.

Published in Jour. Acoust. Soc. Amer., v. 29: 773,
June 1957.

Synchronous neural activity has been recorded by gross
electrodes from the auditory nerve in response to re-
peated impulsive stimuli at rates up to 2000/sec. How-
ever, cortical activity, recorded by gross electrodes
exhibits no directly identifiable stimulus-locked re-
sponses at rates as low as 100/sec. For rates higher
than 5/sec the amplitude of cortical responses to re-
peated stimuli decreases. Overlapping of and inter-
ference between successive responses as well as a lack
of synchrony contribute to the reduction in size of the
cortical responses. Gross electrodes were placed on
and in the auditory cortex of cats and steady-state re-
sponses recorded to repeated clicks, bursts of noise,
and bursts of tone. Stimuli were delivered at intensity
levels at which the auditory system is clearly mechani-
cally linear. Responses from both anesthetized and un-
anesthetized preparations were recorded on magnetic
tape and processed by a special analog computer in
order to obtain the characteristics of the average re-
sponse. This method permits the detection of small
responses in the presence of large ongoing activity. In
unanesthetized preparations synchronous cortical re-
sponses were found at rates up to 200/sec.

SMALL SIGNAL POWER THEOREM FOR ELECTRON
BEAMS, by H. A. Haus and D. L. Bobroff. Nov. 19,
1956 [11]p. incl. diagrs. refs. (Sponsored jointly by
Signal Corps, Office of Naval Research, and Air Force
Office of Scientific Research under [DA 36-039-sc-
64637]) Unclassified

Published in Jour. Appl. Phys., v. 28: 694-704, June
1957.

An analysis is presented of a filament beam in arbitrary
dc electric and magnetic fields. The trajectory of the
filament beam in the absence of ac fields may thus follow
an arbitrary curve. It is shown that the electromagnetic
power delivered by the filament beam is, within the as-
sumptions of small signal theory, balanced by a decrease
in the beam of a quantity, the "generalized ac power" in
the beam. This ac power involves products of the small
signal beam-excitation amplitudes. The ac power theo-
rem for a filament beam can be extended to a thick beam.
This is done to find the small signal ac power theorem
for a two-dimensional rectilinear beam of finite thick-
ness. The power theorem presented here is applicable
to M-type and E-type traveling-wave devices. Applica-
tions to the noise theory and signal analysis of electron
beams are indicated. (Contractor's abstract)

ANALYSIS OF CIRCUITS WITH MULTIPLE-HOLE
MAGNETIC CORES, by L. S. Onyshkevych. July 9, 1957,
63p. incl. illus. (Technical rept no 329) (Sponsored
jointly by Signal Corps, Office of Naval Research, and
Air Force Office of Scientific Research under DA 36-
039-sc-64637) AD 214554 Unclassified

Multiple-hole magnetic cores, also called transfluxors,
which have been developed recently, promise to be very
useful in computer, control, and other logical circuitry.
They are ferrite cores, with square hysteresis loops,
of various complicated geometries. A workable analysis
procedure for circuits that contain transfluxors is de-
veloped; it is based on the square-wave-shape approxi-
mation. This analysis forms a basis for a design pro-
cedure. Sample circuits were designed and tested, and
the results were found to be within 10% of the predicted
values. The main problems in circuit design were flux
division and loading effects. Diode elimination presented

another problem, which is treated at some length. Diodeless operation of a transfluxor circuit was found to be possible, but slow, unreliable, and critical. In the field of logical design, a symbolic notation was developed, and an approach to design was density using "gate boxes." A description of the physical properties of transfluxors is given; it includes some new special effects encountered with multiple-hole cores. (Contractor's abstract)

THEORY OF LOW-DISTORTION TRANSMISSION OF FM SIGNALS THROUGH LINEAR SYSTEMS, by E. J. Baghdady. July 30, 1957, 48p. incl. diagrs, tables, refs. (Technical rept. no. 332) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 201536 Unclassified

The convergence properties of the Carson and Fry and of the Van der Pol-Stumpers expansions for the complex amplitude of the steady-state response of a filter to an FM excitation are discussed. The theory of quasi-stationary analysis and of FM-to-AM conversion with low distortion is presented. The use of Taylor's formula leads to error estimates and to a simple condition that specifies an upper bound on the error incurred in restricting the solution to the quasi-stationary term (the instantaneous-frequency method). A sluggishness ratio and an index of stiffness are defined for filters whose system functions have poles only in the upper left half-plane. Sluggishness ratios and indices are given for various filters of wide practical interest. The results indicate that filter band-widths must be prescribed on the basis of the fastest rate at which the instantaneous frequency of the excitation is swept. Applications to sinusoidal modulation and to two-path interference that emphasize the limitations of specifying filter bandwidths on the sole basis of frequency deviation are offered. Applications to the reproduction of FM video waveforms are discussed. The discussion concludes with an analysis of harmonic and intermodulation distortion in the quasi-stationary response. SOME APPLICATIONS OF THE ISOMETRIC CIRCLE METHOD TO IMPEDANCE TRANSFORMATIONS THROUGH LOSSLESS TWO-PORT NETWORKS (Abstract), by E. F. Bolinder. [1957] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at IRE-URSI Symposium, Washington, D. C., May 22-25, 1957.

Published in I.R.E. Trans. of Professional Group on Antennas and Propagation, v. AP-5: 331, July 1957.

The isometric circle method is a graphical method of transforming a complex quantity by the linear fractional transformation. If the quantity is a complex impedance Z , then the linear fractional transformation

$$\frac{Z' - aZ + b}{cZ + d'} \quad ad - bc = 1 \quad (1)$$

can be interpreted as an impedance transformation through a bilateral two-port network which, for a fixed frequency, is characterized by the four complex constants a , b , c , and d . The isometric circle is defined as the circle which is the complete locus of points in the neighborhood of which lengths are unaltered in magnitude by (1). The isometric circle of the direct transformation, C_d , has its center at $O_d = -d/c$ and a radius $R_c = 1/|c|$; the isometric circle of the inverse transformation, C_i , has its center at $O_i = a/c$ and the same radius. Mathematically, (1) is divided into two classes of transformations: the loxodromic transformation, characterized by $a + d = \text{complex}$, and the nonloxodromic transformation, characterized by $a + d = \text{real}$. The latter transformation is further divided into the hyperbolic, parabolic, and elliptic transformations specified by $|a + d| > 2$. If the two isometric circles are drawn in the complex plane,

MIT.12:193 - MIT.12:195

the following graphical constructions yield a graphical method for the loxodromic case: (1) an inversion in the isometric circle of the direct transformation C_d ; (2) a reflection in the symmetry line L to the two circles; and (3) a rotation around the center O_1 of the isometric circle of the inverse transformation through an angle $-2 \arg(a + d)$. If the bilateral two-port network is lossless, it is shown that the impedance transformation corresponds to a nonloxodromic transformation. In this case the third operation above is eliminated. A plotting of the isometric circles immediately specifies the nonloxodromic transformation. If the two circles intersect, the elliptic, above-cutoff, case exists; if the circles are tangent the parabolic, cutoff, case exists; and, finally, if the two circles are external the hyperbolic, below-cutoff, case exists. The isometric circle method is applied to impedance and reflection coefficient transformations through some simple bilateral, lossless, two-port networks. The examples chosen are: a uniform transmission line, a lossless transformer, an exponentially tapered transmission line, and uniform waveguide sections (TE and TM modes). Graphical constructions for simple numerical examples are shown both in the impedance plane and the reflection coefficient plane (Smith chart). The connections between the constructions in the two planes are shown by mapping the planes stereographically on the unit sphere. It is shown that the transformation through the uniform transmission line is elliptic and that it corresponds to a rotation of the sphere around a line through the fixed points. The ideal transformer, on the other hand, is hyperbolic and corresponds to a stretching of the surface of the sphere along a line through the fixed points. Finally, the exponentially tapered line and the waveguide section may both be elliptic, parabolic, or hyperbolic depending on simple relations between the mechanical dimensions and the frequency.

SEQUENTIAL DECODING FOR RELIABLE COMMUNICATION, by J. M. Wozencraft. Aug. 9, 1957, 1v. incl. diagrs. refs. (Technical rept. no. 325) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 145016 Unclassified

Shannon's coding theorem for noisy channels states that it is possible to communicate information, with arbitrarily small error, at any rate of transmission less than the channel capacity. The attainable probability of error has previously been bounded as a function of capacity, transmission rate, and delay. This investigation considers the behavior of a new parameter, the average number of decoding computations. A convolutional encoding and sequential decoding procedure is proposed for the particular case of the binary sym-

metric channel. With this procedure, the average number of decoding computations per information digit can be constrained to grow less rapidly than the square of the delay. The decoding process converges for constant rates of transmission that are not too close to capacity. Although it has not been possible to prove this rigorously, it appears that the probability of error decreases exponentially with delay, and is essentially optimum for transmission rates near the limit of convergence. It also appears that the sequential decoding technique can be extended to more general channels. (Contractor's abstract)

ELASTIC CONSTANTS OF MAGNESIUM FROM 4.2°K TO 300°K, by L. J. Slutsky and C. W. Garland. [1957] [5]p. incl. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 214, Apr. 25, 1957.

Published in Phys. Rev., v. 107: 972-976, Aug. 15, 1957.

The adiabatic elastic constants of magnesium single crystals have been measured by an ultrasonic pulse technique. The values at 298°K are in good agreement with the recent values of Long and Smith. The values extrapolated to 0°K are $c_{11} = 0.635$, $c_{33} = 0.664$, $c_{44} = 0.1842$, $c_{12} = 0.259$, $c_{13} = 0.217$ in units of 10^{12} dynes/cm². A Debye characteristic temperature, θ , of $388 \pm 3^\circ\text{K}$ has been calculated at 0°K by averaging the inverse cube of the longitudinal and transverse wave velocities over all directions of propagation. Atomic force constants for a central-force model with an electron gas term are also obtained. (Contractor's abstract)

THE DESIGN AND OPTIMIZATION OF SYNCHRONOUS DEMODULATORS, by R. C. Booton, Jr. and M. H. Goldstein, Jr. [1957] [17]p. incl. diagrs. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at Western Electronic Show and Convention, San Francisco, Calif., Aug. 20-23, 1957.

Published in I.R.E. WESCON Convention Record, Pt. 2: 154-170, 1957.

Suppressed-carrier modulation involves multiplication of a sinusoidal carrier by a message signal. Synchronous demodulation is the recovery of the message signal by means of a time-varying circuit the parameters of which are varied periodically at the carrier frequency. It is shown that the operation of most practical demodulators can be represented by two cascaded operations, multiplication by a periodic function followed by a time-invariant filter. The effects of message bandwidth and disturbances, such as noise and quadrature, are analyzed for basic practical demodulators. The optimization theory for time-varying linear systems is applied to the demodulation problem. The minimum mean-square error is calculated numerically and compared with the results obtained for practical demodulators. (Contractor's abstract)

A variety of topics that bear directly upon the use of molecular-beam spectroscopic methods for precise frequency determination with the use of alkali-halide molecules are discussed. The rotational-energy spectrum, including resolvable hyperfine structure arising from quadrupole and magnetic interactions, is calculated. An analysis of integrated line strength, or intensities, is presented. State selection is discussed in terms of the appropriate high-field Stark effect, for which new calculations are given. State selection with both axial and transverse-rod configurations is discussed and trajectories for sodium chloride with the use of a transverse-rod state selector are indicated. The limitations of any state selector which arise from nonadiabatic losses are analyzed. The design parameters of a microwave spectroscope, including signal-to-noise ratio and ultimate precision, are related to its geometric configuration, and a description of an apparatus that is adequate for high-resolution work is given. Related topics, such as the concept of efficiency of frequency measurements and frequency pulling, are discussed in generalized fashion. Conclusions that can be derived from this work, as to both present limitations and necessary future development, are drawn. (Contractor's abstract)

Two (211) crystals in tantalum ribbon are used as emitter and collector in a three-element retarding-potential experiment. The electrons from one crystal are accelerated through a small aperture which, in conjunction with a strong axial magnetic field, collimates a beam and directs it to the collector crystal. The uniform work-function of single crystals, plane geometry, and the collimating magnetic field completely remove the deleterious effects of conventional retarding-potential experiments that prevent the exact determination of the energy distribution. The resulting retarding-potential plot indicates close agreement with the theoretically predicted two intersecting straight lines on semi-logarithmic paper, with the transition region extending less than 20 mv. This indicates a Maxwellian distribution with no large energy-dependent reflection. The temperature, the saturated current density, and the temperature derivative of the work-function, as found from different retarding-potential plots, are used in a Richardson analysis to derive the thermionic constants. Published in I.R.E. WESCON Convention Record, Pt. 2: 94-104, 1957.

Shannon's fundamental coding theorem for noisy channels states that such a channel has a capacity C , and that for any transmission rate R less than C it is possible for the receiver to use a received sequence of n symbols to select one of the 2^{nR} possible transmitted sequences, with an error probability P_e which can be made arbitrarily small by increasing n , keeping R and C fixed. Recently upper and lower bounds have been found for the best obtainable P_e as a function of C , R , and n . This paper investigates this relationship for a modified decoding procedure, in which the receiver lists L messages, rather than one, after reception. In this case for given C and R , it is possible to choose L large enough so that the ratio of upper and lower bounds to the error probability is arbitrarily near to 1 for all large n . This implies that for large L , the average of all codes is almost as good as the best code, and in fact that almost all codes are almost as good as the best code. (Contractor's abstract)

ABOUT SUCH THINGS AS UNISTORS, FLOW GRAPHS, PROBABILITY, PARTIAL FACTORING, AND MATRICES, by S. J. Mason. [1957] [8]p. incl. diags. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Published in I.R.E. Trans. of Professional Group on Circuit Theory, v. CT-4: 90-97, Sept. 1957.

The purpose of this paper is to point out three things. (1) Topological circuit analysis, in which one looks for trees, and topological flow-graph analysis, in which one looks for loops, are intimately related, since both have to do with simultaneous, linear algebraic equations. The intimate relationship becomes an identity when one deals with Markoff probability diagrams, for which the circuit model of the problem and the flow-graph model of the problem are one and the same. (2) The expression for a flow-graph transmission in terms of the branch transmissions can often be made much more compact by a process called partial factoring. Fortunately, this process has a simple topological interpretation, so that the compact form is obtainable by inspection of the flow graph. (3) Simultaneous linear matrix equations may be conveniently expressed in flow-graph form, whereupon the solution is obtainable by standard flow-graph reduction techniques.

Published in Rev. Scient. Instruments, v. 28: 844,
Oct. 1957.

Precision measurements of the thickness of nonab-
sorbing films may be obtained with the Rothen photo-
electric ellipsometer. The author points out that while
this may be true for films which may be built up to thick-
nesses of greater than ~300A, it is not true for films
restricted to the 0-300-A region (such as adsorbed
protein films). A summary of this report is included
and contains the following information: (1) For a
precise determination of film thickness, d , by the
Rothen method, one requires knowledge of the film
index n ; (2) For films which cannot be built up to thick-
nesses > 300A one cannot obtain n by the Rothen tech-
nique or any other standard procedure; and (3) There-
fore, the Rothen method is incapable of providing a pre-
cise determination of film thickness for films restricted
to the range 0-300A. The author mentions in his con-
clusion that a simple way exists in which the photoelec-
tric ellipsometer may be modified to allow simultaneous
measurement of thickness and refractive index of films
10A to 250A. This method employs a stepped barium
stearate interference reflector and white light interfer-
ence fringes.

Published in Nature, v. 180: 978-979, Nov. 9, 1957.

Data are presented on the aromatic systems cyclopentadienide ion, $C_5H_5^-$, and tropylium ion, $C_7H_7^+$.

NaC_5H_5 in tetrahydrofuran was prepared from Na sand and freshly distilled tetrahydrofuran. Tropylium bromide was prepared by the method of Doering and Knox from tropyliene, a product of the isomerization of bicyclo [2.2.1] hepta-2,5-diene. The proton resonance spectra were observed on a high-resolution spectrometer and extrapolated to infinite dilution in aqueous solutions for $C_5H_5^-$ and in both aqueous and methanol solutions for $C_7H_7^+$.

Although agreeing in sign, observed differences were much more extreme than calculated ones. It was concluded that, besides the effect of free electrons, other contributing factors exist which have to do with differences in electron density at the protons.

Presented at meeting of the Acoust. Soc. Amer., Michigan U., Ann Arbor, Oct. 24-26, 1957.

Published in Jour. Acoust. Soc. Amer., v. 29: 1257, Nov. 1957.

Listeners report hearing beats in repeated bursts of

tone of low intensity provided the burst rate stands in a nearly harmonic relation to the frequency of the tone and provided that certain conditions of rise time of the bursts and frequency of the tone (carrier) are met. A typical signal that will give rise to beats at a rate of 2/sec might be one in which bursts of a tone of 2001 cps are repeated at a rate of 200 per second; the bursts of tone are presented at a level of 35 db above threshold with a rise time of 0.25 msec for each burst, and a sound-time fraction of 0.5. In these experiments, listeners were asked to report the presence or absence of beats as the frequency of the carrier was slowly changed. For a given test, repetition rate, sound-time fraction, and rise time were held constant. For a nearly harmonic situation the probability of detection of beats is greater for short rise times, and carriers of relatively low frequency. Data on the masking of the beats with wide-band noise, high-pass filtered noise, and low-pass filtered noise are also presented. These experiments permit comparison of various mathematical representations of these stimuli with respect to their ability to predict the listeners responses.

ELECTRICAL RESPONSES OF THE AUDITORY SYSTEM TO DIFFERENT TYPES OF TRANSIENT STIMULI (Abstract), by E. de Boer. [1957] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637])
Unclassified

Presented at meeting of the Acoust. Soc. Amer., Michigan U., Ann Arbor, Oct. 24-26, 1957.

Published in Jour. Acoust. Soc. Amer., v. 29: 1249, Nov. 1957.

In physiological experiments on the cat's auditory system clicks have often been used because of their ability to produce synchronized neural firings. In this study the class of impulsive stimuli has been extended. The electrical signals fed to the earphone are close approximations to members of the family of singularity functions. In the present experiments doublets, impulses, step, and ramp functions have been used. Each of these functions is the time integral of the previous one, with a conversion factor involving the time dimension. The actual wave form of the acoustic stimulus at the animal's eardrum could not be observed. The above-mentioned integral relation, however, holds for what may be thought of as the linear part of the system. As a typical result, it has been found that the peripheral neural response, N_1 , to the step is equal to that of the pulse provided the pulse has the same height as the step, and a length of 20 μ sec. This holds over a fairly large range of amplitudes (20-40 db). Similar re-

suits have been found for the other signals. Preliminary results will also be reported with respect to both microphonic and cortical responses to the above-mentioned stimuli.

Presented at meeting of the Acoust. Soc. Amer., Michigan U., Ann Arbor, Oct. 24-26, 1957.

Published in Jour. Acoust. Soc. Amer., v. 29: 1249, Nov. 1957.

In a previous report (November, 1956, 52nd meeting of the Acoustical Society) we concluded that cortical off-responses observed in cats under barbiturate anesthesia are in fact responses to acoustic transients that appear in the signal as it is turned off. We have since found in unanesthetized cats with high spinal sections off-responses that seem to occur in the absence of such acoustic transients. This conclusion is based on the following considerations: first, these off-responses are observed when bursts of noise are turned off and are abolished by injections of barbiturates; secondly, the latencies of these off-responses are 6-8 msec longer than the latencies of the previously reported off-responses to acoustic transients; and thirdly, these off-responses occur also under stimulus conditions which produce no off-responses in the anesthetized animal (burst durations shorter than 60 msec and fall times longer than 10 msec). These findings suggest that these off-responses in unanesthetized animals may involve neurons other than those which give rise to on-responses; the possibility that inhibitory neuronal links at levels below the auditory cortex are involved will be discussed.

Published in Nature, v. 180: 1290-1291, Dec. 7, 1957.

The authors have devised voltage clamps for measuring membrane currents in both the node of Ranvier and cell bodies. An isolated node N_2 is laid across a window cut in a polyethylene tube through which flows Ringer solution. Two adjacent nodes, N_1 and N_3 , lie on glass slips separating the tube by air gaps. External shunts along the internodes are minimized by bathing the preparation in isotonic sucrose and playing an air jet on the internodes after gaps are made. The amplifiers used are direct-coupled through head stage emitting a current of less than 10^{-14} amp. Preliminary experiments indicate that the monophasic action potentials from isolated nodes are of 2 types: one shows a smooth fall-away from the peak; the other a marked downward inflexion somewhere in the falling phase.

THEORY OF QUASI-STATIONARY ANALYSIS WITH APPLICATION TO FM INTERFERENCE AND VIDEO PROBLEMS (Abstract), by E. J. Baghdady. [1958] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

The convergence properties of the Carson and Fry and of the van der Pol-Stumpers expansions for the complex amplitude of the steady-state response of a filter to an FM excitation are discussed. The theory of quasi-stationary analysis and of FM-to-AM conversion with low distortion is presented. The use of Taylor's formula leads to error estimates and to a simple condition that specifies an upper bound on the error incurred in restricting the solution to the quasi-stationary term (the instantaneous-frequency method). A sluggishness ratio and an index of stiffness are defined for filters whose system functions have poles only in the left half-plane. Sluggishness ratios and indices are given for various filters of wide practical interest. The results indicate that filter bandwidths must be prescribed on the basis of the fastest rate at which the instantaneous frequency of the excitation is swept. Applications to sinusoidal modulation and to two-path interference that emphasize the limitations of specifying filter bandwidths on the sole basis of frequency deviation are offered. Applications to the reproduction of FM video waveforms are discussed.

The difference between "electrostatic potential" and "electric potential" is used to discuss the "work function" as it pertains to the forces acting on an electron either within the interior of a crystal or as the electron escapes through the surface boundary. The function is defined as the energy difference between the Fermi level in the interior of the conductor and an electron at rest in a field free space outside the conductor. The various principal plane surfaces of tungsten crystals are analyzed to determine the effects of atom spacing (i.e. subject to the presence of impurities and incomplete lattice structures) on the work functions. A close relation is

shown to exist between the variation in the tungsten work function with crystallographic direction and the probable perfection of the mirror-image surface that the electron "sees" as it leaves the metal.

A semiclassical analysis of the variation of spin orientation in 180° and 90° domain walls is presented which takes into account both the rotational or latitude angle θ and the precessional or longitude angle ϕ of the macroscopic magnetization vector in ferromagnetic single crystals. The Euler equations for the crystal are derived for both ϕ and θ variations. Further static solutions of the Euler equation for 360° walls or two adjacent 180° walls of similar rotation driven together by an applied field are obtained. Some experimental verification of this is obtained from recent observations of Williams on double walls in thin films of nickel iron. By including the kinetic energy term characteristic of gyroscopic motion in the Lagrangian and assuming a Rayleigh dissipation function, the Euler equations for wall motion are obtained. A very general upper bound to the domain wall velocity is predicted, based only on known constants of the ferromagnetic lattice. A transient solution for the general equation of wall motion is obtained where the effects of wall mass are included. An interpretation of wall mass in terms of the macroscopic inertial moments of the spin system is given. (Contractor's abstract, modified)

levels. By a combination of magnetic scanning and double resonance it was possible to resolve the 2537A line of mercury. By plotting the maxima of the microwave resonance versus scanning field, a separate curve was obtained for each F level of the odd isotopes. In the same way a curve was obtained showing the maxima of the resonance signals from all of the even isotopes. Information about the odd isotopes obtained from a 3000-mc/sec "double-resonance" experiment is also reported. Only minor disagreements with existing data were observed. (Contractor's abstract)

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 9, Jan. 29, 1958.

Interpretation of the operational properties of a solid-state maser, which we have operating in our laboratory, indicate that the process conventionally described as a spin-lattice relaxation indeed plays a dominant role in the operation of these devices. As has been pointed out, the spin-relaxation process must be extended to include phonon relaxation processes which in fact can dominate, in the sense that anomalous phonon temperatures can exist in the vicinity of the saturation frequency.

LOW PRESSURE MICROWAVE PLASMA IN A MAGNETIC FIELD (Abstract), by D. O. Akhurst, S. J. Buchsbaum, and E. I. Gordon. [1958] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at the Tenth Annual Gaseous Electronics Conf., Cambridge, Mass., Oct. 2-4, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 87, Jan. 29, 1958.

A low pressure hydrogen plasma in a magnetic field is described. The plasma is contained in a narrow cylindrical quartz tube along the axis of a cylindrical microwave cavity that oscillates in the TE_{111} mode at a resonant wavelength of 10 cm. The configuration and strength of the magnetic field is such that electrons can gain energy from the microwave field through the cyclotron resonance effect. At high pressures both the breakdown and maintaining fields exhibit the well-known cyclotron resonance effect. However, at low pressures when the electron mean free path (in the absence of a magnetic field) is larger than the length of the quartz tube, it is easier to produce and maintain the plasma with a magnetic field a few percent off the value of magnetic field required for cyclotron resonance. Phenomena responsible for this "displaced" resonance are described.

A THEORY OF SIGNALS, by R. E. Wernikoff. Jan. 31, 1958, 98p. incl. diagrs. refs. (Technical rept. no. 331) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 158737 Unclassified

An experiment is presented in which an attempt is made to arrive at a mathematical description of physical signals that embodies, more realistically than the usual functional representation, our limitations in performing measurements. The object is to achieve a closer relation between the structure of the mathematical description and the finite-resolution properties of the detector that characterizes any real measurement process. An algebra of signals is obtained, appropriate to the model in which essentially frequency-limited signals interact with linear, time-invariant systems, and observations are made by means of a linear, finite-resolution oscilloscope. The properties of this algebra are studied, and a metric that indicates which operators give physically indistinguishable outputs is defined. The algebra is used to study problems in uniform and non-uniform sampling, the discrimination of two events from one in noisy, radar-like systems, and the conditions under which a signal is indistinguishable from its short-time average. A general procedure for linear, least-peak-error prediction is obtained. In the limit as the detector resolution becomes perfect, the present model is shown to tend smoothly to the usual functional model. (Contractor's abstract)

Published in Proc. Inst. Radio Engineers, v. 46: 432-440, Feb. 1958.

Under conditions of high-level interference fm receiver performance is often impaired because of improper low-frequency time constants in the limiter and discriminator circuits. The computation of the upper bounds on the permissible values of these time constants is illustrated.

Severe restrictions are indicated which often conflict with other fundamental requirements. The computational results of this paper demonstrate that these severe restrictions can be alleviated by means of simple schemes that will greatly enhance the capture performance of the fm receiver. Published in Jour. Acoust. Soc. Amer., v. 30: 107-114, Feb. 1958.

Electric responses evoked by transient acoustic stimuli were recorded by gross electrodes from the periphery and cortex of the cat. The responses to clicks and to the rapid onset of bursts of noise or tones are characterized by a sharp N_1 peak in the peripheral response and by a broader cortical response. When the rise time of the onset of bursts of noise (or tones) is lengthened, or when a burst of sudden onset is presented in a noise

background, it is possible to obtain cortical responses under conditions for which the N_1 component of the peripheral response is undetectable. These results and associated findings are interpreted by considering the degree of synchronization of the discharge and the wave forms of the activity of units that contribute to responses recorded by gross electrodes. A simple statistical interpretation is presented. (Contractor's abstract)

ALGEBRAIC DECODING FOR A BINARY ERASURE CHANNEL, by M. A. Epstein. Mar. 14, 1958 [14]p. incl. diagrs. refs. (Technical rept. no. 340) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-(537) AD 208649) Unclassified

Also published in I.R.E. National Convention Record, Part 4: 56-69, 1958.

This paper presents an optimum decoding procedure for parity check codes that have been transmitted through a binary erasure channel. The erased digits are decoded by means of modulo 2 equations generated by the received message and the original parity check equations. Most previous decoding procedures required a number of computations that grew exponentially with code length. At best, the required number of computations grew as a polynomial of code length. The decoding procedure for convolution parity check codes presented here will decode with an average number of computations per digit that is bounded by a finite number, which is independent of code length, for any rate less than capacity. ANALYSIS OF NONLINEAR SYSTEMS BY MEANS OF GENERALIZED POLYNOMIALS (Abstract), by M. B. Brilliant. [1958] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at I.R.E. National Convention, New York, Mar. 24-27, 1958.

A form for the representation of nonlinear systems is developed. The dependence of the output on the past of the input is to be specified by a series of integral operators analogous to a power-series representation of a real function. The form is shown to be capable of arbitrarily close approximation to a fairly general class of systems. With the use of this form, methods are developed for computing the results of cascade and feedback combinations, and for approximating minimum-mean-square-error nonlinear filters. CAPTURE OF THE WEAKER OF TWO COCHANNEL FM SIGNALS (Abstract), by E. J. Baghdady. [1958] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at I. R. E. National Convention, New York, Mar. 24-27, 1958.

Methods for achieving capture of the weaker of two co-channel FM signals are described. One approach extracts the modulation of the stronger signal and uses it to shift the resonant frequency of a dynamic trap that attenuates this signal. Another approach suppresses the stronger signal by an appropriate combination of the outputs of two signal paths that contain different numbers of narrow-band limiters. Alternative methods depend upon standard spectrum-resuffling techniques to synthesize a signal whose average frequency equals the frequency of the weaker signal. (Contractor's abstract)

INVARIANCE PROPERTY OF CORRELATION OF RANDOM PROCESSES UNDER NONLINEAR TRANSFORMATION (Abstract), by A. H. Nuttall. [1958] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at I.R.E. National Convention, New York, Mar. 24-27, 1958.

When a certain class of random processes is transformed by a nonlinear, no-memory (instantaneous) device, the input-output cross-correlation function is identical, except for a known scale factor, with the input autocorrelation function, regardless of the kind of nonlinear device used. A necessary and sufficient condition for the invariance property to hold is formulated and proved. This condition is found to be related to an integral of the input second-order probability density function, and generalizes past results on the invariance property. Some general characteristics of the invariance-property class are derived; examples are given of the use of this property. (Contractor's abstract)

CHANGES ASSOCIATED WITH POST-TETANIC PO-

TENTIATION OF A MONOSYNAPTIC REFLEX, by P. D. Wall and A. R. Johnson. [1958] [11]p. incl. illus. diags. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Published in Jour. Neurophysiol., v. 21: 148-158, Mar. 1958.

This paper examines post-tetanic potentiation of the monosynaptic reflex arc in the cat. It is shown by microelectrode stimulation that excitability is decreased in the primary afferent fibers and is unaffected in the motoneurons and neighboring passive fibers. The potentiation is, therefore, probably attributable to hyperpolarization of the presynaptic fibers. It is suggested that the delayed onset of the full potentiation is also attributable to presynaptic events, possibly anodal block. Evidence is presented that the post-tetanic change is greater in the terminal arborization than in other parts of the afferent axons. This difference may be an explanation of the "DRIV reversal" potential. (Contractor's abstract)

SPIN-LATTICE RELAXATION, by M. W. P. Strandberg. [1958] [5]p. incl. diags. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Published in Phys. Rev., v. 110: 63-69, Apr. 1, 1958.

The measurement of electron spin-lattice relaxation times for paramagnetic crystals at low temperatures is complicated by the fact that the spin specific heat can be much larger than the lattice specific heat. At low temperatures direct processes dominate in the spin-lattice relaxation mechanism and evidence exists that indicates that only a narrow portion of the phonon spectrum takes part in the relaxation processes. This situation is not

encompassed by usual treatments of the spin-lattice problem and a microscopic treatment is presented which allows for this selective excitation of the phonon spectrum. It is pointed out that phonon relaxation times can be the dominant quantity measured in the usual saturation spin-lattice relaxation measurements. The analysis indicates how pulse measurements may be used to evaluate the actual spin-lattice relaxation time independent of the phonon relaxation time. A discussion of some conditions under which the concept of temperature may be applied to quantum-mechanical systems interacting with electromagnetic fields; such as in solid-state amplifiers or absorbers, is given. ELECTRON BEAM WAVES IN MICROWAVE TUBES, by H. A. Haus. [1958] [44]p. incl. diags. refs. (Technical rept. no. 316) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 210913 Unclassified

Also published in Proc. Symposium on Electronic Waveguides, Polytechnic Inst. of Brooklyn, N. Y. (Apr. 8-10, 1958), N. Y., Interscience Publishers, 1958, p. 89-132.

A review is presented of wave propagation along electron beams and of the interaction of these waves with the fields of microwave structures, providing a basis for a unified theory of microwave amplifiers with distributed interaction. Beams with generalized momentum p which satisfies $\nabla \times p = 0$ are considered and a small signal power theorem is given. This theorem and the better-known theorem for longitudinal beams are interpreted. The waves along longitudinal beams, cylindrical Brillouin beams, and Brillouin strip-beams in crossed fields are reviewed and their small-signal power flows are studied. The interaction of waves in a longitudinal-beam, traveling-wave tube is analyzed with the aid of Pierce's coupling-of-modes formalism. The small-signal power theorem is used in deciding whether or not exponential growth of a wave signifies gain. A variational principle is derived for longitudinal beams and beams with zero curl of the generalized momentum. For reasonable trial fields, the principle leads to Pierce's coupling-of-modes formalism, and can also be applied to study cases of stronger coupling than those analyzable by the coupling-of-modes theory. Equations of the magnetron amplifier are derived from the variational principle. (Contractor's abstract, modified)

THEORY OF STRONGER-SIGNAL CAPTURE IN FM RECEPTION, by E. J. Baghdady. [1958] [11]p. incl. diagrs. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Published in Proc. Inst. Radio Engineers, v. 46: 728-738, Apr. 1958.

The characteristics of the FM disturbance that is caused by two-signal interference are pointed out and compared with the characteristics of message modulation. The comparison suggests a new role for the amplitude limiter in FM receivers. The limiter spreads out the spectrum which carries the FM disturbance over a frequency range that often exceeds many times the bandwidth requirements of the message modulation. This makes it possible to reject important parts of the interference spectrum by proper filtering in the output of the limiter without substantially affecting the spectrum of the message modulation. A repeated cycle of amplitude limiting and spectrum filtering is found to be an effective scheme for suppressing the disturbance ahead of the discriminator stage, and for improving the capture capabilities of an FM receiver. ELECTRON-STIMULATED ION OSCILLATIONS, by P. Chorney. May 25, 1956, 61p. incl. diagrs. refs. (Technical rept. no. 277) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 200516 Unclassified

Certain ion oscillations that are sometimes excited in microwave tubes were investigated on a theoretical basis. A study of some general properties of propagation in plasma-loaded waveguides was made; the plasma consisted of both stationary ions and an electron beam. The effect of an axial magnetic field was included in the analysis. Specifically, the propagation in waveguides that were loaded merely with a stationary ion plasma was studied. It was found that these waveguides are propagating structures at frequencies that are very low, as compared with the empty waveguide cutoff frequency. A short-circuited section of an ion-loaded waveguide, which was considered as a resonant cavity, was found to have resonant frequencies of the order of the ion plasma frequency and ion cyclotron frequency (a few megacycles per second for positive gas ions such as hydrogen). The energy transfer from a beam traversing an oscillating ion-loaded cavity to the fields of the cavity was established. (Contractor's abstract)

THEORY AND APPLICATION OF THE SEPARABLE CLASS OF RANDOM PROCESSES, by A. H. Nuttall. May 26, 1958, 57p. incl. illus. (Technical rept. no. 343) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 214552 Unclassified

The separable class of random processes is defined as that class of random processes for which the g -function, $g(x_2, \tau) = \int_{-\infty}^{\infty} (x_1 - \mu) p(x_1, x_2; \tau) dx_1$, separates into the product of 2 functions; a function only of x_2 , and a function only of τ . The second-order probability density function of the process is $p(x_1, x_2; \tau)$ and μ is its mean.

Various methods of determining whether a random process is separable are developed, and basic properties of the separable class are derived. A proof is presented that the separability of a random process that is passed through a nonlinear no-memory device is a necessary and sufficient condition for the input-output cross-covariance function to be proportional to the input autocovariance function, whatever nonlinear device is used. The uses of this invariance property are pointed out. If a

nonlinear no-memory device is replaced by a linear memory-capable network, so as to minimize the mean-square difference between the two outputs for the same separable input process, analysis shows that the optimum linear network has no memory. Simple relations among correlation functions for these circuits are derived. Some results on Markov processes and best estimate procedure are derived, important examples of separable processes are given, and possible generalizations of separability are stated. FINITE STATE LANGUAGES, by N. Chomsky and G. A. Miller. [1958] [22]p. incl. diagrs. tables. (Rept. no. AFCRC-TR-56-50) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]; National Science Foundation and Social Science Research Council) AD 146781 Unclassified

Also published in *Information and Control*, v. 1: 91-112, May 1958.

A finite state language is a finite or infinite set of strings (sentences) of symbols (words) generated by a finite set of rules (the grammar), where each rule specifies the state of the system in which it can be applied, the symbol which is generated, and the state of the system after the rule is applied. A number of equivalent descriptions of finite state languages are explored. A simple structural characterization theorem for finite state languages is established, based on the cyclical structure of the grammar. It is shown that the complement of any finite state language formed on a given vocabulary of symbols is also a finite state language, and that the union of any two finite state languages formed on a given vocabulary is a finite state language; i.e., the set of all finite state languages that can be formed on a given vocabulary is a Boolean algebra. Procedures for calculating the number of grammatical strings of any given length are also described. (Contractor's abstract)

NUCLEAR RESONANCE SPECTRUM AND STRUCTURE OF SF₄, by F. A. Cotton, J. W. George, and J. S. Waugh. [1958] [2]p. incl. diagrs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Published in *Jour. Chem. Phys.*, v. 28: 994-995, May 1958.

The nuclear resonance spectrum of SF₄ has been found to have: (1) two equal intensity triplet lines which are 1920 cps apart; (2) an intensity ratio of 1:2:1 in the lines comprising each line; and (3) equal hyperfine separation (78 cps) in each triplet. These data suggest the nonplanar C_{2v} structure as most likely, in agreement with previous vibrational spectrum studies. This structure has five pairs of valence electrons in trigonal-bipyramidally directed sp³ d hybrid orbitals with the unshared pair in an equatorial orbital. The line spacing and temperature variation of line position yield an activation energy of 4 ± 1 kcal/mol.

ON THE QUANTIZATION OF FINITE DIMENSIONAL MESSAGES, by M. P. Schützenberger. [1958] [6]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Published in *Information and Control*, v. 1: 153-158, May 1958.

Let L be the average value of a measure of quantization noise, and let H be the negentropy of the quantized signal. Some reciprocal relationship exists between these quantities, since, for example, increasing the number of possible quantized values reduces L but increases H . A lower bound to L is given as a function of H and shows that it may be realized up to a constant factor. Roughly speaking, this shows that every bit added to H multiplies

MIT.12:247 - MIT.12:250

L a factor depending on the dimensionality of the message and the measure of quantization noise used.

THEORY OF NOISY TWO-PORT NETWORKS, by E. F. Bolinder. June 14, 1958, 27p. incl. diags. refs. (Technical rept. no. 344) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 208705 Unclassified

A new geometric-analytic theory of noisy two-port networks is presented. It is based, geometrically, on the isometric sphere method, a generalization of the isometric circle method to three dimensions, and, analytically, on a three-dimensional conformal transformation which was originally derived by Poincaré and Picard. The transformation is used in a study of transformations of noise ensemble average ratios through bilateral two-port networks. The study is facilitated by interpreting the transformations as non-Euclidean movements in the Poincaré and Cayley-Klein models of three-dimensional hyperbolic space. By a simple extension, noise ensemble average transformations are performed in four-dimensional spaces by means of four-vectors which are analogous to the Stokes vectors used in optics and antenna theory. The new theory has been used for studying several problems pertaining to noisy two-port networks: the Rothe and Dahlke method of splitting a noisy two-port network into noisy and noise-free ports, cascading of noisy two-port networks, noise

tuning and noise matching, the wave representation of noisy two-port networks, and the optimum noise factory. (Contractor's abstract)

NUCLEAR DIPOLE-DIPOLE INTERACTIONS, by I. S. Waugh. [1958] [27]p. incl. diags. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637], and Petroleum Research Fund) Unclassified

Published in Ann. New York Acad. Sciences, v. 70: 900-926, June 16, 1958.

The broad span of molecular problems that can be illuminated by nuclear magnetic resonance (NMR) experiments, particularly of the high resolution variety is presented. The entirely different range of effects that are observed in experiments on samples in the solid state is described. As a by-product, the sources of some limitations of high-resolution experiments will become evident. This paper is not a comprehensive review of "broad-line" spectroscopy; the literature of this field is voluminous and has already been thoroughly reviewed in a number of places. Rather, this material is intended as an introduction to and illustration of the better known effects of dipolar interactions for those who are not acquainted with them, but who are aware of the nature of the basic nuclear resonance phenomenon. Subject matter is limited to the direct nuclear dipole-dipole broadening of resonance lines and some remarks on spin-lattice interaction. Interesting and important subjects such as quadrupole coupling, electron paramagnetism, spin echoes, and electron-coupled interactions are omitted, although some of them have been customarily included in discussions of NMR spectroscopy in solids. EXCITABILITY CHANGES IN AFFERENT FIBRE TERMINATIONS AND THEIR RELATION TO SLOW POTENTIALS, by P. D. Wall. [1958] [21]p. incl. illus. diags. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Published in Jour. Physiol., v. 142: 1-21, June 18, 1958.

A method is described by which the excitability of a group of axons may be tested along their course within the spinal cord. The experiments used a penetrating

stimulating microelectrode and peripheral recording of the size of the antidromic volley originating from around the microelectrode. The results show that, after the passage of a single orthodromic volley, the excitability changes in the terminal arborization of afferent fibres differ, depending upon the nature of the fibre. The excitability changes in active proprioceptive fibres do not affect the excitability of their passive neighbors. The changes in both types of fibres do not depend on the presence of action potentials in post-synaptic cells. The excitability changes in the spinal course of the skin nerve axons are closely related to the dorsal root potentials.

The theoretical aspects of machine translation are discussed. Electronic computers now available have many properties which seem to make them well suited to this task, including input and output, memory units, and the ability to store, move, and compare information. The word-for-word method of machine translating is examined and its inadequacies enumerated. Another method, which appears to offer great promise of success, is a machine which would accurately translate sentences rather than words. The design, construction, and operation of such a machine is proposed and described.

Presented at meeting of the Acoust. Soc. Amer., Washington, D. C., May 7-10, 1958.

Published in Jour. Acoust. Soc. Amer., v. 30: 674, July 1958.

Recently, interest has been shown in the perception of acoustic stimuli embedded in a sequence of sounds, particularly in relation to studies of speech perception. The particular question we have asked is: How is the perception of a given sound influenced by the physical parameters of a sound adjacent to it in temporal sequence? In the present experiments each stimulus comprises two components separated by a 10 msec gap; each component is a noise of specified band width, center frequency, intensity, and duration. Two of these stimuli are chosen as standards in a given experiment, and listeners are required to place other stimuli into one of the two categories typified by the standard stimuli. In a typical experiment, each of the standard stimuli consisted of two components that were equal in all respects except duration. After hearing these standards, subjects were required to categorize each of a series of ambiguous stimuli in which relative duration and intensity were manipulated. Results demonstrated a trading between intensity and duration, although the relations did not follow a simple pattern. In other experiments using different pairs of stimuli as standards, we have studied the influence of noise center frequency and band width as experimental variables.

Line widths and second moments of the proton and F^{19} resonances in $\text{Co}(\text{NH}_3)_6\text{X}_3$ ($\text{X} = \text{Cl}, \text{Br}, \text{I}, \text{NO}_3, \text{BF}_4, \text{PF}_6$) were measured from 90° to 400°K . In the first four, unusual and very broad ($\sim 200^\circ\text{K}$) line-width transitions were observed. These are interpreted by postulating crystal structures containing nonequivalent sites for $\text{Co}(\text{NH}_3)_6^{+++}$ ions in relative abundances 3:1, 1:1, 1:1, and 2:1, respectively. This interpretation was verified in one case by x-ray diffraction. $\text{Co}(\text{NH}_3)_6(\text{BF}_4)_3$ showed a normal line-width transition which is interpreted both by the usual correlation theory and by a very detailed analysis to give $\Delta E \approx 12$ kcal/mol and $\tau_0 \approx 10^{-14}$ sec. At 90°K rapid reorientation of $-\text{NH}_3$ groups and of BF_4^- and PF_6^- ions occurs in all of these salts. At 330°K and above, rapid tumbling of $\text{Co}(\text{NH}_3)_6^{+++}$ ions occurs. Presented at meeting of the Acoust. Soc. Amer., Washington, D. C., May 7-10, 1958.

Published in Jour. Acoust. Soc. Amer., v. 30: 681-682, July 1958.

Synthetic three formant vowels were recorded with thirty-two different intonation contours, by varying the fundamental frequency as a function of time. The perceptual effects of these variations were investigated in a test in which listeners were required to discriminate between different intonation patterns. The reliability of the discriminations was correlated with the direction in which the intonation contour shifted, the rate of the shift and its magnitude. The relevance of the results to the problem of English sentence intonation is briefly discussed.

POWER-FLOW RELATIONS IN LOSSLESS NONLINEAR MEDIA, by H. A. Haus. [1958] [8]p. incl. diagrs.

[Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637]
Unclassified

Published in I.R.E. Trans. of Professional Group on Microwave Theory and Techniques, v. MTT-6: 317-324, July 1958.

The Manley-Rowe relations, originally derived for nonlinear lumped circuit elements, are generalized to include the power flow in the fields produced in the presence of lossless, nonlinear media. The generalization is carried out first for nonlinear anisotropic media with single-valued relations between the instantaneous \bar{E} and \bar{P} , and \bar{H} and \bar{M} . The proof is extended to include gyromagnetic media under small-signal excitation at the signal frequency (but large excitation at the pump frequency). The relations are applied to show under what conditions power gain can be achieved with a three-frequency and a four-frequency excitation of a ferrite. The form of the coupling coefficients in the electromagnetic operation of a ferrite amplifier is shown to be a consequence of the generalized Manley-Rowe relations. (Contractor's abstract)

Published in Proc. Inst. Radio Engineers, v. 46: 1517-1533, Aug. 1958.

A single quantitative measure of amplifier spot noise performance is established. It removes difficulties heretofore associated with the effect of feedback upon spot noise performance. This measure, $(M_e)_{opt}$, is a function of the amplifier noise and circuit parameters alone. It determines the lowest spot noise figure achievable at high gain with a given amplifier, which is used either alone or in a passive interconnection with other amplifiers of the same $(M_e)_{opt}$. Moreover, passive interconnection of amplifiers with different $(M_e)_{opt}$ cannot lead to a spot noise figure at high gain better than that obtainable by using only amplifiers of the smallest $(M_e)_{opt}$. $(M_e)_{opt}$ is, therefore, a valid measure of the absolute quality of amplifier noise performance. In many important cases the best noise performance attainable with a particular type of amplifier is actually achieved by a simple cascade in which the input of each stage is properly mismatched. The mismatch conditions for each stage do not in general coincide with those normally used to "minimize" its noise figure. In the case of a two-terminal-pair negative resistance amplifier, a limiting form of which is the maser, optimization may always be obtained using an ideal circulator. (Contractor's abstract)

CANONICAL FORM OF LINEAR NOISY NETWORKS, by H. A. Haus and R. B. Adler. [1958] [7]p. incl. diags. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637)

Unclassified

Published in I.R.E. Trans. of Professional Group on Circuit Theory, v. CT-5: 161-167, Sept. 1958.

Lossless network transformations are performed on noisy networks, keeping the number of terminal pairs fixed. These transformations are used to find the fundamental form of the network which explicitly uncovers the noise characteristics of the network which are independent of the form of the network. An n-terminal-pair network has n eigenvalues that are independent of the form of the transformed network. A transformation to a single pair terminal network is given which shows that the n values of the exchangeable power of this network are identical, except possibly for sign with the eigenvalues of the characteristic noise matrix. In a network in which no special circuit parameter has been chosen, the invariants are shown to possess different significance. In the general circuit parameter representation it is the noise measure whose extrema are determined by the eigenvalues of the associated noise matrix.

NETWORK REALIZATION OF OPTIMUM NOISE PERFORMANCE, by R. B. Adler and H. A. Haus. [1958] [8]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Published in I.R.E. Trans. of Professional Group on Circuit Theory, v. CT-5: 156-161, Sept. 1958.

The following theorem is derived from the results of this paper: (1) any unilateral amplifier with $U > 1$ may be optimized with input mismatch alone. (2) A nonunilateral amplifier with $U > 1$, which is also stable for all passive source and load impedances, may be optimized with input mismatch alone. (3) Any amplifier with $U > 1$ may be optimized by first making it unilateral, using lossless reciprocal networks, and subsequently employing input mismatch. (4) Amplifiers of the class $U < 0$ can be optimized by first transforming them into the class $U > 1$ by nonreciprocal imbedding. The optimization methods (1) to (3) can then be applied to this class. (5) Negative resistance amplifiers ($0 < U < 1$) can be optimized by first transforming them into the canonic form. The terminal pair of the canonic form which possesses the smaller exchangeable power is connected into a lossless circulator with a positive (1Ω) balancing resistor. The resulting unilateral two-terminal-pair network achieves the optimum noise measure.

THEORY OF LOW-DISTORTION REPRODUCTION OF FM SIGNALS IN LINEAR SYSTEMS, by E. J. Baghdady. [1958] [13]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Published in I.R.E. Trans. of Professional Group on Circuit Theory, v. CT-5: 202-214, Sept. 1958.

The purpose of this paper is to cover certain fundamental aspects of the analysis of linear-system response to variable-frequency excitations. The main objectives are: (1) the presentation of a unified treatment of the fundamental expansions of Carson and Fry and of Van der Pol and Stumpers that simplifies their derivation and brings out their (not so well known) convergence properties; (2) the derivation of bounds on errors incurred in using only a finite number of the earlier terms in these expansions; (3) the derivation of the general fundamental condition for the validity of a quasi-static argument in analyzing the response of a linear system to an FM signal (the instantaneous-frequency approach);

and (4) an analysis of the conditions for low-distortion processing of FM signals that leads to the definition of a more complete, straightforward approach to the design of linear FM transmission and FM-to-AM conversion filters.

THE KINETIC POWER THEOREM FOR PARAMETRIC, LONGITUDINAL, ELECTRON-BEAM AMPLIFIERS, by H. A. Haus. [1958] [8]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Published in I.R.E. Trans. of Professional Group on Electron Devices, v. ED-5: 225-232, Oct. 1958.

A power theorem is developed for parametric, longitudinal, electron-beam amplifiers which may be considered as a generalization of Chu's well-known kinetic power theorem. The new power theorem is used to explore the limitations on noise performance of parametric electron-beam amplifiers. It is shown that the electron-beam noise does not impose a basic limit on the noise performance of a parametric electron-beam amplifier in the way a basic limit is imposed upon the noise performance of conventional longitudinal electron-beam amplifiers. The new power theorem can be employed for understanding the operation of parametric beam amplifiers in the same way as Chu's kinetic power theorem has been used for interpreting the operation of longitudinal beam amplifiers. NEW METHOD OF MEASURING THE NOISE PARAMETERS OF THE ELECTRON BEAM, ESPECIALLY THE CORRELATION BETWEEN ITS VELOCITY AND CURRENT FLUCTUATIONS, by S. Saito. Aug. 22, 1957, 50p. incl. illus. diagrs. tables, refs. (Technical rept. no. 333) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Also published in I.R.E. Trans. of Professional Group on Electron Devices, v. ED-5: 264-275, Oct. 1958.

The noise figure of a microwave beam amplifier has a lower limit that depends entirely upon the noise process in the electron gun at and near the potential minimum. This report is chiefly concerned with the theory and experimental results of a new method of measuring the noise parameters of the electron beam, especially the

correlation between its velocity and current fluctuations, by using a selective beam coupler that has properties similar to the conventional microwave directional coupler. The value of the correlation coefficient of the velocity and current fluctuations was found to be from 0.2 to 0.35 in the space-charge-limited region and zero, or slightly negative, in the temperature-limited region. The probable error of this measuring method is discussed by taking account of the residual selectivity of the selective beam coupler, the effect of the pickup cavities upon the beam, the thermal noise from these cavities, and the higher-order modes. The most recent additions to the solid state field are the microwave amplifiers. These remarkable devices, variously called the maser (microwave amplification by stimulated emission of radiation), or the versitron, when operated at low temperatures show promise of improving receiver sensitivity by a factor of a thousand. This improvement of 30 db will greatly increase the range of radar sets and may well make world-wide television networks a possibility through the use of scatter propagation. (Contractor's abstract)

HOW CAN THE MULTIPLICITY OF THE GROUND STATE WAVE FUNCTION OF LIQUID HELIUM BE INFERRED FROM THERMOSTATICS (Abstract), by L. Tisza. 1958 [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-78108; continuation of DA 36-039-sc-64637]) Unclassified

Presented at Kamerlingh Onnes Conf. on Low Temperature Physics, Leyden (Netherlands), June 23-28, 1958.

Published in Physica, Suppl., v. 24: S137-S138, Sept. 1958.

It was recently pointed out that a sharpened version of the phase rule in conjunction with the observation of λ -line singularity in liquid helium leads to the inference that the ground state wave function is doubly degenerate. This result is surprising, partly, because it conflicts with the tacit or explicit assumption of the existing quantum mechanical theories, partly because the rigorous

MIT.30:002 - MIT.30:005

arguments of traditional thermodynamics do not lead to such quantum mechanical statements. The conclusion in question was reached from a new axiomatization thermodynamics. A characteristic aspect of this approach is that the choice of axioms is flexible and allows one to deal rigorously with questions of increasing incisiveness. In addition to the thermostatics of phase equilibrium, the theory is now developed on statistical lines.

THE STUDY OF PLASMAS THROUGH THEIR INTERACTION WITH HIGH FREQUENCY ELECTROMAGNETIC WAVES (Abstract), by G. Bekefi. [1958] [1]p. (Bound with its AFOSR-TR-58-125; AD 162274) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-ac-78108]; and in part by Atomic Energy Commission) Unclassified

Presented at Conf. on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

The interaction of electromagnetic radiation with a gaseous plasma is used in the study of some physical properties of plasmas. In general, the interaction is characterized by two quantities: by the attenuation and by the phase shift which an electromagnetic wave suffers in its passage through the plasma. Experiments yield such basic parameters as the electron density, electron-atom and ion-atom collision cross sections, electron temperatures, electron energy losses on impact, and depletion rates of electrons by diffusion and recombination. In particular measurement of the following parameters is discussed both in isotropic plasmas and in plasmas acted upon by dc magnetic fields: (1) high electron densities, (2) electron-molecule collision cross sections and electron energy loss on impact, and (3) microwave noise radiation emitted.

COLLISION CROSS SECTION AND ENERGY LOSS OF SLOW ELECTRONS IN HYDROGEN, by G. Bekefi and S. C. Brown. [1958] [6]p. incl. diagrs. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-ac-78108] and in part by Atomic Energy Commission) Unclassified

Published in Phys. Rev., v. 112: 159-164, Oct. 1, 1958.

Values for the collision cross section for momentum transfer and the fractional energy lost by an electron

on collision with a hydrogen molecule were obtained from measurements of the microwave conductivity of a gaseous plasma. The experiments were made in the afterglow of a pulsed discharge in a cavity resonating at a wavelength of 10 cm. The mean electron energy was varied from 0.04 ev (room temperature) to 0.08 ev by heating the gas, and from 0.04 ev to 1.6 ev by microwave agitation of the electrons alone. The collision probability in molecular hydrogen at electron energies in the neighborhood of 0.04 ev is found to be $28.5 (\nu/\nu_0)^{0.55}$

$(\text{cm-mm Hg})^{-1} \pm 3\%$, where ν is the electron velocity, and ν_0 the most probable velocity at 300°K. Measurements in deuterium gas gave the same result. The collision probability in hydrogen increases to a peak value

of $64 (\text{cm-mm Hg})^{-1} \pm 7\%$ at an electron energy of approximately 1.4 ev. The energy loss of electrons near room temperature was found by comparing the conductivity measurements obtained by thermal agitation with those obtained by microwave agitation of the electrons. The fraction of the excess electron energy lost on collision with the hydrogen molecule is $(3.5 \pm 0.5) \times 10^{-3}$.

In the higher energy range, the loss and the collision probability were computed from a comparison between microwave conductivity measurements and electron drift velocity and diffusion experiments.

AUTOCORRELATION AND CROSSCORRELATION ANALYSIS IN ELECTROENCEPHALOGRAPHY (Abstract), by J. S. Bariow. [1958] [1]p. (In cooperation with Massachusetts General Hospital, Boston)

(Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-78108) Unclassified

Presented at Eleventh annual Conf. on Electrical Techniques in Med. and Biol., Minneapolis, Minn., Nov. 19-21, 1958.

Also published in I.R.E. Trans. of Professional Group on Medical Electronics, v. ME-6: 179-183, Mar. 1959.

Autocorrelation and crosscorrelation analysis, which have been used extensively in statistical communication theory in the last several years, may be applied to the study of the EEG, with certain limitations. Autocorrelation functions for normal subjects may be classified into several categories, according to the dominant frequency or frequencies (if any) present, and other parameters. Crosscorrelation of EEG recordings from different locations on the head permit a comparison of the electrical activity at the two locations. Correlation functions and power density spectra contain equivalent information, since the one may be obtained from the other by Fourier transformation, but, because of the squaring and multiplication which appear in the computation process, the data so obtained are not exact equivalents of the frequency spectra derived from tuned resonators. A special case of crosscorrelation analysis, viz., crosscorrelation of a repetitive signal with a synchronously occurring brief pulse, may be applied to the detection of electrical responses evoked by sensory stimulation. This process is equivalent to averaging a large number of individual responses. The types of analyses described above may be used in a complementary fashion to study the rhythmic activity of the brain under a variety of conditions. Illustrative examples, obtained from semi-automatic computers especially designed for the purpose, are shown. (Contractor's abstract)

STATISTICAL CHARACTERISTICS OF EVOKED CORTICAL ACTIVITY (Abstract), by T. [T.] Sandel and T. Weiss. [1958] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-78108) Unclassified

Presented at Eleventh annual Conf. on Electrical Techniques in Med. and Biol., Minneapolis, Minn., Nov. 19-21, 1958.

The experimenter analyzing cortical activity evoked by sensory stimuli is faced with at least two major sources of difficulty. First, he is unaware of the number and nature of the processes responsible for the potentials he observes and second, the system under study is so complex that even if the processes were known, it is

unlikely that he could predict population responses with any precision on the basis of single unit responses. In such a situation a probabilistic approach to the problem is desirable. An attempt to utilize such a probabilistic approach in the analysis of cortical activity evoked by various auditory stimuli has been made. Since such an approach is predicated on large samples of evoked responses, two digital computers, one special purpose (ARC-1) and another general purpose (TX-0), have been used for analysis. The analysis consists essentially of: (a) averaging large numbers of responses evoked by an invariant stimulus, (b) obtaining amplitude distributions at various times following stimulus delivery, and (c) computing the medians, quartiles, and quartile intervals of these amplitude distributions. Results are presented and discussed. (Contractor's abstract)

APPARATUS FOR THE GENERATION OF PSYCHO-ACOUSTIC STIMULI VARYING IN COMPLEXITY FROM NOISE BURSTS TO SYLLABLES (Abstract), by G. Rosen and K. N. Stevens. [1958] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-78108) Unclassified

Presented at meeting of the Acoust. Soc. Amer., Chicago U., Ill., Nov. 20-22, 1958.

Published in Jour. Acoust. Soc. Amer., v. 31: 114, Jan. 1959.

Apparatus designed to control a speech synthesizer is described. The equipment is also useful for the generation of a large class of complex acoustic stimuli. It may be likened to a computer with both digital and analog elements. In the digital portion a system of counters and gates generates a 100-point time base. These points can be "picked-off" as pulses to trigger flip-flops, relays and function generators in a large variety of possible temporal programs. In the analog portion, the function generators provide piecewise-linear amplitude envelopes for buzz and noise sources and are also used in the synthesizer for programming changes in articulation or in formant frequencies as well as changes in fundamental frequency. The buzz and noise generators use novel diode amplitude control circuits to circumvent the shortcomings of balanced modulators. The logical design of the timing circuits is such that, in many cases, each experimental variable may be under the control of a single switch, so that tests may be recorded rapidly and accurately. Examples of the use of the apparatus in studies of the synthesis of speech and in the generation of stimuli for more general psychophysical experiments are given.

THE DETECTABILITY OF SMALL IRREGULARITIES IN A BROAD-BAND NOISE SPECTRUM (Abstract), by C. I. Malme and K. N. Stevens. [1958] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-78108) Unclassified

Presented at meeting of the Acoust. Soc. Amer., Chicago U., Ill., Nov. 20-22, 1958.

Published in Jour. Acoust. Soc. Amer., v. 31: 129, Jan. 1959.

The detectability of small changes in the energy content of a narrow frequency band in an otherwise white noise spectrum is measured using standard psychoacoustical testing techniques. The test stimuli are obtained by passing a white noise spectrum (100 cps - 10 kc) through a filter having a simple resonance and antiresonance. The positions of the corresponding pole and zero in the transfer function are varied to produce either a peak or notch (alone or simultaneously) in the output spectrum. The bandwidth and center-frequency of the resulting irregularities are specified in terms of the positions of the poles and zeros in the s-plane plot. The stimuli are presented to the subjects by an electrostatic loudspeaker having a relatively flat frequency response throughout the range of interest. The experimental results show the magnitude of a generally detectable spectrum irregularity as related to the pole and zero position in the transfer function of the filter. For example, a spectrum notch centered at 1000 cps requires a bandwidth of about 75 cps to be detectable by an average listener when compared with the flat noise spectrum.

This corresponds to a zero at $s = -235 + j6280 \text{ sec}^{-1}$ in the filter transfer function. The application of the experimental results to determine the amount of frequency response irregularity allowable in high-fidelity loudspeakers is discussed. Other possible applications in the field of speech research and audio engineering are enumerated.

EFFECT OF DURATION UPON VOWEL IDENTIFICATION (Abstract), by K. N. Stevens. [1958] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, Air Force Office of Scientific Research under DA 36-039-sc-78108, and National Science Foundation) Unclassified

Presented at meeting of the Acoust. Soc. Amer., Chicago U., Ill., Nov. 20-22, 1958.

Published in Jour. Acoust. Soc. Amer., v. 31: 109, Jan. 1959.

The purpose of this experiment is to determine the extent to which both duration and formant frequencies play a role in the identification of American English vowels. A resonance analog synthesizer was used to generate a number of cvc syllables in which the initial and final consonants were always [d] and [s] respectively. The durations of the vowels were given values from 20 to 500 msec. Two series of stimuli were recorded and were presented to listeners in random order. In the first test the frequencies of the first three formants of the vowel varied in several steps to encompass values appropriate for the front vowel series [i I A e], and the listeners were asked to identify the vowel as one of these; in the second test the back vowels [u U A o] were studied. The results indicated the [i I] and [u U] distinctions [e e] and [A o] are strongly influenced by duration. In a similar experiment in which the stimuli were mixed with noise, the influence of vowel duration was even more marked. The results are discussed in the light of existing data on vowel perception.

DIPOLE AND QUADRUPOLE MOMENTS OF ISOMERIC RADIOACTIVE Hg^{197} ; ISOMERIC ISOTOPE SHIFT (Abstract), by A. C. Melissinos and S. P. Davis. [1959] [1]p. (Sponsored jointly by Signal Corps, Office of Naval

Research, and Air Force Office of Scientific Research under DA 36-039-sc-78108) Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 28-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 371, Nov. 28, 1958.

The hyperfine structure (hfs) of five optical lines of the 65-hour radioactive Hg^{197} and the 25 hour isomeric Hg^{197} atom has been measured with a 10 in. grating in the 15th order. Radioactive mercury was produced by cyclotron bombardment; electrodeless discharge tubes with 5×10^{12} atoms gave satisfactory results. The analysis of the hfs confirmed the nuclear dipole moment and isotope shift of Hg^{197} in the $I = 1/2$ ground state (known from double resonance) (1), and gave the following values for the isomeric nucleus: Spin $I = 13/2$; dipole moment $\mu_{197} = -1.037 \pm .020$ nuclear magnetons; quadrupole moment $Q_{197} = (+1.50 \pm .50 \times 10^{-24} \text{ cm}^2 - .75 \times 10^{-24} \text{ cm}^2)$ and isotope shift in the 2537 Å line $(+69 \pm 6) \times 10^{-3} \text{ cm}^{-1}$ (mk). Thus an (isomeric) shift of atomic energy levels due to the excitation of the nucleus is observed, and found to be -22 ± 8 mk.

PERIPHERAL AND CORTICAL RESPONSES TO MECHANICAL STIMULATION OF THE CAT'S VIBRISSAE (Abstract), by W. D. Keidel, U. O. Keidel, and N. Y.-S. Kiang. [1958] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-78108) Unclassified

The space-time pattern of electric responses to pulling of cats' vibrissae was studied by recording with gross electrodes placed on maxillary nerve and somatic cortex. Single and repetitive mechanical stimulation at many intensities was used. Particular attention was paid to the time course of adaptation of responses to trains of stimuli. The results show that even with single stimulus patterns, the response patterns are complex. There is clear indication that adaptation can be demonstrated in cortical responses which does not correspond to any adaptation at the periphery. Some differences were observed between responses from unanesthetized cats with high spinal sections and from cats that were anesthetized with Dial. (Contractor's abstract)

THE EFFECT OF ELECTRICAL STIMULATION OF THE HYPOTHALAMUS OR PITUITARY GLAND ON THYROID ACTIVITY, by G. W. Harris and J. W. Woods. [1958] [28]p. incl. illus. diagr. refs. (AF 61(514)953) Unclassified

Published in Jour. Physiol., v. 143: 246-274, Sept. 23, 1958.

Various areas in the hypothalamus and pituitary gland have been electrically stimulated for periods of 24 to 72 hr, using a remote control method, in 43 conscious rabbits. The effect of such stimulation on thyroid activity has been assessed by measuring the rate of release of ^{131}I -labelled hormone from the gland and by studies of the blood concentration of $\text{PB } ^{131}\text{I}$. Stimulation in rabbits with intact adrenal tissue results in increased thyroid activity if the electrode tips are

situated in the anterior part of the median eminence adjacent to the supraopticohypophyseal tract. Stimulation of more posterior and superior areas of the hypothalamus, and different regions of the pituitary gland, did not elicit thyroid activation. The mechanism of the change in thyroidal response after complete adrenalectomy was investigated in animals subjected to adrenal denervation or to adrenal cortical "blockade" with high doses of cortisone. The evidence indicates that it is removal of the adrenal cortex, rather than the adrenal medulla, which is effective in reversal of the thyroid response after adrenalectomy. Since stimulation of the hypothalamus is known to activate release of pituitary ACTH, and since adrenal corticoids have been shown to inhibit TSH secretion, it is suggested that the effect of adrenalectomy is to prevent a sudden rise of adrenal steroids in the blood simultaneous with the period of stimulation.

MEASUREMENTS OF THE ENERGY ABSORPTION IN RADIATION FIELDS OF ELECTRON SOURCES, by A. E. Grün. [1957] 19p. incl. diagr. refs. (Technical note no. 1) (AFOSR-TN-57-118) (AF 61(514)911) AD 120471 Unclassified

Abstract published in Aeronaut. Eng. Rev., v. 16: 142, June 1957.

The energy absorption $\alpha(z)$ of air in the radiation field of a special electron source was measured as a function of the penetration depth z (depth dose curve). As a measure of the absorption the luminescence of air was used. The electron source delivered an electron beam that was transferred from the vacuum into the air by dynamical pressure stages. The primary energy E_0 of the electrons was varied from 5 - 54 kev. A power law was found for the range R of the electrons as a function of E_0 . The measured function $\alpha(z)$, plotted against z/R and suitably normalized, show a remarkably little dependence of E_0 . The energy loss $-dE/ds$ of the electrons, taken from the measured curves, are in good accordance with BETHE's theory. (Contractor's abstract)

RESEARCH ON INVESTIGATION OF THE INTERACTION OF SOUND AND TURBULENCE, by [W. Tellmien] [Annual] survey rept. Dec. 1, 1956-Nov. 30, 1957. [1958] 34p. incl. diagrs. (AFOSR-TN-58-236) (AF 61(514)1143) AD 154138 Unclassified

Investigation was made of the elementary process of scattering of sound by a vortex and of the dependence of the scattering properties of the characteristic parameters of the problem. Consideration is given to superposition of the effects of elementary scattering in a field of flow in which the vortices are statistically distributed due to an arbitrarily given distribution function controlling direction of the axis, size and circulation of the vortices. Arbitrary choice of the distribution function enables treatment of both isotropic and non-isotropic turbulence.

[EXPERIMENTAL STUDY OF THE STAGNATION TEMPERATURE IN A FREE MOLECULAR SYSTEM] Etude expérimentale de la température d'arrêt en régime moléculaire libre, by E. A. Brun and F. M. Devienne. [1957] [20]p. incl. diagrs. tables. (AFOSR-TN-57-83) [AF 61(514)930] AD 120429 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 24: 403-406, 412, June 1957.

The object of this research is the measurement of the temperature of a small plate in rapid displacement in a free molecular flow normal to the velocity when the plate is thermally insulated. The permanent temperature elevation, that it presents in relation to the rarefied gas which surrounds it, is given by a formula derived by assuming that the velocity distribution is that of Maxwell. Two methods are used. A plate placed normally to a free molecular flow in a cylindrical tube and a fixed plate on a support insulated at the end from a high-velocity turning arm, with the plane of the plate containing the axis of rotation. The second method varies the pressure and velocity in a continuous fashion. A correction adjusting for heat exchange with the support is given. This correction is effected by an original method.

STUDY OF STAGNATION TEMPERATURE AND PRESSURE IN A FREE-MOLECULAR FLOW REGIME, BY MEANS OF THE REVOLVING ARM METHOD, by F. M. Devienne. Mar. 1957 [102]p. incl. diagrs. tables (AFOSR-TR-57-32) (AF 61(514)930) AD 126495 Unclassified

This report is divided into four parts. The first part gives the theory regarding stagnation pressure and also that concerning the rise in temperature of a plate moving perpendicular to its velocity. It is shown that for relatively small rises in temperature the influence of the rotational energy of the molecules of rarefied gas is generally negligible. In the second part the results of stagnation pressure measurements taken up to speeds a little above 150 m/s are discussed. The measurements were taken by means of ionization gauges of a special type. The third part gives the results concerning rise in temperature and measurements of the ratio $\frac{a}{c}$ and $\frac{a}{c}$

for plates of different kinds in different gases up to speeds slightly above 300 m/s. The gases used were dry air, helium, argon, carbon dioxide, methyl chloride and freon 12. These measurements were taken at different pressures and for speeds in general between

MED.03:001-003, MUF.01:007

50 and 300 m/s. They were taken by using the revolving arm method. The last part of the report is devoted to new series of measurements taken up to speeds definitely above 300 m/s. These measurements differ from the preceding ones in that the apparent value of the thermal emissivity ϵ' was determined by the aid of a new method which permitted calculation of the values of the accommodation coefficient α . For these measurements considerable alterations had to be made in the apparatus because very great difficulties were encountered in achieving very high speeds.

CONSTRUCTION AND CALIBRATION OF A LOW DENSITY WIND TUNNEL, by F. M. Devienne, G. M. Forestier, and A. F. Roustan. Jan. 1958 [55]p. incl. illus. diagra. tables, refs. (AFOSR-TN-58-212) (AF 61(514)1126) AD 154113 Unclassified

A description is given of a low wind tunnel whose static pressure in the test chamber may, during the flow, vary between 0.1μ and a few μ of Hg. The pumping in this wind tunnel is principally ensured by four large three-stage vacuum pumps. In order to calibrate the wind tunnel a preliminary study of the measurement of the impact pressure and of the corrections required by this measurement, is carried out with different pressure probes and for very different diameters. The results obtained after correction of the pressures lead us to admit that for a given nozzle and a static pressure in the range of 0.57μ , the ratio of the impact pressure to the static pressure is given by the Superaerodynamic formula. The application of this formula leads us to the conclusion that the Mach number on the axis is very close to 4. The study of the field of pressure enables us to show that the velocity is fairly constant in the neighborhood of the axis in a cylinder having a diameter of approximately one third of that of the nozzle. THE REVOLVING ARM METHOD AND ITS APPLICATION TO RAREFIED GAS DYNAMICS AND AEROTHERMODYNAMICS, by F. M. Devienne. May 1958 [34]p. incl. illus. diagra. (AFOSR-TN-58-769) (AF 61(514)1126) AD 201866; PB 136872 Unclassified

After having brought to mind the principle of the revolving arm method device, and the possibilities of measuring the stagnation temperature and the total pressure, the advantages and disadvantages of these methods are discussed. The essential advantage of the revolving

arm method is that the experimental conditions are perfectly determined. In particular the pressure and the temperature of the gas, as well as the speed of the arm are accurately determined. The revolving arm method is however limited by the fact that it is impossible to reach extremely high speeds. In the free molecular flow regime or the transition flow regime the revolving arm method can be applied without correction for Knudsen number values superior or equal to 0.6 in the case of dry air. This value is besides more or less the same for other gases with which studies of the phenomena in the vicinity of the arm, namely, argon and carbon dioxide were made. At higher pressures, which correspond to lower Knudsen numbers, it is necessary to make some corrections in order to keep account of the heating of gaseous layers in the vicinity of the arm. RETRACTS FROM NEIGHBORHOOD RETRACTS, by W. L. Strother and L. E. Ward, Jr. Apr. 30, 1957 [8]p. incl. refs. (Rept. no. 8) (AFOSR-TN-57-227) (AF 18(600)1449) AD 126525 Unclassified

Also published in Duke Math. Jour., v. 25: 11-14, Mar. 1958.

A compact Hausdorff space X is called a CAR* (or CANR*) if it is a retract (or neighborhood retract) of a Tychonoff cube. If $S(X)$ is a space of closed subsets of an X which is CANR*, then $S(X)$ has a fixed point property and if X is metric, then $S(X)$ is CAR*. It is conjectured that the metric condition in the last statement can be dropped. The following theorems are proved: Theorem 1. Let X

MUF.01:008, 009; MUF.02:001-004

be a connected metric space. If X is a CANR*, then $S(X)$ is a CAR*. Theorem 2. If X is a CANR*, then $S(X)$ is a CANR*. Theorem 3. If X is a connected CANR*, then $S(X)$ has the fixed-point property. Analogies between neighborhood retracts and the null-homotopic fixed-point property suggest the question of equivalence between the fixed-point property in $S(X)$ and the null-homotopic fixed-point property in X .

FIXED POINTS, by W. L. Strother. [Final] technical rept. June 1, 1955-Sept. 30, 1958 [24]p. incl. refs. (AFOSR-TR-58-142) (AF 18(600)1449) AD 204551
Unclassified

The strong bond is exploited which exists among functions, M -functions, and the space of closed subsets as a tool for proving fixed point theorems. Specific problems are: (1) if X is a CAR, is $S(X)$ a CAR?; (2) classify the functions, $f: S(X) \rightarrow S(Y)$; (3) conditions on X , Y and the continuous M -function $F: X \rightarrow Y$ so that there exists a continuous trace $f: X \rightarrow Y$ of F ; (4) conditions on X so that there exists a continuous function $f: S(X) \rightarrow X$ such that, for each element A in $S(X)$, $f(A) \in A$; and (5) for what spaces X and functions $f: S(X) \rightarrow S(X)$ will there exist fixed points. CAR is the retract of a Tychonoff cube.

MULTI-VALUED FUNCTIONS AND PARTIAL ORDER, by C. E. Capel and W. L. Strother. [1958] [7]p. (AF 18(600)1449) AD 204551
Unclassified

Published in Portugal. Math., v. 17: 41-47, 1958.

Some results are presented on traces and fixed points for multi-valued functions on spaces which have a continuous partial order. In Section 1 some basic definitions are given. In Section 2 a fairly general result is presented to show when a continuous, multi-valued function will have a trace. Some examples then show how this leads to fixed point theorems. In Section 3 it is shown that a weakly continuous, point-connected, multi-valued function on a tree has a fixed point. This is an order-theoretic version of a theorem of Wallace where tree is defined in a combinatorial sense. (Contractor's abstract)

THE CONTINUITY POSTULATE FOR MARKOV

PROCESSES. ABSTRACT SPACE CASE, PART I, by D. G. Austin and R. V. Chacon. Sept. 27, 1957, 19p. (Rept. no. 9, pt. 1) (AFOSR-TN-57-586) (AF 49(638)-184) AD 136575a
Unclassified

The continuity properties of stationary Markov transition functions are defined on an abstract space X . A number of conditions weaker than Doob's continuity postulate are found to be sufficient to insure that the transition functions are continuous. A necessary and sufficient condition for this result is obtained and some examples are given to show that the results are the best possible.

STOCHASTIC PROCESSES WITH DISCRETE STATE SPACE, by D. G. Austin. [1958] [76]p. incl. refs. (AFOSR-TN-58-967) (AF 49(638)184) AD 205779
Unclassified

A study is made of stochastic processes with state space, the positive integers; time-parameter, the non-negative real line; and with conditional probabilities that depend only on the increment of time. That the process is Markovian is assumed. Sample function properties and analytic properties of conditional probabilities are developed without the Markov hypothesis, so that the exact effect of the Markov hypothesis on these properties will be in evidence. The results obtained are grouped under the following general headings: measure theoretic results, real and strong form continuity properties of the sample functions, the strong Markov property, the entrance boundary problem, and analytic properties of the transition matrix. A discussion follows on the significance of the results obtained.

RELATIVISTIC EFFECTS IN THE COHESIVE ENERGIES OF THE ALKALI METALS, by J. Callaway, R. D. Woods, and V. Sirounian. May 1957 [21]p. incl. diagr. tables, refs. [Technical rept. no. 4] (AFOSR-TN-57-208) (Sponsored jointly by Air Force Office of Scientific Research under AF 49(638)62 and Office of Naval Research under [Nonr-84006]) AD 128505 Unclassified

Also published in Phys. Rev., v. 107: 934-939, Aug. 15, 1957.

The relativistic corrections to the cohesive energies of the alkali metals are studied from two points of view. In the first, perturbation theory is applied to the second approximation to the Dirac equation. Calculations are made for potassium and cesium. The limitations of this approach are discussed. In the second, the quantum defect method is extended to include almost all relativistic effects. A relativistic analog of Bardeen's expression for the effective mass ratio is derived. Application is made to cesium. (Contractor's abstract)

INFRARED OPTICAL CONSTANTS OF GALLIUM ARSENIDE (Abstract), by A. Perlmutter. [1957] [2]p. [AF 49(638)62] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 66-67, Jan. 30, 1957.

The transmission and reflectivity of a sample of n-type GaAs have been measured in the region from 0.86 to 25μ . The free carrier absorption is found to be proportional to the square of the wavelength, beginning about 7μ , in agreement with the Drude and Kronig theory. The effective mass of the conducting electrons, which is determined from these data and the carrier concentration ($6.9 \times 10^{17} \text{ cm}^{-3}$ at room temperature), is found to be 0.075 or about double the value reported from thermoelectric measurements. Measurements of the reflectivity as a function of the wavelength will also be described. The optical energy gap was found to be about 1.35 eV, a value which is about equal to that found previously. A long tail at the absorption edge masks the possible effect of indirect transitions.

EFFECTIVE MASS OF ELECTRONS IN GALLIUM ARSENIDE, by L. C. Barcus, A. Perlmutter, and J. Callaway. Mar. 5, 1958 [8]p. incl. diagr. (AFOSR-TN-58-152) (Sponsored jointly by Air Force Office of Scientific Research under AF 49(638)62 and Office of Naval Research) AD 152178 Unclassified

Presented at annual meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 3: 30, Jan. 29, 1958.

Also published in Phys. Rev., v. 111: 167-168, July 1, 1958.

The optical properties of n type gallium arsenide have been studied by a method of reflection of polarized light from a surface of the sample. The dielectric susceptibility has been determined from measurements of the index of refraction $n(\lambda)$ and the extinction coefficient K in the wavelength region between 0.78 and 22μ . The susceptibility has been used to calculate the effective mass of the conduction electrons. It has been found that K has a value of 0.1 or less throughout the wavelength range used and that $n^2(\lambda) = 11.06 - c\lambda^2$. The value of the

effective mass $0.43 \pm .005 m_0$ obtained supports the hypothesis that the minimum of the conduction band is at the center of the Brillouin zone.

A summary of the work done under this contract is presented and a list of the publications is included. The relativistic effects in the calculations of the cohesive energies of the alkali metals have been studied and reported upon. The dependence of the results of band calculations on the crystal potential assumed has been studied with respect to the general form of the bands and the specific calculations using a pseudo-potential for calculations of energy bands in sodium. Further information on the dependence of energy bands with respect to the crystal potential assumed can be obtained from study of materials which have similar crystal structure but different atomic constituents. The effective mass of gallium arsenide has been determined and the value obtained indicates that in GaAs the band minimum is at the center of the Brillouin zone. Studies on the Fourier analysis of crystal potentials by means of an orthogonal plane wave method and the existence of surface eigenstates for a finite one-dimensional lattice have been carried out.

SURFACE STATES IN LINEAR CHAINS, by H. A. Brown. Final technical rept. Sept. 1958 [43]p. incl. diagr. (AFOSR-TR-58-128) (AF 49(638)62) AD 203493
Unclassified

The additional allowed energy levels introduced in the solution of a finite one-dimensional lattice as compared with the states allowed in a non-terminating lattice have been studied. The potential in each cell is assumed to be symmetric about the center of each cell. It is found that the surface states are possible even in the case in which there is no crossing of energy bands. The generalization of the Bloch theorem to include a complex wave vector has been found to be not justified in accounting for the finite lattice. It has been concluded that the restriction of using the generalized Bloch function in this case has caused the error in the assertion of the impossibility of surface states except when bands cross. The only restriction now imposed is that a surface state cannot pass through a cross-over point for the bands. The surface states have been shown to occur as singlets rather than as pairs as previously asserted.

MUO.01:002 -004; MSU. 01:001

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 146, Mar. 27, 1958.

It has been a usual procedure in band calculations to include the effects of the valence electron distribution by assuming it to consist of overlapping spheres of uniform charge density. This is not self-consistent, and a procedure has been developed within the scope of the OPW method, for taking the symmetry and radial dependence of the distribution into account. A valence charge distribution in the unit cell is obtained from an initial estimate of the electron wave functions and Poisson's equation is used to obtain the Fourier coefficients of the desired potential. As a test, the procedure has been applied to silicon and the results compared with those obtained from a spherical approximation.

X-RAY STUDIES OF METAL HALIDES IN THE MELT AND IN SOLUTION (Abstract), by H. L. Ritter. [1956] [1]p. [AF 18(600)485] Unclassified

Presented at the Southwide Chemical Conf., Memphis, Tenn., Dec. 8, 1956.

The calculation of a radial distribution curve from Debye-Scherrer x-ray patterns of liquids by the method of Warren, Krutter, and Morningstar has been carried out for certain metal halides in the fused state and in solution. In many cases a clear insight into the structure of the liquid is afforded. Thus fused aluminum chloride appears to be composed of Al_2Cl_6 molecules

of determinable structure; indium iodide of similar molecules either much more poorly defined or partly dissociated into monomers or ions; tin (IV) iodide of tetrahedral monomeric molecules; and fused cadmium iodide is a curious transition between the known structures of the crystalline and gaseous state. In solution, SnI_4 in benzene and CdI_2 in water are molecular, the latter showing no change on dilution. CsI in water shows little evidence of association; BaI_2 and LaI_3 in water show considerable structure due either to ion association or hydration.

AN X-RAY STUDY OF WATER SOLUTIONS OF CADMIUM IODIDE, by G. R. Simmons and H. L. Ritter. [1958] [2]p. (AFOSR-TN-58-40) (AF 18(600)485) AD 148081 Unclassified

Patterns of x-ray diffraction have been obtained for water solutions of cadmium iodide having various concentrations of which 0.042 mol ratio of CdI_2/H_2O is a nearly saturated solution. Using crystal-monochromated Mo-K α radiation, three exposures were made of each solution, each ranging from 60 to 80 hr. Radial distribution curves for the solutions were computed by means of the Fourier analysis of Warren. The great visual difference in diffraction patterns of CdI_2 solutions as compared with BaI_2 solutions indicates that there is a considerable difference in solute structure. A difference anticipated by knowledge of the fact that CdI_2 is much less ionized than BaI_2 .

AN X-RAY STUDY OF WATER SOLUTIONS OF BARIUM IODIDE, by A. K. Prince, P. Bender, and H. L. Ritter. [1958] [21]p. incl. illus. table. (AFOSR-TN-58-1071) [AF 18(600)485] AD 207240 Unclassified

Presented at meeting of the Phys. and Inorg. Chem. Div. of the Amer. Chem. Soc., Miami, Fla., Apr. 7-12, 1957.

Abstract published in 131st meeting of the Amer. Chem. Soc. Abstracts of Papers, 1957, p. 44-R-45-R.

X-ray patterns have been obtained for different concentrations of barium iodide solutions in water. Radial distributions were derived by the method of Warren, Krutter, and Morningstar, all showing significant features in the regions of 2.8, 3.7 to 4.0, and 5.0 to 6.5A. The first is identified with the O-O distance in water and the Ba-O distance in hydrated Ba^{++} . The shift of the position of this feature with concentration and the excess of its associated area over that of the corresponding peak in water make possible estimates of hydration numbers and distances. A hydration distance of 2.8A and hydration numbers ranging from 7 in saturated solution to 12 in dilute solution are consistent with curves observed in this study. Peaks near 3.8A range monotonically from 3.7A in saturated to 4.0A in dilute solution. These distances are identified with the Ba-I distance in crystalline barium iodide and provide evidence of ion association in solution. Decrease in peak prominence and shift in peak position agree with the notion that ion association should decrease with concentration. Broader humps in the 5 to 6.5A region are explained on the basis of loose, incipient ion clusters.

RESIDUAL RESISTIVITY OF COPPER AND SILVER ALLOYS. THE PERIOD DEPENDENCE, by F. J. Blatt. June 15, 1957, 10p. diagrs. tables, refs. (AFOSR-TN-57-315) (AF 49(638)70) AD 132386 Unclassified

Also published in Phys. Rev., v. 108: 285-290, Oct. 15, 1957.

Attention is given to the fact that polyvalent impurities of the Ag period of the periodic table give rise to a smaller residual resistivity in both Cu and Ag than do polyvalent impurities belonging to the Cu period. An explanation of this experimental result is presented which is based on a modification of the Friedel sum rule suggested by Harrison by which one may take lattice distortion into account. The calculated results reflect the qualitative features of the experimental data and, moreover, lead to better quantitative agreement between theory and experiment than previous calculations based on the free electron model. The occurrence of a similar period dependence of the thermoelectric power of these alloy systems is suggested and is being investigated.

RESIDUAL RESISTIVITY OF GOLD ALLOYS: DEPENDENCE ON PERIODIC TABLE, by F. J. Blatt. Aug. 28, 1957 [12]p. incl. diagrs. tables, refs. (AFOSR-TN-57-503) (AF 49(638)70) AD 136493 Unclassified

Also published in Phys. Rev., v. 108: 1204-1206, Dec. 1, 1957.

The residual resistivities, $\Delta\rho$, of dilute alloys of Au were calculated by a method suggested earlier (item no. MSU.02:001). With the exception of those for Au-Cu and Au-Ag alloys, the calculated resistivities agreed reasonably well with the observed residual resistivities. The numerical results differed from the observed resistivities by significant amounts, especially for $Z = 2$, where Z is the valence difference between solute and solvent atoms. The dependence of $\Delta\rho$ on the row of the periodic table which the solute occupies is reflected in the calculated values for the ratios $\text{Au}(\text{Cu})/\text{Au}(\text{Ag})$. The influence of Z and of lattice strain due to the solute may be taken into account by the modification of the Friedel sum condition (Advances in Phys., v. 3: 446, 1954), except when $Z = 0$ where differences in the core potential are important.

THE MAGNETIC SUSCEPTIBILITY OF METALS, by F. J. Blatt. Sept. 12, 1958 [3]p. incl. table. (AFOSR-TN-58-287) (AF 49(638)70) AD 154191 Unclassified

Also published in Jour. Phys. Chem. Solids, v. 6: 301-303, Aug. 1958.

A discrepancy has been found to exist between the theoretical values for the diamagnetic susceptibility of the conduction electrons in the close-packed monovalent metals and the values obtained by subtracting the experimental value for the susceptibility of the electronic spin from the total susceptibility. An interaction susceptibility is proposed similar to that suggested by Jones (Proc. Roy. Soc. London, A240: 321, 1957) for the interaction of the conduction electrons and the lattice vibrations. The correction afforded by this extra susceptibility has the right sign and the magnitude necessary to bring calculated and experimental results into substantial agreement is not unreasonably large.

DIPOLE SCATTERING IN SEMICONDUCTORS, by R. R. Slocum. June 23, 1958, 5p. (AFOSR-TN-58-472) (AF 49(638)70) AD 158283 Unclassified

Presented at meeting of the Amer. Phys. Soc., St. Louis, Mo., Nov. 29-30, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 346, Nov. 29, 1957.

Recent work on the interaction of defects in semiconductors has suggested that ion-pairs are formed and that

MIC. 14:001; MIC. 15:001-003

dipole scattering effects in these substances should be considered. Using a formulation due to Massey for scattering centers of polar symmetry, the cross-section for dipole scatterers has been calculated, and subsequently a relaxation time obtained. Comparison of this relaxation time with that of Conwell and Weisskopf for ionized impurities and that for neutral impurities showed that over all temperature ranges, the dipole scattering is negligible with respect to both. The relaxation time for the dipole scattering process exhibits an energy dependence of $E^{\frac{1}{2}}$. (Contractor's abstract, modified)

FLOW FIELD OF A BUNSEN FLAME, by M. S. Uberoe, A. M. Kuethe, and H. R. Menkes. [Final rept.] May 14, 1957 [29]p. incl. illus. diags. (AFOSR-TR-58-95) (AF 18(600)1512) AD 132444 Unclassified

Also published in Phys. Fluids, v. 1: 150-158, Mar.-Apr. 1958.

The flow field of a 2-dimensional Bunsen flame is examined by approximating the zone of combustion by a surface of discontinuity across which the density drops and normal velocity increases. Even though the flow of unburned gases is potential, the flow of the burned gases is always rotational which is therefore not amenable to complete analysis. Interaction of flame shape and flow field is obtained analytically and experimentally. The entire flow field of unburned and burned gases is mapped by taking stroboscopic photographs of small particles suspended in the combustible gases. The measured flow field is considered in the light of the above analysis. (Contractor's abstract)

ON CURVATURE AND CHARACTERISTIC OF HOMOGENEOUS SPACES, by H. Samelson. Jan. 1958, 18p. (AFOSR-TN-57-572) (AF 49(838)104) AD 136557 Unclassified

Also published in Mich. Math. Jour., v. 5: 13-16, Jan. 1958.

Let G be a compact connected Lie group, U a closed subgroup of G , and $M = G/U$ be the homogeneous space formed by the left cosets of U . A simple geometric proof is given of the fact that all values of the sectional Riemannian curvature of M , in the induced Riemannian metric, are nonnegative. A new proof is given of the fact that the Euler-Poincaré characteristic $\chi(M)$ of M is non-negative and is positive exactly if U is of maximal rank.

POINCARÉ DUALITY IN HOMOLOGY MANIFOLDS, by F. A. Raymond. [1958] [71]p. incl. diags. refs. (AFOSR-TN-58-457) (AF 49(838)104) AD 158264 Unclassified

The problem is studied which considers the conditions which must be imposed on a topological space X such that there exists an isomorphism between the p -dimensional terms of the homology sequence of X and the $(n-p)$ -dimensional terms of the Čech cohomology sequence of X such that naturality holds. A suitable homology is defined on the space like a singular homology and the Poincaré and Alexander-Pontrjagin duality isomorphisms are studied for combinatorial manifolds of dimension n . Chapters 1 and 2 give a very general concept of chains and homology. The definition of homology manifolds and the proofs of several theorems are given, which enable the uses of the algebraic duality cohomology theorem of H. Cartan. The problem of the dimension of a closed set without any interior is resolved in Chapter III by the characterization of interior and boundary points of closed subsets of homology manifolds.

THE ACTIONS OF THE GROUPS $SO(3)$ AND $Sp(1)$ ON THE SPHERE S^4 AND S^5 , by R. W. Richardson. [1958] 81p. incl. refs. (AFOSR-TN-58-488) (AF 49(838)104) AD 158296 Unclassified

All actions to within equivalence of $SO(3)$, the group of proper orthogonal transformations of E^3 , and $Sp(1)$, the group of unit quaternions, are considered on the 4-dimensional sphere, S^4 , and the 5-dimensional sphere, S^5 . No differentiability assumptions are made. Restriction was made to cases in which there exists a 3-dimensional orbit. Two theorems are proved which characterize the orbit space if a compact Lie group acts on the n -sphere with $(n-1)$ - or $(n-2)$ -dimensional orbits. Actions of $SO(3)$ and $Sp(1)$ on S^4 are all linear. Within equivalence, there are exactly 2 actions of $SO(3)$ on S^4 and one effective action of $Sp(1)$ on S^4 . There is only one action of $Sp(1)$ on S^5 which is effective and it is linear. There are, at most, 3 such actions of $SO(3)$ on S^5 . Two of them are linear. An indecisive theorem regarding the possible nonlinear action, states that there is, at most, one action of $SO(3)$ on S^5 , such that all orbits are either 3-dimensional or fixed points. Such an action exists only if S^5 is homeomorphic to the double suspension of $SO(3)/H_1$.

ACYCLIC CONTINUA IN THE PLANE AND QUASI-COMPLEXES, by J. E. Keisler. July 1958, 15p. (AFOSR-TN-58-656) (AF 49(838)104) AD 182187; PB 138980
Unclassified

Quasi-complexes, a class of spaces to which the Lefschetz fixed point formula applies, are related to finite Euclidean complexes, all parallelotopes, and all snake-like continua. It is demonstrated that there are acyclic plane continua, possessing the fixed point property, which are not quasi-complexes, even in the event of a T-like plane continuum. A covering is a finite open covering and an ϵ -covering of a metric space is a covering such that the diameter of each element of the covering is less than ϵ . For coverings A_1, A_2 such that A_1 refines A_2 ($A_1 > A_2$), $N(A_1)$ denotes the complex which is the nerve of the covering A_1 and $\pi(1,2)$ denotes one of the projection chain maps $\pi(1,2):N(A_1) \rightarrow N(A_2)$ induced by the inclusion map.

For s an element of the covering A , St_s is the union of all those elements of A which intersect s . A_1 star refines A_2 ($A_1 \gg A_2$) if the covering C , whose elements are the sets St_s for all s which are elements of A_1 , refines A_2 . Further definitions are given and proofs of lemmas and corollaries introduced.

THE TORSION OF SHAFTS OF VARYING CIRCULAR CROSS SECTIONS, by H. L. Hunzeker. Oct. 1958, 85p. incl. diagrs. refs. (AFOSR-TN-58-738) (AF 49(838)104) AD 201504; PB 137839
Unclassified

The torsion of a shaft of varying circular cross sections is considered. The problem is the following: The elastic body under consideration is a solid of revolution with plane ends perpendicular to the axis of revolution, and the body is twisted by twisting couples applied to the ends. It is desired to find the components of stress, strain, and displacement throughout the body. The chapters discuss the following topics: I. The fundamental equations of elasticity are considered and reduced for the case of the torsion of a shaft of varying circular cross sections, using a tensorial approach from Hay. II. The torsion of a hollow prolate ellipsoidal shaft and of a shaft of nearly uniform cross sections with an arbitrary prolate ellipsoidal cavity is considered for non-orthogonal coordinates. III. Hay's analysis obtains the solution to the Saint Venant torsion problem for a shaft of nearly uniform cross sections with an arbitrary symmetrically located oblate ellipsoidal cavity. IV. A re-

sult is given for the torsion of a shaft bounded by a portion of an arbitrary hyperboloid of revolution of two sheets, in classical elliptical coordinates. V. Consideration is given to the torsion of a general shaft of varying circular cross sections.

ASYMPTOTIC THEORY OF SECOND ORDER DIFFERENTIAL EQUATIONS WITH TWO SIMPLE TURNING POINTS, by N. D. Kazarinoff. [1958] [22]p. incl. diagrs. (AFOSR-TN-58-485) (AF 49(838)192) AD 219117
Unclassified

Also published in Arch. Rational Mech. Anal., v. 2: 129-150, 1958.

The author considers second order ordinary linear differential equations of the form

$$(1) \quad d^2y/ds^2 - \lambda^2 P(s, \lambda)y = 0,$$

where $P(s, \lambda) = \sum_{j=0}^{\infty} p_j(s)\lambda^{-j}$ is analytic in s in a region D of the complex plane s and in λ for $|\lambda| > N$, and where $p_0(s)$ has exactly two simple zeros α, β in the interior of D (two turning points in the terminology now well known after the work of Langer). As in Langer's theory, which has a great bearing in the present paper, the problem is to find asymptotic expansions for the solutions of (1) uniformly valid in D for $|\lambda| \rightarrow \infty$. The equation (1) is transformed first into an analogous equation of the form

$$(2) \quad d^2u/dz^2 - \lambda^2 Q(z, \lambda)u = 0,$$

where $Q(z, \lambda) = \sum_{j=0}^{\infty} q_j(z)\lambda^{-j}$, $q_0(z) = z^2 - 1$, and $Q(z, \lambda)$ is analytic in a region R containing the two turning points $z = \pm 1$ in its interior. The main point consists in taking as "leading terms" of the asymptotic expansion for (2), or "first approximation", the solutions of the Weber equation

$d^2v/dt^2 + [v/2 - t^2/4]v = 0$, which is here transformed into $d^2v/dt^2 - \lambda^2[(z^2 - 1) + \lambda^{-1}c + \dots]v = 0$, by a convenient change of variables and choice of the parameter. Finally, as in Langer's theory, successive approximations are defined, the n th approximation satisfying an equation of the same form, where the expression in brackets coincides with $Q(z, \lambda)$ up to the terms of degree $n - 1$ in λ . Previous results of Langer and McKelvey are used. It is then proved that the n th approximation is a valid asymptotic expansion to $n + 1$ terms of solutions of (2). Specific hypotheses are made during the process which cannot be referred to here. The behavior of the solutions of equation (2) are known inasmuch as one knows the behavior of the Weber functions, which are the leading terms of the expansion. In particular, results of Erdelyi, Kennedy and McGregor

MIC.17:001 - MIC.17:003

are used. An algorithm is given to determine recursively the terms of the asymptotic expansions of these Weber functions. (Math. Rev. abstract)

PHOTOGRAPHIC SEQUENCE EXPOSURE EXPERIMENT, by J. H. Enns and E. Katz. Feb. 2, 1957 [7]p. incl. illus. diagrs. tables. (AFOSR-TN-57-53) (AF 49(638)69; continuation of AF 18(600)750) AD 115092
Unclassified

Also published in Jour. Opt. Soc. Amer., v. 47: 758-764, Aug. 1957.

An instrument is described which has been built for the automatic recording of sequence exposures on 4 x 10-in. photographic plates. Twelve shutter slides are independently timed so that on one plate up to 384 4 x 5-mm rectangles can be uniformly exposed to high and low intensity radiation. The present design is for an intensity ratio of 100:1, where both intensities are below optimum. With minor modifications the instrument can be converted to operate at other intensity ratios. The densitometer readings are checked from calibration strip data placed adjacent to the sequence exposures. The corrected data, following conversion to Seidel values, are plotted as families of characteristic curves, with the sequence exposure ratio as the constant parameter. Isodense loop data are read from the curves at the intersection with a line drawn parallel to the exposure axis. A theoretical discussion of isodense loops is presented which is based on the hypothesis that for isodense exposures the probability of rendering the last grains developable must be equal. It is shown how this method should yield the limiting slope of the low intensity failure curve and the minimum number of quanta absorbed by the average grain to become developable. Preliminary results presented here for Eastman Kodak Emulsion Type 33 are within expectation.

PHOTOGRAPHIC EMULSION STUDIES BY THE SEQUENCE EXPOSURE EXPERIMENT (Abstract), by J. H. Enns and E. Katz. [1958] [1]p. [AF 49(638)69]
Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 100, Mar. 27, 1958.

The basic principles of the photographic sequence experiment are reviewed briefly, and experimental data for

several emulsion types are presented and discussed. The results show that the just developable grain of a commercial emulsion, color-sensitized in the blue, is a perfect (or nearly so) absorber of all incident photons at 4358A. More extensive data (varying average grain size, total and internal image development) is presented for a pure silver bromide emulsion of minimum sulfur sensitization. An interesting result for this emulsion type is, among other things, an increase in the absorbed photons determined for the just developable grain with increasing grain size or increasing sensitivity. This effect is discussed on the basis of dispersed latent image formation due to an increase in the number of effective trapping centers per grain.

GALVANOMAGNETIC CONSTANTS OF BISMUTH BETWEEN 120° AND 300°K, by E. Katz and W. Tantraporn. [1958] [9]p. incl. tables. [AF 49(638)69]
Unclassified

Published in Proc. Internat'l. Conf. on Electronic Properties of Metals at Low Temperatures, Geneva, N. Y. (Aug. 25-29, 1958), Schenectady, N. Y., General Electric Research Lab., 1958, p. 141-149.

The effect of a weak magnetic field \vec{B} on the components p_{ij} of the electrical resistivity tensor is described by a series of constants, called brackets, which have been enumerated systematically by Kao and Katz:

$$p_{ij}(\vec{B}) = \sum_{n=0}^{\infty} \sum_{m=0}^n \sum_{p=0}^m (m-p, p, n-m) B_1^m B_2^p B_3^{n-m}$$

The values of all brackets up to terms corresponding to the fourth power of B ($n \leq 4$) were measured by W. Tantraporn for single crystals of bismuth in the temperature range 120° - 300°K. Moreover the temperature dependence of the brackets with $n = 5, 6$ was established for a few cases. Experimental procedures are discussed. The temperature dependences found do not fit conventional trial functions but are well described by the empirical formula

$$\{n\} = T \Gamma e^{-\beta_n \sqrt{T}} \text{ for } n \leq 4.$$

Here Γ differs for each bracket but β_n only depends on n . The latter feature enabled us to obtain β_n also for $n = 5, 6$. It is found that $\beta_n \sim \frac{2n}{n+4}$ for $n \leq 6$.

Comparison with results of other authors is discussed. (Contractor's abstract)

STUDIES OF TRANSITION TO TURBULENT FLOW IN A TUBE, by A. M. Kuethe and K. R. Raman. [1957] 2p. [AF 18(600)350] Unclassified

Also published in Proc. Ninth Internat'l. Congress of Appl. Mech., Brussels (Belgium) (Sept. 5-13, 1956), v. 3: 349, 1957.

The work is a continuation of previous work (item no. MIC.04:001) in which it was shown that fully developed laminar flow in a circular tube is stable to small disturbances. In the continuation of the work, two types of disturbances were introduced in the flow at a tube Reynolds number of 4000. The first consisted of an annular ring of 0.0625-in. diameter wire extending from 0.68 to 0.78 radius; the second was an annular 0.0615-in. projection from the wall. Measurements of longitudinal and radial velocity fluctuations and turbulent shearing stresses were obtained with a hot-wire anemometer. Traverses were made at various distances up to 48 diameters downstream of the disturbances. A brief discussion of the investigations is included.

BRILLOUIN ZONE THEORY AND PHOTOGRAPHIC LATENT-IMAGE STUDIES, by G. B. Spence, R. L. Martin and others. Final rept. Mar. 1957, 28p. incl. illus. diags. tables. (Rept. no. 2158-8-F) (AFOSR-TR-57-22) (AF 18(600)750; continued by AF 49(638)69) AD 120475 Unclassified

A theoretical study is made of Brillouin zones, with special regard to the question of the appearance of energy gaps. It has a bearing on the Jones-Hume-Rothery theory of the physical properties of binary substitutional alloys. An investigation is undertaken as part of a plan to check the consequences of theories of the photographic latent-image formation, with a view toward finding the number of atoms necessary to form a developable speck of latent-image silver. This study deals with the dependence of low-intensity reciprocity failure on grain size, other factors being unchanged. Another investigation is undertaken as part of a plan to check the consequences of theories of the photographic latent-image formation, with a view toward finding the number of atoms necessary to form a developable speck of latent-image silver. This investigation is based on the order principle which rests on the hypothesis that for isodense exposures the probability of rendering the last grains developable must be equal. This investigation utilizes isodense data obtained from the sequence exposure experiment. (Contractor's abstract)

THEORY OF HYDROGEN LINE BROADENING IN HIGH-TEMPERATURE PARTIALLY IONIZED GASES, by A. C. Kolb and O. Laporte. Mar. 1957, 155p. incl. illus. diags. tables, refs. (Rept. no. 2189-3-T) (AFOSR-TN-57-8) (AF 18(600)983) AD 115040 Unclassified

An investigation is undertaken to study theoretically the broadening of the hydrogen Balmer lines observed in the radiation of high-temperature partially ionized gases. The theory is based on the classical path approximation for the motion of the perturbers. The general problem of the broadening of a group of lines arising from transitions between "nearly degenerate" states is considered. The method employed is not restricted by the usual assumption of binary collision. The formalism is subsequently specialized to the case where the broadening due to the interactions between an ensemble of ions and a hydrogen atom can be treated as a static perturbation. The validity of this approximation is discussed in detail. The static ion field removes the normal degeneracy of the states of the hydrogen atom. The high-velocity electrons present in the electrically neutral plasma are then shown to cause phase changes and transitions between these nearly degenerate states. The phase shifts due to adiabatic effects and the collision-induced transitions due to nonadiabatic effects are of comparable importance as sources of broadening by electrons. The resultant profile caused by the electron-atom collisions is then averaged over the static ion field splitting with the Holtsmark distribution function. Series expansions for the line profile are obtained which reduce to the Holtsmark expansion for zero electron density and to the dispersion distribution for zero ion density. The principal result of these calculations is that both ions and electrons must be taken into account in the derivation of Balmer line absorption coefficients. (Contractor's abstract)

LUMINOSITY OF STRONG SHOCK BOUNDARY LAYERS (Abstract), by G. Charatis and T. D. Wilkerson. [1957] [1]p. [AF 18(600)983] Unclassified

Presented at meeting of Div. Fluid Dynamics, Amer. Phys. Soc., Lehigh U., Bethlehem, Pa., Nov. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 292, June 19, 1958.

It is possible to make certain features of strong shock flows in the rare gases self-luminous by addition of small amounts of organic vapors to the expansion chamber gas of a shock tube. This technique has been applied to the photographic study of boundary layers in the shock tube. A typical experimental situation is the following: behind a shock wave moving with velocity 2.989 mm/ μ sec through a 99.5% neon — 0.5% CH_4 mixture, the flow velocity is ~ 2.19 mm/ μ sec, pressure ~ 84.9 cm Hg, temperature $\sim 4340^\circ K$, and therefore the specific

Reynolds number is $\sim 1.15 \times 10^4$ /cm. A vertical slit photograph shows the main stream C_2 band emission behind the shock to be separated from the wall by a non-luminous laminar boundary layer which grows to a thickness of about 2 mm until transition to turbulence occurs approximately 14 cm behind the shock. The turbulent boundary layer emits the Swan bands of C_2 by virtue of the mixing of cold gas near the wall with hot gas from the main stream. The thickness of the turbulent region appears to grow linearly with distance behind the shock and is 7 mm at the driving interface (42 cm behind the shock).

HIGH-TEMPERATURE SHOCK WAVES, by O. Laporte. [1958] [26]p. incl. diagrs. tables, refs. [AF 18(600)983] Unclassified

Published in Combustion and Propulsion, Third Agard Colloquium; Noise, Shock Tubes, Magnetic Effects, Instability and Mixing, Palermo (Italy) (Mar. 17-21, 1958), London, Pergamon Press, 1958, p. 499-524.

The phenomena of modern high-speed aerodynamics with concomitant high temperatures make it necessary for the aerodynamicist to become familiar with such quantum phenomena as molecular vibration, dissociation and ionization. Of the few flow patterns which can be discussed quantitatively, the normal shock has been chosen for detailed presentation because by means of normal shock high temperatures can be produced in the laboratory with relative ease. The methods used are gradually developed in order to make it possible for the investigator to calculate other flows like rare-factions or oblique shocks. The discussion of strong waves is divided into three sections. The first section deals with monatomic gases; whether noble gases or metallic vapors. In the second section an account of shocks in molecular, especially diatomic gases, is given. In the third section, nonequilibrium phenomena and experimental results are reported.

EFFECT OF OZONE UPON FLAME SPEEDS OF SOME COMBUSTIBLE MIXTURES, by R. J. Kelley, R. L. Brehm, and M. E. Gluckstein. Final rept. Mar. 1957, 17p. incl. diagrs. (Rept. no. 2279-10-F) (AFOSR-TR-57-33) (AF 18(600)1186) AD 126510 Unclassified

A study was made of the effect of ozone addition in amounts up to three percent of total mass flow upon the flame speeds of propane, hexane, and carbon monoxide burned with air. It was found that in the combustion of all three fuels the effect of ozone was to increase flame speed. Some specification is made as to the possible mechanism of the observed effects. A qualitative examination was also made of the pre-flame reaction product of ethylene and an air-ozone mixture. Resulting from this, an additional discussion is presented of the possible mechanism that causes decrease in the flame speed of ethylene-air mixtures when ozone is added. The latter phenomenon was observed previously. (Contractor's abstract)

REGENERATIVE HEAT EXCHANGER WITH HEAT-LOSS CONSIDERATION, by E. K. Dabora. Aug. 1957, 19p. incl. diagrs. refs. (Rept. no. 2284-14-T) (AFOSR-TN-57-613) (AF 18(600)1199) AD 136803 Unclassified

The differential equations describing the regenerative type heat exchanger with heat-loss consideration are solved by using Laplace transform. The solution is carried out for two cases: (a) heating the bed from a uniform initial temperature equal to that of the surroundings with fluid at constant inlet fluid temperature, and

(b) cooling the bed from a uniform temperature with fluid at constant inlet temperature equal to that of the surroundings. Typical curves of the transient bed temperature are included for both cases. The steady-state temperature in heating is shown to depend solely on the ratio of the heat loss and fluid heat capacity

$[(s_o U_o / G_p^c) \cdot x]$; therefore, for any heat-exchanger design where the maximum temperature that can be attained at the exit is of importance, this term should be carefully estimated. (Contractor's abstract)

A PRELIMINARY STUDY OF THE APPLICATION OF STEADY-STATE DETONATIVE COMBUSTION TO A REACTION ENGINE, by R. Dunlap, R. L. Brehm, and J. A. Nicholls. Sept. 1957, 16p. incl. diagra. (Rept. no. 2284-15-T) (AFOSR-TN-57-657) (AF 18(600)1189) AD 136648 Unclassified

Also published in Jet Propulsion, v. 28: 451-456, July 1958.

A reaction type engine employing steady-state detonative combustion is considered. A simplified analysis treats the supersonic mixing of fuel and air together with the requirements necessary to achieve steady-state detonative combustion. Calculations of specific thrust and specific fuel consumption as functions of flight Mach number are made for hydrogen and acetylene fuels. The results of this study indicate that some supersonic diffusion of the air is necessary even though supersonic combustion exists. It is concluded that the speed range of air-breathing engine may be materially extended. (Contractor's abstract)

DESCRIPTION AND EXPERIMENTAL RESULTS OF TWO REGENERATIVE HEAT EXCHANGERS, by E. K. Dabora, M. P. Moyle and others. Feb. 1958, 23p. incl. diagra. refs. (Rept. no. 2284-18-T) (AFOSR-TN-58-226) (AF 18(600)1199) AD 154128 Unclassified

Two pebble-type regenerative heat exchangers are described, and experimental results obtained with them are presented. The heat exchangers are for the production of high-temperature (2500°R) air and hydrogen. Hot gases produced by the combustion of a propane-air mixture are passed over a bed of refractory pebbles until the downstream end of the bed reaches the temperature required or slightly above it. Then the gas which is to be heated is passed through the heat exchanger. Since the gases are compressed, the heat exchangers must withstand pressures of about 1000 psi.

STUDIES IN CONNECTION WITH STABILIZED GASEOUS DETONATION WAVES, by J. A. Nicholls, E. K. Dabora, and R. L. Gealer. [1958] [7]p. incl. illus. diagra. (AFOSR-TN-58-886) (AF 18(600)1199) AD 204100 Unclassified

Also published in Seventh Symposium (Internat'l.) on Combustion, Oxford U., London (Gt. Brit.) (Aug. 28-Sept. 3, 1958), London, Butterworths Scientific Publications, 1959, p. 766-772.

The approach used, the experimental technique, and some of the preliminary results obtained in the attempt to achieve a standing detonation wave are presented. In order to stabilize a gaseous detonation wave certain dynamic conditions must be met, of course, which are dictated by the detonation characteristics of the fuel-oxidant combination employed. Mach numbers of detonation differ for various combustible mixtures but all are relatively high (in the hypersonic range). Further, there is a temperature effect (static temperature of the unburned gases) such that the Mach number of detonation varies approximately inversely with the square root of the temperature. The pressure effect is relatively slight although the Mach number can be reduced somewhat for sub-atmospheric pressures. It is evident, then, that the problem requires that a detonatable mixture be accelerated to a high Mach number with high stagnation temperature and pressure. There must then be some mechanism for generating and stabilizing the detonation. In view of the high stagnation temperatures required, mixing of the fuel and oxidant under stagnation conditions is precluded.

This report presents one phase of an experimental investigation of the effect of intense nuclear radiation upon flames. Equipment was designed to obtain the spectral emission at a series of elevations through a

MIC.09:003; MIC.11:002-004

flat flame subjected to nuclear radiation. The intensities of the C_2 , CH, and OH bands were measured quantitatively. The source of radiation for the emission studies was the same 30 grams of irradiated gold wire used in the flame-speed studies. The flame-speed measurements were carried out at source intensities as high as 10,000 curies. The reported data on spectral emission were obtained after the gold had decayed to 1000 curies. Intense irradiation of propane-air mixtures and flames increases the emission due to CH and C_2 but hardly affects the emission due to OH.

RATE OF PROPAGATION OF PROPANE-AIR FLAME IRRADIATED WITH A 10,000-CURIE GOLD SOURCE, by S. W. Churchill, A. Weir, Jr. and others. [1957] [4]p. incl. illus. diagrs. tables, refs. [AF 16(600)1218] Unclassified

Presented at meeting of the Gas and Fuel Chem. Div. of the Amer. Chem. Soc., Miami, Fla., Apr. 7-12, 1957.

Abstract published in 131st meeting of the Amer. Chem. Soc. Abstracts of Papers, 1957, p. 1-J.

Published in Indus. Engineering Chem., v. 48: 1419-1422, Sept. 1957.

Eunsen flames of premixed propane and air were irradiated with an irradiated gold source having an initial strength of about 10,000 curies. Both the flame zero and the propane-air mixture were exposed to the radiation. The rate of propagation of the flame was increased up to 50% by the radiation. The flame speed fell off rapidly to the normal value as the source decayed below 10,000 curies. The effect of radiation appeared to be about the same over a range of propane to air mass ratios from 0.055 to 0.080 and a range of pressures from 4 to 10 in. of mercury absolute. The effect is attributed to beta radiation, since the estimated number of ion pairs produced by beta radiation exceeds the number produced by gamma radiation.

REVERSIBLE PROPERTIES OF POLYCRYSTALLINE FERROMAGNETS. II. EXPERIMENTAL VARIATION OF THE REVERSIBLE SUSCEPTIBILITY AND Q WITH MAGNETIZATION, by D. M. Games. May 1957 [29]p. incl. diagrs. tables, refs. (Technical rept. no. 2; rept. no. 2495-2-T) (AFOSR-TN-57-209) (AF 18(603)8) AD 126506 Unclassified

Detailed experimental results on four samples are re-

ported and analyzed in terms of the expected Q variation as well as the expected susceptibility variation described in Part I (Item no. MIC.11:001). It is concluded that two of the samples have susceptibilities arising very predominantly from domain rotation, one from wall motion and one from both. It is assumed that no other mechanisms are operative. It is concluded that Frei and Shtrikman's analysis of the remanent position is valid under only the more restricting conditions described herein.

ADDITIONS OF Fe_2O_3 TO $BaTiO_3$ - $SrTiO_3$ FERRO-ELECTRICS, by H. Diamond and V. Chang. Dec. 1957, 10p. incl. diagrs. (Technical rept. no. 3) (AFOSR-TN-57-391) (AF 18(603)8) AD 132466 Unclassified

If small percentages of Fe_2O_3 are added to polycrystalline $BaTiO_3$ and fired at 1400° as a ceramic, the Curie temperature of the ceramic remains constant while the peak permittivity is lowered. However, if the Fe_2O_3 is added to BaO and TiO_2 , the iron goes into the lattice predominately in the titania sites and decreases the Curie temperature as well as the peak permittivity. Additions of Fe_2O_3 to mixed $BaTiO_3$ - $SrTiO_3$ compositions result both in a lowering of the Curie temperature and a depression of the peak permittivity of the single phase system. No changes in lattice dimensions with the additions were observed when the Ba to Sr ratio was held fixed. (Contractor's abstract)

AN INVESTIGATION OF REACTIONS IN FERROSPINELS BY DIFFERENTIAL THERMAL ANALYSIS, by C. F. Jefferson. July 1957, 8p. incl. diagrs. refs. (Technical rept. no. 4; rept. no. 2495-6-T) (AFOSR-TN-57-540) (AF 18(603)8) AD 136526 Unclassified

Differential thermal analysis has been used to follow the oxidation of magnetite in solid solution with a nickel-zinc ferrosipinel, and the solid-state reaction leading to the formation of the ferrosipinel from the oxides. Differential thermal curves for the series $Ni_{.474}Zn_{.526}Fe_2O_4 - Fe_3O_4$ are shown and explained. An attempt was made to follow the solid-state reaction which occurs during the formation of the ferrosipinel from the oxides. (Contractor's abstract)

LOW-TEMPERATURE HEAT CAPACITIES AND THERMODYNAMIC PROPERTIES OF ZINC FERRITES. III. EFFECT OF COPPER SUBSTITUTION, by D. M. Grimes and E. F. Westrum, Jr. Jan. 1959, 17p. incl. diagrs. tables. (Technical rept. no. 6) (AFOSR-TN-58-980) (AF 18(603)8) AD 205877 Unclassified

Also published in Jour. Phys. Chem. Solids, v. 10: 120-125, July 1959.

The heat capacities of annealed and quenched samples of $\text{Cu}_{0.05}\text{Zn}_{0.90}\text{Fe}_{2.05}\text{O}_4$ have been determined over the range 5-350°K. The Néel temperature is the same as previously reported for a similar lithium-substituted zinc ferrite. The result is discussed in terms of sublattice population and molecular field coefficients. (Contractor's abstract)

Presented in part at Conf. on Magnetism and Magnetic Materials, Washington, D. C., Nov. 1957.

Published in Jour. Phys. Chem. Solids, v. 6: 280-286, Aug. 1958.

The heat capacities of annealed and quenched samples of $\text{Li}_{0.005}\text{Zn}_{0.90}\text{Fe}_{2.05}\text{O}_4$ and of quenched ZnFe_2O_4 have been determined over the range 5-350°K. Addition of lithium to zinc ferrite lowers the temperature of the cooperative thermal anomaly associated with antiferromagnetic ordering transition in accord with theory, and quenching of either material results in nearly complete disappearance of the λ -anomaly but modifies the pronounced high-temperature tail less significantly. The effects on the thermal properties are interpreted in terms of sublattice populations. (Contractor's abstract)

EFFECT OF THERMAL HISTORY ON THE ANTIFERROMAGNETIC TRANSITION IN ZINC FERRITE, by D. M. Grimes and E. F. Westrum, Jr. [1958] [2]p. incl. diagr. (AF 18(603)8) Unclassified

INSTABILITY OF THE BOUNDARY LAYER NEAR THE NOSE OF A BLUNT BODY, by A. M. Kueth. [Oct. 22, 1957] 1p. (In cooperation with the Rand Corp., Santa Monica, Calif.) [AF 18(603)34] Unclassified

Presented at Conf. on Magnetism and Magnetic Materials, Washington, D. C., Nov. 1957.

Published in Jour. Appl. Phys., v. 29: 384-385, Mar. 1958.

Quenched zinc ferrite is ferrimagnetic, annealed ferrite paramagnetic at 300°K. Although annealed zinc ferrite has a lambda-type heat capacity transition at about 9.5°K, quenched zinc ferrite retains only elementary vestigia of this transition. A similar effect exists in $\text{Li}_{0.05}\text{Zn}_{0.90}\text{Fe}_{2.05}\text{O}_4$ in which the transition temperature is slightly lowered relative to that of zinc ferrite. This temperature shift does not appear to exist for $\text{Ni}_{0.1}\text{Zn}_{0.9}\text{Fe}_2\text{O}_4$. The magnetic entropy at 300°K is essentially unaltered by lithium substitution or thermal history. (Contractor's abstract)

Near the nose of a body the positive $\partial\mu/\partial x$ causes stretching of that vorticity component parallel to the streamlines. Therefore if the boundary layer contains three dimensional disturbances the stretching will have a destabilizing effect on the flow. This destabilizing effect is counteracted by the stabilizing effect of the convex curvature near the nose (Taylor-Görtler stability). It is shown by means of an approximate analysis that, since velocities, and therefore centrifugal forces on displaced particles within the boundary layer, are small near the stagnation point the destabilizing effect of stretching will overbalance the stabilizing effect of curvature near the nose of a body. In this region the effect of cooling the body is to further destabilize the boundary layer. It is inferred therefore that under conditions of high heat transfer to the body the instability of the flow may become great enough to cause transition to turbulent boundary layer to occur near the nose. Disturbances with a vorticity component normal to the streamlines (Tollmien-Schlichting waves) will also stretch and thus tend to amplify near the nose of a body because of the diverging streamlines in that region. TRANSITION TO TURBULENT FLOW IN TUBES AND

MIC. 12:004, 005; MIC. 18:001, 002

IN BOUNDARY LAYERS (Abstract), by A. M. Kuethe. Oct. 22, 1957 [1]p. [AF 18(803)34] Unclassified

Investigations in tubes and in boundary layers have given some insight into the processes of transition. Measurements in tubes show traverses of the Reynolds stress throughout the transition region. The high stresses developed are interpreted as a cause for the relatively high recovery factor in the transition region. Preliminary measurements in boundary layers show the effect of stability of the layer on the rate of growth of turbulent spots. Other aspects of transition will be discussed.

ON THE STABILITY OF FLOW IN THE BOUNDARY LAYER NEAR THE NOSE OF A BLUNT BODY, by A. M. Kuethe. [Jan. 1958] [18]p. incl. illus. diags. (AFOSR-TN-58-21) (AF 18(803)34) AD 148080
Unclassified

Abstract published in Zeitschr. Angew. Math. Mech. (ZAMM) v. 38: 312-313, July/Aug. 1958.

An approximate analysis indicates that the stretching of vortex filaments because of the change in body cross-sectional area and the positive velocity gradient near the nose of a body is a destabilizing influence on the flow in the boundary layer. The analysis predicts that the destabilizing influences of stretching and of surface cooling on the flow over the convex surface exceeds the stabilizing influence of curvature up to a certain distance from the nose. Hot-wire observations near the nose of a body of revolution show regular fluctuations which lie in the range of Reynolds numbers for which the linearized theory predicts stability for Tollmien-Schlichting disturbances. The observations can be rationalized qualitatively in terms of the analysis given here. (Contractor's abstract)

ON THE CHARACTER OF THE INSTABILITY OF THE LAMINAR BOUNDARY LAYER NEAR THE NOSE OF A BLUNT BODY, by A. M. Kuethe. [1958] [2]p. incl. illus. diagr. (AF 18(603)34) Unclassified

Published in Jour. Aeronaut. Sciences, v. 25: 338-339, May 1958.

Records were obtained of the hot-wire response to velocity of fluctuations in the boundary layer of a body of revolution with a hemispherical nose 11.5 in. in diameter at wind speeds up to 134 ft/sec in a 5x7 ft low-turbulence tunnel. Bursts of approximately sinusoidal

fluctuations which occurred indicate that the instability is probably of the Tollmien-Schlichting type. It is suggested that one of the sources of instability that has never been mentioned before might be the stretching of the vortex filaments in the region of diverging flow near the stagnation point. Approximate analysis of the destabilizing influences of stretching and surface cooling compared with the stabilizing influence of curvature indicates that near the nose the net effect is destabilizing. Also, when convex curvature is introduced, the centrifugal force acting on a displaced particle causes a destabilizing influence. It is believed that if the curvature is large enough, the effect of cooling a surface may be destabilizing to Tollmien-Schlichting disturbances.

This paper contains a derivation of suitable stress-strain relations for elastic isotropic plates of variable thickness which include the effects of transverse shear deformation and normal stress, as well as the variation in thickness. The significance of the results is examined in the light of some simple examples, where in particular for torsion of plates whose thickness is such as to give rise to equilateral triangular and elliptic cross-sections, exact agreement is obtained for the stress distribution with the corresponding results of Saint-Venant's theory of torsion. RESPONSE OF SHALLOW VISCOELASTIC SPHERICAL SHELLS TO TIME-DEPENDENT AXISYMMETRIC LOADS, by P. M. Naghdi and W. C. Orthwein. Nov. 1958 [24]p. incl. refs. (Technical note no. 4; rept. no. 2500-5-T) (AFOSR-TN-58-993) (AF 18(603)47) AD 205905 Unclassified

Also published in Quart. Appl. Math., v. 18: 107-121, July 1960.

The response of shallow viscoelastic spherical shells to arbitrary time-dependent axisymmetric loads is investigated. The medium is assumed homogeneous and isotropic. Emphasis is placed on unlimited shallow spherical shells, but shallow spherical shell segments are also discussed. The solutions employ the differential equations governing the transverse motion of thin shallow elastic shells, and are obtained with the joint use of the Laplace and the Hankel transforms. The order of the inversions is interchanged, avoiding an otherwise intricate task of contour integration in the complex Laplace transform-plane. Explicit results in integral form are deduced for viscoelastic shells under instantaneous pulse loading, and are particularized to the cases of Maxwell and Kelvin solids. The solutions for a shallow elastic shell and for the case of a flat plate are also given as by-products of the general solution and comparison is made with known results.

ON THERMO-ELASTIC STRESS-STRAIN RELATIONS FOR THIN ISOTROPIC SHELLS, by P. M. Naghdi. [Nov. 1958] 5p. [Technical note no. 3; rept. no. 2500-4-T] (AFOSR-TN-58-994) (AF 18(603)47) AD 205904 Unclassified

Also published in Jour. Aero/Space Sciences, v. 26: 125, Feb. 1959.

It is the purpose of the present note to extend previous results of the author (Quart. Appl. Math., v. 14: 369-380, Jan. 1957) and to modify the stress-strain relations so as to include the thermal effects in a manner consistent with the assumptions made in the aforementioned work. The defect in the usual formulation of problems of thermoelastic shells that an initially stress-free isotropic shell remain stress-free in a uniform temperature field can be avoided by assuming a particular form for the displacement.

CALCULATION OF THE REFLECTION OF RADIATION FROM SAW-TOOTH SURFACES AND THE REFLECTION AND TRANSMISSION OF RADIATION BY PARALLEL CYLINDER SYSTEMS, by W. C. Meecham, S. T. Choh, and D. W. Moomaw. Final rept. Jan. 1958, 36p. incl. diagrs. table, refs. (Rept. no. 2607-5-F) (AFOSR-TR-58-44) (AF 49(638)26) AD 154160 Unclassified

The report is divided into two main parts, comprising Sections II and III. The first part is concerned with the calculation of the reflection of radiation from saw-tooth surfaces. The calculations performed for this problem are based on a variational method. A review of this method is presented. The results of the calculations are given. The computations are restricted to the class of reflection problems where the propagation vector of the incident plane wave is normal to the corrugations of the reflecting surface and where the incident electromagnetic wave is polarized with the electric vector parallel to the corrugations. For an acoustic wave this is equivalent to a pressure release surface. In Section III the problem considered is that of the reflection and transmission of radiation by an infinite system of parallel, circular, equally-spaced cylinders whose axes lie in a plane. Computations are restricted to the case where the propagation vector of the incident plane wave is perpendicular to the axes of the cylinders, and further, to the case where the wave is normally incident on the plane formed by those axes. The theory of Ignatowsky is used in making calculations. The results reported here are all for the case where the radiation wavelength, λ , is greater than the spacing of the cylinders, D . Hence there are no propagating diffracted orders; in this case the sum of the directly transmitted and reflected intensities must be equal to the incident intensity.

AN INVESTIGATION OF THE EFFECTS OF ULTRASONIC ENERGY ON COMBUSTION, by J. A. Boit, D. H. Holkeboer, and W. Mirsky. Final rept. June 1958, 14p. incl. illus. diagrs. (Rept. no. 2634-4-F) (AFOSR-TR-58-75) (AF 49(638)180) AD 158329 Unclassified

This report covers an investigation of the effect of high-intensity sound fields, in the frequency range of 20 to 50 kc, on combustion of natural gas and kerosene. It follows a previous investigation by Mirsky which showed that the presence of ultrasonic energy increases the evaporation rate of fuel drops. Three transducers were developed, two of which were applied to combustion processes. It was noted that ultrasonic energy decreased smoke and carbon formation, apparently increased the burning rate, and increased the tendency for flames to be quenched or extinguished. An attempt was made to find paramagnetic materials suitable for maser applications. The electron-spin resonance properties of ruby ($Al_2O_3:Cr$) were investigated. Evidence of oscillations and amplification was obtained. Ruby crystals have been used in microwave cavities to test their use as microwave amplifiers. Preliminary measurements have confirmed MASER action involving a $-3/2 - 1/2$ and $-1/2 - 3/2$ transitions. It has been found that the pulse-height and the repetition rate decrease with decreased pumping power. At 4.2°K and $H = 4230$ gauss, the minimum pulse interval was found to be 0.3 msec and the radiated frequency was 9.22 kmc/sec for a pumping frequency of 24.2 kmc/sec. A net gain of 20 db has been observed. Subsequent measurements are intended (see item no. MIC.21:003)

LUMINESCENCE OF COLOR CENTERS IN KCl, by J. Baker and J. Lambe. Jan. 1959, 13p. incl. diags. tables, refs. (Rept. no. 2616-5-T) (AFOSR-TN-58-914) [AF 49(638)68] AD 204566

Unclassified

Absorption excitation and emission studies were made of the color centers in KCl crystals which were irradiated at 77° and 300°K. A number of absorption bands were observed and tabulated with the basic color centers. The test procedures consisted in warming the crystal to 300°K, decreasing to 77°K to study the absorption and emission properties, and then returning to 300°K to bleach with F-center (0.55μ) light; this cycle was repeated until no further significant changes were made. The bright pink color of the crystal at 77°K gradually deepened, becoming a light purple. Observing the emission at successive stages of bleaching showed that the intensity of the F center decreased, and a small, but noticeable, M center appeared. Crystals that were irradiated at 300°K showed the purple appearance observed in the warmed crystals. The spectra of the 300°K irradiated crystals indicated a large F center absorption with noticeably large R_1 , R_2 , and M center absorption. Although the F center absorption was intense, the emission produced by excitation of the F center was weak.

Presented at Electron Tube Research Conf., Laval U., Quebec (Canada), June 26-27, 1958.

Also published in Jour. Appl. Phys., v. 30: 1061-1087, July 1959.

A general study of its properties has shown that ruby possesses numerous advantages as a maser material. Since the energy-level scheme of the ruby system is reasonably simple, four levels can be used, thus making possible push-pull pumping, which substantially increases pumping efficiency. It was found that ruby has suitable spin-lattice relaxation times for good maser operation, and, in addition, that ruby has excellent thermal, electrical, and mechanical properties for its use as maser material. Other materials for which maser action should be investigated have been cited. (Contractor's abstract, modified)

MIC. 21:006; MID. 01:001, 002;
MIL. 01:001Presented at meeting of the Amer. Phys. Soc.,
Chicago, Ill., Mar. 27-29, 1958.Published in Bull. Amer. Phys. Soc., Series II, v. 3:
135, Mar. 27, 1958.

Hurd, Sachs, and Hershberger observed that some of the ESR absorption lines of Mn^{++} in a single crystal of calcite were split into doublets for certain orientations of the magnetic field with respect to the optic axis. The spectrum has been reexamined in order to check the suggestion that this splitting is due to the nonequivalent trigonal fields at the two Ca^{++} sites occupied by Mn^{++} and has the dependence $\sin^3 \theta \cos \theta \times 3\psi$, where θ is the angle between H and the optic axis. For a given θ the doublet separation is zero or a maximum when the direction of H is varied in a plane parallel ($\cos 3\psi = 0$) or normal ($\cos 3\psi = 1$) to a symmetry plane passing through the optic axis, respectively. In the latter case the maximum splitting occurs at $\theta = 60^\circ$ and is about 18 gauss, in good agreement with theory. In addition to the above-mentioned doublets, the spectrum contains five pairs of weak lines occurring midway between the principal hfs lines. The mechanism responsible for these lines will be discussed.

EFFECT OF BLEACHING ON F-CENTER PARAMAGNETIC
RESONANCE (Abstract), by J. Lambe and J. Baker. [1958] 1p. [AF 49(638)68] UnclassifiedPresented at meeting of the Amer. Phys. Soc.,
Chicago, Ill., Mar. 27-29, 1958.Published in Bull. Amer. Phys. Soc., Series II, v. 3:
136, Mar. 27, 1958.

An experimental study has been carried out on the relationship between F-band optical density and paramagnetic resonance absorption as the number of F centers is reduced by bleaching. Crystals of KCl were colored by Co^{60} gamma irradiation. Measurements were then made of the above quantities. F-band optical density was measured at 5460A and F-center paramagnetic absorption was measured using an X-band magnetic resonance spectrometer. The crystals were then bleached for varying periods of time with light of wavelength 5800A and the measurements were repeated after each bleaching. It was found that the paramagnetic absorption decreased more rapidly than the optical density. This is not in agreement with what should be expected on a simple picture of the F-band optical absorption. It indicates that either some other mechanism is operative in producing optical absorption in the F-band region, in addition to the normal F-center absorption, or that the optical properties of the F center are affected by the changes which bleaching induces.

THE PADÉ TABLE AND THE τ -METHOD, by Y. L. Luke.
Aug. 1957, 42p. incl. tables, refs. (AFOSR-TN-57-570)
(AF 49(638)66) AD 136555 UnclassifiedAlso published in Jour. Math. Phys., v. 37: 110-127,
July 1958.

Rational function representations of the function E are presented as defined by a differential equation of a standard form. Closed form expressions for the error are derived and used to appraise the error in a convenient manner. Rational approximations to the transcendents defined by the differential equation are derived by the τ method. Numerical examples are worked out and the true error is compared with that predicted.

A GENERALIZATION OF A THEOREM OF LAGUERRE,
by Y. L. Luke. June 15, 1958, 27p. (AFOSR-TN-58-
48) (AF 49(638)66) AD 158295 Unclassified

Additional results are given concerning the function $E(z) = {}_2F_1(a, b; c; -1/z)$ and a rational approximation to it, $E_n(z) = c_n(z)/f_n(z)$. The differential equation satisfied by $f_n(z)$ is constructed and matched with a known differential equation for $f_n(z)$. This analysis leads to a system of 2 linear differential equations involving $f_n(z)$ and 2 other polynomials, θ_n and H_n . A proof is given that if $\alpha = 0$ (α appears in the definition of $c_n(z)$ in the τ -procedure), θ_n and H_n are independent of $f_n(z)$. This fact is used to prove that $f_n(z)$ and g_n satisfy the same differential equation where $g_n = (c_n - Ef_n)z^{-\alpha}(z+1)^{\alpha-\lambda}$. Various representations of $c_n - Ef_n$ are constructed.

COENZYME A CONTENT IN LIVERS AFFECTED BY
VARIOUS DEGENERATIVE CHANGES, by C. Severi-
Fonnesu, A. Fonnesu, and C. Agostini. [1958] [11]p.
incl. tables, refs. (AF 61(514)1026) AD 226153
UnclassifiedAlso published in Italian Jour. Biochem., v. 7: 215-225,
July-Aug. 1958.

Coenzyme A (CoA) has been estimated in livers affected

MIL. 02:001, 002; MIL. 03:001

by various degenerative changes: cloudy swelling, cell vacuolation and fatty change (CCl_4 and phosphorus).

Livers from animals treated with a single injection of CCl_4 or phosphorus have also been examined for CoA.

With the aim of detecting not only the real changes of intact CoA but also the possible accumulation of CoA precursors, CoA has been determined on each tissue sample by two different methods. With the first method CoA precursors are partially estimated as CoA; the second method is specific for intact CoA. In no case differences have been detected between CoA values obtained by the first method and those obtained by the second method. This indicates that the amount of CoA precursors is very small in both normal and pathological livers. CoA content is unchanged in livers affected by cloudy swelling and cell vacuolation, as compared with normal controls. In fatty livers produced with either CCl_4 or phosphorus, CoA content is markedly decreased.

A marked decrease of liver CoA also occurs after a single injection of phosphorus. The results are briefly discussed. (Contractor's abstract)

Presented at the Internat'l. Symposium on Military Psychology, Brussels (Belgium), July 26, 1957.

Published in *Exper. Med. and Surg.*, v. 16: 166-176, June-Sept. 1958.

Monosynaptic reflexes have been produced in the sciatic territory by means of direct stimulation of this mixed nerve: in this way two responses are collected as action currents from the muscle, the first being due to the stimulation of the motor fibers, the second, delayed, due to stimulation of the sensory fibers, the responses of the muscle in the last event being due to a reflex mechanism. If such a stimulation is repeated at two points well apart along the course of the nerve at a known distance, an exact indication can be obtained of the conduction speed of both motor and sensory fibers and the central delay is then easily calculated together with the end-plate delay. The very short pulse, 75 msec, used for stimulation minimizes the error due to the variability of the position of the active point in the stimulus duration. Another element which has been studied is the so-called Renshaw phenomenon, namely the suppression of a second reflex response following the first at an interval of less than 200-250 msec. This phenomenon is very easily affected by any upsetting condition. The following single components and characteristics of the monosynaptic reflex in man have been studied during

stress: (1) total reflex time; (2) spinal delay; (3) end-plate delay; (4) motor conduction speed; (5) sensory conduction speed; and (6) Renshaw suppression phenomenon. The results are given for the following conditions of stress: (a) hypoxia; (b) hypoglycaemia; (c) muscular fatigue due to prolonged physical effort; (d) action of drugs: caffeine, barbiturates, alcohol; and (e) lack of sleep.

INVESTIGATION OF THE FATIGUE IN MAN. Final rept. [1957] 7p. (AFOSR-TR-58-117) (AF 61(514)637; continued by AF 61(052)23) AD 202359 Unclassified

Some fundamental characteristics of lower neuron activity as a means of investigating fatigue in man, has been studied. Such research was based on the assumption that even if fatigue is a very unprecise and general term covering a number of stress-inducing conditions, a common factor should exist consisting of some widespread change in the central nervous system. In fact, internal or external stresses are bound to cause the earliest possible response in the organism from the central nervous system. It was also assumed that any change in the central nervous system might lead to a variation in lower neuron activity, in the terminal centers of the efferent pathways of the CNS, namely the neurons of the spinal cord, both internuncial and motor.

Rotary and post-rotary cerebellar responses of homing and domestic pigeons, and of migratory and sedentary doves have been studied by means of an orientable centrifuge. Little difference was found in rotary responses among all the animals tested. Spindle-like post-rotary discharges were recorded in the majority of migratory birds while only 6-8% of the domestic pigeons and no sedentary doves showed similar after-charges. The results seem to support Ising's theory regarding the Coriolis force as a base for direction sense in animals.

PROLONGED AFTER-EFFECT OF CENTRIPETAL AND TANGENTIAL ACCELERATIONS ON CEREBELLAR POTENTIALS. Final rept. June 1, 1956-Sept. 30, 1957, 5p. (AFOSR-TR-58-37) (AF 61(514)968) AD 152246 Unclassified

The rotatory and post-rotatory responses of domestic and nonmigratory species were compared with the responses of homing pigeons and migratory birds. Results indicated that the cerebellar cortex of birds is highly sensitive to rotatory acceleration. A response was obtained at a value as low as 0.01 to 0.02 g. The stimulation of the cerebellar neurons resulted from changes of the sensory inflow coming from the labyrinth. Bilateral labyrinthectomy completely abolished the cerebellar response. A highly typical, spindle-like afterdischarge was found only in homing pigeons and migratory birds.

WIDE RANGE ACCELERATION INVESTIGATIONS IN MAN AND ANIMALS, by R. Margaria. [1958] 26p. (AFOSR-TN-58-516) (AF 61(514)968 and AF 61(052)23; continuation of AF 61(514)537) AD 158327 Unclassified

Presented at Twenty ninth annual meeting of the Aero Med. Assoc., Washington, D. C., Mar. 24, 1958.

Also published in Jour. Aviation Med., v. 29: 855-871, Dec. 1958.

On the basis of elementary laws of physics, describing the behavior of bodies floating in a fluid and subjected to acceleration, consideration has been given to possible protection against acceleration forces. Immersion of mammals (mice) in water increases the resistance to acceleration more than ten fold. Impacts of more than 1000 G have been sustained by such animals as opposed to 100 G when not immersed. Animals without air cavities in the body, such as fish or mammalian fetuses, can support higher acceleration forces. The threshold of physiological stimulation of the otolithic apparatus in all directions has been determined in man floating in water. Lack of impulses from this apparatus is possibly of no serious consequences on the functionality of the brain. The threshold for gravity stimulation of the labyrinth in mammals as from the induced changes of the electrical activity of the flocculo-nodular lobe of cerebellum is of the order of 0.01 to 0.005 G. The loss of orientation, as an effect of radar on homing pigeons, is considered as a possible temperature effect. Migratory animals respond to acceleration stimulus with peculiar spindle-like bursts of cerebellar action potentials lasting some time after removal of the stimulus. This peculiarity is in accord with the hypothesis that migration in animals is possibly supported by a higher sensitivity to geodetic forces. The possible geodetic forces that may induce migration are considered, particularly the accessory Coriolis acceleration; they are of the order of magnitude of 1×10^{-6} G, which is much lower than the threshold to stimulation as found experimentally on the same animals. The physiological basis to account for animal migration is still lacking. (Contractor's abstract)

INVERSION FORMULAE FOR CHARACTERISTIC FUNCTIONALS OF STOCHASTIC PROCESSES, by R. H. Cameron and M. D. Donsker. Sept. 1957 [20]p. (AFOSR-TN-57-603) (AF 18(603)30) AD 136592 Unclassified

Also published in Ann. Math., v. 69: 15-36, Jan. 1959.

Let $\{x_t, t \in [0,1]\}$ be a stochastic process in which almost all of the functions $x(t, \cdot)$ equal zero for $t = 0$ and satisfies the condition of Hölder with $\alpha > \frac{1}{2}$ and let $\{p_t\}$ be the Wiener process. The characteristic functional of x_t is defined, in the more general conditions, by the

formula $\phi(p) = E \left[\exp i \int_0^1 x(t) dp(t) \right]$. The following

formula: $E_x \{ G[x] \} = \lim_{\lambda \rightarrow \infty} 2^{-\lambda} \exp \{ \lambda f(\lambda)/2 \}$

$$x E_a^w E_p^w \left[\exp \{ -i \lambda f(\lambda) \int_0^1 a(t) dp(t) G \{ f(\lambda) a \} \phi(\lambda p) \} \right]$$

is proven for every G functional, defined and limited for the space of functions continued according to $[0,1]$ and zero for $t = 0$, continued according to the uniform topology and measurable Wiener and for $0 < f(\lambda) = O(\lambda/\log \lambda)^2$, $1/f(\lambda) = O(\lambda^{1-1/\alpha})$. An analogous formula is proven for the "strictly, absolutely, continuous" process and another formula is proven for the G functionals continued according to the Hilbert topology.

ON A SPECIAL INTEGRAL EQUATION, A LINEAR PARABOLIC DIFFERENTIAL SYSTEM, AND A WIENER INTEGRAL, by D. A. Woodward. Jan. 1958 [4]p. (Technical note no. 5) (AFOSR-TN-58-567) (AF 18(603)30) AD 158386 Unclassified

Also published in Proc. Amer. Math. Soc., v. 10: 853-854, Dec. 1959.

Three questions, which are shown to be equivalent by a paper by Cameron, are answered in the negative by answering the first question in the negative. The first question asks whether $y(t) = x(t) + \int_0^t [x(s)]^2 ds$, $0 \leq t \leq 1$ has a solution $x \in C$ for almost every choice of $y \in C$. C denotes the space of continuous functions on $0 \leq t \leq 1$ which vanish at $t = 0$, and "almost every" means all but a set of Wiener measure zero.

DIMENSIONAL EFFECT ON THE INITIAL PERMEABILITY AND PERMITTIVITY MEASUREMENTS, by D. Chen, W. E. Swanson, and S. P. Yu. [1957] [7]p. incl. diags. (AFOSR-TN-57-18) (AF 18(803)113) AD 115048 Unclassified

A dimensional effect has been observed in the initial permeability measurement of micron-sized γ -Fe₂O₃ particles and paraffin mixtures using the "transmission line method" at 9000 mc. The peaking of the phase angle of the characteristic impedance at sample lengths equal to a multiple of a quarter wavelength apparently cannot be accounted for by higher order modes or a cavity resonance. Calculation reveals that the phase angle is sensitive to the non-ideal terminations of the transmission line and the error in the location of the voltage minimum at these lengths. For optimum accuracy in the permeability and permittivity measurements the sample length should be one-eighth of the wavelength in the material.

EFFECT OF SLIGHT MODIFICATIONS OF BOUNDARY ON POTENTIAL TRANSONIC CHANNEL FLOW, by C.-C. Chang and C.-W. Chu. June 1958 [20]p. incl.

diags. refs. (Rept. no. 2) (AFOSR-TN-58-528) (AF 18(600)1456) AD 158339 Unclassified

This is an extension of the paper by Chang and Chu in which a symmetrical neighboring solution of Temple-Yarwood transonic channel flow along a slightly less convex but still analytic inner boundary was obtained numerically with the relaxation method. Two types of symmetrical inner channel boundary are considered: namely, a slightly less convex contour and a slightly more convex contour than that of the original Temple-Yarwood flow. First, an unsymmetrical flow solution of the case of the slightly less convex contour is obtained. Secondly, the case of a slightly more convex analytic contour is investigated. Both the symmetrical and the unsymmetrical flow solutions are also obtained with the relaxation method. Physical reasoning indicates that the unsymmetrical potential flow solutions are more likely to occur. It is found that within the chosen accuracy, potential transonic neighboring solutions exist for both the more convex and the less convex boundaries. For the unsymmetrical flow solution with the more convex boundary, the characteristics starting from five neighboring points near the crown of the inner channel boundary are calculated and plotted. There appears no tendency of focusing of these characteristics as they propagate downstream, reflected by the sonic line and the inner channel wall. No shock is discovered. (Contractor's abstract)

ELASTIC INSTABILITY OF RECTANGULAR SANDWICH PANEL OF ORTHOTROPIC CORE WITH DIFFERENT FACE THICKNESSES AND MATERIALS, by C.-C. Chang and I. K. Ebcioğlu. Mar. 1958 [54]p. incl. diags. tables, refs. (Composite Structure rept. no. 1) (AFOSR-TN-58-221) (AF 18(603)112) AD 154122; PB 134752 Unclassified

Also published in Jour. Appl. Mech., v. 27: 474-480, Sept. 1960.

This paper treats the elastic instability of rectangular sandwich panels of orthotropic core and faces with different materials and unequal thicknesses. The panel is simply supported and loaded with edge compression. The differential equations and corresponding boundary conditions are derived from the classical energy integral by means of the variational method. The critical edge compression per unit width can be expressed as a product of two parts: the major buckling coefficient and critical buckling load. The complicated geometrical parameters and different component materials are included in a single graph. The effect of different face temperatures on the maximum collapsing load can be interpreted from the present theory. A comparison with current different methods is given. A number of illustrating examples are shown. (Contractor's abstract)

AD 158338 Unclassified

Also published in Proc. Third U. S. Nat'l. Congress of
Appl. Mech., Brown U., Providence, R. I. (June 11-14,
1958), N. Y., Amer. Soc. Mech. Engineers, 1958, p. 273-
280.

Based on small deflection theory, differential equations
for the elastic bending and deflection of an orthotropic
weak-core sandwich panel with small initial warping
are derived by the variational energy method. The loads
applied consist of arbitrarily distributed transverse
loads and eccentrically applied edge loads and/or edge
moments. Solutions of the differential equations for a
simply supported rectangular panel with arbitrary initial
warping and subjected to combined transverse load-
ing and edge compression are obtained in the form of
double Fourier series. (Contractor's abstract)

ON ISOMETRIC EQUIVALENCE AND SIMILARITY OF
CERTAIN VOLTERRA OPERATORS, by G. K. Fallsch.
June 12, 1958, 15p. (AFOSR-TN-58-535) (AF 49(638)-
64) AD 158351; PB 135412 Unclassified

Also published in Proc. Amer. Math. Soc., v. 12: 93-98,
Feb. 1961.

The functions considered are of the general form:

$F(x,y) = (y-x)^{m-1} aG(x,y)$, where m is a positive inte-
ger, $|a| = 1$, $G(x,x) > 0$, and the complex valued function
 $G(x,y)$ is continuously differentiable. Proof is presented
of the theorem: Let c_1 and c_2 be complex numbers and

let r_1 and r_2 be real numbers such that $r_1 \geq 1$, then

$c_1 T_{E1}^{r_1}$ is similar to $c_2 T_{E2}^{r_2}$ if and only if $c_1 = c_2$ and
 $r_1 = r_2$. The class D of the functions F are described

as the functions F are of the general form where G and
m satisfy one of the following: (1) G is analytic in a suit-
able region and m is arbitrary; (2) $G(x,y) = G(y-x)$,
 $G(0) \neq 0$, $G \in C^2$, and m is arbitrary; (3) $G \in C^2$ and $m = 1$.
The property of the operator T_F for $F \in D$ that their
only reducing manifolds are the space $L_p[0,c]$ for all
 $c \in (0,1]$ is crucial for the establishment of unitary in-
variants. A generalization of the case where there is no
restriction on p is described. A theorem is given illus-
trating the relevance of some of the differentiability con-
ditions imposed on $F(x,y)$.

Theoretical results are presented on a study of high-
speed laminar Couette flow with injection of a lightweight
foreign gas. Solutions are given for the velocity, con-
centration, and temperature profiles in the flow between
two parallel porous plates, one of which is stationary and

MIN.07:011 - MIN.07:015

the other of which moves in its own plane with a constant velocity. The stationary plate is imagined to correspond to a single flat plate in boundary layer flow which is to be cooled by injection of a foreign gas through its porous surface. The Couette-flow results are used to derive expressions for the skin-friction coefficient, Nusselt number, recovery factor, and wall temperature for arbitrary injection rates and coolant reservoir temperatures. Specific calculations are made for cases of air-to-air, hydrogen-to-air, and helium-to-air injection under both isothermal and nonisothermal flow conditions, and these results are then compared directly with corresponding exact boundary-layer solutions. In all cases investigated, the agreement is close enough over a limited range of injection rates to recommend the simple calculation procedure based on Couette-flow for use in preliminary trajectory heat-transfer calculations required in the design of high-speed vehicles using the mass-transfer cooling method. MASS TRANSFER COOLING OF A LAMINAR BOUNDARY LAYER BY INJECTION OF A LIGHT-WEIGHT FOREIGN GAS, by E. R. G. Eckert, P. J. Schneider and others. June 1957, 45p. incl. diagrs. tables. (Technical note no. 14) (AFOSR-TN-57-323) (AF 18-600)1226 AD 132395 Unclassified

Also published in *Jet Propulsion*, v. 28: 34-39, Jan. 1958.

Analytical predictions are given for the development of the velocity, temperature, and concentration fields in a laminar air boundary layer on a flat plate in high-speed dissipative flow, the plate being considered porous and cooled by injection of hydrogen from its surface. The admixture of hydrogen, having a low density and high thermal capacity relative to air, is shown to greatly diminish the skin friction and to markedly relieve the adverse thermal effects of intense aerodynamic heating under conditions of hypersonic flow.

MASS TRANSFER COOLING IN A LAMINAR BOUNDARY LAYER IN STEADY TWO-DIMENSIONAL STAGNATION FLOW, by A. A. Hayday. Apr. 1958 [36]p. incl. illus. diagrs. (Technical note no. 19) (AFOSR-TN-58-337) (AF 18(600)1226) AD 154241 Unclassified

An analytical investigation of the effects of the hydrogen injection on flow and heat transfer characteristics near a stagnation point is set forth. Two dimensional, steady flow field with no chemical reactions taking place, is assumed. Results in the form of velocity, concentration, temperature, skin friction, and surface heat flux variations with injection are presented. It is found that under the stated conditions a high reduction in the heat transferred into the surface can be expected. (Contractor's abstract)

ANALYSIS OF A TRANSPIRATION-COOLED HEMI-SPHERE-CYLINDER, by C. J. Scott. Dec. 1957 [54]p. incl. diagrs. tables, refs. (Engineering memo. rept. no. 74) (AF 18(600)1226) Unclassified

Also published in Jour. Aeronaut. Sciences, v. 25: 397, June 1958.

An extension of the analysis of Stine and Wanlass ("Theoretical and Experimental Investigation of Aerodynamic-Heating and Isothermal Heat Transfer Parameters on a Hemispherical Nose with Laminar Boundary at Supersonic Mach Numbers," NACA Technical note no. 3344, Dec. 1954) is presented which predicts the effect of air injection on the heat transfer distribution over isothermal, blunt-nosed bodies of revolution. Only advanced knowledge of the surface pressure distribution is required. Results are presented for a transpiration-cooled hemisphere-cylinder at a free-stream $M = 3.6$. The Mangler transformation and the Stewartson transformation were used to relate the problem in axisymmetric compressible flow, and then to an approximately equivalent two-dimensional incompressible flow where the thermal solutions of the Falkner-Skan wedge-flow cases were applied. The effects of the major assumptions; constant Prandtl number, small temperature differences, and local application of the Falkner-Skan solutions have already been discussed by Lees ("Laminar Heat Transfer over Blunt-Nosed Bodies at Hypersonic Flight Speeds," Jet Propulsion, v. 26, Apr. 1956). No additional assumptions are required to extend the analysis

to the case of air injection. The results display the distribution of local heat transfer parameter along the isothermal surface. The uniform decrease in local heat transfer coefficients with air injection is apparent. The value of the blowing parameter, f_w , varies with angular location and approaches asymptotically, as does the heat transfer parameter, the corresponding flat plate values. MASS TRANSFER COOLING WITH COMBUSTION IN A LAMINAR BOUNDARY LAYER, by J. P. Hartnett and E. R. G. Eckert. [1958] [15]p. incl. diagrs. table. [AF 18(600)1226] Unclassified

Published in Proc. Heat Transfer and Fluid Mech. Inst., California U., Berkeley (June 19-21, 1958), Stanford, Stanford U. Press, 1958, p. 54-68.

Mass transfer cooling is characterized by the fact that some material is released at the surface to be cooled and moves, at least partially, as a gas into the air flow passing the surface. The effectiveness of this method will be influenced by chemical reactions which may occur between the material released at the surface and the air. In order to evaluate this influence, a calculation is performed on a simplified model. Laminar boundary layer flow of the wedge type is considered, properties are assumed constant and equal for all components involved, infinite chemical reaction rate and equilibrium close to complete combustion is specified. Concentration and temperature profiles within the boundary layer, the position of the flame sheet and the heat flow rate to the surface are calculated. Numerical results are presented for some representative reactions. (Contractor's abstract)

ON THE HÖLDER CONTINUITY OF QUASI-CONFORMAL AND ELLIPTIC MAPPINGS, by R. Finn and J. Serrin. June 11, 1957 [24]p. (AFOSR-TN-57-355) (In cooperation with Calif. Inst. of Tech., Pasadena) (AF 18(603)31) AD 132428
Unclassified

Also published in Trans. Amer. Math. Soc., v. 89: 1-15, Sept. 1958.

A simple new proof is presented of the Hölder continuity of quasi-informal mappings which shows that the Hölder constant can be chosen independent of K , a positive constant less than infinity such that $u_x^2 + u_y^2 + v_x^2 + v_y^2 \leq 2K(u_x v_y - u_y v_x)$; $u(x,y)$ and $v(x,y)$ are continuously differentiable functions defined in a domain of the complex z -plane, $z = x + iy$. A more general class of mappings is treated which satisfy an inequality of the form $u_x^2 + u_y^2 + v_x^2 + v_y^2 \leq 2K(u_x v_y - u_y v_x) + K_1$, where K and K_1 are constants $K \geq 1$ and $K_1 \geq 0$. The following result on Hölder continuity of elliptic mappings is proved: Let $w = u + iv$ be an elliptic mapping defined

in a domain A of the z -plane, and assume that $|w| \leq 1$ and $K > 1$: then in any compact subregion B of A , the function $w(z)$ satisfies a uniform Hölder inequality

$$|w(z_1) - w(z_2)| \leq H |z_1 - z_2|^\mu, \text{ where } \mu = K - \sqrt{K^2 - 1}$$

and H depends only on K , K_1 and the distance from B to the boundary of A . Extension of the results is made to the case where w is undefined or not differentiable at isolated points of A but otherwise satisfies the same hypotheses. A close analog is also proved of the Riemann theorem on removable singularities of analytic functions. One-to-one quasi-informal mappings are considered of a domain A onto a domain B , showing that if A and B have sufficiently smooth boundaries, then any such mapping can be extended so that it is one-to-one and continuous in the closure \bar{A} of A , and thus extended, it satisfies a uniform Hölder condition over all of \bar{A} with constants depending in a simple way on A , B , and K . All results remain true for the more general mappings.

Also published in Acta Math. v. 102: 1-22, 1959.

A reformulation is given of Hilbert's theorem which states that if the extremal ϵ can be imbedded in a field ν with slope functions $p(x,y,z)$, $q(x,y,z)$ such that the Weierstrass function obeys $E(x, y, z; p, q; P, Q) \geq 0$ for each set of values (x, y, z) in the field, then ϵ minimizes the integral $I[u] = \int_R F(x, y, u, p, q) dA$ relative to all admissible functions whose values lie in the field. In the new formulation, it is assumed that there is at least one admissible function which gives I a finite value, and the field is required to be an extremal field. On the other hand, by virtue of an extension of the notion of imbedding, it has not been necessary to make any assumption concerning the behavior of ϵ at the boundary, beyond simply requiring that it take on the given boundary values. The proof is a modification and extension of Hilbert's classical argument; at no stage is it necessary to resort to deep theorems of integration or functional analysis. Finally the proof applies equally in n dimensions and to extremals satisfying only the Haar equations.

Published in Jour. Aero/Space Sciences, v. 25: 662-664, Oct. 1958.

This paper is a summary of a study of the effect of small angles of yaw on boundary-layer development on a cone including turbulent boundary-layer data previously obtained in connection with a more general experimental program. Presentation is made of the following: (1) effects of yaw on laminar velocity profiles on the windward surface of a 15° cone at $M_\infty = 2.73$; (2) effect of yaw on velocity profiles on the leeward surface at a 15° cone at $M_\infty = 2.73$; (3) effect of variation of Reynolds number at constant yaw; (4) effect of variation in yaw at constant Reynolds number; and (5) effect of yaw on local skin friction coefficient for laminar flow over a 15° cone at $M_\infty = 2.73$. A comparison of these experimental results with theoretical analyses is shown.

A description of the combustion channels of the Propulsion Research Lab. is presented. The major equipment consists of two channels with test section sizes $2 \times 1 \times 12$ in. and $4 \times 6 \times 20$ in. At present subsonic test sections are installed which permit velocities up to choking and pressure level variation from 3 in. Hg to atmospheric. Modification of the test section windows would permit operation at pressures up to 3 atm. With the proper test section supersonic flow up to approx. $M = 5$ could be obtained. The facility has been designed for maximum flexibility and operation over wide pressure and velocity ranges. Some experimental flame blowoff data is

ON THE AERODYNAMIC INSTABILITY OF SUPERSONIC INLET-DIFFUSERS, by C.-C. Chang and C.-T. Hsu. Jan. 19, 1959, 1v. incl. diagrs. refs. (Research rept. no. 155) (AFOSR-TN-58-887) (AF 18(600)1553) AD 204099; PB 140547 Unclassified

Also published in ARS Jour., v. 30: 468-475, May 1960.

The stability problem of the supersonic inlet-diffuser is first reduced to find the acoustic impedance at the inlet of the plenum chamber. The inlet acoustic impedance is then obtained by solving the linearized viscous compressible flow equations in the entire subsonic regimes. These solutions satisfy Burger's boundary conditions behind the oscillating shock. Essential assumptions of one-dimensional quasi-steady flow and linear velocity distribution are used. It is found that the self-excited shock oscillation is not possible in absence of viscous dissipation. Flow instability is found due to further entropy generated by viscous dissipation in addition to shock oscillation. Neutral stability boundaries are obtained in terms of the ratio of perturbation entropy to the corresponding shock velocity and are in agreement with Stoolman's experimental data. The present analysis confirms Trimpf's theory of instability and also justifies the Sterbenz-Evvard's theory in the range of "steady" subcritical operation. (Contractor's abstract)

A TECHNIQUE FOR EXPERIMENTAL INVESTIGATION OF HEAT TRANSFER FROM A SURFACE IN SUPERSONIC FLOW AT LARGE SURFACE-TO-FREE-STREAM TEMPERATURE RATIOS, by W. S. Bradfield, A. R. Hanson and others. June 1958, 1v. incl. illus. diagrs. tables. (Research rept. no. 150) (AFOSR-TR-58-64) (AF 18(603)16) AD 158252; PB 144952 Unclassified

An experimental technique is reported for studying problems of heat transfer at high surface temperatures and high surface-to-free-stream temperature ratios. The heat flux direction, from the surface to the boundary layer, is in contrast with that usually encountered in flight. With the apparatus developed it has been possible to produce a moderately hot surface in a cooling gas stream which is chemically homogeneous and of known composition and to make measurements of surface temperature, heat flux, and the rate of loss of mass. Preliminary values of local convective and radiative heat transfer at surface temperatures as high as 3440°R have been determined. Maximum surface temperatures reached in a stagnant inert atmosphere have exceeded 6200°R, and in a Mach 2.3 free jet they have gone as high as 4700°R. The highest heat flux measured was 333 BTU/ft²-sec at a surface temperature of 3300°R. The maximum surface-to-free-stream temperature ratio was 20. Some studies were made on the deterioration of graphite surfaces coated with silicon nitride and silicon carbide. (Contractor's abstract, modified)

All magnesium oxide crystals that have been located show a six-line hyperfine splitting pattern found previously upon deliberate addition of manganese. Technical MgO

MIN.12:012 - MIN.12:014

powder shows the same behavior as does also a reagent grade which has been heated to 1200°C. Their line width is as small as 1.5 gauss, very narrow for an ionic crystal, and much narrower than found previously (Phys. Rev., v. 88: 714, 1952). The fourth line (counting from the low field end) shows unusually large variations of intensity relative to the other five. Each of the principal lines has four satellites, explainable for an electronic spin of 5/2. At high spectrometer sensitivity, a number of weak lines are found in pairs. Their origin is being investigated. Heating to 200°C in the resonant cavity of the spectrometer decreases the ESR line intensity by an amount expected from Curie's law. An impurity of nuclear spin 7/2 and electronic spin of 3/2 gives 8 principal lines over a 560 gauss region. Each has 2 satellites.

CRYSTAL VACANCY EVIDENCE FROM ELECTRON SPIN RESONANCE, by J. E. Wertz and P. Auzins. [1957] [15]p. incl. diagrs. (AF)OSR-TN-57-103 (AF 18(600)-479) AD 120453 Unclassified

Also published in Phys. Rev., v. 106: 484-488, May 1, 1957.

Three distinct patterns have been observed in the electron spin resonance spectrum of chromium (+3) ions in single crystals of magnesium oxide. The chromium (present in naturally-occurring amounts or augmented) replaces magnesium (+2) ions substitutionally. The Cr(+3) spectrum depends upon whether compensation for the extra charge occurs in the immediate vicinity, and if so, upon the position of the compensating charge. The first pattern is a single line surrounded by a hyperfine quartet, representing that expected for a F ion in a purely cubic electric field if most of its isotopes have zero nuclear spin I , and one isotope has $I = 3/2$. This means that charge compensation cannot occur in a position as close as that of the next-nearest magnesium ion. The second pattern has 9 lines (each with a hyperfine quartet), the angular dependence of which shows axial symmetry about the principal crystal axes. It is explained in terms of a vacancy in the magnesium position next-nearest the chromium ion. The third pattern arises from ions with axes of symmetry in face-diagonal ($[110]$ -type) directions. This symmetry is ascribed to the effects of a magnesium ion vacancy in a position nearest the central ion. (Contractor's abstract)

ELECTRON SPIN RESONANCE OF F CENTERS IN MAGNESIUM OXIDE; CONFIRMATION OF THE SPIN OF MAGNESIUM-25, by J. E. Wertz, P. Auzins and

others. [1957] [3]p. incl. diagrs. refs. (AFOSR-TN-57-401) (AF 18(600)479) AD 132479 Unclassified

Also published in Phys. Rev., v. 107: 1535-1537, Sept. 15, 1957.

An electron spin resonance (ESR) spectrum induced in magnesium oxide crystals by pile irradiation has been interpreted as arising from F centers. After an oxide ion is displaced from its normal position by neutrons, an electron donated by ever-present divalent impurities may become trapped at the vacancy. Those centers having only Mg^{24} and Mg^{26} neighbors give a single ESR line with $g = 2.0023$, while those with one or more Mg^{25} neighbors give hyperfine patterns corresponding to the nuclear spin value of 5/2. The magnitudes of the isotropic and anisotropic parts of the hyperfine interaction show strong localization of the electron in the vacancy. (Contractor's abstract)

IMPURITY - CONTROLLED ELECTRONIC PROPERTIES OF MAGNESIUM OXIDE (Abstract), by J. E. Wertz, J. L. V. Acrivos, and P. Auzins. [1957] [1]p. (AF 18(600)479) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 185, Apr. 25, 1957.

The large energy gap between the valence and conduction bands in MgO crystals causes impurities to play a controlling role in determining such electronic properties as the absorption spectrum, electrical- and photoconductivity and the luminescence behavior. It is extremely difficult to prepare crystals which do not contain transition elements in amounts which are readily detectable by their electron spin resonance absorption. Of those commonly present, iron and chromium are probably the most important, though manganese and vanadium often play a role. Their ability to exist in either of two stable valence states insures the presence of numerous filled or empty levels in the energy gap. Valence changes are readily detected after such treatments as heating in vacuum, in oxygen or magnesium vapors or ultraviolet or x-irradiation. After some of these an apparently stable state is reached, while especially for radiation, numerous changes occur in decay processes. The pattern of electron transfer among the several impurities serves as a guide to locate relatively the energy levels. In some processes one merely requires a redistribution of the existing positive ion vacancies, while in others they are formed or destroyed. Identification of the spectrum of Cr(+3) with an associated vacancy has permitted the observation of changes in association.

1,1-DIETHOXY-3-(TRIPHENYLSTANNYL)-2-PROPYLENE, by O. H. Johnson and J. R. Holum. [1958] [3]p. incl. refs. (AF 18(600)984) Unclassified

Published in Jour. Org. Chem., v. 23: 738-740, May 1958.

This acetylenic organotin compound containing a potential aldehyde was synthesized by the action of the Ag salt of propionaldehyde diethylacetal, II, on triphenyltin bromide, I. Its structure was assigned on the basis of origin and analytical data. In determining the compound's properties it was found that the Sn-C bond in which the carbon atom is part of the acetylenic linkage is easily broken.

INTERACTIONS OF CHLOROPHYLL IN ITS TRIPLET STATE WITH OXYGEN, CAROTENE, ETC., by E. F. Fujimori and R. Livingston. Aug. 1957, 7p. incl. tables, refs. (AFOSR-TN-57-510) (AF 18(600)1485) AD 136496 Unclassified

Also published in Nature, v. 180: 1036-1038, Nov. 16, 1957.

To test the postulate that the triplet state of chlorophyll is involved in the photosynthesis of green plants, the half life of the triplet state of chlorophyll was measured in various compounds. The materials were (1) analytical-reagent-grade solvents distilled at least once out of contact with air, (2) vacuum-distilled cyclooctatetraene, (3) sublimed quinone, (4) fractionally crystallized reductants, (5) carotenes and xanthophylls purified chromatographically on MgO columns and (6) purified chlorophylls.

MIN. 22:002; MIN. 23:001; MIS. 01:010

Kinetic measurements were made with a flash-photolytic apparatus and a scanning beam of constant intensity which was rendered approximately monochromatic by means of interference filters. More than 70% of the chlorophyll molecules were excited to the triplet state by light from an unfiltered flash; orange filters reduced the conversion to 20%. The half lives observed for 1.5×10^{-6} M solutions of chlorophyll a in benzene containing p-benzoquinone ranged from 4.05 to 1.58 sec $\times 10^4$ at quinone concentrations of 0 to $15.0 \text{ M} \times 10^7$. Oxygen and quinone were efficient quenchers of the triplet states of sensitizers, with bimolecular quenching constants of 1.1 ± 0.3 and $2.4 \pm 0.5 \text{ M}^{-1} \text{ sec}^{-1} \times 10^{-9}$, respectively. Cyclo octotetraene was moderately efficient with a constant of $0.0012 \pm 0.0002 \text{ M}^{-1} \text{ sec}^{-1} \times 10^{-9}$. β -Carotene, α -carotene, and xanthophyll were as efficient as O in quenching the triplet state of chlorophyll a. Also published in Trans. Faraday Soc., v. 54: 765-771, June 1958.

The half-life of the triplet state of anthracene has been measured in several air-free solvents at ambient temperatures. The following values were obtained: 90% C_7H_{16} + 10% CS_2 , 200; $\text{C}_6\text{H}_5\text{Br}$, 430; $\text{C}_6\text{H}_5\text{Cl}$, 790; "liquid petrolatum", 1100; and glycerol 9400 μsec . The quenching of the triplet state by added reactants has been studied in bromobenzene. The values for the bimolecular rate constants are as follows: O_2 , 2.0×10^9 ; benzoquinone, $> 7 \times 10^7$; CHCl_3 , 3.2×10^3 ; and CS_2 , $< 5 \times 10^2 \text{ M}^{-1} \text{ sec}^{-1}$. EQUATIONS FOR THE LIMITING CURRENT AT THE ROTATED DROPPING MERCURY ELECTRODE, by I. M. Kolthoff and Y. Okinaka. Final rept. Aug. 15, 1957 [14]p. incl. diagrs. tables, refs. (AFOSR-TN-57-337) (AF 18(600)1516) AD 132411

Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 3326-3336, July 5, 1957.

Results are described of a theoretical and experimental study of the relationship between the limiting current at the rotated dropping mercury electrode on the one hand and the diffusion coefficient of the electroactive species, the kinematic viscosity of the solution, and the characteristics of the electrode on the other. Two theoretical equations are derived on the basis of hydrodynamics, one for the case when no surface-active substance is present and the other for the case when such substances are present. In view of the fact that the presence of a suitable surface-active substance is necessary for most practical purposes, the relations in the presence of a capillary-active substance were studied more extensively than those in its absence. The proposed equation in the presence of surface-active compounds involves an experimentally determined numerical constant and yields satisfactory agreement between observed and calculated limiting currents in the range of 75 to 210 rpm, provided that an electrode of the proper dimensions is employed. At a suitable speed of rotation in the presence of a surface-active substance, the limiting current at the rotated dropping mercury electrode, as a first approximation, is proportional to $D^{2/3}(\eta t)^{1/2}$ while at the unrotated conventional dropping mercury electrode it is proportional to $D^{1/2} \eta^{2/3} t^{1/6}$. Limitations of the derived equations are discussed both from theoretical and practical viewpoints. (Contractor's abstract)

UNIFORM CONSISTENCY OF ESTIMATORS OF LINEARLY ORDERED PARAMETERS, by H. D. Brunk. Aug. 1957, 13p. refs. (Technical rept. no. 9) (AFOSR-TN-57-516) (AF 18(600)1108) AD 136501

Unclassified

The following problem of estimation is considered: Let k be a positive integer. To each positive integer $1 \leq k$ corresponds a population whose distribution is known except for the unknown value of its mean θ_1 ; the means satisfy certain inequalities. The problem of estimating a distribution function from all-or-none data (bioassay) is of this kind, in which the populations are binomial and the inequalities are of the form $\theta_1 \leq \theta_2 \leq \dots \leq \theta_k$. Even if the populations are not binomial but all belong to a common exponential family, the maximum likelihood estimators (MLE's) subject to $\theta_1 \leq \theta_2 \leq \dots \leq \theta_k$ are determined as follows: Let \bar{x}_1 be the sample mean of a sample of size n_1 from the 1^{th} population whose mean is θ_1 , $1 = 1, 2, \dots, k$. If $\bar{x}_1 \leq \bar{x}_2 \leq \dots \leq \bar{x}_k$, these are the MLE's of the parameters θ_1 , $1 = 1, 2, \dots, k$. If for some i , $\bar{x}_i > \bar{x}_{i+1}$, these 2 means are replaced by the single ratio $\frac{(n_i \bar{x}_i + n_{i+1} \bar{x}_{i+1})}{(n_i + n_{i+1})}$, obtaining an ordered set of only $k-1$

ratios, $k-2$ of which are sample means. This procedure is repeated until an ordered set of ratios is obtained which are monotone nondecreasing. Then for each i , the MLE, $\hat{\theta}_i$, of θ_i is equal to that one of the final set of ratios to which the original ratio \bar{x}_i contributed. If the number, k , of observation points is held fixed while the number of observations at each point increases indefinitely, classical theory assures the strong consistency of the $\hat{\theta}$ and yields their asymptotic distribution; the $\hat{\theta}$ will asymptotically coincide with the sample means. Mainly cases of a large number of observation points, but only a few observations, are considered.

Special cases of linear and nonlinear programming are considered. Solutions are developed to problems of the following type: Find each point $x = (x_1, x_2, \dots, x_n)$

of E_n to maximize $\sum_{i=1}^n f_i(x)$ under the restriction that

x be contained in the set of points of the plane

$\sum_{i=1}^n k_i x_i = K$ where the component x_i lies in a given

interval from a_i to b_i , $i = 1, 2, \dots, n$. The investigation

is limited to the case where $f_i(u)$ is concave and differentiable, $i = 1, 2, \dots, n$. Examples are given to illustrate the procedure.

MINIMIZING INTEGRALS IN CERTAIN CLASSES OF MONOTONE FUNCTIONS, by H. D. Brunk, G. M. Ewing, and W. R. Utz. 1957 [15]p. (AFOSR-TN-57-665) [AF 18(600)1108] AD 136677
Unclassified

Also published in Pacific Jour. Math., v. 7: 833-847, Spring, 1957.

Let R_n be the space of points $t = (t^1, \dots, t^n)$, μ a totally finite, complete measure on R_n , and $\sigma(t)$ a measurable real-valued function. Let F be a real-valued function on R_2 satisfying: (1) $F(\sigma(t), \theta(t))$ is measurable if $\theta(t)$ is; (2) for fixed u , $F(u, v)$ is strictly decreasing (increasing) in v for $v \leq u$ ($v \geq u$) and right (left) continuous in v for $v < u$ ($v > u$); (3) $\int F(\sigma(t), \sigma(t)) d\mu(t) < \infty$. Let $J(\theta) = \int F(\sigma(t), \theta(t)) d\mu(t)$. The existence is shown of functions

minimizing $J(\theta)$ for θ in two classes of monotone functions. One class consists of those $\theta(t)$ which are nondecreasing in each component of t and for which all of the second differences, obtained from pairs of components, are negative. Representation and uniqueness theorems are also proved. The problem is connected with that of obtaining a maximum likelihood estimate of a distribution function. (Math. Rev. abstract)

PROPERTIES OF SOLUTIONS OF CERTAIN SECOND ORDER NONLINEAR DIFFERENTIAL EQUATIONS, by W. R. Utz. [1957] [5]p. (AF 18(600)1108) Unclassified

Published in Proc. Amer. Math. Soc., v. 8: 1024-1028, Dec. 1957.

Theorems on the boundedness of solutions of second order nonlinear differential equations are used as a starting place for a more detailed examination of the behavior of solutions of such equations for large values of the independent variable. The boundedness theorems cited give sufficient conditions for the existence of constants $A, B > 0$ such that if $x = x(t)$ is a solution of the given equation valid for all large t , then $x(t) < B$ for all $t > A$ where A and B may depend upon the particular solution $x = x(t)$. Theorems which guarantee $A, B > 0$, as above, but in which B is independent of the solution selected, have been used to show the existence and uniqueness of periodic solutions. If $d > 0$ and $e > 0$ are real constants, then a solution $x = x(t)$, $x(t) \neq 0$ of the linear equation $x'' + dx' + ex = 0$ is oscillatory or monotonically approaches zero. The theorems secured in this paper may be thought of as generalizations of this remark. In section 2 the theorems proved in the paper are stated and in section 3 the proofs of the theorems are provided. (Contractor's abstract)

The existence of asymptotic orbits in the presence of unstable self-homeomorphisms is discussed. A proof is given of Schwartzman's theorem which states that if x is compact and non-trivial and $T(x) = x$ is an unstable homeomorphism, then there exists at least a pair of positively asymptotic orbits and at least a pair of negatively asymptotic orbits. Williams' paper on unstable homeomorphism of a continuum [Proc. Amer. Math. Soc., v. 6: 308-309, 1955] is discussed and criticized. (ASTIA abstract)

Also published in Jour. Amer. Statist. Assoc., v. 55:
503-520, Sept. 1960.

There are m items to be compared in pairs. S_{ij} is a random variable which measures the score on the comparison of the i th item with the j th. It is assumed that $S_{ij} + S_{ji} = 1$, the conventional situation being one in which the score has only two possible values, 0 and 1. To say that the m items are "ranked" means that a permutation, $R(1), \dots, R(m)$ of the integers $1, \dots, m$ is assigned. Let $e_{ij} = ES_{ij}$ and let $e^{ij} = e_{R(i)R(j)}$. A "utility of a ranking" is defined to be a function of the scores e^{ij} which is nondecreasing in its arguments, and an "optimum ranking" is one which maximizes this function. The spirit of the paper is to unify the many special cases discussed in the literature; many specific kinds of utility functions are examined, analogies with the analysis of variance are exploited and certain technical aspects of utility functions are examined mathematically. ON THE ESTIMATION OF PARAMETERS RESTRICTED
BY INEQUALITIES, by H. D. Brunk. [1958] [18]p. Incl.
refs. (AF 18(600)1108) Unclassified

Published in Ann. Math. Stat., v. 29: 437-454, June 1958.

Remarks on the minimization of convex functions subject to side conditions are given, together with a discussion of the uniform consistency of estimators of linearly ordered parameters. The problem of minimizing a function of several variables is considered, which is subject to side conditions which specify that the variables must satisfy certain inequalities. The maximum likelihood estimation (MLE) of the one-parameter k populations is given. Each one also belongs to an "exponential family". Methods of finding the minimizing point on a given intersection of boundaries of restricting sets are discussed. A sufficiency property related to the MLE's is considered.

The formation and properties of two types of chelated aluminum polymers were studied. Monochelated polymers prepared from diisopropoxy or dichloro aluminum monochelates displayed limited hydrolytic and thermal stability. Polymers of trichelated aluminum were prepared and found to be more resistant to hydrolysis. They varied from low-melting, readily organic-soluble thermoplastics to intractable solids stable at $360^\circ C$. Linear polymers were prepared from dichelated titanium diisopropoxides and organic diols. The most stable of these was the product from an 8-quinolinol chelate and 2,2-bis(4-hydroxyphenyl) propane ("Bisphenol-A"), which was inert toward boiling water and when heated to ca. $400^\circ C$. The properties of the chelated aluminum and titanium monomers are given. (Contractor's abstract)

A method for measuring blood flow through the cephalic vascular bed was postulated. It was believed that cephalic blood flow could be computed from isotope dilution curves obtained simultaneously over the hand and head following a timed intravenous injection. Certain practical difficulties became obvious when studies were begun on rabbits. Dilution curves on rabbits were too flat even when excessive quantities of isotope were used. Measurement of cardiac output was an essential part of the studies. However, no successful means of measurement was obtained and the methods under consideration were abandoned.

CALCULATION OF AERODYNAMIC FORCES ON SLOWLY OSCILLATING RECTANGULAR WINGS IN SUBSONIC FLOW, by A. I. van de Vorren and E. M. de Jager. Oct. 1, 1956 [69]p. incl. diagrs. tables, refs. (Technical note no. F 192) (AFOSR-TN-57-40) (AF 61-(514)879) AD 115078 Unclassified

A method is presented for the calculation of the aerodynamic forces on a slowly oscillating airfoil. The method is essentially a lifting surface theory which takes into account the unsteady effects due to the wake. Results are given as series containing terms of increasing powers in reduced frequency. The method has been applied to rectangular airfoils. It is shown that if the axis of rotation is ahead of the airfoil, the aerodynamic damping is much less than it would be according to quasi-steady theory. Instability is possible if the aspect ratio is larger than a certain value. This limiting aspect ratio decreases with increasing Mach number.

THE INFLUENCE OF NON-STATIONARY DERIVATIVES ON THE SNAKING MOTION AT HIGH SUBSONIC SPEED, by J. Yff. Nov. 23, 1957 [37]p. incl. diagrs. tables, refs. (Technical rept. no. F 208) (AFOSR-TR-58-20) (AF 61-(514)879) AD 152012 Unclassified

Some lateral stability calculations with two degrees of freedom for flight at high subsonic speed have been performed in order to study the influence of the non-stationary stability derivatives $C_{n\beta}$, $C_{y\beta}$, $C_{n\dot{\beta}}$ and $C_{y\dot{\beta}}$

on the damping of the snaking motion. These derivatives can be determined theoretically for the case of small aspect ratios and with compressibility taken into account. It is found that only $C_{n\beta}$ has a small influence

on the damping in yaw, the influence of the other non-stationary derivatives being negligible. Whether the introduction of $C_{n\beta}$ causes a decrease or an increase

of the damping in yaw depends mainly on the aspect ratio of the vertical tail but for nearly all practical tail designs an increase of the damping in yaw will result. Furthermore it is found that the theoretical non-stationary stability derivatives for vertical tails are practically independent of the reduced frequency. (Contractor's abstract)

THE INFLUENCE OF NON-STATIONARY STABILITY DERIVATIVES ON THE LATERAL MOTION AT HIGH SUBSONIC SPEED, by J. Yff. [1958] [13]p. incl. table. (AF 61(514)879) Unclassified

Published in Proc. Third European Aeronautical Congress, Brussels (Belgium) (Sept. 22-27, 1958), Brussels, v. 2: 489-501, 1958.

In view of the uncertainty which exists concerning the influence of unsteady aerodynamic effects upon stability, an investigation has been performed with the purpose of clarifying this question for lateral motions with two degrees of freedom at high subsonic speeds. As the first part of the present investigation, a theory has been developed for the calculation of the aerodynamic forces acting upon a slowly harmonically oscillating finite span airfoil. This theory takes into account also compressibility effects. Moreover, the question has been studied if stability derivatives, which are calculated under the assumption of harmonically varying motions, can be applied to damped motions. Finally some calculations have been made for actual airplanes, in which the importance of the non-stationary stability derivatives has been investigated. It is found that only $C_{n\beta}$ has a small influence on the damping in yaw. (Contractor's abstract)

RESEARCH ON THE STATIC AND FATIGUE STRENGTHS OF BONDED AND RIVETED SINGLE LAP JOINTS IN CLAD 2024 AND 7075 ALUMINUM ALLOY AT ROOM AND ELEVATED TEMPERATURES, by A. Hartman and F. A. Jacobs. Sept. 1957 [34]p. incl. illus. diagrs. tables. (Rept. no. M 2041) (AFOSR-TR-57-100) (AF 61(514)938) AD 148033 Unclassified

The report gives the results of an investigation on the effect of an increase of the temperature from 20 to 150°C on the static tensile shear and fatigue properties at fluctuating tension of 2 row riveted and of Hidux 1033 bonded single lap joints of clad 2024-T and clad 7075-T aluminum alloy. The increase of the temperature to 150°C (long soaking times have not been investigated) did not have a noticeable effect on the fatigue properties of the riveted specimens compared to that at room temperature. At 150°C the static strength of light alloy riveted lap joints deteriorates more rapidly than the fatigue properties. The tests on the Hidux bonded specimens showed a noticeable superiority of the bonded clad 2024-T specimens at 150°C over the bonded clad 7075-T specimens, both for the static and the fatigue

NBS.04:004; NBS.29:001;
NBS.06:005; NBS.07:017

properties. The fatigue properties of the Hidux bonded joints decrease gradually at higher temperatures. At 150°C the bonded lap joints showed a better endurance than the riveted specimens at low stress amplitudes with failure in the metal; the opposite occurred at high stress amplitudes. This transition occurred for the bonded clad 2024-T specimens at a higher stress amplitude than for the 7075-T specimens. Posttouring at 150°C did not have a noticeable effect on the mechanical properties of the Hidux bonded joints. (Contractor's abstract)

Also published in Jour. Res. Nat'l. Bur. Standards, v. 60: 569-592, June 1958.

The relative strengths of benzoic acid, 31 of its mono-substituted derivatives, 7 disubstituted derivatives, and one trisubstituted derivative have been measured in terms of the equilibrium constants (K'') for association with the reference base 1,3-diphenylguanidine in benzene at 25°C. The measurements were performed spectrophotometrically, using the indicator acid bromophthalein magna E (tetrabromophenolphthalein ethyl ester) as the reference acid, the equilibrium constant K' for an association of the indicator with diphenylguanidine being known from previous work. Equilibrium constants for p-orsellinic (2,6-dihydroxy-p-toluic) acid and 2,4,6-trinitrobenzoic acid could not be measured, as these acids appear to associate completely with diphenylguanidine under the conditions of the experiments. Plotting $\log K''$ values against the corresponding pK values for aqueous solutions of the acids gives an essentially linear relationship in the case of acids with meta- and para-substituents only, but the line for para-substituted acids has a slightly different slope from the line for m-substituted acids. Similar comparisons were made with published data on relative strengths in alcohols or dioxane-water mixtures. Marked solvent effects were shown by ortho-substituted acids. Explanations of the solvent effects have been suggested, and various theoretical implications and possible applications of the results are discussed. The theoretical discussion includes evaluation of constants of the Hammett equation. (Contractor's abstract)

A study was made (1) to develop methods for the electrophoretic deposition of refractory metals, metalloids, and oxides and their conversion to practical coatings by heat treatment; and (2) to obtain some insight into the theory and mechanism of electrophoretic deposition through a study of the electrokinetic properties and electrode reactions of these systems. Operating conditions and techniques were developed and defined for electrophoretically depositing a number of metals, metalloids and refractory oxides. Conversion of these deposits to practical coatings by sintering and compaction was shown to be very difficult and requires further development. A coating of Ti-Ni alloy on steel was obtained that may warrant further investigation. The ultramicroscope was used to observe the deposition process in order to obtain information that would add to the knowledge of the mechanism of formation of electrophoretic deposits. The results of several experiments, designed to test proposed theories, tended to favor the accumulation theory, but observations with the ultramicroscope of deposit formation disclosed events that are not in accord with either the accumulation or the ion-flocculation theory.

THEORY OF THE FORBIDDEN TRANSITIONS OF NITROGEN ATOMS TRAPPED IN SOLIDS, by C. M. Herzfeld. [1957] [7]p. incl. diagrs. tables, refs. (AFOSR-TN-57-705) [CSO-680-56-21] AD 138699
Unclassified

Also published in Phys. Rev., v. 107: 1239-1245, Sept. 1, 1957.

A detailed theory of the forbidden transitions of nitrogen atoms trapped in solids is given. The trapped atoms are perturbed by the solid. Configuration interaction, produced by the solid, is important. Splittings and shifts of levels, and reduction of half-lives are explained in one consistent scheme. The trapping sites of atoms are shown to have low symmetry and to be nearly identical for different atoms. (Contractor's abstract)

LUMINOUS REACTION BETWEEN CARBON MONOXIDE AND ATOMIC NITROGEN, by H. P. Broida and D. F. Heath. Jan. 1957 [1]p. (AFOSR-TN-57-24) (CSO-680-56-30) AD 115058
Unclassified

NBS.07:018, 019; NBS.30:001, 002

Also published in Jour. Chem. Phys., v. 26: 1352, May 1957.

The spectra observed for the reaction of atomic nitrogen and CO were predominantly the red ($A^2\Pi - X^2\Sigma^+$) and violet ($B^2\Sigma^+ - X^2\Sigma^+$) CN systems. Also present under some conditions was the first positive system of N_2 with the vibrational distribution typical of the afterglow. When the CO was contaminated with $Fe(CO)_5$, the spectrum of the glow showed intense iron lines. Comparisons are made with the spectra obtained from atomic nitrogen and acetylene.

SEPARATION OF THE PRODUCTS OF COOL FLAME OXIDATION OF PROPANE, by C. R. Yokley and R. E. Ferguson. July 1957 [24]p. incl. illus. diagrs. tables. (NBS rept. no. 5418) (AFOSR-TN-57-96) (CSO-680-56-33) AD 120445 Unclassified

Also published in Combustion and Flame, v. 2: 117-128, June 1958.

The techniques of gas chromatography and low-temperature, low-pressure distillation were used for the separation and isolation of most of the major products of cool flame oxidation of propane. The products were separated by volatility into 5 fractions, each of which was resolved on one of 3 columns: (1) a charcoal adsorption column for noncondensable gases, (2) a silica gel column for hydrocarbons and CO_2 , and (3) a gas-liquid partition column with bis[2-(2-methoxyethoxy) ethyl] ether as the liquid phase for the separation of oxygenated compounds. The products were identified by a combination of mass spectrometry and gas chromatography. The apparatus included a reaction bulb and manometer, a gas handling system, a low-temperature still, and a gas chromatography line, all of which were constructed as one integral vacuum system. The purity of the smallest samples was in the range of 99.9% as determined by mass spectrometry. Impurities included HCHO and an unidentified compound of molecular weight 104.

THE PRODUCTS OF COOL FLAME OXIDATION OF PROPANE-2- C^{13} , by R. E. Ferguson and C. R. Yokley. Final rept. Apr. 30, 1958, 16p. incl. tables, refs. (NBS rept. no. 5884) (AFOSR-TN-57-97) (CSO-680-56-33) AD 120446 Unclassified

Also published in Seventh Symposium (Internat'l) on Combustion, Oxford U., London (Gt. Brit.) (Aug. 28-Sept. 3, 1958), London, Butterworths Scientific Publications, 1959, p. 113-117.

The major products were isolated by low temperature distillation and gas chromatography; the isotopic composition of each was determined by mass spectrometry. Three separate experiments were conducted with equimolar propane-2- C^{13}/O mixtures. The main products were unreacted propane, propylene, propylene oxide, EtCHO, iso-PrOH, ethane, ethylene, ethylene oxide, AcH, CH_4 , MeOH, HCHO, CO, and CO_2 . Nearly all the Me and methoxy radicals participating in the cool flame reactions came from the end Me groups of propane. AcH was a 2-carbon fragment of the propane, and the C atom in the -CHO group was from the 2-position of the parent molecule. Formaldehyde arose from all 3 atoms of the propane. Most of the CO_2 came from the 2-position in propane. Evidence was obtained for the Me radicals to form ethane and for reactions of Me radicals and CO to give Me_2CO .

RELATION BETWEEN THE ABSORPTION SPECTRA AND THE CHEMICAL CONSTITUTION OF DYES. XXIX. INTERACTION OF DIRECT AZO DYES IN AQUEOUS SOLUTION, by M. N. Inscoe, J. H. Gould and others. Sept. 1957, 38p. incl. diagrs. tables, refs. (Research paper no. 2823) (AFOSR-TN-57-564) (CSO-680-57-3) AD 206804
Unclassified

Also published in Jour. Res. Nat'l. Bur. Standards, v. 60: 65-83, Jan. 1958.

Interaction of dyes in aqueous solution results in differences in the spectrum of the mixture when compared with the sum of the spectra of the individual dyes. A general survey, chiefly with azo dyes, was made to determine the effect of dye structure on this interaction. The effect of other factors on the interaction of direct azo dyes was investigated. The addition of alcohol or non-ionic detergent prevents this interaction, while the presence of inorganic salts or an increase in dye concentration appears to increase the extent of interaction. The effect of acids and bases is dependent upon the nature of the dyes in the mixture. The results obtained are consistent with the assumption that the forces involved in the interaction of direct azo dyes in mixtures are the same as those causing the aggregation of individual dyes and those binding these dyes to fibers. Presented at meeting of the Org. Chem. Div. of the Amer. Chem. Soc., Chicago, Ill., Sept. 7-12, 1958.

Abstract published in 134th meeting of the Amer. Chem. Soc. Abstracts of Papers, 1958, p. 95-P.

Several dyes were prepared by the methylation of hydroxyazo dyes, which showed no phototropism in H_2O ,

in order to test the hypothesis that chrysofenine is phototropic in H_2O . The effects of illumination on the spectra of aqueous solutions of the dye derivatives were similar to those for related compounds in nonhydroxylic media. The spectra of a solution of the Na salt of m-(4-methoxyphenylazo)benzenesulfonic acid obtained on illumination with a yellow filter was close to the spectra of the pure trans form. illumination of the spectra

with a blue filter resulted in an equilibrium mixture containing somewhat more of the cis form. The cis form was relatively stable with a half life of about a week. The absence of fixed isosbestic points in the spectra of chrysofenine indicated that there must be conjugation between the 2 azo groups and therefore 3 inconvertible forms, trans-trans, trans-cis, and cis-cis, exist. In dis-azo dyes prepared from benzidine-2, 2'-disulfonic acid, the sulfonic acid groups prevented coplanarity of the 2 halves of the molecule.

AN ISOTOPIC TRACER STUDY OF CARBON FORMATION IN HYDROCARBON FLAMES, by R. E. Ferguson. Feb. 1957, 15p. incl. tables. (NBS rept. no. 5201; Technical note no. 1) (AFOSR-TN-57-95) (CSO-680-57-12) AD 120444
Unclassified

Also published in Combustion and Flame, v. 1: 431-437, Dec. 1957.

Fuel-rich mixtures of oxygen and propane-2- C^{13} were burned in explosion flames and the isotopic composition of the carbon formed was determined. The results indicated that carbon does not arise from a two-carbon fragment of the propane. Determination of the C^{13} abundance in methane and carbon monoxide in the explosion products indicated that they come equally from the three carbon atoms of the propane. The acetylene recovered contained a nearly random isotope distribution. An investigation of the products of a propane plus $C^{13}O$ /oxygen mixture has provided evidence against the participation of carbon monoxide in carbon formation in typical soot-forming hydrocarbon flames.

ELECTRONIC QUENCHING OF $\text{OH}(\Sigma^+)$ IN FLAMES AND ITS SIGNIFICANCE IN THE INTERPRETATION OF ROTATIONAL RELAXATION (Abstract), by T. Carrington. July 2, 1957 [1]p. (AFOSR-TN-57-340) [CSO-680-57-15] Unclassified

Presented at Symposium on The Structure and Reactivity of Electronically-Excited Species, Ottawa U. (Canada), Sept. 5-6, 1957.

Experiments on the quenching of fluorescence of OH free radicals in oxy-acetylene flames indicate that almost every collision which an excited OH radical undergoes is effective in removing its electronic energy. Hence, the molecules from which radiation is observed have not been perturbed by any previous collisions, and the rotational intensity distribution in the spectrum is characteristic of the collision process in which the OH radicals were excited. In particular, the molecules whose radiation is observed are not in equilibrium with other energetic molecules in the flames, and their nonthermal distribution does not imply an abnormal persistence of rotation.

Also published in Jour. Chem. Phys., v. 27: 933-939, Oct. 1957.

A spectroscopic study has been made of electronic temperatures and electronic excitation in flames from an analysis of the intensity distribution of selected parts of the iron spectrum. The iron was added to the flames in the form of ferrocene to serve as a temperature and excitation "indicator". The flames investigated were the stoichiometric $\text{H}_2 - \text{O}_2$ and $\text{C}_2\text{H}_2 - \text{O}_2$ flames at

atmospheric pressure, a stoichiometric $\text{C}_2\text{H}_2 - \text{O}_2$ flame at low pressure (2.1 mm) and a $\text{N} + \text{CO}$ atomic flame (3.7 mm). This study shows that the iron spectrum can be used as a spectroscopic "thermometer" to determine electronic temperatures in good agreement with adiabatic flame temperatures and OH rotational temperatures in flame regions at thermal equilibrium. The reaction zones of the $\text{C}_2\text{H}_2 - \text{O}_2$ and $\text{N} + \text{CO}$

flames showed a marked departure from equilibrium as indicated by the nonthermal excitation of the added iron, the observed iron spectrum resembling that of an iron arc. This nonthermal excitation of the iron spectrum, which is readily evidenced by the appearance of iron lines originating from high energy levels ($E_n \geq 50,000$

cm^{-1}), can serve as a very sensitive indicator of the departure from equilibrium in a high-temperature reaction system. A brief discussion is given of the possible chemical and energy exchange mechanisms which may give rise to the abnormal excitation of iron in various reaction systems.

Products of electric discharges in gases have been condensed on surfaces cooled by liquid helium. Such films of nitrogen, hydrogen, oxygen, water vapor, and ammonia have been studied by absorption spectroscopy over the spectrum range 0.22 to 3.5 μ . In nitrogen, two very weak absorption bands are observed near 3400Å. Hydrogen shows no absorption, but does show a very weak green emission in the gas surrounding the cold surfaces. In oxygen 24 bands are observed in the visible portion of the spectrum, and two in the infrared. Preliminary observations on absorption in water vapor and ammonia are described. In addition, the spectrum has been photographed of the green emission produced by ammonia discharge products condensed on a surface at 77°K. (Contractor's abstract)

A study is presented of the rotational intensity distribution in the $2\Sigma^+ - 2\Pi$ electronic transition of OH radicals excited in electrodeless discharges through argon containing about one-half percent water vapor, at a total pressure of 0.05 mm Hg. Two independent rotational distributions appear, their relative importance depending on the temperature of the wall of the discharge tube, the density of power dissipation in the discharge, and on the frequency of the exciting field. In the sensitivity of the spectrum to changes in discharge conditions, the wall plays a determining role. (Contractor's abstract)

Solutions of the exact linear elastic-shell equations for all stresses and displacements are presented for a typical corrugated-diaphragm shape for three thicknesses varying over a 6 to 1 range. Results were obtained by numerical integration using an electronic digital computer. The effect of thickness-diameter-ratio variation is discussed with respect to both stresses and resultants, and peak values needed for design purposes are presented. Circumferential and meridional stresses are found to be equally important throughout the thickness range analyzed. Bending and membrane stresses are likewise equally important throughout the range. Peak values in some cases occur near the outer rim. (Contractor's abstract)

Numerical experiments are undertaken to determine how close Nehari's estimates of the error committed by replacing infinite orthogonal expansions by finite ones in harmonic boundary value problems come to the actual errors in a number of particular examples. The best approximation in each of the seven cases studied gave values which are exact within at most ten percent for many points of the region. The Nehari estimate gives a considerably better bound for the error in the interior of the region than the maximum modulus principle. With respect to the actual error the Nehari estimate is, however, still off by a factor which varied in the examples from 5 to almost 100.

UNSTEADY NON-LINEAR WAVES IN SLOPING CHANNELS, by R. F. Dressler. Feb. 5, 1958 [24]p. incl. diagrs. (NBS rept. no. 5768) (AFOSR-TN-58-130) [CSO-680-57-16] AD 152157 Unclassified

Also published in Proc. Royal Soc. (London), v. 247A: 186-198, 1958.

It is shown in general that the exact solution to every non-degenerate unsteady water wave problem in a straight channel inclined at arbitrary slope, governed by the non-linear hydraulic equations, can be obtained in terms of the complete elliptic integral of the second kind, E. By means of a non-Newtonian reference frame, every such wave problem for a sloping channel can be

replaced by an associated problem for a horizontal channel. For the latter, the partial differential equations become reducible and thus permit hodograph inversion. The Riemann integration method for the resulting Euler-Poisson equation yields an auxiliary function for these hydraulic problems which is transformable into a Legendre function and then into the elliptic integral. In particular, the procedure is applied to obtain the exact solution for the water wave in a sloping channel produced by sudden release of the triangular wedge of water (the reservoir) initially at rest behind a vertical wall. The behavior of the solution is exhibited for convenience in two level-line charts, and representative wave profiles and velocity distributions are presented. (Contractor's abstract)

THE STOKES FLOW PROBLEM FOR A CLASS OF AXIALLY SYMMETRIC BODIES, by L. E. Payne and W. H. Pell. Apr. 1, 1959 [35]p. incl. diagrs. tables, refs. (NBS rept. no. 6372) (AFOSR-TN-58-523) [CSO-680-57-16] AD 158336 Unclassified

Also published in Jour. Fluid Mech., v. 7: 529-549, Apr. 1960.

Consideration was given to the solution of the Stokes flow problem for axially symmetric bodies with the aid of the generalized axially symmetric potential theory. After the formulation of the problem and a general discussion of the techniques employed in its solution, discussion is restricted to simply connected regions (in a meridional plane). A general expression for the drag of the simply connected axially symmetric body is obtained, and the Stokes flow problem is solved for the general lens-shaped body. Some interesting special cases of this body are discussed. As examples of the method, some previously solved problems are discussed briefly. Finally, a table of the drag of various bodies in Stokes flow is given. (Contractor's abstract)

THE STOKES FLOW PROBLEM FOR CLASS OF AXIALLY SYMMETRIC BODIES. II. THE FLOW ABOUT A SPINDLE, by W. H. Pell and L. E. Payne. July 31, 1959 [10]p. incl. diagr. (NBS rept. no. 6474) (AFOSR-TN-58-523a) [CSO-680-57-16] AD 220570 Unclassified

Also published in Quart. Appl. Math., v. 18: 257-262, 1960/61.

The solutions of the system are shown by the use of the solution of the repeated operator equation

$L_{-1}^2 \psi_1 = 0$ subject to initial conditions and where ψ_1 (a second stream function) is given by $\psi = \frac{1}{2} U r^2 - \psi_{-1}$. In certain regions, a solution can be represented as a linear combination of any two functions: (1) $r^2 \psi^3$, (2) $x r^2 \psi^3$, (3) $\rho^2 r^2 \psi^3$, (4) $r^2 \psi^1$, and (5) $r^4 \psi^5$. Bipolar coordinates (ξ, η) are introduced into the (x, r) plane by the transformation $z = i b \cot \xi / 2$ where $z = x + i r$, $\xi = \xi + i \eta$, and $b > 0$ is a constant. The flow is then studied around a spindle which is the object obtained by revolving the arc $\xi = \xi_0$ ($0 < \xi_0 < \pi$), $r \geq 0$ about the x -axis. The curve is the circle arc with center at $(0, -b \cot \xi_0)$ and lies in $r \geq 0$. The spindle surface is $\xi = \xi_0$ and the region of flow studied is $0 \leq \xi \leq \xi_0$, $-\infty < \eta < \infty$ with ξ and η chosen as independent variables.

KINETIC EQUATION FOR A PLASMA WITH UNSTEADY CORRELATIONS, by C. M. Tchen. Jan. 1, 1959, 56p. (NBS rept. no. 6274) (AFOSR-TN-58-636) [CSO-680-57-16] AD 162167 Unclassified

Presented at Conf. on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

Also published in Phys. Rev., v. 114: 394-411, Apr. 15, 1959.

As a generalization of the Boltzmann equation, the kinetic equation for a plasma is derived in the form of a generalized Fokker-Planck equation, by considering unsteady

correlations, including non-Markovian and nonlinear behavior. Both the binary and ternary correlations are used for many kinds of particles with different temperatures. The coefficients of the kinetic equation depend on the law of interaction for a pair of particles and are influenced by relaxation. The effective potential of friction consists of two parts: the static part corresponds to the Debye potential and is isotropic, the dynamical part is axially symmetrical about the direction of motion, and causes a dynamical friction. The results show that the friction is proportional to the velocity for slow particles, and inversely proportional to the square of velocity for fast particles. This tendency of the fast particles to overcome repulsion is a property connected with the "run-away" of electrons. A criterion for maximum friction is derived. The triplet interaction, which mainly affects the shielding phenomena, assures the convergence of the coefficients in case of distant interaction. Since the length scales of interaction are well determined in this way, the kinetic equation can be expected to be valid over a longer range than does the Boltzmann equation. The large scale agrees with the Debye radius, when the shielding term is linearized, as should be expected. When time relaxation is left aside and linearization is made, the kinetic equation degenerates to the classical Fokker-Planck equation with convergent coefficients. (Contractor's abstract)

SHAPE OF THE HIGH ENERGY END OF THE ELECTRON-BREMSSTRAHLUNG SPECTRUM, by E. G. Fuller, E. Hayward, and H. W. Koch. Aug. 1957 [19]p. incl. diagrs. tables, refs. (AFOSR-TN-57-679) [CSO-680-57-2] Unclassified

Also published in Phys. Rev., v. 109: 630-635, Feb. 1, 1958.

The elastic scattering of photons by the 15.11 mev level in C^{12} has been used to study with good energy resolution the number of photons at the high-energy end of a bremsstrahlung spectrum. The bremsstrahlung was produced by electrons accelerated in a betatron, the energy of which was varied in 35-kev increments. Targets were a 0.025-in.-diameter tungsten wire and the following foils: 0.010-in. tungsten, 0.001-in. thorium and 0.010-in. nickel. The foils were used to study the dependence of the spectrum shape upon target thickness and atomic number. When compared with Bethe-Heitler spectra corrected for target thicknesses, the data indicate an excess number of photons in the tip of the spectrum. The experimental number depends on the atomic number of the target and cannot vary more rapidly than Z^2 . (Contractor's abstract)

MASS-ABSORPTION COEFFICIENTS FOR 40- TO 80-MEV X-RAYS IN CARBON, WATER, AND ALUMINUM (Abstract), by J. M. Wyckoff and H. W. Koch. [1958] [1]p. [CSO-680-57-2] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 174, May 1, 1958.

A good geometry measurement has been made of 90-mev synchrotron x-ray spectra transmitted through long cylinders of carbon, water, and aluminum. A "hydrogen" measurement was made using a cyclohexane-benzene difference method. The x-ray detector system was a 5-in. diam by 9-in. long NaI (Tl) spectrometer and a 256 channel pulse-height analyzer. The pulse-height distributions clearly show the nuclear absorption below 40 mev. The distributions also permit an accurate evaluation of the total absorption processes in the energy range from 40 to 80 mev. The carbon measurement at 60 mev gives $\tau = 0.01434 \pm 0.00005 \text{ cm}^2/\text{g}$ which is 1% and 5% higher respectively than the published values. The values measured for water and aluminum at 60 mev of 0.0170 and 0.0239 cm^2/g are also higher. For hydrogen at 60 mev $\tau = 0.0128$, a value between those in the two tables. The differences are largely accounted for by the triplet cross section estimates of Joseph and Rohrllich.

ELASTIC SCATTERING OF PHOTONS, by E. G. Fuller and E. Hayward. Final rept. Jan. 1, 1959, 1v. incl. illus. diagrs. tables, refs. (NBS rept. no. 6255) (AFOSR-TR-58-162) (CSO-680-58-16) AD 207250 Unclassified

The work of the project is summarized and the principal publications emanating from the research are appended. Betatron γ -rays were used to measure the elastic scattering cross sections for a number of elements in the energy range 4-40 mev. The results indicated that in regions where the scattering cross section is flat with photon energy the experimental points should be plotted at $.94E_0$, where E_0 is the maximum energy in the bremsstrahlung spectrum. Where the cross section is either rising or falling rapidly the points should be plotted at $.93E_0$. In all cases the measured cross sections are averages over a photon bin approximately $0.1 E_0$ wide.

No matter what the shape of the scattering cross section, inelastic scattering can only be measured to levels within

$0.15 E_0$ of the ground state. For a sharply rising cross section only levels within $0.10 E_0$ should be considered.

The scattering cross sections calculated in this experiment are sensitive to the choice of end point channel. These errors will be of the order of 5-10% providing the end point channel is chosen high enough in the pulse height spectrum.

THE NUCLEAR PHOTOEFFECT AND NUCLEAR DEFORMATIONS, by E. G. Fuller. [1958] [4]p. incl. diagrs. table. [CSO-680-58-16] Unclassified

Published in Internat'l. Congress on Nuclear Phys., Paris (France) (July 7-12, 1958), Paris, Dunod, 1959, p. 642-645.

The correlation of the shape of the giant resonance for photon absorption with the ground state nuclear deformation as predicted by Okamoto and Danos has been studied by a "poor energy resolution" survey of the shape of the neutron production cross section for nuclei ranging from tin through the rare earths to lead and by a "good energy resolution" determination of the shape of this cross section for terbium, tantalum and gold. After correction for the neutron multiplicity above the $(\gamma, 2n)$ threshold the data indicate a considerable broadening of the giant resonance for the highly deformed nuclei. The "good energy resolution" data show a splitting of the giant resonance for the deformed nuclei terbium and tantalum into two peaks while only one such peak is observed for gold. These data can be well fitted by the superposition of two Lorentz lines. The intrinsic quadrupole moments determined from these fits were: Tb: $+5.6 \pm 0.6$ barns, Ta: $+5.7 \pm 0.3$ barns, and Au: $+1.6 \pm 0.6$ barns. Preliminary measurements of the elastic scattering cross section for tantalum also show the splitting of the total absorption cross section into two peaks. (Contractor's abstract)

Elastic scattering cross sections for lead, uranium, and bismuth have been measured in the energy range

NBS. 36:004; NBS. 20:004, 005;
NBS. 21:020

from 4 to 10 mev. Self-absorption measurements have been made at photon energies below the (γ, n) thresholds. These measurements, made both at room temperature and at liquid nitrogen temperature, indicate that the levels responsible for the scattering in radiolead have widths between 0.2 and 3.0 ev while those in lead and bismuth must be greater than 3.0 ev wide. Evidence has also been obtained that a large fraction of the scattering by bismuth is produced by a single strong level which overlaps a similar level in ^{208}Pb . (Contractor's abstract)

A SCINTILLATION SPECTROMETER STUDY OF THE PHOTODISINTEGRATION OF O^{16} , by N. L. Svantesson.

[1957] [26]p. incl. illus. diagrs. tables, refs. [CSO-630-55-35] Unclassified

Published in Nuclear Phys., v. 3: 273-298, Apr. 1957.

The nuclear reactions $\text{O}^{16}(\gamma, p\gamma)\text{N}^{15}$ and $\text{O}^{16}(\gamma, n\gamma)\text{O}^{15}$ were used to study the photodisintegration of O^{16} . Various bremsstrahlung spectra with peak energies ranging between 16 and 30 mev were used to excite the target nuclei. The photons emitted in the two reactions were measured with a NaI(Tl) scintillation spectrometer covering photon energies from 2 to 11 mev. The results support the belief of the 6.1 and 6.3 mev states in O^{15} and N^{15} , respectively, being $p_{3/2}^{-1}$ states. Transitions to these two states, 30 percent, are together with ground state transitions, 70 percent, the only ones observed between 20.0-22.5 mev excitation energies. In the regions between 22.5 and 25.0 mev also transitions to 7, 9, and 10-11 mev states were observed. Ground state transitions in this interval occurred in about 40 percent, while the transition probability to excited states was shared roughly equally between the 6.1-6.3 mev states and all the other states, mainly the 7 mev states. σ_{int} from 20-25 mev amounted to about 0.1 mev · barn.

The ratio between σ_{int} for (γ, p) and (γ, n) reactions was about 3:2. The nuclear elastic scattering of photons was also measured and was used to determine the integrated cross section for photon absorption up to 40 mev which was found to be 0.3 mev · barn. (Contractor's abstract)

A PRELIMINARY SURVEY OF ELECTRICAL RESISTANCE-STRAIN CHARACTERISTICS OF EVAPORATED FILMS, by A. Krinsky and R. L. Parker. Feb. 1957, 42p. incl. illus. diagrs. tables, refs. (NBS rept. no. 5139) (Sponsored jointly by Office of Naval Research under NAord 21-48, Air Force Office of Scientific Research under CSO-640-55-9, and Atomic Energy Commission) AD 130128 Unclassified

A preliminary investigation of the electrical-resistance-strain characteristics of evaporated films has been undertaken. A total of 22 materials (Pt, Pd, Sb, Co, Au, Ni, Te, Al, Fe, Cu, Cr, Ag, Sn, Ge, Mg, Mn, Ti, Se, V, Be, Nichrome, Kanthal 'A') has been studied. Methods of preparation and test are described. Results for tests performed at room temperature on about 300 samples are presented and discussed. In general, strain-sensitivity is found to be a function of film specific resistance. For films of specific resistance 1-10 ohms/square, for the strain-sensitivity approaches the bulk value. For higher specific resistance films, the strain-sensitivity decreases to reach a minimum value. For films of even higher specific resistance (up to 10^6 - 10^7 ohms/square) the strain-sensitivity increases

Also published in *Phys. Rev.*, v. 108: 652-658, Nov. 1, 1957.

By applying a tensile stress to specially prepared and oriented samples, the piezoresistivity coefficients of both n- and p-type indium antimonide have been measured over the temperature range 77°K to 300°K. The results for extrinsic p-type material are similar to those for p-type Si and Ge, indicating that the valence band structure is similar. Extrinsic n-type InSb results confirm the picture of a conduction band having its minimum at the center of the Brillouin zone. The largest effect that was observed in intrinsic material was in the volume coefficient and can be attributed to the change in the forbidden gap due to dilatation of the lattice. The value of this gap per unit strain was estimated to be $E_{1g} = -7.0$ ev. (Contractor's abstract)

THE IONIC CHARACTER AND ELASTIC MODULI OF ZINC BLENDE LATTICES, by R. F. Potter. [1957] [6]p. incl. diagr. tables, refs. (CSO-670-53-12)
Unclassified

Published in *Jour. Phys. Chem. Solids*, v. 3: 223-228, 1957.

The elastic moduli for a number of materials with the diamond or zinc blende (sphalerite) crystal structure are available in the literature. It has been noticed that the ratio C_{11}/C_{12} has values between 2.6 and 2.7 for Si and Ge, respectively, and 1.65 or 1.50 in the case of ZnS. InSb and GaSb have elastic moduli that give intermediate values for this ratio. A scale which gives the

ionic character as a function of the ratio C_{11}/C_{12} has been constructed based on the Born diamond lattice theory and the relationship between the longitudinal optical mode and transverse optical modes when the lattice has some ionic character. This scale indicates that InSb has the ionic character that corresponds to an ionic charge of 0.65 electron. GaSb has an ionic character approximately two-thirds of that for InSb. Conversely, the elastic moduli may be estimated for crystals of this type if the optical data are available. (Contractor's abstract)

STATISTICAL MECHANICS AND THE BOLTZMANN EQUATION, by M. S. Green. [1958] [7]p. (AFOSR-TN-56-556) [CSO-880-58-24]
Unclassified

Also published in Proc. Internat'l. Symposium on Transport Processes in Statistical Mechanics, Brussels (Belgium) (Aug. 27-31, 1956), N. Y. Interscience Publishers, Inc., 1958, p. 8-14.

It was determined that although the equations for the distribution functions have many solutions corresponding to arbitrary specifications of the initial values of all the distribution functions, the memory of these initial conditions are lost except for widely separated points which are of no significance for most properties of the system. The time for initial correlations to be scattered in such a harmless way depends on the magnitude of the initial regions of correlations. While this time may be large for some initial conditions, it may be expected that it is usually of the order of magnitude of the duration of a collision. (Contractor's abstract)

Also published in Jour. Appl. Phys., v. 29: 204-212, Feb. 1958.

The Born-Green Theory, employing the Kirkwood superposition approximation, is investigated as a means of calculating the intrinsic bulk viscosity - a bulk viscosity due solely to Van der Waals interactions - in a monatomic gas. It is found that the Kirkwood approximation lacks a principle of irreversibility, so that homogeneous integral equations are obtained with no normalizing conditions. By the neglect of terms of the order of contributions from triple collisions, expressions for the bulk viscosity are derived in terms of other thermodynamic quantities which yield rough values of the order of one micropoise for argon and nitrogen at 0°C , 1 atmos. A high-Q resonant-cavity method has been developed for the measurement of very small microwave absorption coefficients. The present status of theoretical and experimental knowledge in the field of microwave absorption and pressure broadening of spectral lines is discussed. For some obscure reasons it was found to be extremely difficult to obtain stable conditions in experimental tests of the method. The observed behavior was such as to suggest that unexpected, and as yet unexplained, surface phenomena were operative. In the limited time available it was not possible either to determine the exact nature of these effects or to exploit the

NBS. 38:001, 002; NBS. 39:001;
NBS. 40:001

full possibilities of the method, although it shows great promise for further refinement. Measurements were made of the absorption coefficient of pure water-vapor very near the resonance frequency of the 22,237 mc spectral line. These results are compared with those of previous investigators, and it is suggested that the considerable discrepancies between theory and experiment, previously pointed out by Van Vleck, may be due to spurious surface effects. (Contractor's abstract)

Published in I.R.E. Trans. on Microwave Theory and Techniques, v. MTT-5: 208-212, July 1957.

Excess noise produced by microwave excitation of silicon crystal diodes was studied for operation of the crystal as a detector and as a microwave harmonic generator. The noise appears at the detector terminals and also as noise sidebands off the microwave harmonic, thus degrading the spectral purity of the harmonic relative to that of the fundamental. Possible models of the processes involved are presented. Difficulties and technique of measurement are discussed. Observations for 1N26 crystals, used as detectors, doublers, and triplers, and excited by X-band power in the range 8 to 100 mw are presented, showing limitations on spectral purity set by the process of noise production during harmonic generation. PERFORMANCE OF THREE-MILLIMETER HARMONIC GENERATORS AND CRYSTAL DETECTORS, by J. M. Richardson and R. B. Riley. [1957] [5]p. incl. diagrs. tables. (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Atomic Energy Commission under [CSO-680-57-11])

Unclassified

Published in I.R.E. Trans. of Professional Group on Microwave Theory and Techniques, v. MTT-5: 131-135, Apr. 1957.

Because of growing applications of millimeter wave measurements, a fairly thorough investigation of what could be expected from sources and detectors in the 3 mm region was made. The sources consisted of fourth-harmonic generators from a 1.25 cm fundamental. A type of crystal holder for both harmonic generators and detectors in which a small crystal wafer is positioned in the broad wall of the millimeter waveguide, being contacted by a whisker passing across the waveguide (the open-guide type) was found to be superior in general to units using crystal cartridges or modifications thereof. Factors affecting the performance of these units have been investigated statistically. It was found that the short-circuit current sensitivity in microamperes per microwatt of a good crystal detector of the type described above is not greatly less than the value for crystals at lower microwave frequencies, so that the minimum detectable signal is about the same. As an additional result, evidence for an important effect in which harmonic generation process degrades the signal-to-noise ratio of the source is presented and discussed. (Contractor's abstract)

Lifetimes of optically created electron-hole pairs have been evaluated from the short wavelength limit of the photoconductance and PEM short-circuit current. Investigations were carried out for n- and p-type crystals of Mg_2Sn over the temperature range 400°K to 78°K. At room temperature the lifetimes for all samples were in the range 0.12 to 0.17 μ sec. At high temperatures $\tau \sim \exp E_g(0^\circ K)/2kT$ applied. Possible interpretations in terms of direct recombination (radiative) or

NBS. 40:002, 003; NBS. 41:001

recombination through centers are discussed. The spectral dependence of the photoconductance and PEM short-circuit current was investigated for wavelengths between 0.5μ and 5.5μ . Theoretical expressions which apply for thick samples are presented. The experimental results are adequately described by theory. Surface recombination velocities and absorption coefficients were evaluated from the spectral dependence studies. Absorption due to indirect transitions can account for the energy dependence of the absorption coefficient which was observed (146°K). The forbidden energy gap calculated from the threshold frequency is in agreement with values which have been reported for the thermal band gap. (Contractor's abstract)

MAGNETIC FIELD DEPENDENCE OF THE HALL COEFFICIENT AND ELECTRICAL CONDUCTIVITY IN SEMICONDUCTORS (Abstract), by J. H. Becker. [1957] [1]p. [CSO-680-56-39] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series 11, v. 2: 57, Jan. 30, 1957.

The spherical energy surface approximation used by Johnson and Whitesell to calculate the Hall coefficient and electrical conductivity when mixed ion-lattice scattering is present in a one-carrier or intrinsic semiconductor, has been extended to include arbitrary number of bands and concentrations. The formulas reduce to those of Willardson, Harman, and Beer for a system of electrons, fast and slow holes with lattice scattering. When mixed ion-lattice scattering is present in a many-band system, the magnitude of the Hall coefficient and the electrical conductivity as well as their rate of change with magnetic field can be considerably reduced compared to when only lattice scattering is present. The large contributions of the light mass carriers (i.e., light holes in p-type germanium) to the Hall coefficient and magnetoresistance are most easily reduced by small amounts of ion scattering. Under some conditions the change of the Hall coefficient with magnetic field can even be opposite to that which would take place if only lattice scattering were present.

LIFETIMES IN MAGNESIUM STANNIDE (Abstract), by E. I. Sochard and J. H. Becker. [1957] [1]p. [CSO-680-56-39] Unclassified

Presented at meeting of the Amer. Phys. Soc., Philadelphia, Pa., Mar. 21-23, 1957.

Published in Bull. Amer. Phys. Soc., Series 11, v. 2: 120, Mar. 21, 1957.

Determination of both the photoelectro magnetic effect and photoconductivity under steady state conditions permits a direct evaluation of the electron-hole pair lifetime for optically created carriers. This method has been applied to studies of lifetime as a function of temperature between 350 and 90°K on single crystals of the semiconductor $Mg_{1-x}Sn_x$ (extrinsic n- and p-type concentra-

tions $10^{15} - 10^{17}/cc$). Cleaved samples, and those subjected to sandblasting and annealing treatments, have been investigated. Radiation from a Nernst glower (chopper at 3000 cps) and the use of suitable filters allowed determination of the response to various wavelength regions. The responses were linear with applied electric and magnetic fields, and approximately linear with light intensity. Samples with the highest lifetimes followed approximately $\tau \sim \exp X (-E_g/2kT)$ between 350 and 250°K.

For lower temperatures the lifetimes either decreased or remained constant. Below 150°K photovoltaic effects and large "anomalous lifetimes" occurred (not observable by transient decay checks). Bulk electron-hole pair lifetimes at 300°K ranged from 10^{-6} to 10^{-7} sec.

UNIFORM TRANSIENT ERROR, by E. L. R. Corliss. [1958] [6]p. incl. diagrs. (Research paper no. 2879) (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [CSO-680-57-1]) Unclassified

Published in Jour. Res. Nat'l. Bur. Standards, v. 61: 25-30, July 1958.

The economy of transient error is discussed. Equations describing error in power-level measurements of transients can be used to compute the design of analyzers so as to distribute transient error in a way compatible with experimental requirements. In addition, consideration of a limiting power-discrimination factor provides a measure of the largest number of bandpass filters by calculating the effective number of those overlapped on adjacent channels to yield meaningful information about a rapidly changing signal. A scanning filter can be compared with a set of bandpass filters by calculating the effective number of overlapped bandpass filters providing the same resolution as the scanning filter. The results are applicable to autocorrelation analyzers. Restrictions on rapid signal analysis also are considered for the special case in which power-level discrimination is limited by noise. FROZEN FREE RADICALS, by C. M. Herzfeld and A. M. Bass. [May 1957] [6]p. incl. illus. diags. (AFOSR-TN-57-329) [CSO-680-58-9 and CSO-680-56-21] AD 132402
Unclassified

Also published in Scientific American, v. 196: 91-102, Mar. 1957.

A method is described by which short-lived free radicals were frozen by rapid cooling and studies made of their properties. Free radicals in a highly excited state were produced by flowing gases (water vapor, oxygen, nitrogen, and hydrogen) through a high-frequency electric discharge powered by a 2,450-megacycle medical diathermy unit. The products were then rapidly pumped to a surface cooled by liquid helium to about 4° above absolute zero, where they immediately froze into solids. Observations of the breakdown products revealed the following: Nitrogen emitted a bright blue-green glow upon freezing, attributed to isolated excited nitrogen atoms. Spectrographic examination revealed 5 intense emission lines, 3 broad bands, and many weaker bands distributed over the whole visible spectrum. Experiments with oxygen produced a clear glassy deposit upon freezing, which emitted no light and which showed 25 separate bands of absorption distributed over the whole visual spectrum and extending into the ultraviolet and infrared. When warmed to 20° absolute, this deposit changed to a violet colored solid which was identified as a mixture of oxygen and ozone with a fairly high concentration of ozone. Further warming produced additional ozone in large quantities, which suggests the possibility of using this frozen-radical method in the commercial production of ozone. Brief discussion is given to the breakdown products from discharges through hydrogen, water vapor, and ammonia gas. The possibilities presented by these studies for providing information on the role free radicals play in electric arcs, flames, interstellar dust, comets, stars, etc., and their use as new tools with which to probe the structure of solids are suggested.

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 3: 180, May 1, 1958.

Also published in Jour. Res. Nat'l. Bur. Standards, v. 61: 117-121, Aug. 1958.

The effects of a crystal field of octahedral symmetry and of spin-orbit coupling on an ion with f^2 electron configuration are considered. Only fourth-degree terms in the crystal-field potential are taken into account. The eigenvalues and eigenvectors of the resulting 33×33 secular determinant are determined numerically on the 704 electronic computer at the National Bureau of Standards for eight values of D/ζ , where D is a crystal-field parameter, and ζ the spin-orbit coupling constant of the ion. Perturbations by an external magnetic field are computed using second-order perturbation theory. All eigenvalues are tabulated for eight values at $(-D/\zeta)$ in the range from 10^{-4} to 10^{-1} . These eigenvalues can be adapted directly to any finite nonzero positive value of ζ and, by interpolation, for values of D/ζ not tabulated. The magnetic susceptibility of a powder is calculated and displayed as a function of temperature and D/ζ , for $\zeta = \text{---}$, 10^3 cm^{-1} , and $5 \times 10^2 \text{ cm}^{-1}$. The relation of the results of the calculations to measurements on compounds of U^{+4} is discussed. (Contractor's abstract)

HEATING EFFECTS ACCOMPANYING PHOTOCONDUCTIVITY AND THE PHOTO-ELECTRO-MAGNETIC EFFECT IN SEMICONDUCTORS (Abstract), by I. I. Sochard and J. H. Becker. [1958] [1]p. [CSO-680-58-15] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 114, Mar. 27, 1958.

A well-known method for determination of lifetimes of electron-hole pairs in semiconductors uses photoconductivity and photoelectromagnetic (PEM) short-circuit current measurements. Sample heating always occurs and produces "bolometer" action and "thermo-electromagnetic" effects (diffusion of thermally excited carriers in a magnetic field). These can seriously hinder evaluation of the lifetimes, especially for intrinsic materials with small ambipolar diffusion lengths ($l = \sqrt{D\tau}$). When the heating phenomena are dominant the thermal diffusivity can be estimated. In lifetime measurements it is customary to modulate the incident radiation at

NOL.01:002; NRL.01:001;
NRL.02:001, 002

audiofrequencies. Increasing this "chopping" frequency f decreases the thermal signals (for "thick samples,"

$Bol \sim f^{-1}$, $TEM \sim f^{-1/2}$) which facilitates lifetime measurements; for a lifetime determination in Mg_2Sn

$f > 10^4$ cps is required above room temperature. Data at "chopping" frequencies between 20 and 13,000 cps will be shown for intrinsic and extrinsic samples of Mg_2Sn . Analysis will include an estimate of the minimum lifetimes determinable by the PC-PEM method in terms of the "chopping" frequency and known electrical and thermal properties of a semiconductor. It has been shown that with the use of fast photo-conductive detectors, infra-red spectroscopy can be applied to the study of free radicals and other short-lived molecules with conditions of resolution approaching those of conventional instruments using thermal detectors.

Furthermore, by direct photometric techniques, kinetic studies can be made easily and relatively accurately.

APPLICATION OF LUMINESCENCE CHANGES IN ORGANIC SOLIDS TO DOSIMETRY, by J. H. Schulman, H. W. Etzel, and J. G. Aillard. [1957] [4]p. incl. diagrs. refs. [CSO-670-54-8] Unclassified

Published in Jour. Appl. Phys., v. 28: 792-795, July 1957.

The degradation of photoluminescence in anthracene and in naphthalene has been studied under gamma-ray and electron irradiation over the range 3×10^5 to 2×10^8 rep. For both materials the variation of brightness with CO^{60} gamma-ray dose D , in rep, may be represented by $(I/I_0) = (1 + AD)^{-1}$, where $A = 8.5 \times 10^{-7}$ for anthracene and $A = 14 \times 10^{-7}$ for naphthalene. Irradiation also produces a radiophotoluminescence in naphthalene, with emission in the visible spectral region. Both the degradation and radiophotoluminescence are stable with time at room temperature. The employment of these effects for dosimetry is discussed. (Contractor's abstract)

THE IRRADIATION OF POLYVINYL METHYL ETHER WITH ELECTRONS AND GAMMA RAYS TO FORM ELASTOMERS, by D. Duffey. Aug. 19, 1957, 33p. incl. diagrs. tables, refs. (Rept. no. 4938) [Sponsored jointly by Air Force Office of Scientific Research and Office of Naval Research under CSO-680-56-12]

Unclassified

Polyvinyl methyl ether and mixtures of this ether with a variety of powdered fillers were irradiated with electrons from a Van de Graaff and gamma rays from cobalt-60. The ether crosslinked on irradiation, however, fillers were necessary to give products with much strength. The fillers, carbon black, magnesia, silica, iron oxide, and calcium phosphate produced significant reinforcement. Ordinary chemical methods of cross-linking, or vulcanization, were ineffective. The optimum amount of fillers for strength was about 30% of the mixture by volume, and the required radiation levels were the order of 40 megaroentgens. Tensile strengths of over 1500 psi with elongations at breaking of 100 to 200% were obtained. The products swelled in the solvents of the crude ether. In particular, cold water swelled the products, which could be a serious limitation to many uses. Some liquids, such as straight chain hydrocarbon and caustic solution, did not effect the product appreciably. (Contractor's abstract)

LUMINESCENCE OF Z CENTERS IN KCl: Sr CRYSTALS, by E. J. West and W. D. Compton. [1957] [4]p. incl. diagrs. [CSO-600-56-12] Unclassified

Published in Phys. Rev., v. 108: 576-579, Nov. 1, 1957.

A search has been made for emissions that are characteristic of the Z_1 and Z_2 centers in additively colored crystals of KCl containing strontium. No emission was found for the Z_1 center. The Z_2 center was found to emit at 1.14μ at 77°K. A study of the polarization of the emission of the Z_2 center with polarized exciting light leads to the conclusion that this center is of high symmetry. A study of the transfer of energy between centers that have been formed by irradiating with F light leads to the conclusion that these centers (i.e., F, Z_1 , R_1 , R_2 , M, and a center with absorption at 860 m μ) are formed in the neighborhood of each other. SYMMETRY PROPERTIES OF THE V_1 CENTER, by J.Lambe and E. J. West. [1957] [4]p. incl. diags.
[CSO-660-56-12] Unclassified

Published in Phys. Rev., v. 106: 634-637, Nov. 1, 1957.

The symmetry of the V_1 center was studied using a technique of bleaching with polarized light. The V_1 band in KCl and KBr produced by x-rays and 2-mev electron bombardment was examined. In addition, the effect of bleaching with polarized light on the phosphorescent emission of KCl was observed. It is concluded that the center responsible for the V_1 absorption band in KCl and KBr was cubic symmetry insofar as its optical absorption is concerned. The phosphorescent emission of KCl became anisotropic under polarized bleaching light, indicating the presence of a center of noncubic symmetry. This second center has a [011] axis of symmetry. CRACK-EXTENSION-FORCE NEAR A RIVETED STIFFENER, by J. P. Romualdi, J. T. Frasier, and G. R. Irwin. Oct. 11, 1957, 20p. incl. diags. tables. (Rept. no. 4956) (AFOSR-TN-56-140) (MIPR-680-56-47) AD 152167 Unclassified

Knowledge of the characteristic value of the crack-extension-force for onset and arrest of rapid fracturing should, conceptually, permit direct calculation of the load-bearing capacity of structural components from the viewpoint of fracture fail-safe design. This possibility is illustrated by two examples of calculation of the crack-extension-force in the presence of rivet forces. One case is a crack centrally located at a stiffener, and the second case is a crack centrally located between stiffeners. The results indicate that in both cases the riveted stiffeners serve as effective crack arresters. The calculations were checked experimentally, and satisfactory agreement was obtained. Errors in strain-gage determinations of the crack-extension-force, it was found, become negligible when an appropriate correction for gage position is applied.

Also published in Second Interdisciplinary Conf. on Decisions, Values and Groups, New Mexico U., Albuquerque, June-Aug. 1958, New York, Pergamon Press, v. 2: 227-256, 1962.

An analysis was made of a social interaction in which one person exercises control over the behavior of one or more other persons. A person A was considered to have authority over B, in a given situation, when a response of A, under the control of deprivation or aversive stimulation and specifying its own reinforcement, is reinforced by B. Authority so defined was analyzed as a function of the following variables: (1) reinforcing stimulus variables; (2) deprivation and aversive stimulus variables affecting A; and (3) discriminative stimulus variables. A paradigm of an authority sequence was analyzed in terms of these variables. Series of functionally related sequences were defined as sequences under the control of one another or of common variables. Three classes of functionally related consequences were analyzed: (1) where one sequence exercised functional control over another; (2) where a common variable exercised functional control over 2 or more sequences; and (3) authority conflict. The study suggests how authority

evolves, is maintained, and may be weakened. In addition, the analysis showed that, if authority has any locus, it is in all interactors in the sense that behavior on the part of all interactors is essential for authority to exist. (ASTIA abstract)

INTERNAL REFERENTS AND THE CONCEPT OF REINFORCEMENT, by W. Bevan and R. Adamson. [1958] 31p. incl. diagrs. refs. (In cooperation with Emory U., Atlanta, Ga.) (AFOSR-TN-58-1101) (AF 49(638)33) AD 207822 Unclassified

Also published in Second Interdisciplinary Conf. on Decisions, Values and Groups, New Mexico U., Albuquerque, June-Aug. 1958, New York, Pergamon Press, v. 2: 453-472, 1962.

A reconceptualization is outlined of reinforcement based on assumptions that the organism is capable of averaging input over time, thus deriving internal norms, that the magnitude of reinforcement depends directly on these norms, that reinforcement exerts its influence upon performance through its effect upon tension level, and that there is a curvilinear relation between tension level and performance efficiency. The results of experiments relating to the validity of these assumptions are presented; and implications of the present point of view for understanding changes in the efficacy of reinforcing agents, partial reinforcement, extinction and reacquisition, and the performance of anxious and non-anxious subjects are reviewed. THE EFFECTS OF VERBAL EXPRESSION OF HOSTILITY, by R. DeCharms and M. E. Rosenbaum. [1958] 14p. incl. table. (In cooperation with Iowa State U., Ames) (AFOSR-TN-58-1102) (AF 49(638)33) AD 207823 Unclassified

The experiment reported was an examination of the relationship between aggressive statements directed toward an aggressor and residual hostility toward the aggressor. Forty male subjects (Ss) engaged in interaction and by prearrangement were verbally attacked. They were then permitted to reply to the attacker and then wrote a personality sketch of him. Results showed that for Ss with high self esteem and those with low self esteem there was a high positive correlation between the amount of hostility shown in the reply to the attacker and that shown on the subsequent personality sketch. In addition, it was found that Ss with low self esteem showed a large and significant increase in hostility from the first to the second measure, but this was not true for Ss with high

self esteem. These results were interpreted as casting doubt on a simple catharsis hypothesis of hostility reduction. (Contractor's abstract)

SOME REQUIREMENTS FOR QUANTITATIVE METHODS IN BEHAVIORAL SCIENCE RESEARCH, by P. H. DuBois and D. Gold. [1958] 41p. incl. diagrs tables. (In cooperation with Washington U., St. Louis, Mo.) (AFOSR-TN-58-1104) (AF 49(638)33) AD 207825
Unclassified

Also published in Second Interdisciplinary Conf. on Decisions, Values and Groups, New Mexico U., Albuquerque, June-Aug. 1958, New York, Pergamon Press, v. 2: 4-65, 1962.

Some requirements are discussed for quantitative methods of analysis in behavioral research in relation to the order of measurement which characterizes the data. For categorical data, it is considered that the partitioning of chi-square answers questions about the differences between degrees of association in a set of partial contingency tables, and that a limited method of decomposing a total association answers questions about the proportion of the total association between two variables that can be accounted for by the relationship of each to a third. With interval data two primary problems of interest to the behavioral scientist are discussed: (1) the development of means of identifying unitary variables manifested in diverse acts of behavior by groups of individuals, and (2) the application of factor analytic techniques to determining the basic variables underlying a set of observed variables. While these methods have already had wide-spread application, it appears that their further perfection would help to provide tools needed for further discoveries in this area of research. Several leads for their further refinement are noted. (Contractor's abstract)

Also published in Second Interdisciplinary Conf. on Decisions, Values and Groups, New Mexico U., Albuquerque, June-Aug. 1958, New York, Pergamon Press, v. 2: 189-200, 1962.

An exploratory analysis of the conceptual dimensions of rank differentiation is reported. Data for the present study were provided by "prestige judgments" which psychology graduate students in a large metropolitan university made of their faculty. It was found that: (1) sufficiently similar judgmental standards were used by the students to evidence the operation of a commonly defined rank system; (2) a professor's rank (i.e., overall prestige) in the university, as well as being related to the formal status he holds in the institution and his effectiveness in carrying out the positional mandates, was related to the possession of inherited or acquired personal qualities which the students deemed appropriate for the status incumbent; and (3) rank distinctions in this institutional setting were judged in affectively-neutral fashion, both in terms of the criteria of rank employed and in terms of the impersonal manner with which rank and its criteria were judged. INTELLIGENCE. TIME FOR A CHANGE, by S. Liverant. [1958] 23p. incl. refs. (In cooperation with Ohio State U., Columbus) (AFOSR-TN-58-1111) (AF 49(638)33) AD 207837 Unclassified

Also published in Second Interdisciplinary Conf. on Decisions, Values and Groups, New Mexico U., Albuquerque, June-Aug. 1958, New York, Pergamon Press, v. 2: 88-85, 1962.

The concept of intelligence was analyzed with respect to its ability to explain behavior. Evidence from the literature of the past 20 yr was used to challenge accepted conceptions of the general and innate nature of intelligence. The suggestion was made that the term intelligence be relegated to a descriptive function applicable to certain kinds of behavior whose explanation can be attempted by the continued development of existing constructs. In addition, it was suggested that I.Q. tests be interpreted as culturally expected standards of academic achievement involving a number of complexly interrelated variables (e.g., motives, habits, expectancies, reinforcements, etc.) to account for the results.

A DESCRIPTIVE THEORY OF COMMUNICATION, by H. Maclay. [1958] 55p. (In cooperation with Illinois U., Urbana) (AFOSR-TN-58-1112) (AF 49(638)33) AD 207838 Unclassified

Also published in Second Interdisciplinary Conf. on Decisions, Values and Groups, New Mexico U., Albuquerque, June-Aug. 1958, New York, Pergamon Press, v. 2: 201-228, 1962.

This report is a first attempt to develop a theoretical basis for describing some aspects of the process of communication. It is a descriptive theory in that its aim is confined to describing what occurs in a communicative process. The author is interested in defining the units of communicative behavior in the same way that a structural linguist is concerned with the units of language behavior. The result of this attempt is a model which describes communication in terms of several variables and the rules by which they combine. A set of procedures for discovering the units of communicative behavior is also presented.

DETERMINISTIC THEORIES, by R. Montague. [1958] 84p. incl. refs. (In cooperation with California U., Los Angeles) (AFOSR-TN-58-1113) (AF 49(638)33) AD 207839 Unclassified

Also published in Second Interdisciplinary Conf. on Decisions, Values and Groups, New Mexico U., Albuquerque, June-Aug. 1958, New York, Pergamon Press, v. 2: 325-370, 1962.

An investigation was made to analyze the properties of the notions of a deterministic theory and a deterministic system. This investigation is conducted within metamathematics in the wide sense and employs the apparatus of syntax and set theory in an intuitive manner, making no attempt to trace it back to its theoretical foundations. Explicit definability and determinism are discussed in which the metamathematical methods employed are deeper and contribute to the well-known n-body problem of physics.

A THEORETICAL ANALYSIS OF CONFLICT, by A. Peppone and S. Feshbach. [1958] 27p. incl. refs. (In cooperation with Pennsylvania U., Philadelphia) (AFOSR-TN-58-1114) (AF 49(638)33) AD 207840 Unclassified

Also published in Second Interdisciplinary Conf. on Decisions, Values and Groups, New Mexico U., Albuquerque, June-Aug. 1958, New York, Pergamon Press, v. 2: 440-452, 1962.

An attempt was made to develop a formal treatment of the notion of conflict. Attention was focused upon the immediate source of most human conflict, namely, the psychological environment of the individual (an environment which has predictable effects upon the organism). This environment, at any given time, was considered a finite set of behavior possibilities. These possibilities were regarded as alternatives in choice or decision situations with states and positions in addition to the kind of actions that follow formal decisions. The following conceptual tools were used in developing a formalized treatment of conflict: (1) positive value (this quantity is conceptually equivalent to the notion of goal, reward, positive valence, etc.); (2) negative value (this quantity is the equivalent of punishment, negative valence, avoidance, etc.); and (3) difficulty (associated with each positive value or negative value are quantities which represent the difficulty (work, cost, etc.) involved in realizing the positive value or in minimizing the negative value).

NEU.01:017 - NEU.01:020

Three simple conflict types were analyzed. In addition, a discussion is presented of uncertainty, distance and time gradients, sources of conflict, consequences of conflict, compromise solutions, and defense mechanisms.

NOTES ON A CONSTRUCTIONAL FRAMEWORK FOR A THEORY OF ORGANIZATIONAL DECISION MAKING, by R. S. Rudner and R. J. Wolfson. [1958] 72p. incl. refs. (In cooperation with Michigan State U., East Lansing) (AFOSR-TN-58-1116) (AF 49(638)33) AD 207842

Unclassified

Also published in Second Interdisciplinary Conf. on Decisions, Values and Groups, New Mexico U., Albuquerque, June-Aug. 1958, New York, Pergamon Press, v. 2: 371-409, 1962.

A preliminary treatment is given of the study of the construction of a definitional framework of concepts held to be pivotal in any adequate theory of organizational decision making. The definitional framework is comprised of 91 definitions, grouped into 4 related categories. The categories are (1) a pool of preliminary concepts, (2) decision behavior, (3) conflict and cooperation, and (4) decision making in organizations. The number of extralogical primitive terms indigenous to the behavioral sciences is minimized in favor of terms which have received explication in physical science.

INFORMATION STORAGE IN GROUPS, by R. B. Zajonc. [1958] 10p. incl. diags. (In cooperation with Michigan U., Ann Arbor) (AFOSR-TN-58-1117) (AF 49(638)33) AD 207843

Unclassified

Also published in Second Interdisciplinary Conf. on Decisions, Values and Groups, New Mexico U., Albuquerque, June-Aug. 1958, New York, Pergamon Press, v. 2: 279-290, 1962.

An attempt in the area of memory is made to predict group performance on the basis of individual abilities interacting with one another. This approach consists of a combinatorial analysis of individual products and abilities. By analyzing the recall potential of individual members, derivations are made regarding the storage of information in the group as a whole. The problem is presented of how a given amount of information should be distributed among a number of individuals so as to assure maximal recovery of the information. By imposing a set of restrictions, a solution is obtained by generating a constant distribution value independent of the amount of information and the number of individuals involved. A set of solutions obtained by specifying various restrictive conditions provides standards against which empirical results can be compared.

Also published in Second Interdisciplinary Conf. on Decisions, Values and Groups, New Mexico U., Albuquerque, June-Aug. 1958, New York, Pergamon Press, v. 2: 119-130, 1962.

Two experiments were performed in which subjects (Ss) attitudes were changed by inducing them to express, in debate or structured discussion, opinions which they did not initially hold, then rewarding them for the verbal behavior. The first experiment served to confirm results previously reported by W. A. Scott (Jour. Abnormal Social Psychol., v. 55: 72-75, 1957), and further indicated that the procedure was effective for Ss with extreme, moderate, or neutral attitudes. The newly acquired attitude showed a significant degree of saving, as measured by a subsequent test approximately 10 days later. The second study was aimed at testing the hypothesis that Ss whose initial attitudes were cognitively consistent would be more resistant to attitude change than cognitively inconsistent Ss. On the basis of pretest responses to a set of questions concerning 8 values, and of the perceived relevance of the issue under discussion to each of the values, Ss were classified as either cognitively consistent or inconsistent in their attitudes toward the issue. As predicted, the cognitively consistent Ss were less likely to change their attitudes under the experimental conditions than were the cognitively inconsistent Ss. (ASTIA abstract)

DIRECT AND VICARIOUS REDUCTION OF HOSTILITY, by M. E. Rosenbaum and R. DeCharms. [1958] 25p. incl. diagr. table, refs. (In cooperation with Iowa State U., Ames and Washington U., St. Louis) (AFOSR-TN-58-1122) (AF 49(638)33) AD 207848 Unclassified

Also published in Jour. Abnormal Social Psychol., v. 60: 105-111, 1960.

The effectiveness of vicarious experience in reducing hostility toward an instigator was examined. Hypotheses which are related to the role of communication in the reduction of aggressive impulses were tested. Fifty subjects (Ss) participated in a simultaneous interaction in which each was verbally attacked by a standard tape-recording. The experimental conditions were as follows: (1) Ss sat in silence after the attack; (2) Ss heard a third person denounce the attacker; and (3) Ss were permitted to communicate back to the attacker themselves. Ss in each group were classified as to level of self-esteem. A measure of residual hostility toward the attacker constituted the primary dependent variable. Results were

Published in Behavioral Science, v. 3: 14-25, Jan. 1958.

Also published in First Interdisciplinary Conf. on Decisions, Values and Groups, New Mexico U., Albuquerque, June-Aug. 1957, New York, Pergamon Press, v. 1: 185-201, 1960.

Before a social aggregate can be examined for its status as an organic system its status as entity must be evaluated. Indices of common-fate, similarity, and proximity may be appropriate to this task. Social groups as entities do not have an epistemological status different from such middle-sized entities as stones and rats, but are apt to be fuzzier, less discrete, less multiply confirmed, and in this sense less real. The degree of entitativity and the possibility of a sociology at a level of analysis separate from psychology is a matter for empirical determination rather than a priori decision. A "PURE" MEASURE OF PERCEPTUAL DEFENSE UNCONTAMINATED BY RESPONSE SUPPRESSION, by A. Mathews and M. Wertheimer. [1958] [4]p. incl. tables. (In cooperation with Colorado U., Denver) (AF 49(638)33)

Unclassified

Published in Jour. Abnormal Social Psychol., v. 57: 373-376, Nov. 1958.

Using a tachistoscopic recognition technique, an experiment was designed that provided measures both of "perceptual defense" and of response suppression. The "perceptual defense" measure could be corrected by the response suppression measure to yield a "pure" perceptual defense measure. With this method, it was found that subjects scoring high on the hysteria scale of the MMPI demonstrate a significant perceptual defense effect over and above a response suppression effect, when confronted by words preselected so as to be emotional for each subject individually. It is therefore concluded that perceptual defense effects cannot be accounted for entirely on the basis of response suppression. (Contractor's abstract)

THE SPECTRUM OF INDIVIDUAL INTERACTION CHARACTERISTICS: AN INTER-DIMENSIONAL ANALYSIS, by E. F. Borgatta, L. S. Cottrell, Jr., and J. H. Mann. Feb. 1958 [40]p. incl. diagrs. tables. (In cooperation with New Mexico U. Albuquerque, AF 49-(638)33) (AFOSR-TN-58-422) (AF 49(638)195) AD 158225 Unclassified

Also published in *Psychol. Repts.*, v. 4: 279-319, 1958.

This research attempted to replicate work reported by Carter that indicated three factors were sufficient to account for most of the variance in the ratings of interaction. Forty-seven graduate students participated in 5 small groups in roles which rotated among the members. Rankings of peers were obtained for 16 personality trait names, 24 behavioral descriptive categories, and other salient variables. Bales' category system was utilized in classifying the groups behavior. Intercorrelations were calculated and factor-analyzed according to the complete centroid technique. Two major factors, individual assertiveness and Sociability, extracted from a matrix of 18 trait names and 24 behavioral descriptive phrases, corresponded directly to Carter's work. Three other factors were found: manifest intelligence, task interest and manifest emotionality. Data are examined in detail.

RANKINGS AND SELF-ASSESSMENTS: SOME BEHAVIORAL CHARACTERISTICS REPLICATION STUDIES, by E. F. Borgatta. [1958] [49]p. incl. tables. (AFOSR-TN-58-737) (AF 49(638)195) AD 162270 Unclassified

Also published in *Jour. Social Psychol.*, v. 52: 279-307, 1960.

Five replications investigate the general nature of behavioral characteristics as they occur in ratings and rankings. Two of the analyses are of the characteristics of persons as perceived in the consensus of group members. These permit a comparison of male and female subjects. A third replication examines the self-ranking which the members make within the context of ranking the total group. The fourth replication involves the ratings, essentially allowing the members an opportunity not only to indicate how they ordered the various qualities, but also to introduce a more abstract frame of reference and the freedom of choosing the level for the ratings. The fifth replication represents the most abstract consideration of the characteristics, being an analysis of the ways the characteristics themselves are judged to belong together. The results suggest that four behavioral characteristics recur fairly consistently: individual assertiveness, sociability, intelligence, and emotionality. The structural arrangement of the characteristics is altered depending on the circumstances of the replication. In terms of judging qualities compared to characteristics of judging persons, the frame of reference involved appears to be different, but the organization of the other characteristics involved seems to be similar.

THE COINCIDENCE OF SUBTESTS IN FOUR PERSONALITY INVENTORIES, by E. F. Borgatta. Oct. 20, 1958 [22]p. incl. tables. (AFOSR-TN-58-923) (AF 49-(638)195) AD 204557 Unclassified

Also published in *Jour. Social Psychol.*, v. 56: 227-244, 1962.

This paper examines the interrelationship of subtests from four well-known personality inventories that stress subtests with independent content. Two main clusters were found and several minor ones, suggesting construct validity for possibly eight content areas. Problems of subtest meaning, of reliability, and of second order factors are discussed, as well as specific shortcomings of the tests, such as the omission of an emotional stability subtest in the Edwards Personal Preference Schedule. Other limitations may be seen through

NYU.08:004; NYU.02:010, 011;
NYU.04:002; NYU.05:003

comparison as well, such as the fact that if one does not examine male and female data in parallel, it is likely that some subtleties associated with the gross differences in the sexes and which are reflected in the personality structure will be missed. Indeed, one of the ways of establishing the power of a set of subtests is to indicate that they maintain their structure across such grossly different categories as male and female. While the limitations of the tests should be recognized, however, it needs to be stressed in closing that the status of these tests, while improvable, is far from primitive and reflects a tremendous accumulation of experience. MOOD, PERSONALITY, AND INTERACTION, by E. F. Borgatta. [1958] [44]p. incl. tables. (AFOSR-TN-58-978) (AF 49(638)195) AD 205855 Unclassified

Mood was studied by means of a checklist which consisted of 40 items that were drawn from a questionnaire utilized by Nowlis at the University of Rochester in 1957. The short adjective checklist was administered before and after a 2½ hr session spent completing questionnaires of various types. The two sets of checklist responses for 180 male college subjects were factor analyzed by the complete centroid method, and rotation was done by quartimax. Six factors were found which were sufficiently well defined to warrant construction of scores to represent the factors. These were: lonely, warmhearted, tired, thoughtful, defiant, and startled. Six scores were constructed on 2 to 4 items each as follows: (1) lonely, insecure, frustrated and fearful; (2) affectionate, forgiving, kindly, and warmhearted; (3) drowsy, tired, and sluggish; (4) serious, engaged in thought, concentrating, and earnest; (5) defiant and rebellious; and (6) startled and shocked. Examination of the male data revealed that, both for the before-and after-tests mood, lonely correlates with moods 5 and 6 (defiant and startled), and moods 5 and 6 are also positively correlated. Mood 3 (tired) is positively correlated and mood 4 (thoughtful) is negatively correlated with moods 1, 5, and 6, but mood 2 (warmhearted) appears to be clearly independent in the matrix for male data. Data obtained from 35 females tended to show a similar structure with several specific variations. (ASTIA abstract)

[RESEARCH IN THE FIELD OF RADIATION DETECTION EQUIPMENT, SPECIFICALLY COUNTERS], by S. A. Korff. Nov. 1, 1957, 2p. (AFOSR-TR-57-93) (AF 18-(600)1460; continued by AF 18(600)1555) AD 136735 Unclassified

The 2 main areas investigated under this contract were: (1) negative ion effects in halogen-quenched counters; and (2) the radius effect in counters. Using pulsed x-rays, it was found that time lags are probably due, not to negative ions, but to the relatively long period required for halogen molecules to deexcite the metastable atoms formed in the discharge. In studying radius effect a series of counters of different radii was constructed and their counting rate curves were measured as a function of gas pressure. Changing the electric field distribution affected the results very little, but purification of the gas reduced the effect markedly.

A RAPID SCANNING SYSTEM FOR RECORDING THERMOCOUPLE OUTPUTS, by H. Trampusch, R. Papirno, and G. Gerard. Mar. 1958 [11]p. incl. illus. diagrs. (Technical rept. no. SM 58-3) [AF 18(600)1471]
Unclassified

A method for the measurement and recording of the transient temperatures at a large number of locations within a body is described. The temperatures are sensed by thermocouples which are connected to a switching unit and a single cathode ray oscilloscope. The thermocouple voltages appear as a dot array on the oscilloscope screen that is photographed to give a record of the temperature distribution as a function of time and location. The described system is adaptable to measurements other than temperature providing the desired parameter can be transduced to an analogue voltage. In this category would be included strain, velocity, pressure, acceleration and others. (Contractor's abstract)

RECENT STUDIES OF COUNTERS, by S. A. Korff. [1957] [4]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)1555; continuation AF 18(600)1460] Office of Naval Research, and Atomic Energy Commission)
Unclassified

Published in Proc. Third Internat'l. Congress on Ionization Phenomena in Gases, Venice (Italy), (June 11-15, 1957), Milan, 1957, p. 558-561.

The results of investigations on time lags and non-flat plateaus of halogen-quenched counters, the ultraviolet spectrum of BF_3 , and the "radius effect" in BF_3 counters

are reported. In the study of halogen-quenched counters it was found that the time lag depends on overvoltage and the filling gases. Analysis of the discharge mechanism suggested that the lags were caused by the comparatively long time needed for the metastable states formed in the buildup of the avalanche to become deexcited. The plateau slope is dependent on the halogen concentration. Increasing the halogen concentration decreases the time lag, but increases the plateau slope. The investigation of the ultraviolet absorption spectra of BF_3 showed

strong absorption in the regions of 2700 to 2515 and 2300 to 1215 Å. The "radius effect" is that it appears to be difficult to produce large diameter counter with good plateaus but it is easy to make good ones of small diameter. Preliminary work on this problem shows that the radius effect is not caused by a simple effect such as negative ion effects, and the phenomenon is not an end effect. The limiting radius was found to be 2.5 cm.

RADIUS EFFECT IN BORON TRIFLUORIDE COUNTERS, by R. M. Chang. Dec. 1957, 1v. incl. illus. diagrs. refs. (AFOSR-TN-58-139) (AF 18(600)1555) AD 152166
Unclassified

The radius effect in boron trifluoride counters is defined as the progressive diminution of the flatness of the plateau as the radius of the counter is increased. This report concerns itself with a set of systematic tests of this effect. First, by using ordinary BF_3 it is shown at what radius the effect sets in. Second, by careful purification, it is shown that the effect can be reduced. However, it was not reduced to zero. Third, the possibility that the effect is due to field distortion inside the counter is critically examined, tested, and shown not to be the principal factor. Finally, in the discussion, the directions for future research are indicated. (Contractor's abstract)

A USEFUL METHOD FOR INTEGRATING THE TIME-DEPENDENT, VISCOUS EQUATIONS OF MOTION, by L. Filler, H. F. Ludloff and P. Treuenfels. [1957] [1]p. (Sponsored jointly by [Air Force] Office of Scientific Research under [AF 18(603)25] and Office of Naval Research) Unclassified

Published in Jour. Aeronaut. Sciences, v. 24: 147, Jan. 1957.

As a preliminary to numerical integration of the three time-dependent, viscous equations of motion, it is instructive to study the "Burger equation," which contains both characteristic features of the motion of a real fluid—viz., the nonlinear as well as the viscosity effects. The most interesting difference procedure to be used for integrating this parabolic differential equation (as well as the true equations of motion) is an implicit scheme, in which the time steps may be taken arbitrarily large. The authors have carried out an analysis of stability and of convergence of iterations before carrying out the numerical integration and comparing it with an analytic solution.

ATTEMPTS AT DERIVATION OF TRANSITION FROM LAMINAR INTO TURBULENT FLOW ALONG A FLAT PLATE, by H. F. Ludloff and F. Reiche. June 1958, 21p. incl. diagr. table. (Rept. no. 3) (AFOSR-TN-58-493) (AF 18(603)25) AD 238163 Unclassified

A review of the magnitude of the flow parameters to be expected has shown that the orders of magnitude assumed in the convergence of iterations—proof have to be changed, and as a consequence, the convergence proof had to be altered. In this connection, it was also possible to improve the rate of convergence of successive iterations, by adopting a novel scheme. The analytic problem, consisting of the difference equations of motion, the boundary and initial conditions, was re-formulated. The convergence of iterations of the new procedure was proven, the convergence mechanism was further elucidated by considering the one-dimensional case of the Burgers equation. The computation of the initial field is described. Finally, two important general features of the solution method are exposed: (1) the limitations due to the finite mesh width of the difference scheme, which cuts off the high frequencies of the turbulence spectrum, and (2) the fact that the theory is developed for given, constant Re-number, while the experiments of Schubauer produce conditions, in which the Re-number varies with time. Both difficulties could be satisfactorily resolved. (Contractor's abstract, modified)

ORIENTATION OF RESEARCH NEEDS ASSOCIATED WITH ENVIRONMENT OF CLOSED SPACES, by W. T. Ingram. [1958] [21]p. incl. tables, refs. (AFOSR-TN-58-106) (AF 18(603)71) AD 152015 Unclassified

Also published in Proc. Fourth annual meeting of the Amer. Astronaut. Soc., New York (Jan. 29-31, 1958), N. Y., Amer. Astronaut. Soc., 1958, p. 17-1-17-18.

A study of several aspects of the environment of closed space has provided a basis for orientation of research needs in coping with the requirements of a healthful, safe, working space under a closed ecology. A discussion is offered of present knowledge and work on such essentials as CO_2 - O_2 conversion, treatment of bodily wastes, recovery of usable water from contained air, urine, and other sources, removal of pollutants from contained air, and purification or disposal of various liquid wastes. The problems of closed-space ecology may be divided into those occurring during extra-terrestrial flight (1) of short duration amounting to hours, (2) of intermediate duration, amounting to days, and (3) of long term, amounting to weeks and months. This discussion deals almost entirely with the third problem, but the orientation of research needs emphasizes that careful study should be made of factors affecting weight and volume of equipment required to process and maintain an environment with total conservation of mass balance and recycle of matter, as opposed to the principle of replacement of essentials such as oxygen and water by withdrawal from storage while polluted matter is ejected from the closed system environment. For conditions introduced by flight of short or intermediate duration, engineering economics may justify provision for partial or even total replacement of environmental constituents. Long-term operations seem impractical without plans for cyclic use of the contained matter. Re-use of contained matter demands positive mechanical, chemical, or biological action that has no chance of failure, since the closed environment will be totally dependent on the continuous and proper functioning of reclamation and conversion operations. THE ENGINEERING BIOTECHNOLOGY OF HANDLING WASTES RESULTING FROM A CLOSED ECOLOGICAL SYSTEM. THERMAL ENERGY EXCHANGE WITH SPECIFIC APPLICATION TO WASTE HANDLING IN A CLOSED ECOLOGICAL SYSTEM, by L. Slote. Progress rept. July 1957, 7p. (AFOSR-TN-58-268) (AF 18(603)-71) AD 154169; PB 137795 Unclassified

The analysis attempts to show the variation in the total surface temperature of a perfect heat conducting or spinning biosatellite for a given orbit and for various conditions of irradiation. As the thermal capacity of the satellite is reduced a temperature distribution is obtained about the surface of the sphere. Therefore, it becomes evident that various temperatures can be obtained depending upon the geometry, surface and trajectory of the biosatellite. With this in mind, it seems feasible to use thermal energy sources in connection with processes for cracking of human waste and for the purification of urine by freezing, if these processes are used.

This report is directed to an examination of the status of existing information and the areas of research requiring attention in connection with the handling of wastes resulting from human occupancy of a closed ecological system. Probable wastes to be handled are classified. The problems related to handling and treatment and to cycling and reuse of treated end products in liquid, solid, and gaseous form are discussed. Five detailed reports discussing the present status of knowledge of wastes handling in closed systems are included as appendices. Areas of research and development are suggested with respect to skin excretions, algae, culture, carbon dioxide conversion to oxygen, the handling of closed space air, and the handling of bodily and other wastes. A master file of 174 annotated references and an alphabetical author index to those references are included. (The 5 detailed repts. included in the appendices are also published separately, see item nos. NYU.11:001, 002, 004-006)

Part I also published in Jour. Math. and Mech., v. 6: 847-858, Nov. 1957.

Part II also published in Communications in Pure and Appl. Math., v. 10: 491-502, Nov. 1957.

Part III also published in Ann. Math., v. 67: 72, 1958.

Part IV also published in Archiv. Rational Mech. and Analysis, v. 1: 139-153, 1957.

The subject of this report is the asymptotic theory of solutions, u , of the reduced wave equation, $\Delta u + k^2 u = 0$, defined in infinite domains. In Part 1, new proofs are furnished of three well-known theorems concerning u . These are Rellich's growth estimate, the uniqueness theorem for the exterior boundary-value problem, and the representation theorem. A new result, the representation theorem for u when the boundary of the domain of definition of u is infinite, is also given. In Part 2, Rellich's growth estimate is extended to solutions of the equation $\Delta v + k^2(x)v = 0$. From this result it was possible to deduce various uniqueness and representation theorems for solutions of this equation. In Part 3, it is shown that the normal boundary values of a radiating solution, u , of $\Delta u + k^2 u = 0$ is bounded by a homogeneous quadratic functional of its boundary values. This result combined with the representation theorem for u yields an L^2 -maximum principle for u . Finally, in Part 4, the behavior of u when the parameter k becomes large is considered. The method of G. Birkhoff is explained for obtaining formal asymptotic expansions for u , and deduce several results concerning the existence and validity of these formal expansions. BASIC MATHEMATICAL RESEARCH FOR ELECTROMAGNETIC THEORY, by M. Kline. June 15, 1952-June 14, 1958 [17]p. incl. refs. (Research rept. no. BR-25) (AFOSR-TR-58-80) (AF 18(600)367) AD 158369; PB 138985
Unclassified

Mathematical tools in the fields of ordinary and partial differential equations, integral equations, special functions, and asymptotic series solutions of electromagnetic problems are investigated. A determinant of infinite order which arises when a solution of Mathieu's equation is expressed in the form $y = \sum_{n=-\infty}^{\infty} c_n \exp(i2nx)$ is considered.

The relationship between Hill's determinant and the values of the solutions is shown (item no. NYU.06:001; item no. NYU.06:024). Conditions are stated under which general operators L occurring in equations such as $Lx = a$ possess the property of having a closed range in the Hilbert space (item no. NYU.06:018). On the assumption that the atmosphere is horizontally stratified so that the dielectric tensor varies in one direction only, Maxwell's equations applied to this anisotropic medium can be reduced to a system of 4 first-order linear ordinary differential equations in which 4 of the 6 components of E and H are the dependent variables (item no. NYU.06:003; item no. NYU.06:012). Portions of the theory of partial differential equations which have a bearing on electromagnetic problems are studied (item no. NYU.06:002; item no. NYU.06:013; item no. NYU.06:014). New methods of solving the Wiener, Hopf, and Fredholm integral equations are considered (item no. NYU.06:015; item no. NYU.06:017; item no. NYU.06:022). Addition theorems for Bessel and Legendre functions, spherical harmonics, Mathieu functions and other special functions are considered, and are adapted to a particular transformation of coordinates (item no. NYU.06:020; item no. NYU.06:021). Special functions called Whittaker functions and E-functions are expanded (item no. NYU.06:025; item no. NYU.06:026). Asymptotic series solutions of Maxwell's equations are presented (item no. NYU.06:009; item no. NYU.06:016; item no. NYU.06:023).

DETERMINATION OF BUCKLING CRITERIA BY MINIMIZATION OF TOTAL ENERGY, by S. Lubkin. July 1957, 60p. incl. diags. (Rept. no. IMM-NYU 241) (AFOSR-TN-57-579) (AF 49(638)161) AD 136567
Unclassified

With the assumption of constancy of the elastic constants in Hooke's Law over the range of strains involved, but no limitation upon magnitude of strains or displacements, formulae for strain energy are derived for several cases of interest. Exact buckling criteria are derived from the effect of small perturbations, from displacements in an unbuckled state, upon the total energy. This method is applied to (1) a column of rectangular section, compressed so as to keep its end flat and parallel to their original position; (2) a hollow circular cylinder, subjected to uniform pressure on its outer surface; and (3) a hollow sphere, subjected to uniform external pressure. In all cases, for thin sections, results agree with those derived by other means. It is shown that with the given

NYU.13:002; NYU.14:001, 002;
NYU.15:001

assumption, a buckling or critical load always exists, no matter what the geometric proportions. As an interesting sidelight, it is also shown that a finite pressure may expand the cylinder or sphere to infinity. (Contractor's abstract)

Finite deformations of ideal elastic materials are mathematically analyzed. A geometric analysis, independent of the physical properties of materials, was made for the case of a square plate of side a and thickness h , where $h \leq a$. Analysis of the equation

$|f(x) - g(x)| \leq M\epsilon a^2/h$ shows that a deformation of a plate differs from a rigid motion by a quantity of order ϵa , unless the thickness h of the plate is small in comparison to its width a . For thin plates the components of displacement tangential to the plate stay of order ϵa while the normal components can be of order $\epsilon a^2/h$. The amount by which the transformation f differs from a rigid motion g by the maximum of $f - g$. An exposition is given of the classical equations for ideal elastic isotropic materials. Stress-strain relations and changes in potential energy resulting from changes in the transformation $x' = f(x)$ are analyzed. Equations are derived for bending of thin plates using Lagrange coordinates. The complete system of differential equations for the first non-vanishing quantities constitutes what may be considered as the differential equations for thin plates. Differential equations for the lowest order non-vanishing quantities are found to involve only 2 material constants, the Lamé constants λ and μ . (ASTIA abstract)

STATISTICAL MECHANICS OF COUPLED PARTICLES IN THE SCHRÖDINGER REPRESENTATION, by R. H. Kraichnan. Aug. 5, 1958 [6]p. incl. diags. (AFOSR-TN-58-692) (AF 49(638)341) AD 215307
Unclassified

Also published in *Phys. Rev.*, v. 112: 1058-1057, Nov. 15, 1958.

A perturbation treatment is presented for the operator $u(t)$ giving the evolution of the state vector of a system of N particles coupled by 2-body forces. The total Hamiltonian is divided into a diagonal part H_0 and off-diagonal part H_1 in the representation with N -particle plane-wave states as basis. An effective pair-interaction operator \bar{H}_1 is defined which includes "vertex" corrections of all orders, and the off-diagonal part of u is expressed exactly by an expansion which involves only \bar{H}_1 and the exact diagonal part of u . A closed set of equations determining \bar{H}_1 and the diagonal part of u are obtained by retaining only the leading terms in the expansion. These equations include all the corrections included in the Brueckner approximation and, in addition,

NYU.15:002-004; NYU.07:003

they contain 3-body effects, iterated to all orders, which are omitted in that approximation. No appeal has been made to one-to-one correspondence between the eigenstates of H_0 and those of the total Hamiltonian, and the ground state plays no special role. The connection with statistical mechanics follows since the partition function is $\text{Tr}[u(-i/kT)]$. The theory simplifies greatly for very large N . (Contractor's abstract)

STATISTICAL MECHANICS OF COUPLED BOSONS IN THE HEISENBERG REPRESENTATION, by R. H. Kraichnan. Aug. 5, 1958, 5p. incl. diags. (AFOSR-TN-58-693) (AF 49(638)341) AD 215308 Unclassified

Also published in Phys. Rev., v. 112: 1054-1055, Nov. 15, 1958.

A system of bosons interacting by 2-body forces is treated in momentum space in the Heisenberg representation, assuming a statistically homogeneous and stationary state. The principle of weak statistical dependence of different momentum modes, previously applied to turbulence dynamics, is used to obtain an exact expansion expressing quadrilinear (2-body) time-displaced correlation functions of the second-quantized field variables in terms of bilinear time-displaced correlation functions and average impulse-response functions. The last-named functions are defined in terms of the exact Green's operator, for infinitesimal sources, of the nonlinear Heisenberg equations of motion. A set of coupled integral equations are then obtained which determine both the bilinear correlation functions and the response functions. By retaining in these equations only the lowest terms in the cited expansion, a theory is obtained which includes particle "self-energy" interactions with the medium of all orders. A modification of the theory is briefly outlined which includes, at finite temperatures, all the processes described at absolute zero by the Brueckner approximation and, in addition, 3-body effects, iterated to all orders, which are omitted in that approximation. HIGHER ORDER INTERACTIONS IN HOMOGENEOUS TURBULENCE THEORY, by R. H. Kraichnan. [1958] [2]p. incl. diags. (AF 49(638)341) Unclassified

Published in Phys. Fluids, v. 1: 358-359, July-Aug. 1958.

In an earlier paper by Kraichnan (Phys. Rev., v. 109: 1407-1422, Mar. 1, 1958) a theory of homogeneous

turbulence was developed from the two statistical assumptions of weak-dependence and direct-interaction. Further work is now described which suggests that the second assumption is more properly termed the direct-interaction approximation. It yields the leading nonlinear terms in a pair of coupled integral equations for the time-covariance and impulse-response functions of the Fourier amplitudes of the velocity field. The full equations contain, in addition, sums over higher order contributions. It is conjectured that the direct interaction approximation quite likely is a good one at all Reynolds numbers. The theory is supported by application to a model system for which an exact solution for comparison can be obtained by other means.

STATISTICAL MECHANICS OF MANY-BODY SYSTEMS (Abstract), by R. H. Kraichnan. [1958] [2]p. (Bound with its AFOSR-TR-58-125; AD 162274) (AF 49(638)341) Unclassified

Presented at Conf. on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

This research is concerned with the application to quantum-mechanical and classical many-body problems of new statistical-mechanical methods employed successfully in turbulence theory. These methods are equally valid for equilibrium states, strongly non-equilibrium states, and strongly dissipative states.

PERSISTENT INTERNAL POLARIZATION, by H. P. Kallmann. Progress rept. no. 6, Vol. i (Annual) Oct. 15, 1955-Oct. 14, 1956. June 1957, 80p. incl. diags. tables. (AFOSR-TN-57-371) (AF 18(600)1004) AD 132443 Unclassified

Persistent Internal Polarization (PIP) Effects in Various An-Cd Phosphors: The dark decay and release of polarization of light were experimentally found to obey the following respective laws:

$$\frac{d\sigma(t)}{dt} = -\frac{\bar{K}\sigma(t_0)}{t + \alpha} = -\frac{\bar{K}\sigma(t_0)}{t} \quad \text{and} \quad \frac{d\sigma(\tau)}{d\tau} = -\frac{\sigma_0\beta}{(\tau + \beta)^2} = -\frac{\sigma(\tau)^2}{\sigma_0\beta}$$

t represents time after termination of the polarizing process; τ , the light-release time scale; t_0 , the time at

which polarization is first determined either by light release or electrode lifting; K and β are the characteristic constants associated with the dark-decay and light-release processes, respectively; and $\sigma(t)$, $\sigma(t_0)$, $\sigma(\tau)$,

NYU.07:004 - NYU.07:007

and σ_0 represent the charge densities of polarization in a sample during t , t_0 , τ , and when $\tau = 0$, respectively.

Further Development of the Phenomenological Model:

The double charge layer model was a good approximation to the type of polarization encountered in K powders.

Thickness Effects in Unwaxed K Powders:

Proof was obtained that polarization density is nearly independent of field strength but depends only on the polarizing voltage.

Thickness Effects in Wax Impregnated Samples:

Measurements on K powders indicated that polarization is not of a grain nature.

Dilute Powder Suspensions in Different Matrices:

The charge transfer from grain to grain and its separation over many grains was studied.

Charge Injection in Wax Impregnated Samples:

Qualitative measurements were made of the detection of charge injection in waxed K powders. IR Effects in Unwaxed K Powders: A quenched powder can be excited by IR even for wavelengths longer than those used during the quench.

voltages in the order of 10^2 V and charge concentrations of about 10^{-7} coulombs/cm², energies of about 10^2 ergs/cm² can be stored in these materials. Thicknesses of the phosphor layers are tenths mm. It should be noted here that these persistent internal polarization materials are sensitive to radiation of wave lengths as short as fractions of Angstrom units to as far in the infrared as microns. The state of excitation decays only slowly in some materials. In such cases it is actually possible to polarize a sample by applying a voltage to it subsequent to excitation. The broad sensitivity spectrum, the considerable amount of energy which can be stored and the flexibility of the methods for obtaining polarization and releasing it may be exploited in memory devices, electrophotography, dosimetry and infrared work. Some of these practical objectives have already been reduced to practice. (Contractor's abstract)

PERSISTENT INTERNAL POLARIZATION AND APPLICATIONS, by H. [P.] Kallmann and J. Rennert. [1957] [8]p. incl. diags. table. [AF 18(600)1004]

Unclassified

Published in Proc. Symposium on The Role of Solid State Phenomena in Electric Circuits, Polytechnic Inst. of Brooklyn, N. Y. (Apr. 23-25, 1957), N. Y., Interscience Publishers, 1957, p. 325-332.

In this survey, practical applications of persistent internal polarization (PIF) in photoconductive materials to memory devices as well as electrophotography with ultraviolet, visible and infrared radiation are discussed. The phenomenon itself which has been known for a long time as an interfering effect in photoconductivity studies has been investigated extensively at New York U. The results of these findings are summarized and the practical applications are described. (Contractor's abstract)

The Polarization of Single CdS Crystals: Large PIP effects were found in single CdS crystals. These effects could be almost completely masked by the induction of photocurrents unless precautions were taken. Visible radiations as low as 10^{-2} μ w/sq cm nullified the separation of charge almost immediately. IR wavelengths

could be used to produce polarization to 2 or 3 x 10^{-8} coul/sq cm with a 200-v polarizing voltage. This polarization had a persistence of several days. Polarization Process in Anthracene: Anthracene layers of almost single-crystal structure were developed which were suitable for use in investigating the build-up and distribution of the polarization. The internal field distribution in these layers was measured, and information was obtained concerning how the charge set free in anthracene is transferred to adjacent layers.

THEORY OF THE CAVITY MICROWAVE SPECTROMETER AND MOLECULAR FREQUENCY STANDARD, by Y. Beers. Sept. 12, 1958 [18]p. incl. diagr. refs. (AFOSR-TN-58-871) (Sponsored jointly by Air Force Office of Scientific Research under AF 4c(838)259; continuation of AF 18(800)968 and Office of Naval Research under Nonr-28535) AD 203714 Unclassified

Also published in Rev. Scient. Instruments, v. 30: 9-16, Jan. 1959.

A short section of a wave guide is considered as a non-resonant absorption cell and then as a resonant cavity. It is shown that the latter gives a better signal-to-noise ratio by a factor which depends upon the relative intensity of the various noise sources but which increases with the Q. It is shown that the voltage signal-to-noise ratio is proportional to the square root of the product of the volume and the Q and otherwise is independent of the shape. This result leads to the conclusion that it is possible in theory to build microwave spectrometers having signal-to-noise ratios some 50 db larger or capable of detecting absorption coefficients some 300 times smaller than spectrometers which are now widely used. However, practical considerations probably would prevent all of this advantage from being realized. These results are applied to a frequency standard using an absorption line. It is shown that it is possible to build a standard using the 3,3 line of NH_3 with a fractional stability of about 4×10^{-12} over an extended interval of time. Some discussion of spectrometers with long non-resonant cells is included also. (Contractor's abstract)

THE COMPARISON OF WAVE GUIDE AND CAVITY MICROWAVE SPECTROMETERS (Abstract), by Y. Beers. [1958] [1]p. (AF 49(838)259) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 213, May 1, 1958.

A short section of wave guide is considered alternately as a true wave guide absorption cell terminated by its characteristic impedance and as a high Q resonator. With the assumption of a detector which is linear in voltage, which usually is valid, it can be shown that in resonator operation the voltage signal-to-noise ratio is larger by a factor from about $(Q/2)^{1/2}$ to about $Q/2$, depending upon whether or not saturation of the sample is imminent and upon how the noise is divided between the oscillator and detector. If saturation is imminent, the input voltage to the resonator must be smaller by a factor of $Q^{1/2}$, and then a simple crystal video detector may not be adequate. A variety of evidence indicates that a considerable portion of the noise probably comes from the oscillator.

S BAND MICROWAVE SPECTRUM N^{15}O_2 (Abstract), by J. Rosenthal. [1958] [1]p. [AF 49(838)259] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 214, May 1, 1958.

A rotational transition of N^{15}O_2 , predicted by G. R. Bird has been observed in the S band microwave region. Using a Stark-modulated spectrometer, the following multiplet was discovered: (a) 4321, (b) 4243, (c) 4082, (d) 3900, (e) 3759, and (f) 3661 mc/sec. The precision is approximately 1 mc/sec and will be increased in further measurements. It is suggested that the above are magnetic fine structure components for the $8_{08} - 7_{17}$ rotational transition. These data offer further confirmation of a combination rule, arrived at independently by Bird and C. C. Ida. It is seen that the frequency difference of 239 mc/sec between lines (a) and (c) also holds for (d) and (f). A search will be made for the $22_{1, 21} - 21_{2, 20}$ transition.

GROUND-STATE INVERSION SPECTRUM OF N^{14}D_3 , by G. Herrmann. [1958] [5]p. incl. diagrs. tables, refs. [AF 49(838)259] Unclassified

Published in Jour. Chem. Phys., v. 26: 875-879, Oct. 1958.

The inversion spectrum of N^{14}D_3 has been investigated between 1500 and 1620 mc/sec. A revised formula for

the rotational fine structure was obtained to fit 17 observed lines. Splitting of $K = 3$ lines into two components was found in good agreement with predicted values. Nitrogen satellites were observed and the values $(eQq)_N = 4080 \pm 3$ kc/sec and $a = 2 \pm 2$ kc/sec were assigned to the nitrogen quadrupole and magnetic coupling constants, respectively. Hyperfine structure due to removal of the K degeneracy was observed to $K = 1$ lines. Applying the theory of Hadley, calculated and observed line contours were brought into agreement. Assuming cylindrical symmetry about bonds, the value $(eQq)_D = 200 \pm 20$ kc/sec was obtained for the deuteron quadrupole coupling constant. A value $\epsilon = 1.9 \pm 0.5$ kc/sec was obtained for the magnetic coupling constant between deuteron spins and molecular rotation.

The energy band structure of hexagonal close packed titanium has been worked out using a modified Slater-Koster LCAO approach for the 3d band and an effective mass approach for the 4s band. The two-center integrals in the LCAO approach for Ti are taken as being proportional to those for Ni derived by Wohlfarth and

Fletcher. The energy levels at 300 points in the Brillouin zone for the 3d band have been obtained by diagonalizing a 10×10 Hermitian matrix with the aid of an IBM 704 Electronic Digital Computer. (A production program for computing the wave functions in the 3d band has also been completed.) A universal density of states was constructed from the energy levels. The constant of proportionality mentioned previously was estimated from the observed cohesive energy. From this result, it is found that 3.4 and 0.6 electrons/atom occupy the 3d and 4s bands respectively. A 3d band width of about 3.8 ev was found. The theoretical electronic specific heat (valid in the liquid helium temperature range) derived from the density of states curve at the Fermi level is about 80% larger than that observed by Smith and Wolcott. Possible reasons for this discrepancy are given. Hall effect measurements have been carried out on pure polycrystalline Ti and Cu between 1.2°K and room temperature. The Hall coefficient versus temperature curves are characterized in both metals by a weak temperature dependence in the residual resistivity region; a strong temperature dependence in the small angle electron-phonon scattering region; and a weak temperature dependence in the linear resistivity region. Magnetoresistance measurements have been carried out on pure polycrystalline Ti and on a single crystal of Ti containing Mn and Al impurity. The former exhibited a very small positive magnetoresistance, while the latter exhibited a sizeable negative magnetoresistance. Possible interpretations of these results are discussed, and the experimental apparatus and techniques are described.

SOME ELECTRICAL PROPERTIES OF URANIUM, TITANIUM, AND COPPER (Abstract), by T. G. Berlincourt. [1957] [1]p. (Sponsored jointly by [Air Force Office of Scientific Research under AF 18(600)-1575] and Atomic Energy Commission) Unclassified

Presented at meeting of Amer. Phys. Soc., Philadelphia, Pa., Mar. 21-23, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 136, Mar. 21, 1957.

Hall effect measurements have been carried out on polycrystalline uranium, titanium, and copper between 1.2°K and room temperature. The Hall coefficient vs temperature curves are characterized in all three metals by a weak temperature dependence in the residual resistivity region; a strong temperature dependence in the small angle electron-phonon scattering region; and a weak temperature dependence in the linear resistivity region. Such behavior in a simple metal like copper supports the view that the effect of scattering is comparable to the effect of charge carrier concentration even in a

NAA.02:003 - NAA.02:006

one-band metal. Values of the Hall coefficient, R_T in units of $\text{cm}^3/\text{coulomb} \times 10^{-5}$, are listed below at three temperatures:

	$R_{4.2^\circ\text{K}}$	$R_{77^\circ\text{K}}$	$R_{300^\circ\text{K}}$
Uranium	1.45	3.9	4.1
Titanium	-4.1	-0.95	-0.05
Copper	-6.8	-6.1	-5.1

The results of low-temperature transverse magneto-resistance measurements on a uranium single crystal for various orientations are also reported. (Contractor's abstract)

Measurements were made on the Hall effect, resistivity, and magnetoresistivity of Cu, Zr, Ti, and Nb at about 1°K and room temperature and in magnetic fields up to 30 kilogauss. Results indicated that the relationship between electron transport properties and electronic

structure is more complicated than is generally appreciated. Anomalous behavior was observed in the Hall effect of Cu in that size effects were evident for sample thicknesses considerably greater than the generally accepted mean free path. Strong temperature dependences were observed in the Hall coefficients of Cu, Ti, and Zr, which suggests that scattering is comparable with charge carrier concentration in determining the Hall coefficient. The Hall coefficients of Zr and Ti were found to be extremely sensitive to impurity content. Comparisons with theory were carried out, and it was concluded that existing theories are not sufficiently general to account quantitatively for the observed temperature and magnetic field dependences of the Hall effect and resistivity. Unusual behavior was observed in the magnetic field induced superconducting transition of Nb. Apparatus was constructed for the measurement of specific heats of metals and alloys in the liquid helium temperature range. (ASTIA abstract)

HALL EFFECT, MAGNETORESISTANCE, AND SIZE EFFECTS IN COPPER, by T. G. Berlincourt. [June 1958] [28]p. incl. diagrs. table, refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1575 and Atomic Energy Commission) Unclassified

Also published in Phys. Rev., v. 112: 381-387, Oct. 15, 1958.

Measurements of the Hall coefficient of several annealed polycrystalline Cu strips of resistivity ratio $\rho(273^\circ\text{K})/\rho(4.2^\circ\text{K}) \sim 450$ and thicknesses ranging from 0.05 to 1.6 mm have revealed the existence of a marked size effect at low temperatures. The effect is orders of magnitude greater than that to be expected on the basis of free electron theory. It is suggested that earlier low-temperature data on the Hall effect of thin high-purity samples are subject to uncertainties arising from such effects. Size effects were also evident in the transverse magnetoresistance. At high fields, a tendency toward saturation in the transverse magnetoresistance was observed for thick samples. The temperature dependence of the Hall coefficient has also been studied. (Contractor's abstract)

Also published in Jour. Aero/Space Sciences, v. 27: 261-271, Apr. 1960.

Experiments were performed in the 12-inch supersonic wind tunnel of the Jet Propulsion Lab. of Caltech to investigate the effect of three-dimensional roughness elements (spheres) on boundary-layer transition on a 10° (apex angle) cone with zero heat transfer. Data were obtained at local Mach numbers of 1.90, 2.71, and 3.67 by varying trip size, position, spacing, and Reynolds number per inch. The results indicate that (1) transition from laminar to turbulent flow induced by three-dimensional roughness elements begins when the double row of spiral vortices trailing each element contaminates and breaks down the surrounding field of vorticity, (2) transition appears rather sudden, becoming more violent with increasing roughness height relative to the boundary layer thickness, (3) after the breakdown of the vorticity field, the strength of the spiral vortices may still persist in the sub-layer of the ensuing turbulent flow, (4) lateral spacing of roughness elements has little effect upon the initial breakdown (contamination) of the laminar flow, and (5) the trip Reynolds number $(uk/\nu)_\delta$, where u and ν are the velocity and kinematic viscosity at the outer edge

NAA. 04:001; NAA. 05:001-005

of the boundary layer and k is roughness height, such that transition occurs at the roughness position, varies as the position Reynolds number to the one-fourth power, viz., $(u_{x_k}/\nu)^{1/4}$, where x_k is trip position.

SHATTERING OF BURNING AND NON-BURNING PROPELLANT DROPLETS BY SHOCK WAVES, by E. Rabin and F. B. Cramer. Feb. 20, 1958, 12p. incl. diagrs. (Rept. no. R-695) (AFOSR-TN-58-82) (AF 18(603)98) AD 148104 Declassified

Investigations of the effect of shock waves in shattering burning and non-burning droplets of RP-1 have been conducted in a shock tube having a one-inch square cross-section. Test results confirm data of earlier investigators that there are two distinct modes of drop break-up associated with transient and steady-state flow conditions. Much higher "transient" flow velocities (duration of flow less than the natural period of oscillation of the liquid drop) are required to break up a drop than are required for steady flow conditions. The critical velocity for shattering burning droplets appears to be of the order of ten percent lower than for non-burning droplets. There appeared to be little if any difference in drag coefficient between the burning and non-burning droplets; thus, the difference in critical shattering velocity appears to be associated with differences in surface tension of the droplet liquid, not the pressure field around the droplet.

ION ROCKET STUDIES (Abstract), by R. H. Boden. [1958] [1]p. (Bound with its AFOSR-TR-58-125; AD 162274) [AF 49(638)16; continued by AF 49(638)344] Unclassified

Presented at Conf. on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

The main objectives of the analytical study were to carry out the general analysis of the ion rocket engine, to establish the significant component and overall design parameters, to define an approach toward an experimental ion thrust chamber, and to determine the engine system thrust level for interplanetary missions. The scope of the study included the complete engine system and its components from the heat source to the exhaust jet. A major conclusion of this study was that three parameters, the ratio of the accelerating voltage to the effective atomic or molecular weight of the propellant per unit charge (V/A), the gross weight of the vehicle Mg, and the thrust-to-weight ratio G, determine the design characteristics of the ion rocket engine.

CRITICAL POWER SUPPLY PROBLEMS IN ION PROPULSION, by A. L. Huebner and R. H. Boden. [1958] 18p. incl. diagrs. (AFOSR-TN-58-691) (AF 49-638)244; continuation of AF 49(638)16 Unclassified

Presented at meeting of the Inst. Aeronaut. Sciences and Amer. Rocket Soc., Aug. 5-6, 1958.

A survey is presented of the basic theory and application of ion propulsion. The ion rocket engine system is described and a schematic diagram is included to show its operations and functions. A discussion of power conversion of the ionic propulsion system includes the following: (1) Theoretical considerations; (2) Power source; (3) Thermomechanical power conversion; and (4) Electrical power generation systems. Characteristics required by the Brayton and Rankine cycle working fluids which are to be used as nuclear reactor coolants are given, and assumptions made in analyzing these cycles and calculating the requisite radiator areas are discussed. Important results are also given of the studies of power conversion cycles. Referring to the power plant development program, those areas are delineated which are critical to the power supply system of an ion rocket system.

RESEARCH ON NOISE IN HIGH POWERED KLYSTRONS, by W. R. Atkinson. Mar. 31, 1957, 35p. incl. diagrs. tables. (Technical rept. no. 114) (AFOSR-TN-57-211) (AF 18(603)33) AD 126508 Unclassified

Experimental work was done in an attempt to improve a previously used noise measuring system. The method of attack was to reduce as far as possible extraneous noises that tended to mask the tube noise about which

information was desired. The advantage gained by using several simultaneously excited crystals was demonstrated. A method for resolving the output noise of a crystal into tube noise and crystal noise components was studied. A description is presented of the commercial equipment which was considered as an aid to the study of noise in klystrons. Presentation is made of formulas which have been derived as a result of a theoretical study aimed at understanding the mechanisms which convert beam fluctuations into power and frequency fluctuations of the microwave energy. RESEARCH ON NOISE IN HIGH POWERED KLYSTRONS, by W. R. Atkinson. Final rept. May 31, 1958, 44p. incl. illus. diagrs. refs. (Technical rept. no. 129) (AFOSR-TR-58-90) (AF 18(603)33) AD 162122; PB 137551 Unclassified

Several techniques were used to measure the spectral dependence of the mean square frequency deviations of two-cavity klystron oscillators having an integrated rms frequency deviation of a few hundred cycles per second over the entire audio frequency range. Comparison of the measurements with existing theories of electronic noise indicated that mechanisms which were not purely electronic in nature were present in all the klystrons tested. Additional measurements indicated that the rapid rise in the spectral density of frequency fluctuations which occurred in progressing to lower audio frequencies was not the result of microphonic variation of the resonant frequencies of the cavities. Some observations suggested that the noise was connected with temperature fluctuations of critical parts of the klystron. Proposed experiments which would more definitely identify the noise sources were mentioned. (Contractor's abstract)

CONCERNING THE EFFECT OF SURFACE ACTIVE SUBSTANCES ON POLAROGRAPHIC CURRENTS, by R. W. Schmid and C. N. Reilley. Mar. 1957, 25p. diagrs. tables, refs. (Rept. no. UNC-Chem. no. 9-CNR) (AFOSR-TN-57-121) (AF 18(600)1160) AD 120476
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 80: 2087-2094, May 5, 1958.

Surface active materials have a marked effect upon electrode processes and a systematic investigation of various ways by which this action takes place in polarography is reported. Oscillographic current-time curves during the life of single mercury drops furnish considerably more information than usual polarograms and a detailed study of such curves allows an interpretation of the various types of phenomena encountered. The time delay usually observed before the surface active material affects the electrode process is explained from the viewpoint of diffusion-controlled transport of the surface active agent to the electrode and of the rate of its adsorption on the electrode. The inhibition of the electrode process, caused by the adsorption of the surface active material at the electrode, is discussed with chief attention devoted to the mechanism and kinetics of electrode reactions. The ideas presented can readily be extended to explain unusual polarographic waves observed in other cases, such as in electrode processes where insoluble or strongly surface active products of the electrode reaction are formed. CHELOMETRIC TITRATIONS WITH POTENTIOMETRIC ENDPOINT DETECTION. MERCURY AS A pM INDICATOR ELECTRODE. PART I. PRINCIPLES, by C. N. Reilley and R. W. Schmid. June 1957 [23]p. incl. diagrs. table. (Rept. no. UNC-Chem. no. 11-CNR) (AFOSR-TN-57-472) (AF 18(600)1160) AD 136464
Unclassified

Also published in *Anal. Chem.*, v. 30: 947-953, May 1958.

Principles concerning the use of mercury as a pM indicator electrode for chelometric titrations are described. The effect of pH, buffer type and concentration, chelon, and metal ion on the potentiometric titration curve may be quantitatively determined in terms of potential-pH diagrams. The interference levels of competitive redox systems - e.g., chloride, iodide, sulfate, and oxygen - are considered similarly. The mercury electrode may also be used to characterize a new chelon in its interaction with various metal ions.

Presented at meeting of the Analyt. Chem. Div. of the Amer. Chem. Soc., New York, Sept. 8-13, 1957.

Abstract published in 132nd meeting of the Amer. Chem. Soc. Abstracts of Papers, 1957, p. 30-B.

Also published in *Chemist. Analyst*, v. 46: 59-60, 1957.

Triethylenetetramine, a typical polyamine with the structure, $H_2N-CH_2-CH_2-NH-CH_2-CH_2-NH-CH_2-CH_2-NH_2$, forms very stable, soluble, 1:1 complexes with cobalt, nickel, copper, zinc, cadmium, and mercury. Consequently, this chelon is useful for the titration of these metal ions. In addition, it appeared to offer special advantages since the alkaline earths and rare earths, as expected, do not react with triethylenetetramine and consequently would not interfere in the titration. The polarographic behavior of the cadmium ethylene

NCU.01:016 - NCU.01:019

diamine tetraacetate complex (CdY^{--}) has been studied. Kinetic waves of three different types were found. Between pH 1 and 4 a kinetic wave attributed to free cadmium ions, dissociated from the complex, occurs. In the pH region from 2 to 5 a second wave occurs which results from the reduction of the species $CdYH^-$. Above pH 3.5 this wave is controlled by the rate of recombination of CdY^{--} with hydrogen ions to form $CdYH^-$. In the pH region above 4 the wave height is independent of pH and yet is strongly dependent on kind, charge and concentration of "inert" cations present in solution. The cation effect is attributed to the formation of an ion pair between CdY^{--} and the cation or to the formation of an activated bridge complex involving the surface of the mercury electrode, the cation and the CdY^{--} . The ion pair or activated bridge complex is then reducible, in contrast to the species CdY^{--} . The kinetics of the formation of such ion associates or complexes are discussed. METHODS OF INDIRECT SPECTROPHOTOMETRY. DETERMINATION OF CALCIUM OR MAGNESIUM, by C. N. Reilley and G. P. Hildebrand. Aug. 1957 [17]p. incl. diagrs. tables, refs. (Rept. no. UNC-Chem. no. 16-CNR) (AFOSR-TN-57-523) (AF 18(600)1160) AD 234956 Unclassified

Also published in *Anal. Chem.*, v. 31: 1763-1766, Nov. 1959.

Inquiry is made into the modes of photometric measurement in cases where the introduction of sample causes a decrease in absorbance of the chromogenic reagent solution. Four methods are distinguished, of which two are new. These new methods yield a linear absorption scale versus concentration plot analogous to the usual "Beer's Law" and "Transmittance-Ratio" relationships. Magnesium is determined using calcon as the chromogenic reagent and calcium in a similar way by introduction of magnesium-EDTA to the calcium solution. The sensitivity of the method is 0.003 (Mg) and 0.005 (Ca) micrograms per cm^2 per 0.001 absorption units. (Contractor's abstract)

ULTRAMICRO CHELOMETRIC TITRATIONS WITH POTENTIOMETRIC END POINT DETECTION, by F. S. Sadek and C. N. Reilley. Dec. 1957 [23]p. incl. diagrs. tables. (Rept. no. UNC-Chem. no. 17-CNR) (AFOSR-TN-57-788) (AF 18(600)1160) AD 148019 Unclassified

Also published in *Microchem. Jour.*, v. 1: 183-201, 1957.

Chelometric titrations with EDTA have been successfully applied to the ultramicro determination of certain metal ions using various metallochromic indicators for end point detection. These indicator methods, in addition to being tedious and often disturbed by the presence of certain other trace metal ions, failed for the analysis of certain metal ions such as barium or strontium. Furthermore a given metallochromic indicator is applicable on a macro scale only to a restricted set of metal ions and conditions of pH and buffer type. In contrast the mercury electrode has been employed for potentiometric end point detection for the analysis of whole and fractional microgram amounts of metal ions. The results indicate that this procedure is a general one, applicable for most metal ions over a wide range of pH using different buffer solutions and several types of chelons. INDIRECT CHELOMETRIC ANALYSIS WITH THE AID OF LIQUID AMALGAMS, by W. G. Scribner and C. N. Reilley. Jan. 1958 [41]p. incl. diagrs. tables, refs. (Rept. no. UNC-Chem. no. 19-CNR) (AFOSR-TN-58-60) (AF 18(600)1160) AD 148102 Unclassified

Also published in *Anal. Chem.*, v. 30: 1452-1462, Sept. 1958.

The application of liquid amalgams lends a new perspective to the field of chelometric titrations. The principle

involves reduction of one or more components of the sample by a metal amalgam with liberation of an equivalent quantity of metal ion from the amalgam. Thus species (e.g. Ag(I) or Tl(I)) which are not readily amenable to direct EDTA titration can be reduced with zinc amalgam, the zinc ions liberated being easily titrated. Another application is to swap an easily masked metal (Cu(II)) for one that is not masked (Pb(II)) or vice versa (e.g. Zn(II) for Pb(II)). In addition, advantage can be taken of the difference between equivalent weights for reduction and for chelometric titration, e.g. analysis of a Bi(III), Pb(II) mixture by titration of aliquots before and after reduction with zinc amalgam. Certain multi-component mixtures as well as reducible organic compounds can be analyzed by these techniques. The method is related to controlled-potential coulometry and similar equations apply, the titration yielding a rapid convenient integration of the current-time curve. An important advantage of the amalgam method is the greatly decreased time required for quantitative reduction (half-reduction in 15-20 sec). A complete operation from introduction of sample through final titration requires only 15-20 min. (Contractor's abstract)

SELECTIVE POTENTIOMETRIC TITRATION OF METAL IONS WITH TRIETHYLENETETRAMINE, by C. N. Reilley and M. V. Sheldon. [1958] [11]p. incl. diags. tables, refs. [AF 18(600)1160] Unclassified

Presented at Fifteenth Congress of the Internat'l. Union of Pure and Appl. Chem., Lisbon (Portugal), 1956.

Published in *Talanta*, v. 1: 127-137, July 1958.

The theoretical conditions necessary for the potentiometric titration of metal ions with triethylenetetramine ("trien") and for the selective titration of mixtures of ions with this reagent, alone or in conjunction with EDTA, are discussed. It is shown that it is possible to choose conditions suitable for selective titrations, and this is illustrated by titrations of Cu, Zn, Ni, Cd and Hg, singly and in two-component mixtures. Alkaline earths do not interfere in the titrations. (Contractor's abstract)

DIFFERENTIAL SYSTEMS WITH INTERFACE AND GENERAL BOUNDARY CONDITIONS, by T. J. Pignani and W. M. Whyburn. [1956] [15]p. (AFOSR-TN-57-202) (AF 18(600)1139) AD 102008 Unclassified

Also published in *Jour. Elisha Mitchell Scientific Soc.*, v. 72: 1-14, May 1956.

In the first part the authors study the system (1) $Y' + P(x)Y = Q(x)$, (2) $A_r Y(t_r^+) + B_r Y(t_r^-) = C_r$ ($r = 1, 2, \dots, m-1$), (3) $AY(a) + BY(b) + \int_a^b F(s)Y(s)ds = D$.

Capital letters in (1), (2), (3) denote $(n \times n)$ matrices; A_r, B_r, C_r, A, B and D are matrices of constants, while $P(x), Q(x)$ and $F(x)$ are Lebesgue summable matrix functions of the real variable x on the interval (a, b) . (2) are interface conditions. The interface points t_1, t_2, \dots, t_{m-1} are $Y(t_r^\pm)$ designate the limits of $Y(t)$ as t approaches the point t_r from the left and right, respectively.

A d -solution of (1) and (2) on (a, b) is a matrix, $Y(x)$, which is absolutely almost everywhere continuous on (t_{i-1}, t_i) ($i = 1, 2, \dots, m$) satisfies (1) almost everywhere on (a, b) and satisfies (2). (3) are general boundary conditions. The results of the authors are extensions of those of Stallard (Oak Ridge Nat'l. Lab. Rep. ORNL 1876 (1955)). The second part is concerned with the same system with the exception that the number of interface points may be countably infinite. (Math. Rev. abstract)

NCU.02:008-010; NCU.03:003, 004

Also published in Jour. Math. and Mech., v. 7: 533-555, July 1958.

This report is a study of the problem $U_{xx}(x,t) = U_t(x,t)$ $x > 0, t > 0$ with the boundary conditions $U(x,0) = 0$ and $U_x(0,t) = g[U(0,t), \phi(t)]$ which corresponds to nonlinear diffusion from a variable heat source to a semi-infinite rod initially at zero temperature throughout. The problem is reduced to a nonlinear integral equation of the form

$$y(t) = \int_0^t \frac{G[y(\tau), \tau]}{\sqrt{\pi(t-\tau)}} d\tau.$$

Existence and uniqueness theorems are established under the most general, physically reasonable hypotheses on g , and ϕ . It is shown that if the variable source temperature $\phi(t)$ is non-negative and non-decreasing, then the surface temperature $U(0,t)$ is non-decreasing and lies between 0 and $\phi(t)$ for all $t \geq 0$. If $\lim_{t \rightarrow \infty} \phi(t) = 1$,

then $\lim_{t \rightarrow \infty} U(0,t)$ also exists, and is also equal to 1.

Furthermore, $U(x,t)$ is found to be a non-decreasing functional of $\phi(t)$. (Contractor's abstract)

A POINCARÉ PROBLEM, by K. Padmavally. July 1958, 30p. (Rept. no. 9) (AFOSR-TN-58-599) (AF 18(600)-1139) AD 162124 Unclassified

Also published in Jour. Indian Math. Soc., v. 22: 181-205, 1959.

A solution of the partial differential equation $\phi_{xx} + \phi_{yy} = \phi - 1$ is sought, which approaches 1 at infinity, and vanishes on the closed segment $[0, 1]$ of the x axis. These conditions are satisfied by the density ϕ of neutrons in a reactor (assumed to be infinite) in which the portion $0 < x < 1$ of the y -plane is occupied by a control rod. The symmetry of the problem about the x -axis reduces the problem to determining a solution ϕ of the differential equation in the upper half-plane, which vanishes on the closed segment $[0, 1]$ of the x axis, approaches 1 at infinity, and has zero normal derivative on the rest of the boundary. Using a suitable Neumann function this problem is reduced to the solution of a Fredholm equation of the first kind. Then using a formula due to W. Schmeidler it is further reduced to the solution of a Fredholm equation of the second kind. (Contractor's abstract)

EQUIVALENT NONLINEAR PROBLEMS, by W. R. Mann. [1958] [3]p. (AF 18(600)1139) Unclassified

Published in Jour. Elisha Mitchell Scientific Soc., v. 74: 114-116, Nov. 1958.

In earlier papers (Quart. Appl. Math., v. 9: 163-184, 1951 and Proc. Amer. Math. Soc., v. 5: 979-987, 1954) certain nonlinear diffusion problems in which the non-linearity occurs in a boundary condition have been treated rather completely. In this paper it is shown that these problems are equivalent to, i.e. have the same solutions as, certain boundary value problems in which all boundary conditions are linear but the differential equation is quasi-linear.

A METHOD FOR THE COMPUTATION OF THE

GREATEST ROOT OF A POSITIVE MATRIX, by A. [T.] Brauer. Dec. 1957, 6p. (Technical rept. no. 6) (AFOSR-TN-57-751) (AF 18(603)38) AD 136739
Unclassified

Presented at Conf. on Matrix Computations, Wayne State U., Detroit, Mich., Sept. 3-6, 1957.

Also published in Jour. Soc. Indust. Appl. Math., v. 5: 250-253, Dec. 1957.

A theorem of Perron (Math. Ann., v. 64: 248-263, 1907) and Frobenius (Sitzungsberichte Preussischen Akad. Wissensch. Berlin, 1908: 471-478 and 1909: 514-518) states that a positive matrix A of order n has a positive characteristic root ω^* which is simple and greater than the absolute value of the other roots. This root lies between the greatest and smallest row-sum, and it is greater than the maximum of the main diagonal elements. The coordinates of a characteristic vector belonging to ω^* can be chosen as positive numbers. For all these results, a new simple proof has been published (Duke Math. Jour., v. 24: 367-376, 1957). Not only the existence of ω^* is proved, but also a convergent method is obtained for the computation of ω^* . This mathematical study is concerned with improving the original method in order to obtain a quicker convergence and to simplify the computation by replacing square roots of row-sums by rational functions of them. It is now shown that the greatest positive root of a positive matrix can be found as exactly as needed by multiplying certain rows successively by given constants and dividing the corresponding columns by these constants.

LIMITS FOR THE CHARACTERISTIC ROOTS OF A MATRIX. VII, by A. T. Brauer. July 1958, 14p. incl. diagr. (AFOSR-TN-58-659) (AF 18(603)38) AD 162190
Unclassified

Also published in Duke Math. Jour., v. 25: 583-590, Dec. 1958.

In the recently published book of E. Bodewig, Matrix Calculus, some results of an earlier paper of this author are mentioned. Bodewig states that this author obtained $n(n-1)/2$ ovals of Cassini which contain the characteristic roots of a given square matrix of order n instead of the well-known n circles for these roots. Bodewig also states that these results are of theoretical interest, but have no practical value. In this paper it is shown that they can easily be used for practical computations.

CONFIDENCE BOUNDS ON THE "RATIO OF MEANS" AND THE "RATIO OF VARIANCE" FOR CORRELATED VARIATES, by S. N. Roy and R. F. Potthoff. May 1957, 16p. (Mimeograph series no. 170) (AFOSR-TN-57-210) (AF 18(600)83; continued by AF 49(638)213) AD 126507
Unclassified

Presented at meeting of the Inst. of Math. Stat., Atlantic City, N. J., Sept. 10-13, 1957.

Abstract published in Ann. Math. Stat., v. 28: 1059, Dec. 1957.

Also published in Ann. Math. Stat., v. 29: 829-841, Sept. 1958. (Title varies)

In this paper confidence bounds are obtained (1) on the ratio of variances of a (possibly) correlated bivariate normal population, and then by generalization; (2) on a set of parametric functions of a (possibly) correlated $p + p$ variate normal population, which plays the same role for a $2p$ -variate population as the ratio of variances does for the bivariate case; (3) on the ratio of means of the population indicated in (1) and, by generalization; and (4) on a set of parametric functions of the population indicated in (2), which plays the same role for this problem as the ratio of means does for the bivariate case.

TESTS OF MULTIPLE INDEPENDENCE AND THE ASSOCIATED CONFIDENCE BOUNDS, by S. N. Roy and R. Bargmann. June 1957, 23p. (Mimeograph series no. 175) (AFOSR-TN-57-380) (AF 18(600)83) AD 132455
Unclassified

Presented at meeting of the Inst. of Math. Stat., Atlantic City, N. J., Sept. 10-13, 1957.

Abstract published in Ann. Math. Stat., v. 28: 1059, Dec. 1957.

Also published in Ann. Math. Stat., v. 29: 491-503, June 1958.

A test based on the union-intersection principle is proposed for over-all independence between p variates distributed according to the multivariate normal law, and this is extended to the hypothesis of independence between several groups of variates which have a joint multivariate normal distribution. Methods used previously (NCU.04:029) are applied in order to invert these tests for each situation and to obtain simultaneous confidence bounds on certain parametric functions, with a joint

NCU.04:035 - NCU.04:037

confidence coefficient greater than or equal to a preassigned level. In case I, these parametric functions are the moduli of the regression vectors of the variate p on the variates $(p-1)$, $(p-2)$, ... 2,1, or on any subset of the latter; of the variate $(p-1)$ on the variates $(p-2)$, $(p-3)$... 2,1, or any subset of the latter, etc.; and finally of the variate 2 on the variate 1. In case II, parallel to each case above, there is an analogous statement in which the regression vector is replaced by a regression matrix β , and the modulus of the regression vector is replaced by the positive square root of the largest characteristic root of (β, β') . Simultaneous confidence bounds on these sets of parameters are given. The proposed tests of hypotheses of multiple independence are an alternative to another class of tests on the likelihood-ratio criterion (S. S. Wilks, *Biometrika*, v. 24, 1932; and *Econometrica*, v. 3, 1935).

NEW DESIGNS FOR THE EXPLORATION OF RESPONSE SURFACES, by R. L. Carter. May 1957, 134p. incl. diag. tables, refs. (Mimeograph series no. 172) (AFOSR-TN-57-381) (AF 18(600)83) AD 132456
Unclassified

An investigation is made of the theory of experimental designs for the exploration of response surfaces. A historical background is given for the concept of response surfaces, which points out the necessarily sequential nature of the exploration and the importance of the concept of rotatability. The relationship is discussed between the conventional factorial design and the designs employed in the exploration of response surfaces. A model is presented which gives the response corresponding to any point in the factor space in terms of the component-functions which depend only on the experimental levels employed. Examples are included which show the response expressed as a linear combination of the conventional effect and interactions. In the general multifactor case, the transformation between the conventional effects and the responses at the sample point is shown to be the Kronecker product of matrices whose elements are component-functions for the individual factors. Configurations of points which are unequally spaced are considered; circular designs are obtained when 2 factors are employed. A procedure is given for computing the general nonsymmetric design. Proof is given for a theorem which states the necessary and sufficient conditions for a configuration of sample points to be a rotatable arrangement of specified order. The theorem is applied to cases of configurations possessing a higher order of rotatability.

TESTING OF HYPOTHESES ON A MULTIVARIATE POPULATION, SOME OF THE VARIATES BEING CONTINUOUS AND THE REST CATEGORICAL, by M. D. Moustafa. July 1957, 26p. refs. (Mimeograph series no. 179) (AFOSR-TN-57-440) (AF 18(600)83) AD 136430
Unclassified

Presented at meeting of the Inst. of Math. Stat., Washington, D. C., Mar. 7-9, 1957.

Abstract published in *Ann. Math. Stat.*, v. 28: 528, June 1957.

A $(k+1)$ -variate distribution is considered in which k variates are continuous and 1 variate is categorical. The k variates are assumed to have a conditional multivariate normal distribution with respect to the 1 categorical variate which are assumed to have a multinomial distribution. Appropriate hypotheses are framed in this situation, analogous to the customary hypotheses on a single multivariate normal distribution, large sample tests of such hypotheses are developed and some of their properties studied. Instead of assuming a single multinomial distribution on the 1 categorical variates, a product of multinomial distributions is assumed (in case some of the 1-categorical are ways of classification) and hypotheses are framed in this situation analogous to the customary ones for several multivariate normal distributions, and large sample tests of such hypotheses and some of their properties are studied. ON THE ASYMPTOTIC DISTRIBUTION OF THE LIKELIHOOD RATIO IN SOME PROBLEMS ON MIXED VARIATE POPULATIONS, by J. Ogawa, M. D. Moustafa, and S. N. Roy. Aug. 1957, 36p. (Mimeograph series no. 180) (AFOSR-TN-57-498) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)83 and Office of Naval Research under Nonr-85506) AD 136488
Unclassified

The asymptotic distribution is studied of the statistic $-2 \log \lambda$ defined for testing with hypotheses of certain types on a mixed variates population. A rigorous proof is presented of the fact that $-2 \log \lambda$, on Doob's (*Trans. Amer. Math. Soc.*, v. 36: 759-775, 1934) assumptions, has an asymptotic χ^2 -distribution. The problem of testing hypotheses in the 3-variates (X, Y, Z) population, where X, Y , are continuous and Z is categorical is explained. A theorem is established which guarantees the consistency and the uniqueness of the solution of the

maximum likelihood equation. The validity of Doob's conditions and the assumption of the theorem are verified for the case of 3-variate population. (Contractor's abstract)

A NOTE ON A CLASS OF PROBLEMS IN "NORMAL" MULTIVARIATE ANALYSIS OF VARIANCE, by S. N. Roy and J. Roy. Nov. 1957, 7p. (Mimeograph series no. 184) (AFOSR-TN-57-749) (AF 18(600)83) AD 136737; PB 132980 Unclassified

Also published in Ann. Math. Stat., v. 30: 577-581, June 1959.

Let the columns of X ($p \times n$) be independent non-singular p -dimensional normal variates with a common variance-covariance matrix and expectations given by

$$E X' = A \xi,$$

where A ($n \times m$) is a matrix of known constants and ξ ($m \times p$) is a matrix of unknown parameters. This will be called the model. Under this model consider the hypothesis

$$H: \xi = B \eta,$$

where B ($m \times k$) is a given matrix of constants and η ($k \times p$) is a matrix of unknown parameters. It is shown that the hypothesis H is "completely testable" if and only if

$$\text{rank } A + \text{rank } B - \text{rank } AB = m.$$

Further, if $\text{rank } A \leq n-p$, it is always possible to construct a testable hypothesis H^* which is implied by H ; the test-criterion proposed for H^* is based on the latent roots of the matrix $S_2 S_1^{-1}$ where S_1 and $(S_1 + S_2)$ are the "error-matrices of sums of squares and products" under the model and under H^* , respectively. It is further shown that the rank of the matrix S_2 is $\min [p, \text{rank } A - \text{rank } (AB)]$. (Contractor's abstract)

SOME ASPECTS OF MULTIVARIATE ANALYSIS, by S. N. Roy. N. Y., John Wiley and Sons, Inc., 1957, 214p. Incl. refs. [AF 18(600)83] Unclassified

Samples of a fixed size are treated with the chief emphasis on obtaining confidence bounds on certain parametric functions that are a set of natural measures of deviation from a null hypothesis. The first twelve chapters lead up to the confidence bounds which are discussed in detail in chapters 13 and 14. In chapter 15,

some nonparametric generalizations of analysis of variance and multivariate analysis applied to categorized data in contingency tables are considered. The underlying basis is a heuristic class of tests and a union-intersection principle. Included in the first twelve chapters are discussions of the multivariate normal population and the properties of samples therefrom, distribution problems, least squares, analysis of variance and generalizations, and bounds on the power functions. There are nine appendices included, covering results in matrix theory, quadratic forms, transformations, roots of determinantal equations, Jacobians, canonical reduction of certain distribution problems and integration, in particular, that connected with the distributions of the smallest and largest roots of a determinantal equation. The multivariate confidence bounds discussed are those for multivariate normal populations relating to (a) the mean vector; (b) mean differences in k populations; (c) the general linear hypothesis; (d) multicollinearity of means; (e) the covariance matrix; (f) characteristic roots related to a pair of covariance matrices; (g) regression-like parameters. Chi-square test criteria and results on large-sample distributions are given in relation to the contingency table hypotheses in chapter 15.

STEP-DOWN PROCEDURE IN MULTIVARIATE ANALYSIS, by J. Roy. Dec. 1957, 18p. (Mimeograph series no. 187) (AFOSR-TN-58-33) (AF 18(600)83) AD 148072 Unclassified

Also published in Ann. Math. Stat., v. 29: 1177-1187, Dec. 1958.

The step-down procedure is applied to the multivariate analysis of variance and the comparison of variance-covariance matrices in order to derive new tests of significance and simultaneous confidence-bounds on a number of deviation-parameters. The step-down procedure is not invariant under a permutation of the variates and should be used only when the variates can be arranged on a priori grounds. Some advantages of the step-down procedure are that (1) the procedure uses widely known statistics like the variance-ratio; (2) the test is carried out in successive stages and if significance is established at a certain stage, one can stop at that stage; and (3) it leads to simultaneous confidence-bounds on certain meaningful parametric functions.

SOME USES OF THE DISTRIBUTION OF THE LARGEST ROOT IN MULTIVARIATE ANALYSIS, by D. L. Heck. Mar. 1958, 46p. incl. diagrs. tables, refs. (Mimeograph series no. 194) (AFOSR-TN-58-290) (AF 18(600)83) AD 154195 Unclassified

There has been only limited application of the distribution of characteristic roots for testing purposes and construction of confidence intervals in multivariate analysis largely because a comprehensive set of tables and easy instructions were not available. This present report is a partial attempt to fill this gap. In this paper, testing procedures for three tests in multivariate analysis are given, and for two of the test situations which require the distribution of the largest characteristic root, numerical examples are worked out. Charts of the upper 1%, 2.5%, and 5% points of this distribution for the degrees of freedom $s = 2(1)5$, $m = -\frac{1}{2}, 0(1)10$, and $5 \leq n \leq 1000$ are included, as well as a procedure for obtaining the points for $n \geq 1000$. The method used in computing the percentage points is also described. (Contractor's abstract)

ASYMPTOTIC POWER AND INDEPENDENCE OF CERTAIN CLASSES OF TESTS ON CATEGORICAL DATA, by E. L. Diamond. April 1958, 1v. incl. table, refs. (Mimeograph series no. 196) (AFOSR-TN-58-549) (AF 18(600)83) AD 158386 Unclassified

The analysis of categorical data is studied so as to distinguish between the case in which the sample is assumed drawn from a single multinomial population and the case in which the sample is drawn from several independent multinomial populations. In the first case all marginal totals of the resulting table of data are stochastic variates. In the second case some marginals are fixed by the manner in which the sample is drawn while the rest are stochastic variates. The necessary careful definition of the hypothesis to be tested and its alternation is given. Two properties of the various types of tests are: (1) the asymptotic power of the test; and (2) the necessary and sufficient conditions for the asymptotic independence in probability of two tests of a given type, and these are found to be appropriate to the two sampling situations.

ON THE CONSTRUCTION OF A CLASS OF ERROR-CORRECTING BINARY SIGNALING CODES, by R. C.

Bose and R. R. Kuebler, Jr. May 1958, 173p. incl. diagrs. tables. (Mimeograph series no. 199) (AFOSR-TN-58-551) (AF 18(600)83) AD 158368 Unclassified

The nature of the group alphabet required to encode information for errorless (up to a point) transmission is discussed. The algebra is a commutative ring algebra whose elements are the 2^n distinct binary sequences of length n . Addition is vector addition, modulo 2, of sequences. Multiplication is specified by defining the i^{th} coordinate of a product as the product, modulo 2, of the i^{th} coordinate of the factors. The geometry employs 2 fundamental spaces: a topological space of n distinct points Y_i where the i^{th} point corresponds to the i^{th} position in an n -place binary sequence, and the finite projective space $PG(k-1, 2)$ from whose points the Y_i 's are selected. The space Ω is determined, to within ordering of points, by the assignment of measure n_i to the points P_i of $PG(k-1, 2)$, where n_i is the number of times P_i appears in Ω and $\sum_i n_i = n$. This distribution of n -measure is discussed, and it is shown that the distribution of n -measure over the points of $PG(k-1, 2)$ is equivalent to the distribution of a D -measure over the $(k-2)$ -flats of $PG(k-1, 2)$. Necessary and sufficient conditions are derived that a D -measure define a group alphabet which will admit the correction of all W -tuple errors in transmission. (ASTIA abstract)

North Carolina U. Inst. of Statistics, Chapel Hill.

A CLASS OF TWO REPLICATE INCOMPLETE BLOCK DESIGNS, by J. Roy. June 1958, 21p. incl. tables, refs. (Mimeograph series no. 201) (AFOSR-TN-58-554) (AF 18(600)83) AD 158372 Unclassified

Also published in Biometrics, v. 15: 259-269, June 1959.

A new class of two replicate designs called Simple Partially Linked Block designs is introduced. It is shown that with any of these designs, the variance of the estimate of the difference in effects of two treatments can be at most of seven different types. The general procedure of intra- and inter-block analysis is developed and illustrated with a numerical example. A list of these designs involving ten or fewer plots per block is given together with the values of parameters required in the analysis and the values of the efficiency-factor. It turns out that most of these designs are highly efficient with an efficiency-factor of the order of 75%. It is indicated how other two replicate designs can be derived from these designs. North Carolina U. Inst. of Statistics, Chapel Hill.

THE UNIQUENESS OF THE L_2 ASSOCIATION SCHEME, by S. S. Shrikhande. June 1958, 25p. incl. refs. (Mimeograph series no. 204) (AFOSR-TN-58-608) (AF 18(600)83) AD 162136; PB 138971 Unclassified

Also published in Ann. Math. Stat., v. 30: 781-798, Sept. 1959.

The L_2 association scheme for a class of partially balanced incomplete block designs determines the parameters of the second kind. It is shown that the converse is true and that these parameters imply the L_2 association scheme in the case in which $s = 2$ and integral, $v = s^2$, $n_1 = 2s - 2$, $p_{11}^1 = s - 2$, and $p_{11}^2 = 2$. Necessary conditions for the existence of such designs are obtained if the above conditions hold and $s = 3$ and $s = 4$.

ON A CHARACTERIZATION OF THE TRIANGULAR ASSOCIATION SCHEME, by S. S. Shrikhande. July 1958, 15p. (Mimeograph series no. 206) (AFOSR-TN-58-609) (AF 18(600)83) AD 162137; PB 138977 Unclassified

Also published in Ann. Math. Stat., v. 30: 39-47, Mar. 1959.

A proof is given for the following theorem: A necessary and sufficient condition that a partially balanced incomplete block diagram for $n(n-1)/2$ treatments with 3 given parameters has triangular association scheme is that the first associates of any treatment whatsoever can be divided into 2 sets $(y_1, y_2, \dots, y_{n-2})$ and $(z_1, z_2, \dots, z_{n-2})$ such that $(y_i, y_j) = (z_i, z_j) = 1$ for $i \neq j = 1, 2, \dots, n-2$. The given parameters are (1) the number of first associates of any treatment is $n_1 = 2n-4$, (2) with respect to any 2 treatments θ_1 and θ_2 which are first associates (denoted by $(\theta_1, \theta_2) = 1$), the number of treatments which are first associates of both θ_1 and θ_2 is $p_{11}^1(\theta_1, \theta_2) = n-2$, and (3) with respect to any 2 treatments θ_3 and θ_4 which are second associates (denoted by $(\theta_3, \theta_4) = 2$), the number of treatments which are first associates of both θ_3, θ_4 is $p_{11}^2(\theta_3, \theta_4) = 4$. Two lemmas give the uniqueness of the triangular scheme for $n = 5$ and 6.

[DESIGN OF EXPERIMENTS]. Final rept. Jan. 1, 1952-June 30, 1958 [8]p. (AF 18(600)83) Unclassified

The results of the research performed under this contract are summarized. Topics include the construction and properties of incomplete block designs, sequential methods in the analysis of variance and probit analysis, sequential design and decision problems, the use of order statistics for problems of ranking means, analysis and construction of paired comparison designs, designs for exploring response surfaces, construction of error correcting binary signaling codes, complex hypotheses on normal distributions, and simultaneous confidence interval estimation. Studies related to the analysis of variance include the generalization of all existing techniques of normal variate analysis of variance, covariance, and multivariate analysis, as well as studies of multivariate components of variance analysis and multivariate factor analysis. A list of technical notes and journal articles prepared under this contract is appended.

USEFUL BAYES SOLUTIONS FOR MULTIPLE COMPARISONS PROBLEMS, I (Abstract), by D. B. Duncan.

Preliminary rept. [1958] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18-(600)83] and U. S. Public Health Service)

Unclassified

Presented at meeting of the Inst. of Math. Stat., Gatlinburg, Tenn., Apr. 10-12, 1958.

Published in *Ann. Math. Stat.*, v. 29: 622-623, June 1958.

A Bayes solution is developed for the common t-test problem of testing the hypothesis $\theta < 0$ against the alternative $\theta > 0$ given observed values of x and s where x is normally distributed with θ as mean and variance σ^2 and s^2 is an independent estimate of σ^2 distributed as $\chi^2_{\nu} \sigma^2 / \nu$. The ultimate objective is to solve many forms of multiple comparisons problems generated by the restricted products (Lehmann, *Ann. Math. Stat.*, v. 28: 1-25, Mar. 1957) of problems of the given form, the Bayes solutions to be obtained as corresponding products of solutions of the form developed. The loss function assumes losses proportional to $|\theta|$, the factor for type I errors being k times that for type II errors, $k > 1$. The Bayes function is a normal density with mean 0 and variance $\gamma^2 \sigma^2$. These functions fit, at least to a satisfactory degree of approximation, a wide variety of problems met in practice. The solution (restricted to invariant procedures) has the critical region $x/s > t$ where t is a function of the degrees of freedom ν , loss ratio k and dispersion ratio γ^2 . A brief table of t with these three arguments is presented.

ON THE LIMITING POWER FUNCTION OF THE FREQUENCY CHI-SQUARE TEST, by S. K. Mitra. [1958] [13]p. incl. table, refs. [AF 18(600)83] Unclassified

Published in *Ann. Math. Stat.*, v. 29: 1221-1233, Dec. 1958.

A χ^2 statistic is considered for testing the hypothesis that in q independent, multinomially distributed random vectors the "cell" probabilities are given functions of several unknown parameters, asymptotically efficient estimators of which are used in the statistic. By a method similar to Cramer's [Mathematical methods of statistics, Princeton U. Press, Princeton, N. J., 1946] it is shown that if the true cell probabilities differ from the hypothetical ones by additive terms which suitably decrease to zero as the sample size increases, and regularity conditions analogous to Cramer's are satisfied, then the statistic has a limiting non-central chi-square distribution. The result is applied to two problems in the planning of experiments. (Math. Rev. abstract)

DISTINGUISHABILITY OF SETS OF DISTRIBUTIONS (THE CASE OF INDEPENDENT AND IDENTICALLY DISTRIBUTED CHANCE VARIABLES), by W. Hoeffding and J. Wolfowitz. Apr. 1957, 40p. incl. diagrs. tables. (Mimeograph series no. 166) (AFOSR-TN-57-154) (In cooperation with Cornell U., Ithaca, N. Y. under AF 18(600)685) (AF 18(600)458) AD 126446

Unclassified

Also published in *Ann. Math. Stat.*, v. 29: 700-718, Sept. 1958.

Criteria are developed which determine whether for given sets of distributions \mathcal{F} , \mathcal{G} , and \mathcal{H} , there exists a test which makes the probability of an erroneous decision small when the distribution F belongs to \mathcal{G} or \mathcal{H} , and at the same time exercises some control over the number of observations required to reach a decision when F is in \mathcal{F} , and not only in \mathcal{G} or \mathcal{H} . Several classes of tests are considered such as the class of all fixed sample size tests, or the class of all tests which terminate with probability 1 whenever F is in \mathcal{F} . The distinguishability is studied of 2 sets of distributions in various classes of tests which are defined in terms of properties of the distribution of the sample size function N . Necessary and/or sufficient conditions are sought for the existence of a test in a given class which makes the maximum error probability in $\mathcal{G} \cup \mathcal{H}$ less than any preassigned positive number.

AN UPPER BOUND FOR THE VARIANCE OF CERTAIN STATISTICS, by W. Hoeffding. Mar. 1958, 12p. (Mimeograph series no. 193) (AFOSR-TN-58-243) (AF 18-(600)458) AD 154145 Unclassified

Presented at meeting of the Inst. of Math. Stat., Ames, Iowa, Apr. 3-5, 1958.

Abstract published in *Ann. Math. Stat.*, v. 29: 620, June 1958.

The following bound is demonstrated:

$$r - p^2 \leq H(p) = \begin{cases} p^{3/2} - p^2, & p \geq 1/2 \\ (1-p)^{3/2} - (1-p)^2, & p < 1/2 \end{cases}$$

The context is as follows: $r = E f(X_1, X_2) f(X_1, X_3)$
 $p = E f(X_1, X_2)$. X_1, X_2, \dots, X_n are independent and

NCU.05:024, 025; NCU.06:001, 002

identically distributed random variables, and $f(X_1, X_2)$ is a bounded function such that $f(X_1, X_2) = f(X_2, X_1)$, $0 \leq f(X_1, X_2) \leq 1$.

ON THE PROBABILITY OF LARGE DEVIATIONS OF RANDOM VARIABLES, by I. N. Sanov, tr. by D. E. A. Quade. Mar. 1958, 50p. incl. diagrs. (Mimeograph series no. 192) (AF 18(600)458 and AF 18(600)83) AD 154161 Unclassified

Also published in *Matematicheskii Sbornik*, v. 42: 11-44, 1957.

A series of theorems are presented of which the following two are typical: Given an experiment having n mutually exclusive and exhaustive outcomes. Let p_i ($i = 1, \dots, n$) be the probability of the i th outcome, v_i , its relative frequency in N independent repetitions of the experiment. Let Ω be a closed set of points of the simplex $x_1 + \dots + x_n = 1$, $x_i \geq 0$, (satisfying some slight further condition specified in the paper). Then asymptotically

$$P\{(v_1, \dots, v_n) \in \Omega\} = \exp N \left[\sum_{i=1}^n \lambda_i \ln(p_i/\lambda_i) + O(1) \right],$$

where $(\lambda_1, \dots, \lambda_n)$ denotes the point in Ω at which $\sum_{i=1}^n x_i \ln(p_i/x_i)$ obtains its maximum, $(x_1, \dots, x_n) \in \Omega$, (Theorem 2). Let $F_N(x)$ be the empirical distribution function of a random sample of size N from a population with distribution function $F(x)$. Let $\Phi(x)$ be another distribution function hat $\int_{-\infty}^{\infty} \ln(dF/d\Phi)d\Phi$ exists. Then

$$\lim_{N \rightarrow \infty} \lim_{\epsilon > 0} N^{-1} \left[\ln P \left\{ \sup_x |F_N(x) - \Phi(x)| < \epsilon \right\} \right] = \int_{-\infty}^{\infty} \ln(dF/d\Phi)d\Phi,$$

(Theorem 13). The paper concludes with some indications of the applicability of the given theorems to the solution of known problems. (Math. Rev. abstract)

ANALYSIS OF VARIANCE WITH UNIVARIATE OR MULTIVARIATE, FIXED OR MIXED CLASSICAL MODELS, by S. N. Roy and J. Roy. Aug. 1958, 1v. in. 1. diagrs. tables. (Mimeograph series no. 208) (AFOSR-TN-58-850) (AF 49(638)213) AD 203491; PB 140676 Unclassified

A unified and general theory of univariate analysis of variance is applied to the multivariate case. Both univariate and multivariate (MANOVA) cases with fixed "effects" are elaborated with reference to the main classes of problems like analysis of variance, analysis of covariance and analysis of regression under general designs. The development is made on the basis of linear estimation and the use of least squares. Relevant theorems and results in vector spaces and matrix theory are stated, computational techniques are discussed and a set of charts is given as an appendix at the end as needed for both (model I) MANOVA and several problems on (model II and mixed models) MANOVA.

ISOTOPIC EXCHANGE BETWEEN ALKANES AND

DEUTERIUM ON CHROMIUM OXIDE GEL CATALYST (Abstract), by A. B. Littlewood and R. L. Burwell, Jr. [1957] [1]p. [AF 18(603)132] Unclassified

Presented at meeting of the Petrol. Chem. Div. of the Amer. Chem. Soc., Miami, Fla., Apr. 7-12, 1957.

Published in 131st meeting of the Amer. Chem. Soc. Abstracts of Papers, 1957, p. 16-Q.

Chromium oxide gel catalyzes isotopic exchange between alkanes and deuterium at temperatures of 200°C and above. Unlike the case with metallic catalysts, each adsorption step leads to the exchange of but a single atom of hydrogen. The catalyst becomes active only upon heating to 300°. Maximum activity develops upon increase in the pretreatment temperature to 470°. During this temperature increase, the activation energy of the exchange reaction remains at 16 kcal, but the surface area declines slightly. Hence active sites are being generated.

3,3-DIMETHYL-1,4-PENTADIENE, by R. L. Burwell, Jr. and R. Ciola. Dec. 31, 1957, 3p. (AFOSR-TN-58-16) (AF 18(603)132) AD 148055 Unclassified

Also published in Jour. Org. Chem., v. 23: 1063, July 1958.

The catalytic hydrogenation of 3,3-dimethyl-1,4-pentadiene was studied. A mixture of 0.5 mol of 1,5-dichloro-3,3-dimethylpentane, 2 mol of 2-methylquinoline and 0.1 mol of NaI was refluxed in a flask surmounted by a tubing 40 cm long with a standard taper plug at the top. The reflux rate was maintained so that the temperature at the top of the Vigreux column was between 60° and 70°C. The entire reaction required about 8 hr. The product was dried with Na_2SO_4 and fractionated; the yield was 58% at bp = 70.2°C at 750.5 mm. Further possible purification was effected by storage over Na and azeotropic distillation with methanol, n_D^{20} 1.4067; d_4^{20} 0.7017. 3,3-Dimethyl-1-pentene was made in 88% yield from 1-chloro-3, 3-dimethylpentane by the same process (bp = 77.2°C at 755 mm).

A NOTE ON DERIVATIONS AND DIFFERENTIALS ON ALGEBRAIC VARIETIES, by M. Rosenlicht. [1957] [13]p. (AF 18(600)1571) Unclassified

Published in Portugal. Math., v. 16: 43-55, 1957.

For most of this paper, the author sums up known results on derivations, differentials, local derivations and local differentials on algebraic varieties and group varieties. In the final paragraph, letting P be a simple rational point over K of an algebraic variety V defined over k , the author defines a differential $\omega(P)$ of K over k by $D \omega = \omega(D_p)$, where D is a derivation of K over k , and D_p, ω_p are a local derivation and a local differential of V at P (D_p is the one which is induced by D). Then he shows that, when V is a commutative algebraic group variety, $\omega(PQ) = \omega(P) + \omega(Q)$. (Math. Rev. abstract)

ASYMPTOTIC DISTRIBUTIONS ASSOCIATED WITH THE LAPLACIAN FOR FORMS, by M. P. Gaffney. Feb. 1958, 12p. (AFOSR-TN-58-144) (AF 18(600)1571) AD 152171 Unclassified

Also published in Communications on Pure and Appl. Math., v. 11: 535-545, 1958.

Let M be a compact, n -dimensional, Riemannian manifold of class C^∞ . The author investigates the asymptotic distribution of the characteristic forms and values of the Laplace-Betrami operator $\Delta = d\delta + \delta d$ which acts on p -forms on M . The method used is to study the heat operator $\Delta + \partial/\partial t$. The fundamental solution of the heat equation is given in terms of the characteristic p -forms ω_i of Δ by

$$\theta(P, Q; t) = \sum_{i=1}^k \omega_i(P)\omega_i(Q) e^{-\lambda_i t},$$

where the λ_i are characteristic values of Δ . The author finds the asymptotic behavior of θ and, by applying Karamata's Tauberian theorem, he obtains the following asymptotic distributions:

$$\lambda_k \sim 4\pi \left[\frac{\Gamma(\frac{1}{2}n + 1)k}{\binom{n}{p} V} \right]^{2/n}, \quad \sum_{k=1}^k |\omega_k(P)|^2 \sim K/V.$$

EXTENSIONS OF VECTOR GROUPS BY ABELIAN VARIETIES, by M. Rosenlicht. [1958] [30]p. incl. refs. (AF 18(600)1571) Unclassified

Published in Amer. Jour. Math., v. 80: 885-714, July 1958.

The author develops the theory of simple differentials of the second kind on an algebraic variety by studying the set of all abelian group extensions of direct products of additive groups over a given abelian variety. The set of equivalence classes of extensions of the additive group of one dimension by a given variety A has the structure of a vector space. The chief results of the paper, established in theorems 1 and 3, are that this vector space has the same dimension as A and is isomorphic to the cohomology space $(H^1(A, O_A))$, in which O_A is the sheaf of local rings on A . All of the methods used are purely algebraic, except in the part of proposition 11 dealing with the case of characteristic zero. (Math. Rev. abstract)

PRINCIPAL SOLUTIONS OF NON-OSCILLATORY SELF-ADJOINT LINEAR DIFFERENTIAL SYSTEMS, by W. T. Reid. Aug. 1957, 28p. refs. (Technical rept. no. 1) (AFOSR-TN-57-485) (AF 18(603)88) AD 136456 Unclassified

Also published in Pacific Jour. Math., v. 8: 147-169, Spring 1958.

A generalized definition is presented of the principal solution for a general self-adjoint vector differential equation which is nonoscillatory for large values of the independent variable. Principal solutions are shown to possess certain properties on Γ_0 , the class of all matrix solutions which are nonsingular for large values of the independent variable, which are extensions of properties established by Hartman (Duke Math. Jour., v. 24: 25-35, 1957) for a certain class of solutions, Γ . The principal solution is determined by variational methods and is direct in nature. A discussion is presented of a self-adjoint n -dimensional vector equation with complex coefficients which is a direct generalization of the Euler scalar equation. A general differential system with complex coefficients is treated which is of the general form of the accessory differential equations for a variational problem of the Bolza type.

A CLASS OF TWO-POINT BOUNDARY PROBLEMS, by W. T. Reid. Sept. 1957, 27p. incl. refs. (Technical rept. no. 2) (AFOSR-TN-57-550) (AF 18(603)88) AD 136534 Unclassified

Also published in Illinois Jour. Math., v. 2: 434-453, Sept. 1958.

A previous analysis is extended of the various conditions satisfied by systems which are self-adjoint and definite in the sense of either Bliss or Reid. Consideration is given of a system of the general form

$$A_1(x)y' + A_0(x)y = \lambda B(x)y, \quad a \leq x \leq b, \quad My(a) + Ny(b) = 0$$

with $A_1(x)$ non-singular on ab : $a \leq x \leq b$. In terms of a

non-singular transformation $z(x) = T(x)y(x)$, $a \leq x \leq b$, the conditions for the system corresponding to Bliss are as follows: (1) the system is equivalent to its adjoint under the transformation; (2) $S(x) = T^*(x)B(x)$ is Hermitian on ab ; (3) $S(x)$ is non-negative definite on ab ; and (4) if $A_1 y' + A_0 y = 0$, $My(a) - Ny(b) = 0$, and $By \neq 0$, then $y = 0$ on ab . Reid's conditions are the same as 1, 2, and 4, while 3 is replaced by the condition that

$$\int_a^b y^* T^* [A_1 y' + A_0 y] dx \text{ is positive for arbitrary } y(x)$$

satisfying $My(a) - Ny(b) = 0$, $By \neq 0$ and for which there is an associated vector function $g(x)$ such that $A_1 y' + A_0 y = Bg$. The conditions are discussed and applied. The results are compared to others in literature. A simple method is devised to treat abnormal problems. (ASTIA abstract)

GENERALIZED LINEAR DIFFERENTIAL SYSTEMS, by W. T. Reid. Sept. 1958, 30p. incl. refs. (Technical rept. no. 3) (AFOSR-TN-58-873) (AF 18(603)88) AD 303915; PB 142295 Unclassified

Also published in Jour. Math. and Mech., v. 8: 705-726, Sept. 1958.

The generalized differential system treated is equivalent to a type of linear vector Riemann-Stieltjes integral equation and includes, as special instances, certain differential systems with interface conditions at a finite number of points. An existence theorem and related properties of solutions are considered. For self-adjoint systems, the existence of criteria for oscillation and non-oscillation that are direct generalizations of known criteria for the usual self-adjoint differential system is

NOR.07:001 - NOR.07:002

shown. Such systems are extended to the oscillation, separation, and comparison theorems occurring in the Morse generalization of the classical Sturmian theory. The extension of the results on principal solutions are considered. Also considered is a system of second order difference equations that occurs as a special instance of the general system. [SIMPLE LIE ALGEBRAS ASSOCIATED WITH SIMPLE ALGEBRAIC GROUPS OVER A FIELD OF CHARACTERISTIC $p > 0$] Les algèbres de Lie simples associées aux groupes simple algébriques sur un corps de caractéristique $p > 0$, by J. Dieudonné. [1957] [7]p. (AF 49(638)106) Unclassified

Published in Rend. Circ. Matem. Palermo, Series II, v. 6: 198-204, May-Aug. 1957.

Let g be a simple finite dimensional Lie algebra over the field of the complex numbers. A normalized basis for g , in the sense of Chevalley (Tohūka Math. Jour., v. 7: 14-66, 1955), for which the multiplication table is integral, yields a Lie algebra g^* over the ring Z of the rational integers (having for a basis a normalized basis of g), and g^* is determined up to an isomorphism by g . Hence, if K is any field, of arbitrary characteristic, one can invariantly associate with g a Lie algebra $g_K = g^* \otimes K$ over K . The question arises of how far these Lie algebras g_K are from being simple. For classes A, B, C, D of the classical simple Lie algebras g , the determination of the ideals and composition series of the g_K 's can easily be extracted from results of Jacobson (Amer. Jour. Math., v. 63: 481-515; Trans. Amer. Math. Soc., v. 50: 15-25, 1941). Here, this determination is accomplished for the five exceptional simple Lie algebras g by direct computation. The result is that g_K , with g exceptional and K arbitrary, is simple, except in the following cases: (1) g is of type G_2 and K is of characteristic 3; then g_K has only a single proper ideal u , which is of dimension 7, and the Lie algebras u and g_K/u are simple and isomorphic. (2) g is of type F_4 and K is of characteristic 2; then g_K has only a single proper ideal u , which is of dimension 26, and the Lie algebras u and g_K/u are simple and isomorphic. (3) g is of type E_6 and K is of characteristic 3; then the only proper ideal of g_K is its 1-dimensional center c , and g_K/c is simple. (4) g is of type E_7 and K is of characteristic 2; then the only proper ideal of g_K is its 1-dimensional center c , and g_K/c is simple. (Math. Rev. abstract)

[LIE GROUPS AND LIE HYPERALGEBRAS OVER A FIELD OF CHARACTERISTIC $p > 0$ (VII)] Groupes de Lie et hyperalgèbres de Lie sur un corps de caractéristique $p > 0$ (VII), by J. Dieudonné. [1957] [20]p. (AF 49(638)106) Unclassified

Published in Math. Ann., v. 134: 114-133, Nov. 1957.

A complete classification is given, up to isogeny of formal abelian groups G of finite dimension over an algebraically closed field K of characteristic $p \neq 0$. The fundamental theorems are as follows. (1) G is isogeneous to a direct product of simple groups and Witt groups W_m . (2) A simple group G is isogeneous to one of the groups $G_{n,0,m}$, where m and n are coprime. (3) The ring of endomorphisms of the simple group $G_{n,0,m}$

is isomorphic to an order in the central division algebra of rank $(m+n)^2$ and invariant $n/(m+n)$ over the field of p -adic numbers. The author associates with G a matrix $M(G)$ whose coefficients lie in a certain non-commutative ring \mathbb{C}^+ ; moreover, G_1 and G_2 are isomorphic if, and only if $M(G_1)$ and $M(G_2)$ are equivalent over \mathbb{C}^+ . It is proved in that G_1 and G_2 are isogeneous if, and only if, $M(G_1)$ and $M(G_2)$ are equivalent over a certain

ring \mathcal{U} which contains \mathbb{C}^+ . \mathcal{U} is defined as follows. Let W denote the ring of Witt vectors $A = (a_0, a_1, \dots)$ over K ; W is a complete valuation ring, $\pi = (0, 1, 0, \dots)$ a uniformizing parameter, and the mapping $A \rightarrow A^\sigma = (a_0^p, a_1^p, \dots)$ an automorphism of W . Then \mathbb{C}^+ is the set of all formal non-commutative integral power series $A_0 + tA_1 + t^2A_2 + \dots$, where the $A_i \in W$ and the indeterminate t satisfies $At = tA^\sigma$ for all $A \in W$. \mathcal{U} is the set of all power series $t^h A_h + t^{h+1} A_{h+1} + \dots$ ($h = 0, \pm 1, \pm 2, \dots$). It is proved that (i) \mathcal{U} has a Euclidean division algorithm and (ii) the \mathcal{U} -modules which intervene are all bounded (i.e., they have non-zero annihilator). (i) enables the powerful theory of modules over principal ideal rings to be applied and (ii) allows a further reduction to problems of similarity, etc., within \mathcal{U} itself. It is also shown that each $u \in \mathcal{U}$ can be written in 'quasi-normal' form $u = \pi^{\alpha_0} t^{\beta_0} u_0 + \dots + \pi^{\alpha_r} t^{\beta_r} u_r$, where the u_i are invertible elements of \mathbb{C}^+ , the α_i form a strictly decreasing sequence of integers ≥ 0 , and the β_i a strictly increasing sequence of integers. Finally, an infinity of formal abelian groups of dimension 2 are constructed,

any two of which are isogeneous but no two of which are isomorphic. This (and other evidence) suggests that the classification of abelian groups up to isomorphism may be difficult. (Math. Rev. abstract)

LIE GROUPS AND LIE HYPERALGEBRAS OVER A FIELD OF CHARACTERISTIC $p > 0$ (VIII), by J. Dieudonné. [1958] [33]p. [AF 49(638)106]

Unclassified

Published in Amer. Jour. Math., v. 80: 740-772, July 1958.

In the present paper the author initiates the study of group extensions. (Unless otherwise stated, 'group' will always mean 'formal Lie group of finite dimension over an algebraically closed field K of characteristic $p \neq 0$.) The basic concepts are the factor group H/N and natural homomorphism $h: H \rightarrow H/N$ corresponding to a normal 'typical' subgroup N of the group H ; the definition given here is more direct than that in part VI and avoids the hyperalgebra. A sequence of groups and homomorphisms $0 \rightarrow A \xrightarrow{u} P \xrightarrow{v} G \rightarrow 0$ is called exact if it can be carried by isomorphisms into a sequence $0 \rightarrow N \xrightarrow{h} H \xrightarrow{j} H/N \rightarrow 0$ (N typical, j the natural injection), and such an exact sequence defines an extension (P, u, v) of G by A . Equivalence of extensions is defined in the usual way. In non-formal group theory a splitting extension of G by A gives rise to a 'semi-direct' product $P \rtimes A$; once the mode of action of A on G has been fixed, the semi-direct product can be defined abstractly as the set of pairs (g, a) ($g \in G, a \in A$) under a certain law of multiplication. The author gives an analogous abstract definition of a semi-direct product of formal groups G, A , and the corresponding extension of G by A is called trivial. It is pointed out that (P, u, v) is not necessarily trivial when P contains a subgroup G' isomorphic to G and such that $u(A) \cap G' = e, u(A) \cap G' =$

$P(A, v)$ are defined in part VI); these conditions ensure merely that P is isogeneous to a semi-direct product of G and A . When G acts trivially on A , the semi-direct product becomes the direct product $G \times A$. A group H is called quasi-direct product of its normal subgroups M, N if $M \cap N = e, M \vee N = H$; H is then isogeneous, but not necessarily isomorphic, to $M \times N$ and the corresponding extension of M by N is called quasi-trivial. The main result of this paper is theorem A: Every solvable group is isogeneous to a direct product $P \times Q$, where D is a divisible abelian group and Q a semi-direct product of the largest unipotent subgroup of P and a torus. Theorem A follows readily from results in VI and theorem B: If P is a solvable group and D the largest divisible abelian group in the center of P , then D is a quasi-direct factor of P . For the proof of theorem B, the author introduces formal G -modules and their (non-formal) cohomology groups. Let G be a group, A an abelian group, with respective laws of composition $st = (\phi_i(s, t))_{i \in I}, x + y = (\psi_j(x, y))_{j \in J}$. Then A becomes a G -module if we prescribe a system of power series $s \cdot x = (f_j(s, x))_{j \in J}$, without constant terms, such that (i) $s \cdot (x + y) = s \cdot x + s \cdot y$; (ii) $e \cdot x = x$; (iii) $s \cdot (t \cdot x) = (st) \cdot x$. An m -cochain is defined as a system of power series $g(s_1, \dots, s_m) = (g_j(s_1, \dots, s_m))_{j \in J}$, without constant terms, in m independent sets $s_h = (s_{hi})_{i \in I}$ of variables ($1 \leq h \leq m$). Sum of cochains, coboundary, cohomology groups $H^m(G, A)$ are now defined in an evident way. A difficulty arises, however, in defining 1-coboundaries because there are no 'elements' in A ; $H^1(G, A)$ is identified with the group of homomorphisms of G into A when G acts trivially on A and is left undefined otherwise. The usual correspondence between elements of $H^2(G, A)$ and classes of equivalent extensions of G by A holds good, and the zero of $H^2(G, A)$ corresponds to the trivial extensions as defined above. The principal tool in proving theorem B is the lemma: Suppose that the group G and its subgroups and factor groups act trivially on the abelian group A and let H be a normal subgroup of G such that $H^1(H, A) = 0$ for any perfect extension L of the field K (H_L, A_L are the groups over L defined by the same systems of power series as H, A); then there exists an exact sequence $0 \rightarrow H^2(G/H, A) \rightarrow H^2(G, A) \rightarrow H^2(H, A)$. The proof is not easy and depends on the construction of an auxiliary G -module of infinite dimension. To complete the proof of theorem B, the author shows, using part VI, that there is a sequence of subgroups of the solvable group $P: D \supset R_1 \supset R_2 \supset \dots \supset R_m \supset P$, each normal in its successor, such that R_1 is the center of $P, R_{i+1} \supset R_i$ is isomorphic to the additive group I_m of K for $1 \leq i \leq m-1$, and P/R_m is a torus T . After showing independently that all central extensions of I_m or T by D are quasi-trivial, he applies a modified form of the lemma to obtain the

NOR.07:005; NOR.08:001, 002

theorem by induction. As an application, all 2-dimensional groups are determined up to isogeny. The 2-dimensional nilpotent groups G, with laws of composition of the form

$$\begin{aligned} \phi_1(x,y; x',y') &= x + x', \\ \phi_2(x,y; x',y') &= y + y' + f(x,x'), \end{aligned}$$

provide interesting examples. Firstly, if $f(x, x') = \sum_{h > k > 0} e_{hk} x^h x'^k$ and the e_{hk} are algebraically independent over the prime field F_p of K, then G is a noncommutative unipotent group which is not representable (i.e., not isogeneous to a subgroup of a full linear group). Secondly, if $f(x, x') = \sum_{h \geq 1} e_h x^h x'$ and the e_h are algebraically independent over F_p , then G is isogeneous to a subgroup of GL(3) but not to any algebraic group. [ON THE PARAMETRIC REPRESENTATION OF CAYLEY] Sur la représentation paramétrique de Cayley, by J. Dieudonné. [1958] [3]p. [AF 49(638)106] Unclassified

Published in Arch. der Math., v. 9: 39-41, 1958.

The author extends the Cayley parametrization to classical groups over division rings of characteristic 2. (1) Let K be a division ring of arbitrary characteristic, J an involutory anti-automorphism of K, A an n x n nonsingular Hermitian matrix over K of the form $C + {}^t C^J$. Then the equation $U = ({}^t C^J - S)^{-1}(C + S)$ gives a one-one correspondence between non-exceptional unitary matrices $U ({}^t U^J A U = A, I + U$ non-singular) and skew-Hermitian matrices S such that C + S is non-singular. (2) Similarly, if K is commutative,

$$A = \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix} \text{ in } m \text{ and } C = \begin{pmatrix} 0 & i \\ 0 & 0 \end{pmatrix} \text{ in } m, \text{ the formula}$$

$U = ({}^t C + S)^{-1}(C + S)$ gives a one-one correspondence between non-exceptional symplectic matrices U and symmetric matrices S such that C + S is non-singular. (3) In (2), let K have characteristic 2. It is well known that every orthogonal matrix for the quadratic form

$$Q(x) = \sum_{i=1}^n x_i x_{m+i}$$

is a symplectic matrix for A. It is shown that conversely, a non-exceptional symplectic matrix $({}^t C + S)^{-1}(C + S)$ is orthogonal if, and only if, S is alternating, i.e., all diagonal elements of S are 0.

(1), (2) are proved by specializing a result on rings

with an involutory anti-automorphism and (3) is deduced by direct calculation. (Math. Rev. abstract)

MULTIPLE CONFIDENCE PROCEDURES, by M. Dwass. [1959] [6]p. Incl. table. (AFOSR-TN-57-783) (AF 49-638)151) AD 148014 Unclassified

Also published in Ann. Inst. Stat. Math. (Tokyo), v. 10: 277-282, 1959.

Suppose x_1, \dots, x_n is a set of independent variables having normal distributions $N(\mu_1, \sigma^2), \dots, N(\mu_n, \sigma^2)$ and let s^2 be a random variable independent of x_1, \dots, x_n such that ks^2/σ^2 has a chi-square distribution with k degrees of freedom. Let $\bar{x} = n^{-1} \sum_1 x_i$ and T_p be defined by

$$P\left(\sum_1 |x_i - \bar{x}|^p / k^{1/2} s > T_p\right) = \alpha$$

where $0 \leq p < \infty$ and $0 < \alpha < 1$. It is shown by using Hölder's inequality that the probability is $1 - \alpha$ that

$$\left| \sum_1 a_i \mu_i - \sum_1 a_i x_i \right| \leq \left[\sum_1 (a_i - \hat{a})^q \right]^{1/q} T_p$$

for all (real) vectors (a_1, \dots, a_n) satisfying $\sum_1 a_i = 0$, where $1/p + 1/q = 1$, and where \hat{a} satisfies

$$\sum_1 |a_i - \hat{a}|^q = \inf_c \sum_1 |a_i - c|^q.$$

Similarly, it is shown that the probability is $1 - \alpha$ that

$$\left| \sum_1 a_i \mu_i - \sum_1 a_i x_i \right| \leq \left(\sum_1 a_i^q \right)^{1/q} T_p$$

for all real vectors (a_1, \dots, a_n) satisfying $\sum_1 a_i = 0$, where T_p' is defined by

$$P\left(\sum_1 |x_i - \hat{x}|^p / k^{1/2} s > T_p'\right) = \alpha \text{ and}$$

$$\sum_1 |x_i - \hat{x}|^p = \inf_c \sum_1 |x_i - c|^p.$$

The author shows how various results on simultaneous confidence intervals previously obtained by Tukey, Scheffé, and by Bose and Roy reduce to special cases of these results. (Math. Rev. abstract)

ON HILBERT TRANSFORMS OF FUNCTIONS OF CLASS L^1 , by R. R. Goldberg. [1958] 5p. (AFOSR-TN-58-610) (AF 49(638)383) AD 162138; PB 139438
Unclassified

The similarity between the theory of Hilbert transforms with that of Fourier transforms is pointed out. A similar relationship is demonstrated between f , F , G , and g if $f \in L^1$ where L^1 is used to denote $\int_{-\infty}^{\infty} |f(u)| du < \infty$. It is shown that if $f \in L^1$ then the Hilbert transform of f exists almost everywhere.

CERTAIN OPERATORS AND FOURIER TRANSFORMS ON L^2 , by R. R. Goldberg. [Nov. 1958] 6p. (AFOSR-TN-58-1007) (AF 49(638)363) AD 206150; PB 139437
Unclassified

Also published in *Proc. Amer. Math. Soc.*, v. 10: 385-390, June 1959.

A proof is presented of the following result for a wide class of functions f . If g is the cosine transform of

$f \in L^2$, then $G(x) = \frac{1}{x} \int_0^{\infty} \frac{y}{x} g(y) dy$ is the

cosine transform of $F(y) = \int_0^{\infty} \frac{1}{x} \psi\left(\frac{y}{x}\right) f(x) dx$. The

same result applies to sine transforms. Properties of a certain class of bounded operators on L^2 are developed. A class of self-adjoint bounded operators are constructed which commute with the Fourier cosine (or sine) transform.

APPARATUS FOR PRECISE DETERMINATION OF DYNAMIC YOUNG'S MODULUS AND INTERNAL FRICTION AT ELEVATED TEMPERATURES, by M. E. Fine. May 16, 1957 [11]p. incl. diagrs. refs. (AFOSR-TN-57-267) (AF 18(600)1468) AD 126566
Unclassified

Also published in *Rev. Scient. Instruments*, v. 28: 643-645, Aug. 1957.

The apparatus for the precise determination of dynamic Young's modulus and internal friction at elevated temperatures employs electrostatic excitation and detection of longitudinal vibrations in a rod. Several improvements over the Cabarat apparatus are incorporated which include a somewhat higher range of temperature, a smaller specimen, better precision, improved vacuum, and easier operation. The mechanical and electrical systems are described. Examples of data determined with the apparatus are presented. The internal friction of single crystals of Al determined with the apparatus agree quite well with determinations by the piezoelectric method. The upper temperature limit of the apparatus was the weakness of the signal due to internal friction of the sample rather than any breakdown of the apparatus. Operating temperatures up to 850°C are anticipated for the apparatus with a proper sample.

THE STRENGTH OF AGE HARDENED ALLOYS
(Abstract), by A. Kelly. [1957] [2]p. (AF 18(600)1468)
Unclassified

Presented at meeting of the Metallurgical Soc. of Amer. Inst. Mining and Metall. Engineers, Chicago, Ill., Nov. 4-6, 1957.

Possible crystallographic structures produced during the aging of super-saturated solid solutions of Al-Cu and Al-Ag systems are investigated in order to determine what processes may contribute to the strength of an age hardened alloy. These two systems have been chosen since they have been most thoroughly studied using x-ray methods. The appearance of the various structures correlates very well with the various hardening stages. Stress-strain curves of single crystals of Al-Cu, aged by various amounts, are presented and the appearance of the slip lines discussed. A broad correlation is found between the slip line appearance and the type of stress-strain curve. An attempt is made to account for the strength of age hardened alloys at various stages of the aging sequence in terms of current theories. It is concluded that the overaged condition is the one best understood at present. Measurements of the temperature dependence of the flow stress seem to offer the simplest means of testing the various theories. An explanation of the strength of Al-Cu and Al-Ag alloys in the cold hardening stage is put forward which associates the flow stress with the work done in shearing the Guinier-Preston zones. Estimates of this may be made from the heats of reversion. The calculated flow stresses are in reasonable agreement with measured values.

Also published in Acta Metallurgica, v. 6: 565-571, Sept. 1958.

Measurements have been made of the critical resolved shear stress of single crystals of an aluminum - copper alloy between 77°K and 373°K. The crystals were aged

so that they contained only Guinier - Preston zones of the first kind. By changing the temperature during deformation of these crystals the reversible change of flow stress with temperature during deformation has also been measured. This reversible change of flow stress varies with temperature in a manner similar to that shown by pure aluminum crystals in that, after elimination of the variation of the elastic constants with temperature, it is approximately constant at temperatures above 160°K but increases at lower temperatures. From comparison between the results obtained from crystals containing GP zones and crystals "reverted" so that the zones are redissolved it is suggested that the temperature dependence of the flow stress is governed by some thermally activated process which enables the dislocations to avoid passing through the zones. The most likely process seems to be cross slip. (Contractor's abstract)

AN ACOUSTICAL STUDY OF LOW-TEMPERATURE AGE-HARDENING AFTER REVERSION IN Al - 6 at-% Ag, by H. Herman and M. E. Fine. Dec. 3, 1958 [20]p. incl. diagrs. table, refs. (AFOSR-TN-58-1025) [AF 18-(600)1468] AD 162292; PB 137941 Unclassified

Also published in Trans. Metall. Soc. AIME, v. 218: 44-49, 1960.

A study was conducted to determine the kinetics of re-aging after reversion in single crystals and to determine the mechanism of growth of Guinier-Preston zones. Two Al-6 atomic % Ag single crystals, about 1.3 by 0.05 in. in size, were grown using a modified Bridgeman technique from ingots. The specimens were homogenized for 1 month in a 550°C salt bath. For solution treatment, the specimen was contained in a sealed and weighted pyrex ampule evacuated to 10^{-6} mm Hg which was suspended by a wire in a vertical furnace. For the quench, the wire was cut, allowing the ampule to drop into 25° water. Aging to the fully hardened state was attained by a 42-hr treatment at 100°C. Reversion was accomplished by heating for 15 min at 220°C. Plots were made for the fractional change of the resonant frequency from the initial reading to time t for re-aging after reversion at 50°, 70°, and 100°C. The re-aging reactions at 70° and 100°C were completed while the 50°C re-aging curve was 60% complete after 160 hr. Young's modulus decreased during concentration of Ag atoms into zones, the rate decreasing with increasing aging time. Zone formation occurred while the specimens were being warmed to the re-aging temperature. The decrease in modulus for the completed re-aging reaction was 2 of 3%. The total change from ½ hr to completion was less for direct aging than for re-aging after reversion. Curves obtained for a crystal re-aged for 2 hr at 70°C and dropped to 50°C were extrapolated to 2.5 hr and indicated a 10 ± 2 kcal/mol activation energy.

DEFORMATION OF SINGLE CRYSTALS CONTAINING GUINIER-PRESTON ZONES, by A. Kelly. Dec. 30, 1958, lv. incl. diagrs. tables, refs. (AFOSR-TN-58-1083) (AF 18(600)1468) AD 207530; PB 144852 Unclassified

Presented at Phys. Soc. Conf. on Internal Surfaces, Cambridge (Gr. Brit.), Dec. 17-19, 1958.

The results presented in this report are confined to single crystals of aluminum containing either copper or silver, in the early stages of aging. Under these conditions the precipitates are said to be "coherent"

with the matrix. The formation of a "coherent" precipitate is taken to mean the replacement of a given number of atoms of the solid solution by the same number of atoms of the precipitate, these being arranged on the same type of lattice as those of the matrix.

ACOUSTICAL STUDY OF G. P. ZONE FORMATION AFTER REVERSION IN Al-20 WT. PCT. Ag (Abstract), by H. Herman and M. E. Fine. [1958] [1]p. [AF 18-(600)1468] Unclassified

Presented at meeting of the AIME., Cleveland, Ohio, Oct. 29, 1958.

Published in Jour. Metals, v. 10: 29, Sept. 1958.

Using an acoustical method, the kinetics of reaging after reversion in a single crystal Al-20 wt pct Ag alloy were investigated. Reaging after reversion was studied at four temperatures between 50 and 150, and the results compared with the kinetics for aging after directly quenching from the solution temperature of 525°C. The method employed, which essentially enabled the measurement of the change in the dynamic Young's modulus as precipitation proceeded, showed that the kinetics on reaging after reversion are similar to that observed on aging after the direct quench, though decidedly slower. No incubation time has been detected in any of the above experiments, indicating that nuclei are present after reversion. The determination of an activation energy of approximately 8 kcal per mole and a time law for growth have given information concerning the growth mechanism. The exponent of time in the rate equation for growth of the zones on directly aging after quenching from 525°C is 1/2 and 1 on reaging after reversion. The rate of formation of the zones is anomalously large indicating that, as in aging after the direct quench, there is a defect mechanism available for reaging after reversion which permits the rapid movement of silver atoms to the zones. A supersaturation of vacancies or edge dislocations acting as pipelines or a combination of these two defects may be of significance for the growth of the zones.

Stress-strain curves have been obtained of single crystals of Al-20 atomic % Ag aged varying amounts in the cold-hardening state. The temperature dependence of the flow stress of these crystals has also been measured and compared with that of pure aluminum. A striking difference is found, the flow stress of the alloy crystals depending no more on temperature than do the elastic constants over the temperature range 77°K to 373°K. The slip lines observed on the surface of the alloy crystals are similar to those found in body centered cubic metals, and it is concluded that the dislocations in this alloy behave as if they are undissociated. This behavior may be accounted for by the large stresses needed to produce slip in the alloy if the stacking fault energy is about the same as in pure aluminum.

Experiments have been carried out to study the effect of an applied stress on the strain aging phenomena in steel. It has been found that stress-induced strain aging reaction proceeds rapidly in the temperature range of 0° to 60°C. The variations of stress-induced strain aging with plastic strain, aging times, and temperatures are reported, and the activation energy for the aging found to be 10,000 cal/mol. The results are interpreted as dislocation pipe line diffusion of carbon. (Contractor's abstract)

Also published in Jour. Appl. Phys., v. 30: 1735-1740, Nov. 1959.

The sintering of zinc oxide spheres has been studied in the temperature range of from 700° to 900°C in air, oxygen, helium, and hydrogen. Fresh zinc oxide sinters rapidly in air and oxygen, but it does not sinter appreciably in helium in the same temperature range. Zinc oxide spheres annealed separately in air may be sintered in air at temperatures > 1000°C. However, air-treated spheres, which had been subsequently hydrogen-annealed, do sinter in the temperature range of from 700° to 900°C. These facts are explained on the basis of a mechanism involving the diffusional transfer of stoichiometric excess of zinc ions. The diffusion equation for zinc ions is derived, and the experimental points fit the equation satisfactorily. The treatment shows that the relationship between the width of bridges connecting sintering spheres and time varies with extent of sintering. This fact invalidates the use of this relationship as an unequivocal diagnostic criterion for the sintering mechanism in nonstoichiometric oxides. (Contractor's abstract)

A study was made of the sintering of metal oxides under different conditions of temperature, sphere diameter, gas atmosphere, and heat pretreatment. Single-crystal oxide microspheres (0.1 to 0.5 mm in diameter) were obtained commercially or made from crushed single crystals of ZnO, V₂O₅, and TiO₂. A string of spheres of similar diameter was heated for different time intervals at constant temperature, and the growth of necks or bridges connecting them was observed with a creep-test microscope. The diffusional sintering mechanism explains the experimental data for the 3 oxides and shows that their nonstoichiometric nature is decisive in controlling transport processes within their bulk phases.

The feasibility of sustained hypersonic flight within the earth's atmosphere is examined, utilizing the "coolant-fuel" system as an Aero-Thermodynamic Propulsion (ATP) Method to eliminate excessive aerodynamic frictional heating and to increase propulsive efficiency. Such systems are of current interest for all flight plans in which high speed is the prime requirement, and also for some classes of flight of prescribed range which are handicapped by insufficient unit energy content of conventional fuels (this includes, as a particular case, the problem of extreme long range manned flight). Coolant-fuels are considered from the dual standpoint of the propellant and of the missile aerodynamics. The propellant study contemplates the ability of fuels to absorb heat and the impulse gains achieved thereby. The missile study outlines a method for estimation of aerodynamic friction heating and the extent of heat transfer to the coolant-fuel as functions of the missile speed, configuration, flight plan, and state of the boundary layer. It is found that cooling which reduces equilibrium temperatures to within manageable limits can also be made to increase the energy content of suitably selected coolant-fuels by as much as 50 per cent, leading to most substantial incidental benefits to the propulsive system.

This report summarizes a preliminary investigation of a novel method for preventing overheating of the external structure of a rocket powered aircraft or missile that is traveling at hypersonic speeds within the atmosphere. This method contemplates using the rocket fuel for cooling the structure. In addition to maintaining the structure at manageable temperatures, it also results in a significant augmentation of the thrust of the rocket engine because the propellant energy is enhanced by the absorbed (aerodynamic) heat. It is found that by judicious selection of fuels heat absorption of 1200 to 4000 Btu/lb can be achieved with temperature rise from 77°F to 1500°F, with corresponding augmented specific

impulse of 300 to 400 sec. A preliminary evaluation of the flight performance of this system is carried out. A method for determining the flight envelope for a missile configuration is presented. Cruise range calculations indicate that ranges of a few thousand miles are feasible. It is thus concluded that based on the promising preliminary results the coolant-fuel system merits more detailed studies. (Contractor's abstract)

The governing equations of magneto-aerodynamics are examined for the weak interaction approximation. It is found that for the case where $R_{\nu H} \ll 1$ it is possible to

treat the magneto-aerodynamic interaction as a simple additional body force. Accordingly, the approximate equations for weak interaction are derived. These are applied to several simple one-dimensional flows such as the propagation of small disturbances and one-dimensional flows such as the propagation of small disturbances and one-dimensional channel flow. The stability of incompressible laminar boundary layer on a flat plate with the presence of a transverse magnetic field fixed with respect to the plate is considered in Part II. It is found that for this case the effect of the magnetic field is to de-stabilize the boundary layer, caused mainly due to the modification of the mean velocity profile by the magnetic field. Abstract published in 131st meeting of the Amer. Chem. Soc. Abstracts of Papers, 1957, p. 35-B-36-B.

Oberdorfer in cool-flame combustion studies of the isomeric hexanes determined residual paraffins, residual oxygen H₂, CO, CO₂ and olefins by the usual methods of gas analysis. Water was undetermined. Gas absorption chromatography now has been applied to this purpose. Water, previously estimated on the basis of an oxygen balance, is now determined by measuring the acetylene produced by passing the product mixture over a CaC capsule before entering the silica gel column. In gas chromatography best results are obtained on columns the length of which is not more than eight feet. In the analysis of combustion products chromatographic columns must be developed to analyze for compounds containing specific function groups. Occasionally columns will be found which will separate such groups completely. The Dowtherm-A column is an example of this type. For best results it is found that flow-rates and column temperature should be kept as low as possible but not so low that the products fail to come off the column in less than 45 minutes. The ability to separate the oxygen and nitrogen of the air completely and cleanly is very useful in the combustion analysis of hydrocarbons. It has been shown that almost any hydrocarbon having a research octane number below 90 will form a cool-flame and give a typical temperature profile. It is indicated that under suitable conditions the three n-paraffins all burn at the same rate. (Contractor's abstract)

Presented at meeting of the Petrol. Chem. Div. of the Amer. Chem. Soc., Miami, Fla., Apr. 7-12, 1957.

Abstract published in 131st meeting of the Amer. Chem. Soc. Abstracts of Papers, 1957, p. 12-Q.

This paper is a summary and extension of previously published work on cool flames (see mem nos. OSU.03:010 and OSU.03:015). A completely detailed reaction mechanism is presented to account for the 14 known and measured cool-flame combustion products of n-hexane. Any reaction mechanism which will in a logical, straightforward manner account for this number of intermediate products seems almost self-sustaining. The reaction mechanism not only fits the facts but contains a certain degree of flexibility permitting the known variations, with changes in experimental conditions.

RARE EARTH OXIDES. I. THE VAPORIZATION OF NEODYMIUM SESQUIOXIDE, Nd_2O_3 . DISSOCIATION ENERGY OF NdO AND TaO , by H. [W.] Goldstein, P. N. Walsh, and D. White. Jan. 1958, 18p. incl. tables, refs. (Technical note no. 1) (AFOSR-TN-58-291) (AF 18(600)1545) AD 154198 Unclassified

The vaporization of Nd_2O_3 has been studied by the

Knudsen effusion method in the temperature range 2040 to 2450°K. Both tungsten and tantalum effusion cells were used in the experiments. From the tungsten refractory, the vaporization of Nd_2O_3 proceeds predominately by dissociation to gaseous products, NdO and O , whereas in the case of the tantalum refractory, the Nd_2O_3 reacts with the cell and yields primarily the gaseous species NdO and TaO . From the vapor pressure determinations, with the aid of free energy functions, the heat of reactions were established. The dissociation energies of TaO and NdO were calculated, and the value for TaO was found not to be in agreement with the recent value reported from mass spectrometric studies. Some reasons for this apparent discrepancy are given. (Contractor's abstract, modified)

Also published in Jour. Phys. Chem., v. 63: 1445-1449, Sept. 1959.

The heat capacities of the sesquioxides of yttrium, lanthanum, and neodymium have been determined in the temperature range 16 to 300°K. The entropies, enthalpies, and free energy functions have been calculated from the heat capacity data and are tabulated for several temperatures. Yttrium oxide and lanthanum oxide exhibit typical sigmoidal heat capacity curves with no anomalies in the temperature range studied. The shape of the heat capacity curve for neodymium oxide is similar except that at the lowest temperature there is evidence for the existence of an anomaly. At 298.16°K the entropies are 23.693 ± 0.07 and 30.580 ± 0.07 cal $\text{mol}^{-1} \text{deg}^{-1}$ for yttrium oxide and lanthanum oxide, respectively. For neodymium oxide $S_{298.16} - S_{16}$ is 33.607 cal $\text{mol}^{-1} \text{deg}^{-1}$. The free-energy functions have been extended to 2500°K by the use of some higher temperature heat capacity data available in the literature. (Contractor's abstract)

A HIGH-PERVEANCE ELECTRON GUN ON TOROIDAL DESIGN, by W. E. Hoover. May 1957, 24p. incl. diagrs. table. (Technical note no. 5) (AFOSR-TN-57-334) (AF 18(600)980) AD 132408 Unclassified

The report describes modifications of a high-perveance electron gun designed by A. L. Samuel at Bell Telephone Labs. in 1944. Modifications were made to facilitate construction and to afford more versatile operation of the gun. The perveance of the gun is variable from a maximum of about 45×10^{-6} amp/volt^{3/2} to a minimum which is determined by the cathode-anode spacing. The cathode of the gun is a 120° section of a toroid with a maximum cathode diameter of 0.366 in. The gun's distinguishing characteristic is the presence of a focusing anode immersed in the cathode region. By variation of the position voltage on this electrode, transmission of current through a conventional anode can be maximized, or, if desirable, judicious adjustment of this voltage can be used to shape the electron beam. Beam profiles obtainable with this gun range from a thin, ring-shaped beam to a solid beam. (Contractor's abstract)

A STUDY OF SPACE-CHARGE-LIMITED POTENTIAL DISTRIBUTION IN ELLIPSOIDAL AND PARABOLOIDAL DIODES, by R. P. Anand. June 1958, 121p. incl. illus.

diagrs. tables, refs. (Technical note no. 6) (AFOSR-TN-58-570) (AF 18(600)980) AD 158389 Unclassified

Space-charge-limited potential distributions in certain new geometries were investigated with a view to developing better high-density electron beams. The problems studied include confocal and nonconfocal ellipsoidal and paraboloidal geometries. A cathode and anode were chosen as confocal ellipsoids with axial ratios of 1.3 and 10, respectively. This particular choice was guided by its closeness to the Heil ellipsoidal gun. Results of the study showed that (1) the cathode current density is higher (about 100%) than the corresponding ellipsoidal gun; (2) the electron flow is laminar; (3) the concentration ratio is poor; and (4) the cathode current density is nonuniform. Good convergence can be achieved if a focusing electrode is added and the anode ellipsoid moved further along the axis of symmetry (which is also the minor axis of the ellipsoid). The major axes of cathode and anode are no longer coincident but are parallel. A gun with the following particulars was designed: cathode-ellipsoid with an axial ratio of 1.3; anode-ellipsoid with an axial ratio of 10; and distance between major axes of cathode and anode is equal to half the semi-minor axis of the cathode. The current density at the cathode surface is nonuniform and increasing in the ratio 1:2.

The present investigation discusses the effects of multiple transits on the electronic admittance of the oscillator and the corresponding effects on efficiency and electronic tuning. Limitations on the realizable number of transits are developed and correlated with experimental results. Theoretical values are also obtained for the starting currents and are in good agreement with experiment. Two basic tube types have been tested, one having symmetry about the plane of a flat electron beam, and one having symmetry about the axis of a cylindrical electron beam. The tube having planar symmetry has yielded the better results, probably due to the less severe cathode loading and space-charge effects. A maximum efficiency of 13.5% and maximum power output of 1.8 w have been obtained at 8,400 mc with the planar tube, while the maximum efficiency obtained with the axially symmetric tube was 7% at 12,500 mc. The maximum power output obtained with the latter was 400 mw at 9,100 mc. (Contractor's abstract)

RESEARCH ON PHYSICAL LIMITATIONS ON PRODUCTION AND USE OF RF ENERGY IN MILLIMETER WAVELENGTH RANGE, by M. O. Thurston and W. H. Cornet, Jr. Final rept. July 1958, 54p. incl. diags. tables, refs. (Rept. 719) (AFOSR-TR-58-133) (AF 49(638)53) AD 203968; PB 139464 Unclassified

The results of a survey of the literature on millimeter wavelength devices is presented. The high frequency limit for most conventional sources is in the range from 3 mm to 1 mm. Harmonic generators of several types are discussed. A detailed analysis of a velocity variation harmonic generator is followed by a preliminary analysis of frequency multipliers based on field emission and on the failure of Ohm's law in semiconductors. The feasibility of obtaining sub-millimeter waves from the radiation of electrons in a high magnetic field is also investigated. (Contractor's abstract)

ON SINGULARITIES OF SOLUTIONS OF PARTIAL DIFFERENTIAL EQUATIONS IN THREE VARIABLES, by E. Kreyszig. Dec. 1958 [9p. incl. refs. (Technical rept. no. 1) (AFOSR-TN-58-933) (AF 49(638)362) AD 205098 Unclassified

Also published in Arch. Rational Mech. Anal., v. 2: 151-159, 1958.

Partial differential equations in three variables of the type $v_{x_1 x_1} + v_{x_2 x_2} + v_{x_3 x_3} + \sigma(x_2, x_3) v = 0$ are studied

in such a way as to show the possibility of setting them up for solution by means of using Bergman operators which can "translate" analytic functions into theorems on solutions of partial differential equations in two variables. The situation is expanded to the case where solutions are given of certain classes of more general partial differential equations in three variables with analytic coefficients by means of a further application of Bergman operators.

MULTIPOLAR STARK SPLITTING PATTERNS IN SINGLE CRYSTALS, by P. M. Parker. Dec. 6, 1956 [3p. incl. tables. [Part 3 of technical rept. no. 4] (AFOSR-TN-57-23) (AF 18(600)772) AD 115057(b) Unclassified

Also published in Phys. Rev., v. 105: 1713-1715, Mar. 15, 1957.

The theoretical relative splitting schemes of the energy levels of a nuclear nonspherical charge distribution in the electric field of the crystalline surroundings are calculated for some relevant symmetries of the electric crystalline field. The results are intended as a guide to possible experimental observation of nuclear multipole interactions of order higher than the quadrupole interaction. (Contractor's abstract)

FREQUENCY STABILIZATION OF A REFLEX KLYSTRON WITH RESPECT TO A CRYSTAL-CONTROLLED SECONDARY FREQUENCY STANDARD, by J. E. Geusic, L. D. Farringer, and L. C. Brown. [1957] [3p. incl. diagr. (AFOSR-TN-57-70) [AF 18(600)772] AD 120413 Unclassified

A klystron frequency stabilizer is described which has achieved frequency stabilization comparable to the Pound system without using a resonant cavity as a reference. The system frequency stabilizes the klystron, frequency-tunes a klystron linearly with time over a range of 10mc-sec by simply tuning the HRO-50 receiver and automatically measures and controls the actual frequency of the klystron to a high degree of accuracy.

NUCLEAR RESONANCE SPECTRUM OF Al^{27} IN CHRYSOBERYL, by J. H. Hockenberry, Jr., L. C. Brown, and D. Williams. [1957] 10p. incl. tables. (AFOSR-TN-57-622) (AF 18(600)772) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 225, Apr. 25, 1957.

Also published in Jour. Chem. Phys., v. 28: 367-372, Mar. 1958.

The nuclear magnetic resonance spectrum of Al^{27} in a single crystal of chrysoberyl ($BeAl_2O_4$)₄ has been investigated at room temperature in a field of 7800 gauss. The spectra obtained as the crystal was rotated about the three crystal axes have been interpreted on the

basis of eight Al^{27} sites of two distinct types, the four sites of each type differing only in the orientation of the principal field gradients. Quadrupole coupling constants and electric field asymmetry parameters at the two types of sites were determined to be

	Type I site	Type II site
$C_z = eQ \cdot \frac{1}{2} h$	2830 ± 15 kc/sec	2846 ± 15 kc/sec

$n = \frac{(c_{zz} - c_{yy})}{c_{zz}}$	0.94 ± 0.02	0.76 ± 0.02
--	-------------	-------------

In addition, the orientation of the principal field gradients has been determined at each of the eight sites. (Contractor's abstract)

GROUP THEORY OF THE SPIN-HAMILTONIAN, by J. Korringa. Aug. 1957, 70p. incl. tables, refs. (Technical note no. 5) (AFCSR-TN-57-780) (AF 18(600)772) AD 148012 Unclassified

An investigation is made to determine the possibilities of combining theoretical mechanical perturbation theory and group theoretical arguments in order to develop an analytical formalism for dealing with the symmetry properties of crystals through the so called spin-Hamiltonian theory. Special attention is given to the group-theoretical problems of the spin-Hamiltonian theory. The general principles which underlie the construction of invariant operators and the exclusion of non-physical operators are discussed. A generalization of Kramer's method for discussing the multiplet splitting in free atoms or ions is developed. The entire investigation is limited to situations in which an unperturbed system can be found for which the one-level spin-Hamiltonian is satisfactory.

VALIDITY OF A PERTURBATION TREATMENT OF THE QUADRUPOLE ENERGY LEVELS OF SODIUM CHLORATE (Abstract), by P. M. Parker. [1957] [1]p. (AF 18(600)772) Unclassified

Presented at meeting of the Amer. Phys. Soc., Boulder, Colo., Sept. 5-7, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 329, Sept. 5, 1957.

A fifth order perturbation treatment of the Cl^{35} quadrupolar energy levels of sodium chlorate has been re-examined in the light of a more recent numerical treatment of quadrupolar energy levels in single crystals. This examination ascertained that the fifth order perturbation treatment is substantially valid, even though poor convergence is involved in some of the perturbation coefficients. From this it is concluded that the coupling constants quoted for sodium chlorate are correct, but that the limits of error quoted for the effective nuclear magnetic dipole moment should more appropriately be ± 0.002 nuclear magnetons.

ENERGY MOMENT TREATMENT OF THE QUANTUM MECHANICAL ASYMMETRIC ROTATOR, by P. M. Parker and L. C. Brown. Mar. 1958, 103p. incl. diagrs. tables, refs. (Technical note no. 6) (AFOSR-TN-58-371) (AF 18(600)772) AD 154277 Unclassified

A method has been presented which relates the physical parameters associated with the description of a quantum mechanical system to the energy eigenvalues of the Schrödinger equation of the system. For relatively simple systems the physical parameters can be evaluated from spectroscopic data without effecting a detailed solution for the roots of secular polynomials. Application of the method to a system described by a rigid asymmetric rotator Hamiltonian has resulted in relatively simple closed expressions for effective rotational constants in terms of experimentally determined quantities. Use of the rigid asymmetric rotator expressions has been illustrated for the water molecule. The theory has been extended to include explicitly first order stretching effects for an asymmetric top model. Centrifugal stretching effects in the water molecule are discussed in terms of the first order theory.

ZEEMAN SPLITTING OF NUCLEAR QUADRUPOLE LEVELS IN CUPRITE, by H. L. Cox, Jr. and D. Williams. [1958] 11p. incl. table, refs. (AFOSR-TN-58-453) (AF 18(600)772) AD 158259 Unclassified

Also published in Jour. Chem. Phys., v. 32: 633-634, Feb. 1960.

The radio-frequency spectrum of a single cuprite (Cu_2O) crystal in an external magnetic field has been investigated. The electric quadrupole transition lines in the vicinity of 26 mc/sec for Cu^{63} and 24 mc/sec

for Cu^{65} are split by the magnetic field. From the resulting pattern, it can be shown that the electric asymmetry parameter is $\eta < 0.0012$. The analysis of the spectra obtained for various orientations of the crystal in the magnetic field leads to the following values for the pertinent parameters:

$$(eQq)^{83} = 51.958 \pm 0.04 \text{ mc/sec (at } 28^\circ \text{ C)}$$

$$(eQq)^{85} = 48.085 \pm 0.04 \text{ mc/sec (at } 28^\circ \text{ C)}$$

$$\mu^{83} = 2.2281 \pm 0.007 \text{ n.m.}$$

$$\mu^{85} = 2.3785 \pm 0.007 \text{ n.m.}$$

$$Q^{83}/Q^{85} = 1.0808 \pm 0.009$$

$$\mu^{85}/\mu^{83} = 1.0878 \pm 0.006$$

Within the indicated limits, these values are in agreement with values of eQq obtained for powdered samples of cuprous oxide with values for μ obtained with liquid samples. The temperature dependence of eQq has also been determined; the eQq variation with temperature is the same for Cu^{83} and for Cu^{65} within the limits of the present measurements. COMPUTATION OF THE PRINCIPAL COMPONENTS OF AN ASYMMETRIC g TENSOR FROM PARAMAGNETIC RESONANCE DATA, by J. E. Geusic and L. C. Brown. [1958] 6p. (AFOSR-TN-58-508) (AF 18(600)772) AD 158319 Unclassified

Also published in Phys. Rev., v. 112: 64-65, Oct. 1, 1958.

A straightforward method is developed for obtaining the principal components of the asymmetric tensor g and its orientation in a crystal system. The necessary paramagnetic resonance data involves three crystal rotations about arbitrary orthogonal axes. Although the spin Hamiltonian is probably not applicable except for $S = 1$, the development, which is based upon a calculation of the second moment of the energy levels about their mean, is quite general. PARAMAGNETIC RESONANCE STUDY OF IRRADIATION DAMAGE IN CRYSTALLINE CARBOHYDRATES, by D. Williams, J. E. Geusic and others. [1958] 9p. incl. diagrs. refs. (Technical note no. 7) (AFOSR-TN-58-840) (AF 18(600)772) AD 203082 Unclassified

OSU.08:031 - OSU.08:034

Also published in Proc. Nat'l. Acad. Sciences, v. 44: 1128-1136, Nov. 1958.

In most of the irradiated carbohydrates studied, the existence of hyperfine structure in the paramagnetic resonance spectrum suggests the general nature of the radical produced by the radiation. From a consideration of the chemical structure of some of these sugars, some of the similarities observed in the spectra of different sugars were not surprising. The structures are given for α -D-glucopyranose monohydrate and α -D-galactopyranose. The only difference in structure of these two sugars is the relative configuration about C4. Since there is such a great similarity in the structure of these two sugars, the radicals produced by irradiation of these molecules would give similar paramagnetic resonance spectra. The spectra of the two ketohexoses, β -D-fructopyranose and L-sorbose (detailed structure unknown), are similar. The spectra of erythritol and D-threitol were found to be similar, and again the only difference in structure of these two is the relative position of a hydroxyl group. It is hoped that the results of the paramagnetic resonance studies which have been carried out can be used in helping to decide what radicals are formed by the ionizing irradiation.

THE RESONANCE SPECTRUM OF A PARAMAGNETIC IMPURITY IN TOPAZ (Abstract), by J. E. Geusic and D. Williams. [1958] 1p. (AFOSR-TN-58-1126) (AF 18-(600)772) AD 207835 Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 30-May 2, 1959.

Published in Bull. Amer. Phys. Soc., Series II, v. 4: 260, Apr. 30, 1959.

The paramagnetic resonance spectrum of a single crystal of topaz $(\text{AlF})_2\text{SiO}_4$ containing Fe and Cr as impurities has been investigated at X-band. At present the paramagnetic resonance spectra observed cannot be ascribed to either Cr or Fe ions in the lattice. However, from the symmetry properties of the resonance spectra observed as the crystal is rotated with respect to the magnetic field and from hyperfine structure which is present, the paramagnetic center is identified as occupying Al sites in the topaz lattice.

COMPUTATION OF ASYMMETRIC ROTATOR CONSTANTS FROM ENERGY MOMENTS (Abstract), by

P. M. Parker and L. C. Brown. [1958] [1]p. (AF 18-(600)772) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 53, Jan. 29, 1958.

A procedure has been described previously which relates the rotational constants of the rigid asymmetric rotator to experimental data through moments of the energy levels. This procedure in many cases permits the computation of rotational constants with much less effort than is usually met in either numerical approximation to roots of secular equations or perturbation methods. Moments have been calculated based on a more general asymmetric rotator Hamiltonian which includes terms allowing for first order stretching effects. Also, for the rigid rotator Hamiltonian calculations have been made which are based on the factored form of the secular determinants. The results were presented and discussed.

NUCLEAR MAGNETIC RESONANCE SPECTRA OF ALKALI HALIDE SOLUTIONS (Abstract), by D. D.

Elleman, L. C. Brown, and D. Williams. [1958] [1]p. (AF 18(600)772) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 166, May 1, 1958.

Resonances for Li^7 , Na^{23} , Rb^{85} , Rb^{87} , Cs^{133} , Cl^{35} , Br^{79} , Br^{81} , and I^{127} have been studied in aqueous solutions of alkali halides. Line widths and frequency shifts were measured as functions of concentration. The widths of the broader lines have been interpreted qualitatively in terms of nuclear quadrupole effects. The widths of certain resonance lines in D_2O solutions are not noticeably different from those in H_2O solutions.

Addition of ethanol is found to increase the widths of some lines. The ratio of the line widths of Br^{79} to Br^{81} extrapolated to zero concentration is proportional to the square of the ratio of the nuclear quadrupole moments, an observation in agreement with Pound's results for a single dilute solution. The shift in frequency with concentration is interpreted qualitatively in terms of the ionic environment.

PARAMAGNETIC RESONANCE SPECTRUM OF Fe^{+++} IN BLUE SAPPHIRE AT 300°K (Abstract), by J. K. Geusic and D. Williams. [1958] [1]p. (AF 18(600)772) Unclassified

Presented at annual Conf. of the Cleveland, Ohio, Soc. of Spectroscopy, May 21, 1958.

Paramagnetic resonance of Fe^{+++} in $\alpha\text{-Al}_2\text{O}_3$ has been observed at 300°K by means of a spectrograph operating at 9000 mc/sec. Four resonance lines are observed when the trigonal axis of the crystal is parallel to the external magnetic field. The lines have been tentatively assigned to transitions based on a spin Hamiltonian of the form:

$$H_s = g\beta H \cdot S + D \cdot 3S_z^2 - S(S+1) + F \cdot 35S_z^4 - 30S(S+1)S_z^2 + 25S_z^2 - 6S(S+1) + 3S^2$$

$$(S_+ 1)^2 + \frac{G}{\sqrt{2}} \left[(S_z(S_+^3 + S_-^3) + (S_+^3 + S_-^3)S_z) \right] +$$

$$i \left[S_z(S_+^3 - S_-^3) + (S_+^3 - S_-^3)S_z \right]. \text{ The parameters}$$

obtained from the experimental data are:

$$g = 2.003 \pm 0.008$$

$$D = 7.67 \pm 0.02 \times 10^{-2} \text{ cm}^{-1}$$

$$F = 2.31 \pm 0.03 \times 10^{-4} \text{ cm}^{-1}$$

$$|G| = 1.93 \pm 0.4 \times 10^{-3} \text{ cm}^{-1}$$

Certain discrepancies between the observed spectrum and the predicted spectrum will be discussed.

F-CENTERS IN X-RAY IRRADIATED KCl, NaCl, AND NEUTRON IRRADIATED LiF (Abstract), by F. J. Reid, R. T. Bate, and C. V. Heer. [1957] [1]p. (AF 18(600)-1003) Unclassified

Presented at meeting of the Amer. Phys. Soc., Philadelphia, Pa., Mar. 21-23, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 154, Mar. 21, 1957.

The number of magnetic centers in x-ray irradiated KCl, NaCl and neutron irradiated LiF were determined by measuring the static magnetic susceptibility down to liquid helium temperatures with a sensitive torsion balance. Optical absorption measurements were made at room temperature. Under the assumption that the temperature dependent paramagnetic susceptibility is due primarily to the F-centers, optical oscillator strengths for KCl and NaCl were in agreement with previous results on additively colored crystals. LiF crystals were irradiated with varying neutron fluxes, and the concentrations of magnetic centers exceeded $10^{20}/\text{cc}$ in the intensely colored crystals. Concentration as a function of neutron flux is discussed.

Ohio State U. Research Foundation. [Dept. of Physics and Astronomy] Columbus.

HYPERFINE COUPLING IN METALS (Abstract), by C. V. Heer. [1958] [1]p. [AF 49(638)254] Unclassified

Presented at Kamerlingh Onnes Conf. on Low Temperature Physics, Leyden (Netherlands), June 23-28, 1958.

Published in *Physica*, v. 24: S155, Sept. 1958.

The evaluation of the anomalous specific heat in transition metals below 1°K which is attributed to the hyperfine coupling between the nucleus and the electronic magnetic moment of the atom is of considerable importance in the study of the orientation of nuclei in ferromagnetic materials, in the study of the electronic wave functions in metals, and in low temperature research. The measurement of the specific heat of metallic cobalt has been extended to lower temperatures on the same cobalt specimen and with the same magnetic refrigerator-calorimeter which was used by Heer and Erickson. Data in agreement with that previously reported is obtained. The anomalous specific heat or that part of the specific heat in excess of the electronic and lattice contribution, $C/R = 4.0 \times 10^{-4}/T^2$, is not in complete agreement with the value suggested by the anisotropy of the γ -ray emission of metallic cobalt. The small molar volume of cobalt metal gives rise to a hyperfine coupling specific heat per unit volume comparable to the specific heats of paramagnetic salts and has led to the suggestion that cobalt or other similar metals will be very effective as low temperature heat reservoirs. Below 0.1°K an observable anomaly is expected in iron, nickel, etc. (Contractor's abstract)

STATISTICAL THEORY OF LATTICE DISTORTION—ITS EFFECT ON ORDERING, by T. Usui. June 1958, 13p. (Technical note no. 1) (AFOSR-TN-58-995) (AF 49(638)-264) AD 205903 Unclassified

The effect of difference in atomic size between two components of a simple binary solid solution on the ordering is investigated by assuming a lattice distortion of the type expected in an elastic medium. Statistical conclusions are based on molecular field and quasi-chemical approximations. It is found that the critical temperature is always lowered compared to the case without distortion and that the degree of short range order at the critical temperature also decreases. DISPERSION OF ELECTRON WAVES IN A RANDOM LATTICE (Abstract), by J. Korringa. [1958] [1]p. [AF 49(638)264] Unclassified

Presented at Kamerlingh Onnes Conf. on Low Temperature Physics, Leyden (Netherlands), June 23-28, 1958.

Published in *Physica*, v. 24: S171, Sept. 1958.

The residual resistance of an imperfect metal, though commonly obtained from a transport equation, appears as the imaginary term in the dispersion relation for electrons in the perturbed lattice. This dispersion theory is sketched for the special case that two atomic species, A and B, are randomly distributed in an otherwise perfect lattice, in concentrations C_A and C_B . The basic results are: (1) The stationary states closely resemble Bloch waves; in two cells occupied by A-atoms the wave function differs mainly by a phase factor; the same holds for B-cells. The phase difference is of the form $k \cdot R_{ij} + \eta_{ij}$, where R_{ij} is the vector distance between the two lattice points, and where η_{ij} is a "phase error." For fixed R_{ij} , the phase errors have a Gaussian distribution, with a width $\sigma_{ij} = \sqrt{\sigma} R_{ij}$. (2) The value of $\alpha(k)$ together with the energy $E(k) = \hbar^2 k_0^2 / 2m$, appear together as a complex eigenvalue of Schroedinger's equation in a periodic, but complex and velocity-dependent potential. The scattering matrix, corresponding to this potential in any lattice cell, is given by $U = (1 - i\alpha/k_0)(C_A U_A + C_B U_B)$, where U_A and U_B are the scattering matrices corresponding to the real potentials in an A- and B-cell, respectively. The latter can be obtained by a self-consistent iteration method. The value of α for states at the Fermi level is proportional to the resistance tensor; the function $k_0^2(k)$ describes the band structure of the system. (Contractor's abstract)

SOME PERSONALITY CORRELATES OF DECISION MAKING UNDER CONDITIONS OF RISK, by A. Scodel, P. Ratoosh, and J. S. Minas. [1958] [13]p. Incl. tables, refs. (In cooperation with New Mexico U., Albuquerque) (AFOSR-TN-58-346) (AF 49(638)317 and AF 49(638)33) AD 154251 Unclassified

Also published in *Behavioral Science*, v. 4: 19-28, Jan. 1959.

Also published in *First Interdisciplinary Conf. on Decisions, Values and Groups*, New Mexico U., Albuquerque, Summer 1957, New York, Pergamon Press, v. 1: 37-49, 1960.

How does the personality of the decision maker affect the rules which guide his decisions? Does a gambler normally bet in such a way so as to maximize expected gain? What is the relation between the objective probability of the event and the way this probability appears to the risk taker? A combination of clinical psychological methods and statistical methods reveals some interesting relations among background, inferred personality traits, and observed gambling behavior of people.

CHARACTERISTICS OF A MODEL RETINAL RECEPTOR STUDIED AT MICROWAVE FREQUENCIES, by J. M. Enoch and G. A. Fry. Final rept. Aug. 1957, 53p. Incl. diagrs. table, refs. (AFOSR-TR-57-62) (AF 18(603)63) AD 136544 Unclassified

Presented at meeting of the Opt. Soc. of Amer., Columbus, Ohio, Oct. 17-19, 1957.

Also published in *Jour. Opt. Soc. Amer.*, v. 48: 899-911, Dec. 1958.

A simplified microwave model of the human visual system was constructed in order to study the characteristics of model retinal receptors. A technique devised by O'Brien (*Jour. Opt. Soc. Amer.*, v. 41: 882, 1951) was employed. In this study, two physical distributions, two wavelengths, and two detecting conditions were considered. The relative sensitivity and the directional sensitivity of a model retinal cone ellipsoid were determined when it was irradiated by a point source and when it was placed at several different positions in a diffraction pattern at or near the Gaussian image point. It was found that more energy was absorbed by the detector unit when the model was irradiated by the point source than when it was placed in the Fraunhofer diffraction pattern. Similarly, more energy was absorbed when a shorter wavelength was employed. It was found that the model antenna became more efficient as it was moved away from the center of the diffraction pattern. The direction of maximum sensitivity shifted as a function of the position of the model antenna in the diffraction pattern. Markedly different directional sensitivity patterns were obtained for different physical distributions, for different positions in those distributions, and for different wavelengths. The implications of these findings are discussed. (Contractor's abstract)

1,6-Octadiene undergoes cyclization at 457° to give 1-methyl-cis-2-vinylcyclopentane, and under the same conditions 7-methyl-1,8-octadiene furnishes 1-methyl-cis-2-isopropenylcyclopentane. 1,6-Heptadiene fails to cyclize even at 500°. These results lend support to the intramolecular mechanism previously proposed for the thermal cyclization of 1,6-diolefins. (Contractor's abstract)

The reaction of 2-methyl-1,5-hexadiene when heated to 480°C and the formation of this product from other diolefins has been interpreted in terms of a reversible dissociation which yields only allyl radicals. It is found that 1,5-heptadiene behaves in a radically different manner upon pyrolysis, in which isomeric methylcyclohexenes and toluene are formed. The cyclization process is interpreted in terms of a free radical chain mechanism. (Contractor's abstract)

A summary of the reactions of various 1,5- and 1,8-diolefins at temperatures of 400° to 500°C is given. 1,6-Diolefins having at least one hydrogen-bearing substituent undergo cyclization to give cyclopentane derivatives. An intramolecular mechanism is proposed for this type of cyclization. The kinetics of cyclization of 3,7-dimethyl-1,8-octadiene and the failure of free radical chain initiators and inhibitors to affect the rate of reaction lend support to the proposed mechanism. Additional support is provided by the fact that 1,8-octadiene and 7-methyl-1,6-octadiene undergo cyclization to give 1-methyl-cis-2-vinylcyclopentane and 1-methyl-cis-2-isopropenylcyclopentane, respectively, whereas 1,8-heptadiene fails to cyclize. Two types of reactions are observed when 1,5-diolefins are subjected to high temperatures. The first of these involves a reversible dissociation furnishing allyl-type radicals; 1,5-hexadiene, 2-methyl-1,5-hexadiene, 2,5-dimethyl-1,5-hexadiene and 6-methyl-1,5-heptadiene exhibit this type of behavior. The second type of reaction involves cyclization giving cyclohexene derivatives; 1,5-heptadiene exhibits this type of behavior. A free radical chain mechanism is proposed for this reaction. Also published in Bull. Amer. Phys. Soc., Series II, v. 2: 171, Apr. 25, 1957.

Rectification effects between metal points and Type IIb diamonds have been studied under various conditions. Rectification was observed with each of the metals tested which included indium, aluminum, copper, tungsten, silver, and platinum. The current-voltage characteristics were in qualitative agreement with rectification theory; however, there was no quantitative agreement because the reverse saturation current was not dependent upon the work function of the metal to the extent required by theory. The lack of dependence of rectification with the work function can be explained by Bardeen's theory of surface states. Reverse breakdown occurred between 30 and 60 volts and a luminescence was observed with 45 volts forward bias. Good rectification curves were still obtained at 300°C, the maximum temperature employed. The diamond developed photovoltages in the visible and near infrared extending from 310 m μ to 1.3 μ with the maximum at 660 m μ . In the ultraviolet the photovoltage peaked at 230 m μ . (Contractor's abstract)

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 114, Mar. 27, 1958.

Studies have been made of the photoconductivity in semi-conducting diamond as a function of the wavelength, temperature, electric field strength, intensity of incident radiation, and crystal orientation. At room temperature the region of photoconductivity is broad, extending from 0.375 to 2.1 μ with the maximum at 0.6 μ . Peaks also occur at 0.224 and 0.228 μ . At lower temperatures various peaks in photoconductivity can be resolved. Maxima in photoconductivity at 152°K occur at 0.52, 0.92, 1.24, 1.64, and 2.16 μ . The maxima in photoconductivity shift to shorter wavelengths and decrease in magnitude with decreasing temperature. Above room temperature the photoconductivity increases with increasing temperature to approximately 400°K after which it commences to decrease. The photoconductivity is linear with respect to electric field strength, and it is also linear with respect to the intensity of the incident radiation. A good signal-to-noise ratio can be obtained. The photoconductivity has a slight directional dependence. The photoconducting diamonds used in these experiments were furnished by J. F. H. Custers.

RECTIFICATION, PHOTOCONDUCTIVITY, AND PHOTOVOLTAIC EFFECT IN SEMICONDUCTING DIAMOND, by M. D. Bell and W. J. Leivo. Sept. 1958, 24p. incl. diagrs. table. (Technical rept. no. 1) (AFOSR-TN-58-381) (AF 18(603)40) AD 211034 Unclassified

Also published in Phys. Rev., v. 111: 1227-1231, Sept. 1, 1958.

Studies of the rectification between a metal point and p-type semiconducting diamond show that the formation of the potential barrier is essentially independent of the work function of the metal and is formed by the establishment of equilibrium between charges in surface and interior states. The semiconducting diamonds have been found to be photoconducting in the ultraviolet and visible regions. Agreement has been found between the spectral response of photoconductivity and photovoltages developed at metal contacts, with the exception that photovoltages developed near 440 m μ were not obtained in photoconductivity. LIFETIMES AND TRAPPING OF CARRIERS IN SEMICONDUCTING DIAMOND (Abstract), by J. H. Wayland and W. J. Leivo. [1958] [1]p. (AF 18(603)40) Unclassified

Presented at meeting of the Amer. Phys. Soc., Los Angeles, Calif., Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 400, Dec. 29, 1958.

Lifetimes and trapping of carriers in semiconducting diamond have been studied from the response and decay times of photoconductivity. The gem quality diamond investigated has a resistivity of 3.5×10^5 ohm cm and is photoconducting in the visible region. Hall measurements show p-type conductivity with a hole mobility of 1300 cm²/volt sec. From the rise time of photocurrent, using light in the fundamental absorption region, a lifetime of 9 μ sec was obtained. This is possibly largely independent of trapping. From decay curves, lifetimes, which include trapping, of 125 μ sec, 800 μ sec, 0.25 sec, 12 min, and 84 min were obtained. Using visible light, the response and decay time of the photocurrent is dependent upon the wavelength of the exciting radiation because several intermediate energy levels are present in this region. Various recombination times obtained include 20 msec, 30 sec, 6 min, and 39 min.

INVESTIGATIONS OF THE THERMODYNAMIC PROPERTIES OF INORGANIC SALTS IN NONAQUEOUS SOLVENTS AND IN CONCENTRATED SALT MIXTURES, by T. E. Moore. Final technical rept. July 1957, 49p. incl. diagrs. tables, refs. (AFOSR-TR-57-47) (AF 18-(600)478) AD 132477 Unclassified

Research was undertaken (1) to study the chemical potentials in the systems consisting of H_2O , HCl, and certain of the transition metal salts in concentrated solutions at $25^\circ C$; and (2) to examine new approaches to the problem of obtaining the activity of the solute and solvent in nonaqueous solutions. The thermodynamic activities of $MnCl_2$, HCl, and H_2O at $25^\circ C$ were measured in 3 series of mixtures having constant HCl concentrations of 4.67, 7.05, and 9.01 M, respectively. In each series, the $MnCl_2$ concentration was varied from 0.2 M to saturation. The HCl and H_2O vapor pressures were measured by the gas-transpiration method, and the activity of $MnCl_2$ was calculated from the Gibbs-Duhem relationship. The activities of HCl and $MnCl_2$ in the mixtures were very high in comparison with the corresponding activities in the binary solutions, partly because of higher chloride ion concentrations and ionic hydration. A similar study was made of the activities in the system, $MnSO_4$ -HCl- H_2O at an HCl concentration of 7.27 M. An investigation was made of the principle of the wet-bulb thermometer applied to the problem of measuring vapor-pressure lowerings of ether solutions; although the method could be used with an average error of less than 1%, measurements were tedious, and the behavior of the apparatus was unpredictable and erratic. The use was studied of IR spectrometry in the measurement of the vapor pressures of 2 volatile components in a 3-component mixture. Two novel manometers of high theoretical sensitivity were built and tested.

INVESTIGATION OF NOVEL STATIC METHODS FOR THE DETERMINATION OF VAPOR PRESSURES IN THE PRESENCE OF INDIFFERENT GASES, by C. E. Miller. May 1957, 46p. incl. diagrs. refs. (AFOSR-TR-57-47a) (AF 18(600)478) Unclassified

A novel static method for the determination of partial pressures in the presence of an indifferent gas which gives high sensitivity in the vapor pressure range of 0 to 25 mm Hg and which requires a short time for the determination is given. Campbell's procedure uses a liquid, previously saturated with an indifferent gas at

a definite temperature and pressure, to evaporate into a space containing the same gas, under the same conditions. A single piston and double piston gauge and a displacement weight manometer were built and tested for their applicability to the determination of vapor pressures of solutions following this procedure.

THE HYDROLYSIS OF AMMONIUM CARBAMATE AND THE MECHANISM OF ACTION OF UREASE, by G. Gorin and M. F. Butler. Feb. 1958, 10p. incl. table, refs. (Technical note no. 1) (AFOSR-TN-58-518) (AF 18(603)-135) AD 158331; PB 135411 Unclassified

Presented at meeting of the Biological Div. of the Amer. Chem. Soc., New York, Sept. 8-13, 1957.

Abstract published in 132nd meeting of the Amer. Chem. Soc. Abstracts of Papers, 1957, p. 6-C.

The rate of hydrolysis of ammonium carbamate has been measured in 0.05-0.25 M sodium hydroxide and found to be proportional to the hydrogen in concentration. At this pH, the rate-determining step is the addition of a hydronium ion to the carbamate ion, giving ammonia and carbon dioxide. At pH 9, which is the value developed when ammonium carbamate hydrolyzes in the absence of added buffers, the hydration of carbon dioxide becomes the rate-determining step, and the half-life of the reaction is about 10-20 minutes at 0° ; under these conditions, the presence of ammonium carbamate in aqueous solutions can be demonstrated. In more acidic buffers, the rate of reaction increases again; in a phosphate buffer at pH 7, the reaction was substantially over in less than a minute. Urea hydrolyzed by urease in the presence of no added buffers largely produces carbamate which can be demonstrated analytically, but which subsequently hydrolyzes. In buffer at pH 7 the carbamate cannot be demonstrated, but the observations reported above explain why this would be so, even though carbamate was the first intermediate product. This is considered to be the most likely mechanism of the urease-catalyzed hydrolysis. However, it is possible that the carbamate would have arisen from recombination of ammonia and carbon dioxide, and that these might be the primary products of the urease-catalyzed reaction. June 1959.

Reaction of cystine with sodium sulfide in 0.2 M sodium hydroxide solution produces a product with an absorption peak at 335 m μ ; it is postulated that the species responsible for this absorption is (-SSCH₂CHNH₂COO⁻). In the presence of excess sulfide this species reacts further, and, over-all, there are produced two cysteinyl ions and di- or polysulfide ions. Mixtures of cystine with 5-10 equivalents of sodium sulfide allowed to react to the point of equilibrium, have small but definite levorotations; upon being made acid, they contain little or no cystine. In the conditions indicated it appears that the first reaction producing RSS⁻ goes practically to completion, but that the subsequent reaction has a smaller equilibrium constant. The change of optical rotation in mixtures of cystine and sulfide was followed quantitatively, and approximate speeds of reaction were determined. Sodium sulfide might be useful for splitting disulfide groups in proteins, although there are considerable limitations to its potential utility. (Contractor's abstract)

DETERMINATION OF MERCAPTO GROUPS IN OVALBUMIN WITH FERRICYANIDE, by J. M. Katyal and G. Gorin. [1958] [11]p. incl. diagrs. tables, refs. [AFOSR-TN-58-877] (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)135 and Public Health Service) AD 203911 Unclassified

Also published in Arch. Biochem. and Biophys., v. 82: 319-329, June 1959.

A precise determination of the mercapto-group content of denatured ovalbumin has been made with potassium ferricyanide in phosphate buffer at pH 7.1 by means of a novel amperometric method. The results indicate 4.0 groups per mol of 45,000 mol wt. This has been confirmed by spectrophotometric measurements. A qualitative measurement of the rate of reaction of ferricyanide with ovalbumin in the presence of trimethyldodecylammonium chloride and sodium dodecyl sulfate as denaturants has shown that the reaction proceeds much faster in the presence of the former.

Dec. 1958.

The measurement of extremely small light fluxes photoelectrically requires the use of a multiplier phototube operated at the temperature of liquid air in order to reduce dark current components due to thermionic emission and cesium vapor pressure. It is desirable to operate the multiplier in a vacuum. The refrigerator should be demountable so the multiplier may be withdrawn for minor adjustments. A refrigerator is described that is easy to construct and whose plan can be simply adapted to any type and size tube. The refrigerator specifically described herein is all Pyrex (except the window) and is designed specifically for an EMI 6256B tube. This tube is 5 in. long and 2 in. in diameter; the photosensitive cathode is in the end.

LIMIT THEOREMS FOR THE DISTRIBUTIONS OF THE MAXIMA OF PARTIAL SUMS OF INDEPENDENT RANDOM VARIABLES, by E. G. Kimme. Sept. 1, 1957, 95p. (Technical rept. no. 1) (AFOSR-TN-58-720) (AF 18(603)138) AD 162255 Unclassified

Limit theorems have been used to establish analytic formulations for the functional distributions of sample functions of a stochastic process. Results are given in terms of the distributions of the sample values. Implicit relations appear as integral equations involving the limiting distribution of the distributions of the maxima. These limiting distributions are regarded as the distributions

OSL 01:001; OXF 01:002, 003

of functionals defined on limiting stochastic processes. A resolvent function is obtained for the characteristic function of the supremum functional under certain hypotheses beyond those of the convergence of the sums in distribution. Smoothness hypotheses provide an integral equation for the distributions which is similar to the integral equations in the theory of Markov processes and recurrent events. General convergence theorems are discussed and a summary of results are presented. Asymptotic formulas, primarily unsolved integral equations, relating to the distribution of the supremum functional are developed. The appendix consists of an elementary extension of the Helly convergence theorem.

CRYSTAL STRUCTURE OF THE 1:1 ADDITION COMPOUND FORMED BY ACETONE AND BROMINE, by O. Hassel and K. O. Strømme. [1958] [8]p. incl. diagrs. tables. (AFOSR-TN-58-1066) (AF 81(052)71) AD 207228 Unclassified

Also published in *Acta Chemica Scandinavica*, v. 13: 275-280, 1959.

The crystal structure of the equimolecular compound containing acetone and bromine has been determined at temperatures near -30°C using Weissenberg technique (CuK-radiation) and precession technique (MoK-radiation). The space group is $C2/c$ and the lattice parameters: $a = 7.12 \text{ \AA}$; $b = 7.48 \text{ \AA}$; $c = 12.90 \text{ \AA}$; $\beta = 111.5^{\circ}$. Endless chains are present in this structure, bromine atoms and the carbonyl carbon and oxygen atoms of each chain being coplanar. Each oxygen atom is linked to two neighboring oxygen atoms of the same chain by halogen molecule bridges and the O-Br-Br-O arrangements are linear. The observed Br-Br distance was found equal to the distance observed in free bromine molecules (2.28 \AA), the O-Br distance 2.82 \AA . This structure affords the first example of two halogen molecule bridges starting from a common oxygen atom.

SYNTHESIS OF CELL CONSTITUENTS FROM C_2 -UNITS BY A MODIFIED TRICARBOXYLIC ACID CYCLE, by H. L. Kornberg and H. A. Krebs. [1957] [4]p. incl. diagrs. refs. [AF 61(514)1180] Unclassified

Published in *Nature*, v. 179: 988-991, May 18, 1957.

Recent work has established the occurrence of a metabolic cycle in microorganisms which can derive all their carbon requirements from two-carbon compounds.

The cycle, representing a variant of the tricarboxylic acid cycle, is referred to as the "glyoxylate cycle". The main discoveries which led to the elaboration of the cycle were: (1) the finding that isocitrate, apart from undergoing dehydrogenation, is split enzymically to form succinate and glyoxylate; (2) the recognition of an enzyme system bringing about the synthesis of malate from glyoxylate and acetyl coenzyme A; and (3) the demonstration of the ready occurrence of the combined action of the two enzyme systems in cell-free extracts. The overall effect of one turn of the glyoxylate cycle is the formation, from two molecules of acetate, of one molecule of C_4 -dicarboxylic acid. The cycle is therefore a stage in the synthesis of cell material from acetate, and can account for the net formation from acetate of citric, fumaric and other organic acids in molds, and the conversion of fat to carbohydrate in *Ricinus* seedlings. ACETATE METABOLISM IN ACETATE-GROWN *PSEUDOMONAS* KB 1, by H. L. Kornberg. [1957] [1]p. [AF 61(514)1180] Unclassified

Presented at meeting of the Biochem. Soc., Oxford (Gt. Brit.), Apr. 12-13, 1957.

Published in *Biochem. Jour.*, v. 66: 13P, June 1957.

Pseudomonas KB 1 grows rapidly on synthetic media containing acetate as sole carbon source. The tricarboxylic acid cycle seems to operate in the acetate media as when cells are grown on succinate. This is also supported by degradative studies of labeled amino acids synthesized by organisms grown on $[\text{C}^{14}]$ acetate. When growing cells are incubated with $\text{C}^{14}\text{H}_3\text{COONH}_4$, label appears initially (3-30 sec) only in intermediates of the cycle and in amino acids directly derived therefrom. Mechanisms such as those operating in photosynthetic or autotrophic organisms are not of primary importance. A compound, probably oxaloacetate, occurs in ready equilibrium with CO_2 at an early stage in the metabolism of acetate. When microorganisms grow on acetate as sole carbon source, rapid net synthesis of C_4 -dicarboxylic acids must occur from acetate to provide the acceptor for C_2 units entering the cycle. The high initial radioactivity of C_4 compounds suggests that acetate enters the cycle at least at two sites: citrate forms at one and direct C_4 compounds form at the other. FORMATION OF C₄-DICARBOXYLIC ACIDS FROM ACETATE BY PSEUDOMONAS KB 1, by H. L. Kornberg and N. B. Madsen. [1957] [2]p. [AF 61(514)1180]
Unclassified

Presented at meeting of the Biochem. Soc., Oxford (Gt. Brit.), Apr. 12-13, 1957.

Published in Biochem. Jour., v. 66: 13P-14P, June 1957.

Experiments with cell-free extracts of Pseudomonas KB 1 were undertaken to elucidate the mechanism by which net syntheses of C₄-dicarboxylic acids from acetate are achieved in these organisms. Acetate-grown Pseudomonas KB 1 cells were crushed by the Hughes method, homogenized with 0.1 M potassium phosphate, pH 7.6, and centrifuged at 25,000 g. When this supernatant fraction was incubated with isocitrate, C¹⁴CH₃COONa, coenzyme A, ATP, and glutathione, labeled malate was formed. This incorporation of C¹⁴ also occurred when glyoxylate replaced isocitrate in the above system, but no isotope was incorporated in the absence of enzyme, ATP, glyoxylate or isocitrate. The net formation of malate from acetate and glyoxylate by extracts in the presence of ATP, coenzyme A, and glutathione under anaerobic conditions was also demonstrated. The presence of an enzyme similar to, or identical with, the malate synthetase of Wong and Aji was indicated. It was concluded that the cells of acetate-grown Pseudomonas KB 1 contain all the enzymes necessary to effect the net synthesis of C₄-dicarboxylic acids by the following reactions:

isocitrate - succinate + glyoxylate,
acetate + ATP + coenzyme A - acetyl-coenzyme A (+AMP+PP),
acetyl-coenzyme A + glyoxylate - malate + coenzyme A,

the net result being:

acetate + isocitrate + ATP - malate + succinate (+AMP+PP).

SYNTHESIS OF C₄-DICARBOXYLIC ACIDS FROM ACETATE BY A "GLYOXYLATE BYPASS" OF THE TRICARBOXYLIC ACID CYCLE, by H. L. Kornberg and N. B. Madsen. [1957] [3]p. incl. diagrs. tables, refs. [AF 61(514)1180]
Unclassified

Published in Biochim. et Biophys. Acta, v. 24: 651-653, June 1957.

Pseudomonas KB 1, when grown on acetate as sole source, possesses, in addition to the enzymic reactions of the tricarboxylic acid cycle, an auxiliary mechanism which provides an alternative route from isocitrate to malate. This route is monoxidative and consists of the cleavage of isocitrate by isocitritase and the condensation of acetyl CoA and glyoxylate by malate synthetase. The result of this "glyoxylate bypass" is the formation of two C₄-dicarboxylic acids from isocitrate and acetate.

If this bypass is used instead of the oxidative reactions of the tricarboxylic acid cycle, one turn of the cycle results in the net formation of one molecule of C₄-dicarboxylic

acid from two molecules of acetate. A reaction of this type was first postulated by Thunberg, but the evidence for its occurrence has been disputed. The overall effect of reaction plus the reactions of the tricarboxylic acid cycle leading to the synthesis of isocitrate and to the regeneration of oxalacetate is identical with that of the "Thunberg condensation" although the mechanism is entirely different.

QUANTITATIVE ASPECTS OF CO₂ FIXATION DURING PROTEIN SYNTHESIS FROM AMMONIUM ACETATE, by H. L. Kornberg. [1957] [3]p. incl. diagr. table, refs. [AF 61(514)1180]
Unclassified

Published in Biochim. et Biophys. Acta, v. 25: 200-202, July 1957.

Microorganisms, growing on synthetic media containing ammonium acetate as sole C source, rapidly incorporate isotope from added C¹⁴H₃COONH₄ into protein. In the presence of unlabeled NaHCO₃, this synthesized protein is less radioactive than in its absence. Short-term experiments indicate that the protein initially synthesized under such conditions may derive as much as 70% of its C from the unlabeled bicarbonate. These results could be explained either by the occurrence of a CO₂-fixation reaction of hitherto unsuspected magnitude, or by an increase in the steady-state concentration (due to the addition of bicarbonate) of a compound in ready equilibrium with CO₂ lying on one of the earliest stages of the pathway from acetate to protein. Experiments with Pseudomonas RB1³ support the latter explanation.

QUANTITATIVE DETERMINATION OF 0.5-5 μ g OF AMINO ACID NITROGEN ON PAPER CHROMATOGRAMS AND IN SOLUTION, by H. L. Kornberg and W. E. Patey. [1957] 5p. incl. diagrs. table. (AF 61-514)1180) Unclassified

Published in *Biochim. et Biophys. Acta*, v. 25: 189-193, July 1957.

A method is described for the rapid quantitative micro-determination of amino acids on paper chromatograms and in solutions. Its main advantage is that the interference of ammonia is eliminated by the use of buffered Dowex-50. Quantities of amino acids containing between 0.05 and 5 μ g of α -amino nitrogen can be determined. The accuracy of a single determination is of the order of $\pm 5\%$ at levels of 0.05-1 μ g N, but $\pm 2\%$ when quantities of 1.5-5 μ g N are determined. (Contractor's abstract)

A MECHANISM OF CONVERSION OF FAT TO CARBOHYDRATE IN CASTOR BEANS, by H. L. Kornberg and H. Beavers. [1957] [2]p. incl. illus. table. (AF 61(514)-1180) Unclassified

Published in *Nature*, v. 180: 35-36, July 6, 1957.

The possible occurrence of the "glyoxylate by-pass" in castor beans was investigated in an attempt to account for the conversion of fat to carbohydrate, known to occur in germinating fatty seedlings. Cell-free extracts of the endosperm and cotyledons of castor bean seedlings were prepared and incubated with isocitrate, C¹⁴-labeled acetate, coenzyme A, glutathione, and adenosine triphosphate. Analysis of the samples indicated that malate was the only labeled compound formed. This production of malate indicates that the glyoxylate by-pass operates in castor beans and provides both a route for the interconversion of fat and carbohydrate and information on the origin of glycolic acid in this tissue.

THE GLYOXYLATE CYCLE AS A STAGE IN THE CONVERSION OF FAT TO CARBOHYDRATE IN CASTOR BEANS, by H. L. Kornberg and H. Beavers. [1957] [7]p. incl. diagr. tables, refs. (AF 61(514)1180) Unclassified

Published in *Biochim. et Biophys. Acta*, v. 26: 531-537, Dec. 1957.

Cell-free supernatant fractions of castor beans catalyzed the following reactions: The aldol fission of isocitrate, to produce equal amounts of glyoxylate and succinate; the activation of acetate in the presence of CoA and ATP; the condensation of acetyl CoA with oxaloacetate, to form citrate, and with glyoxylate, to form malate; the overall formation of malate from acetyl CoA and esterase citrate or isocitrate. These reactions of the glyoxylate cycle, when coupled with the reactions leading from fat to acetyl CoA, and from malate to carbohydrate, provide a route for the net conversion of fat to carbohydrate.

THE METABOLISM OF C₂ COMPOUNDS IN MICRO-ORGANISMS. II. THE EFFECT OF CARBON DIOXIDE ON THE INCORPORATION OF [C¹⁴] ACETATE BY ACETATE-GROWN *PSEUDOMONAS* KB 1, by H. L. Kornberg and J. R. Quayle. [1958] [8]p. incl. diagr. tables, refs. (AF 61(514)1180) Unclassified

Published in *Biochem. Jour.*, v. 68: 542-549, Mar. 1958.

The effect of non-radioactive carbon dioxide on the incorporation of C¹⁴ into protein synthesized from ammonium [C¹⁴] acetate by *Pseudomonas* KB 1 has been studied. Addition of unlabeled bicarbonate to cells growing on ammonium [C¹⁴] acetate depressed the initial rate of incorporation of C¹⁴ into protein. Cells growing on a stream of unlabeled CO₂ synthesized protein of specific activity 15-17% lower than those growing in the absence of unlabeled CO₂. The presence of C¹²O₂ did not affect the distribution of isotope within the synthesized alanine, but caused a uniform reduction of radioactivity in the carboxyl carbons of aspartate. The observed labeling patterns, which show that CO₂-fixation plays no part in the synthesis of alanine but participates in that of aspartate, provide evidence for the occurrence of the glyoxylate cycle in these organisms. THE METABOLISM OF C₂ COMPOUNDS IN MICRO-ORGANISMS. III. SYNTHESIS OF MALATE FROM ACETATE VIA THE GLYOXYLATE CYCLE, by H. L. Kornberg and N. B. Madsen. [1958] [9]p. incl. diagrs. refs. (AF 61(514)1180) Unclassified

Published in *Biochem. Jour.*, v. 68: 549-557, Mar. 1958.

Reactions of acetate were studied in cell-free extracts of acetate-grown *Pseudomonas* KB 1. Such extracts are capable of catalyzing the formation of acetyl-coenzyme A from acetate. Acetyl-coenzyme A thus formed reacts both with oxaloacetate, to form citrate, and with glyoxylate to form malate. By the use of extracts from

mutant M 22-64 of *Escherichia coli*, it has been shown that these condensations are catalyzed by different enzymes. The aldol fission of isocitrate, to succinate and glyoxylate, can provide the glyoxylate necessary for the formation of malate. The cell-free extracts catalyze the net anaerobic formation of malate and succinate from acetate and isocitrate. These reactions, in conjunction with the reactions leading from acetate to citrate, from citrate to isocitrate and from malate to oxaloacetate, shown to occur in the bacterial extracts, represent a synthesizing variant of the tricarboxylic acid cycle leading to the formation of one molecule of C₄ dicarboxylic acid from two molecules of acetate. The rate of formation of malate from acetate and isocitrate is at least 3 μmol/hr/extract from 1 mg dry wt of bacteria. Since malate is known to be a precursor of most cell constituents, this rate is sufficiently high to account for the observed rates of growth of *Pseudomonas* KB 1 on ammonium acetate. The bacterial extracts also catalyze an interconversion of malate with pyruvate and carbon dioxide that is linked with triphosphopyridine nucleotide. (Contractor's abstract)

RESEARCH ON SOLID STATE DIFFUSION IN SEMI-CONDUCTOR MATERIALS, by T. J. La Chapelle. Final technical rept. Aug. 1, 1956-July 31, 1957. Sept. 1957, 62p. incl. illus. diagrs. tables, refs. (Rept. no. 3000:5-5-F) (AFOSR-TR-57-63) (AF 18(603)117) AD 136553 Unclassified

Dislocation arrays appear to play a more important role in the solid-state diffusion of impurities into silicon than dislocation density. Several new pit patterns produced by the Dash etch technique are reported and photographs of these are shown. Distribution of impurities appears to be much more structure sensitive than do diffusion rates. An error function complement distribution seems to be closely followed by boron diffusion into silicon under reducing conditions. Silicon surface preparation and properties have been investigated in their relation to diffusion. Flat, damage-free surfaces have been produced by the use of garnet abrasives and special etches. Surface damage of less than a μ appeared to give a 20% faster diffusion rate than an etched surface for a penetration depth of about 90 μ . Junction staining techniques consistently have given 10% higher values for diffusion depth than the sheet resistance and incremental lapping method. The effects of diffusion and heat treatment were studied as they relate to the resistivity, minority carrier lifetime, and structural perfection of silicon. Both p- and n-type silicon showed resistivity increases; the former indicated donor increases up to 10^{15} cm^{-3} , the latter gave acceptor increases in the $10^{13} - 10^{14} \text{ cm}^{-3}$ range. Lifetime after diffusion at 1200°C was severely degraded to less than 1 μsec in most instances, although 6 - 12 μsec were retained in one sample after a particular heating cycle. The structure of diffused silicon appears to be far more imperfect than either heat-treated silicon or virgin (as grown) silicon. Known impurity-dislocation interaction and preliminary experiments suggest that contaminants in raw silicon are still an unknown variable. (Contractor's abstract)

RESEARCH ON SOLID STATE DIFFUSION IN SEMI-CONDUCTOR MATERIALS, by T. J. La Chapelle. Final technical rept. II. Aug. 1, 1957-July 31, 1958, 52p. incl. illus. diagrs. table, refs. (Rept. no. 3000:5-10-F) (AFOSR-TR-58-122) (AF 18(603)117) AD 202923; PB 137815 Unclassified

A continuation of research (see item no. PAC.01:001) has indicated the relationships between structural perfection and the diffusion of impurities into the silicon lattice. High purity p-type Czochralski pulled ingots as

well as floating zone silicon were used in the studies. Diffusion of phosphorus from the elemental form was carried out at 1039, 1105 and 1155°C using a specially constructed Kanthal furnace. High precision techniques are described which were used for carrying out the analyses of incremental lapping and 4-point probe resistivity measurements of 3, 5 and 16 μ deep diffusions. Considerable effects on diffused junction depths were seen for a floating zone sample containing a high density of low angle tilt boundaries. All silicon having surface damage, in spite of careful lapping, produced abnormal impurity distributions which could not be matched to the expected error function complement curves. Etched, supposedly damage-free surfaces were still characterized by flatter impurity concentration vs. depth profiles than predicted, though not as pronounced as the unetched. In general, the diffusion coefficients for the μ -thin runs seemed to be at least a factor of 2 or 3 higher than the current literature. (Contractor's abstract)

CRYSTAL PLASTICITY. I. A THEORY OF GLIDE IN METAL CRYSTALS, by D. A. Aboav. Dec. 31, 1957, 61p. incl. diagrs. refs. (Technical note no. 1) (AFOSR-TN-58-170) (AF 61(514)1078) AD 152197 Unclassified

The object of this research was to seek a simple theory of glide in metal crystals. The known facts were first classified and an attempt made to distinguish the simple, or fundamental, facts from those attributable to secondary causes. It became apparent that, while many of the characteristic glide phenomena can be attributed to a break-up or "disintegration" of the crystal lattice, others, such as the work-hardening of hexagonal metals and crystal recovery, appear to leave the lattice undisturbed, and it is with these phenomena that this work is mainly concerned. The inadequacy of the classical theory of elasticity to account for these phenomena is briefly discussed and an attempt is made to describe them in terms of a geometrically perfect lattice whose elements are not identical. Each lattice-element is assumed to possess a characteristic property, its "state", in terms of which the internal energy, temperature and entropy are tentatively defined, and these assumptions are used as a basis for a theory of glide in metal crystals. The theory accounts qualitatively for the main glide phenomena such as the existence of a critical shear stress, work-hardening and recovery, and predicts a creep behavior closely resembling that observed in practice. The theory also predicts a dependence of critical shear stress of crystal size. The implications of the theory for future research are discussed and attention is particularly drawn to the importance of detailed microscopic examination of the surface of plastically deformed metal crystals. Also published in Nuovo Cimento, Series X, v. 6: 757-779, Oct. 1, 1957.

Solutions are sought for the problem of a 2-body (nucleon-nucleon) interaction in the S-state from the energy dependence of the experimental phase shift; a nonlocal separable central interaction is assumed. The interaction is given, in momentum space, by the solution of a Fredholm inhomogeneous integral equation of second kind. Explicit solutions were obtained when the energy dependence of the phase shift was exactly given by the shape-independent approximation. When the phase shift remained between 0 and π or between 0 and $-\pi$ in the whole range of variation of energy, results were similar to those obtained when a local interaction is assumed. If the physical system has no bound state, at most, one solution exists; with one bound state, there exists a one parameter set of solutions. If the energy dependence is not restricted, a solution can be obtained only if the energy values, where δ goes through $n\pi$, satisfy certain inequalities. The solutions, then obtained, are mathematically correct but their physical interest is questionable. (Contractor's abstract)

Also published in Nuovo Cimento, Series X, v. 7: 290-307, Feb. 1, 1958.

The failure of tensor forces to account for the shell-model spin-orbit coupling was considered a strong indication of the existence of elementary mutual spin-orbit forces in the 2-body interaction. Calculations were made of the nonmodified reaction amplitude for cases in which the exclusion effects were both neglected and included. In the spirit of Brueckner's theory, computations were made of the many-particle terms of a perturbation series of the 2-body reaction amplitude. Up

to the second order in the interaction, only these terms occur if momentum is conserved in 2-body collisions. In the nuclear surface, terms could occur which do not conserve momentum; the question remains open as to whether such 3-particle terms are important in heavier nuclei.

NUCLEON - NUCLEON SCATTERING AT HIGH ENERGY, by M. Gourdin. [1957] 33p. incl. diags. refs. (Technical note no. 7) (AFOSR-TN-57-683) (AF 61(514)1060) AD 136678; PB 133339
Unclassified

Also published in Nuovo Cimento, Series X, v. 7: 338-364, Feb. 1, 1958.

The nucleon-nucleon scattering and polarization experiments cannot be explained by a simple local potential. This method gives good results in the low energy domain. But between 0 and 300 mev, for example, it is well known that the Schrödinger equation is inadequate. It is necessary, at high energies, to use a completely covariant formulation for two body systems - the Bethe and Salpeter equation [Phys. Rev., v. 84: 350, 1232, 1951] - in order to take into account relativistic corrections. With an analytic continuation of the scattering amplitude for the imaginary values of relative time (or relative energy), we can generalize the method of partial waves to a four dimensional euclidian problem. It is shown that, in the simplified case of spinless particles (Klein-Gordon particles), the physical phase shifts corresponding to a given value of the orbital angular momentum are easily obtained. For the more realistic case of spin $\frac{1}{2}$ particles (Dirac particles) it is possible to calculate the differential cross section. Explicit solutions are obtained with an approximate method of resolution for the integral equations. Further, one can determine the value of the coupling constant that gives the correct experimental neutron-proton singlet scattering length, in the case of the "ladder approximation". The δ phase shift,

PAR.01:005; PAR.02:001

calculated for various values of the energy, exhibits a change of sign in the energy region of 140 mev. This result is in agreement with the experiments and the "hard core" theory of Levy [Phys. Rev., v. 81: 165, 1951; v. 86: 806, 1952; v. 88: 72, 725, 1952]. (Contractor's abstract)

NUCLEON-ANTINUCLEON FORCES IN THE INTERMEDIATE COUPLING THEORY, by M. Lévy. [1958] 53p. incl. diagrs. tables, refs. (Technical note no. 8) (AFOSR-TN-58-168) (Also bound with its AFOSR-TN-59-224; AD 211606) (AF 61(514)1060) AD 152195
Unclassified

Also published in Nuovo Cimento, Series X, v. 8: 92-134, Apr. 1, 1958.

A semi-phenomenological approach to meson theory is used in order to calculate the nucleon-antinucleon complex interaction responsible for the scattering and annihilation of antinucleons in hydrogen. It is assumed that the main part of the imaginary potential is due to processes involving virtual annihilation into an arbitrary number of mesons, all of them but one being emitted or absorbed in a p-state. An effective Hamiltonian is derived for such processes, from which a static interaction can be calculated with the nucleon and antinucleon being treated as fixed sources. The intermediate coupling theory of Tomonaga is extended to the two-body problem and applied first to the calculation of ordinary nuclear forces and of the real part of the nucleon-antinucleon interaction. The annihilation Hamiltonian is then treated approximately by the intermediate coupling method. The imaginary part of the potential is found to have a range of the order of 2 to 3×10^{-13} cm, beyond which it becomes a weakly oscillating function of the nucleon-antinucleon distance. The physical meaning of this result is discussed, as well as the effects which would tend to sharpen the definition of the emitted pions multiplicity. In particular, a method is proposed to investigate, in the framework of the intermediate coupling theory, the influence of the excited states of the nucleon-antinucleon system. Also published in Nuovo Cimento, Series X, v. 8: 699-707, June 1, 1958.

The determination of a phenomenological separable interaction fitting the energy dependence of a phase shift δ which is obtained from the experimental study of a collision problem can be reduced to the problem of finding the solution of an integral equation. The method of Muskhelishvili as applied by Ommnes has been used to solve this integral equation for the problem of one meson production by mesons. The interaction in momentum space is given by an expression containing only one integral. The results obtained in a previous paper (PAR.01:001) concerning the existence and multiplicity of the solutions are confirmed. The method is checked by an explicit calculation for the case when the phase shift is exactly given by the shape independent approximation.

Also published in Nuovo Cimento, Series X, v. 8: 485-496, May 1, 1958.

The nucleon-antinucleon cross-sections at 167 mev were computed with 2 complex potential well models. Yukawa shaped complex wells were first studied in Born approximation. A semi-theoretical potential was analyzed on the digital computer IBM 704. The real part of his potential is the Signell and Marshak potential, adapted to the nucleon-antinucleon problem, and the imaginary part, a Yukawa phenomenological well. In order to account for the experimental large total cross-section and small scattering cross-section, it appears necessary to choose a weak real potential and an imaginary potential having a range at least equal to the usual nuclear force range. The fixed source meson theory leads to a real potential, which is much too strong and does not predict an imaginary potential at all; this theory cannot account for the experimental results. A study is made of the extent to which the correlations between protons in nuclear matter manifest themselves in the scattering of high-energy electrons from nuclei. The infinite-order Born is summed, so that dispersion effects that arise from excitation of virtual intermediate nuclear states are included to all orders. Use is made of a high-energy approximation developed earlier, and of the static or adiabatic approximation for the nuclear protons, and these are justified for incident electrons; their validity for nucleon scattering is also discussed. Expressions for the large-angle elastic and inelastic differential scattering cross sections are obtained in this way. It is then shown that correlation effects are difficult to identify so long as the final nuclear state is well-defined. On the other hand, if a sum over final states is carried out, the effects of short-range correlations between protons appear in a characteristic way in the summed differential cross section. These results are in qualitative agreement with those obtained earlier by others on the basis of the first and second Born approximation. (Contractor's abstract)

THEORY OF HIGH-ENERGY POTENTIAL SCATTERING, by D. S. Saxon and L. I. Schiff. [1957] 16p. (Technical note no. 5) (AFOSR-TN-57-509) (Also bound with its AFOSR-TN-57-745; AD 136732) (AF 61(514)1061) AD 136494 Unclassified

Presented at meeting of the Amer. Phys. Soc., Boulder, Colo., Sept. 5-7, 1957.

Abstract published in *Bull. Amer. Phys. Soc., Series II, v. 2: 313, Sept. 5, 1957.*

Also published in *Nuovo Cimento, Series X, v. 6: 614-627, Sept. 1, 1957.*

A new formulation for high-energy potential scattering, presented in a recent paper, is extended to provide explicit formulas for the scattering theory of the three-dimensional nonseparable Schrödinger equation. An integral equation is derived, for which a single iteration gives the scattering when the potential energy is not too large and is slowly-varying compared to a wavelength. The result agrees with those obtained earlier for small and for large scattering angles, but applies as well to intermediate angles and improves the earlier accuracy. Further iterations can provide greater accuracy as well as an error estimate for the first approximation. (Contractor's abstract)

ON THE VALIDITY OF LEVINSON'S THEOREM FOR NON LOCAL INTERACTIONS, by A. Martin. [1957] 25p. Incl. diagrs. (Technical note no. 6) (AFOSR-TN-57-672) (Also bound with its AFOSR-TN-57-745; AD 136732) (AF 61(514)1061) AD 136661 Unclassified

Also published in *Nuovo Cimento, Series X, v. 7: 607-627, Mar. 1, 1958.*

An artificial boundary condition on the one-dimensional wave function is used to compare the number of eigenstates of a non-local Hamiltonian to the number of free eigenstates, provided that the free and interacting eigenstates tend to coincide at high energies. Orthogonality of the wave functions lead to the inequality of the phase shifts $\delta(0) - \delta(\infty) \geq \pi\nu$, where ν is the number of bound states. For well behaved interactions the completeness of the eigenstates of non-local in Hamiltonian is demonstrated. It seems that the completeness of the eigenstates should lead to the inequality $\delta(0) - \delta(\infty) \leq \pi\nu$ and thus to the Levinson theorem $\delta(0) - \delta(\infty) = \pi\nu$. However the possible degeneracy of the wave function for positive energies must be taken into account. Levinson's theorem is modified to the following: $\delta(0) - \delta(\infty) = \pi$ (total number of eigenstates with vanishing asymptotic form). In this group there may be some states with positive energy. Application of these results to the Low equation is discussed.

TECHNICAL REPORT OF RESEARCH PERFORMED BETWEEN OCT. 1, 1956 AND SEPT. 30, 1957 [57]p. Incl. diagrs. refs. (AFOSR-TN-57-745) (AF 61(514)1061) AD 136732 Unclassified

The general approach to high energy scattering has been extended by Schiff to treat scattering of 200 mev electrons from heavy nuclei. The scattering amplitude is found to depend on the proton coordinates and is therefore an operator on the nuclear wave functions. Proton correlations show up only in a sum of the differential cross-section over final states. Saxon and Schiff have extended the scattering amplitude expressions to include intermediate angles. A. Martin has investigated the Levinson theorem for non-local interactions and has shown that it is necessary to alter the theorem.

HEAT TRANSFER AND SKIN FRICTION OF YAWED

INFINITE WINGS WITH LARGE SUCTION, by H. G. Lew and J. B. Fanucci. Nov. 1956 [40]p. incl. diagrs. (Technical rept. no. 8) (AFOSR-TN-57-63) (AF 18(600)575) AD 120404
Unclassified

The flow over yawed infinite bodies with large suction is considered. Both the compressible and incompressible cases are treated. Some simple relations are determined for the skin friction coefficient and heat transfer coefficient variations with the pressure gradient, suction and sweep back parameters. In addition, a modified Reynolds analogy for the compressible case is obtained. In the compressible case, it is determined that the skin friction ratio varies linearly with the pressure gradient parameter β , the sweep back factor ω and the heat transfer parameter S_0 up to and including the $(1/k^2)$ term where k is proportional to the magnitude of the suction velocity. Moreover, the Reynolds analogy $C_{f, eo}/N_u$ to this order of approximation varies linearly with the sweep back parameter ω for any given value of S_0 , k , and β . For very large suction $C_{f, eo}/N_u$ is approximately 2. The effect of yaw for the stagnation point flow is to decrease the ratios of three to two dimensional coefficients of chordwise skin friction and heat transfer. The heat transfer coefficient h_t is decreased considerably by increasing sweep back. In the incompressible case, the spanwise skin friction coefficient is affected by the pressure gradient parameter β only if $(1/K^4)$ or higher order terms are considered, whereas the chordwise skin friction coefficient contains β linearly in the $(1/K^2)$ term. EFFECT OF YAW ON BOUNDARY LAYERS AT HIGH SPEEDS, by H. G. Lew and J. B. Fanucci. Nov. 1956 [52]p. incl. diagrs. tables, refs. (Technical rept. no. 9) (AFOSR-TN-57-221) (AF 18(600)575) AD 126519
Unclassified

The flow over yawed infinite wings in a compressible fluid have been considered with heat transfer at the surface. The main results are the wall shear, heat transfer coefficient, and the modified Reynolds analogy variations with sweepback. It is found that the modified Reynolds analogy $C_{f, eo}/N_u$ increases if the pressure gradient parameter $\beta > 0$ and decreases if $\beta < 0$ with increasing values of yaw and the heat transfer at the wall. The effects of yaw and heat transfer at the wall on the wall shear parameters and the heat transfer parameter are similar: for $\beta > 0$ these parameters are increased and for $\beta < 0$ (to $\beta = 0.1$) they are decreased if the yaw and heat transfer are increased at the wall. A

comparison of these results utilizing the expansions in S_0 and ω , wherever possible, shows that for the usual range of these variables the present method is sufficient for most purposes. It is suggested that the ranges for these parameters be $0 < \omega < 0.5$ and $|S_0| < 0.4$ which encompasses a large practical range of yaw angle, free stream Mach number, and heat transfer at the wall as discussed in the text. The results for the stagnation point flow ($\beta = 1$) show that the heat transfer coefficient is decreased considerably by sweepback. For $\omega = 0$ the two-dimensional results are recovered and these compare very favorably with the more exact calculations of Cohen and Reshotko even to the extreme values of $S_0 = \pm 1$. Thus, this method should be of considerable use for two-dimensional problems. (Contractor's abstract)

BOUNDARY LAYER PROBLEMS, by H. G. Lew and J. B. Fanucci. Final rept. June 1957, 12p. (Rept. no. 12) (AFOSR-TR-57-38) (AF 18(600)575) AD 132394
Unclassified

Research was undertaken to make a critical study of the existing theoretical work on boundary-layer control and to study several problems of importance in the boundary-layer field. The majority of the problems which were considered were related to the behavior of the boundary layer under the influence of a small normal velocity at the boundary, i.e., porous suction or porous injection. Three-dimensional effects in the boundary layer were studied. The effect was determined of transverse curvature of flows over bodies of revolution in cases where the boundary-layer thickness may be of the same order of magnitude as the radius of the body. Some preliminary experimental work was done in determining the optimum suction distribution which may be used to eliminate the separation of the boundary layer. Abstracts of previous papers are also included.

[CHEMISTRY OF BORON COMPOUNDS] by T. Wartik, H. Bowkley and others. Final rept. [1957] 3p. (AF 18(600)311; continued by AF 49(638)86) Unclassified

The studies carried out under this contract involve the determination of some of the thermodynamic properties of certain boron compounds and a study of the chemistry of certain boron-containing substances. The heat capacities of diboron tetrachloride were measured over the range from 13.43°K to 214.51°K. In addition, the heat of fusion, melting point, and vapor pressures over the region from 227.9°K to 272.94°K were determined. The Raman spectrum was determined for the liquid at $35 \pm 5^\circ\text{C}$, and the infrared spectrum was obtained for gas at room temperature. These results, in conjunction with infrared measurements in the low frequency region made at the Bureau of Standards, were used to calculate a potential barrier to internal rotation of the diboron tetrachloride molecule. The heat capacities of tetraborane (B_4H_{10}) were measured in the region from 13.37°K to 170.21°K. In addition, the heat of fusion, melting point, and vapor pressures in the region from 176.08°K to 216.08°K were determined. The reducing action of complex hydrides on carbon-sulfur compounds was studied, both in the presence and absence of solvent. In all cases, sym-trithiane (the trimer of thioformaldehyde) was the major carbon-containing product. In most cases, stoichiometries differing somewhat from integral ratios were encountered, and, on the basis of product distributions, reaction schemes involving parallel processes have been proposed. A relatively short time was devoted to a study of possible improvements in the discharge process for the preparation of diboron tetrachloride. In addition, measurements of the stability of diboron tetrachloride at room temperature were carried out. The production of boron-containing polymers through discharge-tube reactions between boron halides and carbon monoxide was investigated. With trichloroborane, a material of the composition $(\text{BCl}_3 \cdot 2\text{CO})_x$ resulted. This material acted as a thickening agent for water, and its chlorine content was not readily hydrolyzable.

DISCHARGE-INDUCED REACTIONS OF BORON HALIDES WITH SOME NONMETALLIC OXIDES, by R. M. Rosenberg and T. Wartik. [1958] 153p. incl. diagrs. tables, refs. (AFOSR-TN-58-979) (AF 49(638)86; continuation of AF 18(600)311) AD 206769 Unclassified

An investigation was undertaken of the discharge chemistry of B compounds in order to understand the behavior of these substances and to develop new or improved synthetic methods. The behavior of the trihalides of B (except the triiodide) and of diboron tetrachloride, separately and in the presence of nonmetallic oxides, was investigated in an ozonizer-type discharge. Of the 2-component systems, trichloroborane (BCl_3)-CO was examined most extensively. The major discharge product from the reaction of $2\text{BCl}_3 + \text{CO} \rightarrow \text{B}_2\text{Cl}_4 + \text{COCl}_2$ was a nonvolatile film deposited on the discharge tube walls. The reaction of BCl_3 and CO_2 produced a solid which contained no C and which was deposited on the tube walls. Discharge studies of the single components, CO, CO_2 , SO_2 , and N, were used to establish the behavior of these pure substances in the type of apparatus used in these investigations. The systems BF_3 -CO and BBr_3 -CO were also studied. The order of stability with respect to reaction in the discharge was $\text{BF}_3 > \text{BCl}_3 > \text{BBr}_3$. The reaction of C_3O_2 and BCl_3 produced a

mixture of polymerized C_3O_2 and a $C_3O_2-BCl_3$ adduct, the latter bearing little physical or chemical resemblance to the $CO-BCl_3$ film. A new method was developed which permitted the determination of B, Cl, and C from a single sample of a compound containing these elements. (ASTIA abstract)

FIELD DESORPTION BY ALTERNATING FIELDS. AN IMPROVED TECHNIQUE FOR FIELD EMISSION MICROSCOPY, by E. C. Cooper and E. W. Müller. [1958] [4]p. incl. illus. diags. refs. (AFOSR-TN-57-738) (AF 18(600)672) AD 202329 Unclassified

Also published in Rev. Scient. Instruments, v. 29: 309-312, Apr. 1958.

The inclusion of field desorption in field emission microscopy yields additional information on adsorption systems and easily produces clean surfaces of metal tips without the application of heat. An alternating field technique is described using a dc-biased ac power supply for providing the desorption field during the positive portion of the cycle and allowing the observation of the field electron image during the negative portion. Ion and electron current during one cycle are calculated for a tungsten tip. Patterns from clean nickel, iron, and copper are shown. (Contractor's abstract)

PSEUDOSPIRALS, IMPERFECT STRUCTURES AND CRYSTAL HABIT PRODUCED BY FIELD EVAPORATION OF METAL CRYSTALS, by E. W. Müller. Oct. 18, 1957, rev. Feb. 24, 1958 [11]p. incl. illus. refs. (Technical rept. no. 7) (AFOSR-TN-57-739) (AF 18(600)672) AD 211081 Unclassified

Also published in Acta Metallurgica, v. 6: 620-630, Sept. 1958.

Spiral-like structures are frequently observed when the tip of a field emission microscope is subjected to field evaporation at elevated temperatures. Close inspection of tips of various metals with the field ion microscope reveals that these structures are pseudo spirals, appearing as a result of eccentric bunching of complete low index net planes, without requiring the presence of a screw dislocation. The extremely large stress of the field causes various dislocations to move towards and

to pile up at the surface, where they can be seen in the ion image. A picture is shown of the atomic arrangement at a low angle twin boundary in a tungsten crystal parallel to the [100]-zone. Field evaporation carried out at temperatures below the range where imperfections can move to the surface may yield perfect surfaces. Their habit is characterized by a rounded-off shape, with the radius curvature varying in the same sense as the work function of the particular crystallographic region. The field strength for evaporation of tungsten at practically zero temperature is measured to be

1×10^9 v/cm on the 111 plane and 8×10^8 v/cm on the 011 plane, in agreement with the theory. Crystal surfaces, as obtained by low temperature evaporation at slightly lower field strengths, are also shown for platinum, iridium and rhenium. (Contractor's abstract)

AN ATTEMPT TO DETECT POLARIZATION OF FIELD EMITTED ELECTRONS, by W. T. Pimbley and E. W. Müller. [1957] [1]p. (AF 18(600)672) Unclassified

Presented at the Field Emission Symposium, Penn. State U., University Park, June 27-29, 1957.

Under certain conditions, it is conceivable that the electrons emitted from a field emission tip are polarized. An experiment designed to detect such a polarization is described. Mott relativistic scattering of electrons from heavy nuclei is used to detect the polarization. The tube has a provision for electrostatically shifting the image of the emitter surface in two coordinates over a probe hole in the screen, so that, for example, each corner of a molecule quadruplet can be examined separately. The electron beam is then accelerated to above 100 kv and scattered from a gold foil. The distribution of the scattered electrons is recorded photographically with the help of a cylindrical fluorescent screen. Results are expected as soon as some difficulties from spurious emission between the accelerator electrodes are overcome. (Contractor's abstract)

NEW TECHNIQUE FOR FIELD EMISSION MICROSCOPY OF NON-REFRACTORY METALS (Abstract), by E. C. Cooper and E. W. Müller. [1957] [1]p. (AF 18(600)672) Unclassified

Presented at the Field Emission Symposium, Penn. State U., University Park, June 27-29, 1957.

PSU.05:009 - PSU.05:011

Field desorption is an effective means of perfectly cleaning the surface of a field emitter. If the field emission microscope is operated with ac, it is possible to observe the progress of field desorption by increasing the positive half wave independently from the image forming negative half wave. A power supply for these requirements is described. The method allows the study of the dynamics of field desorption of surface films. The binding force to the substrate can be gradually reduced to zero, while the mutual attraction of the adsorbed particles remains essentially unchanged. As an example the desorption of hydrogen and nitrogen from iridium and the effect of the cohesive forces within the film is shown. The production of perfectly clean surfaces by controlled field evaporation of several surface layers of the tip metal itself makes it possible to easily obtain patterns from soft metals like nickel, iron, and copper as well as high melting metals. The patterns obtained by field evaporation are slightly different from the common annealed form because of perfect development of high index planes and a local field enhancement factor specific to the various crystal planes.

RECENT WORK IN FIELD ION MICROSCOPY (Abstract), by E. W. Müller. [1957] [1]p. (AF 18(600)672)
Unclassified

Presented at the Field Emission Symposium, Penn. State U., University Park, June 27-29, 1957.

An experimental study of the resolution under various conditions shows that by far the best results are obtained with helium ions and liquid hydrogen cooling. Rows of adjacent atoms with 2.74Å separation are resolved on the 111-zone lines of tungsten. For demonstration purposes the helium ion microscope can be cooled by liquid nitrogen or better solid nitrogen, and still resolves the single lattice steps and individual atoms on high index planes. With hydrogen ions one needs only half the field strength, so that metals as soft as copper can be observed. However, the resolution at 21°K is not better than 4.5Å. There seems to be only a slight improvement when the temperature is lowered to 13°K. Deuterium ions give better resolution than hydrogen ions, but difficulties arising from adsorption are inconvenient. A number of pictures of tungsten and rhenium surfaces with various degrees of disorder, from cold worked and otherwise disturbed structures over field produced pseudo spirals to high annealed and field desorbed perfect surfaces are discussed. Work with the helium ion microscope is facilitated by a new design with easily replaceable tips.

STUDY OF MOLECULE PATTERNS IN THE FIELD EMISSION MICROSCOPE (Abstract), by A. J. Melmed and E. W. Müller. [1957] [1]p. (AF 18(600)672)
Unclassified

Presented at the Field Emission Symposium, Penn. State U., University Park, June 27-29, 1957.

Since the nature of molecule patterns is still not understood, a series of experiments was carried out to find new facts. The best substance, experimentally, was phthalocyanine. Cooling the tip with liquid nitrogen or liquid hydrogen gives extremely clear and stable patterns, and almost always quadruplets on clean tungsten at low coverages. There is a distinct preference of adsorption sites with respect to the crystal planes of the substrate, and perfect alignment of the molecule patterns with the lattice direction. Appearance and orientation depend upon lattice constant and crystal structure of the substrate as investigated with W, Ta, Re, and Ir. The effect of high field strengths on the stability (persistence) was observed as a preparation for depicting the molecules with the field ion microscope. Superimposed electron and ion images of phthalocyanine were observed using an alternating current method. Some hydrogen ion images were photographed showing small doublets where the electron images were large doublets.

ATOMS VISUALIZED, by E. W. Müller. [1957] [10]p. incl. illus. diags. [AF 18(600)672] Unclassified

Published in *Scient. Amer.*, v. 196: 113-122, June 1957.

This paper shows that the field ion microscope makes pictures of atoms in a metal crystal by accelerating positive ions from a fine needle of the metal to a fluorescent screen. An actual photograph is shown of individual atoms - tungsten atoms on a needle tip a thousand times finer than the tip of an ordinary pin. The photograph was taken by an instrument (the field ion microscope), which is an improved version of the field emission microscope that was introduced by the author in 1936. A description of the field emission microscope and results of its usage are presented. The principal features of the field ion microscope (a modification of the field emission microscope) are discussed and depicted diagrammatically. The new techniques employed in observing atoms have permitted one to study metals at the atomic level with a precision never before possible. So far, good images have been obtained only of

PSU.05:012 - PSU.05:015

metals such as tungsten, rhenium, tantalum and molybdenum and some of the thin highly refractory alloys—carbides and alloys. The technique at present is limited to the very hard metals.

[OPERATING CONDITIONS OF THE LOW TEMPERATURE-FIELD ION MICROSCOPE] Betriebsbedingungen des Tieftemperatur-Feidionenmikroskopes, by E. W. Müller. [1957] [7p. incl. illus. diagr. [AF 18(600)672] Unclassified

Published in Ann. Physik, v. 20: 315-321, July 15, 1957.

Two methods are described for the measurement of the longitudinal and transverse nuclear paramagnetic relaxation time. It is shown that the technique known as the Hahn spin-echo method allows measurement of the longitudinal relaxation time over a practically unlimited region after long times, while for the measurement of the transversal relaxation time the self diffusion sets an upper limit. The influence of the self-diffusion is eliminated through the use of impulses of definite breadth and intensity by Carr-Purcell's method, by means of which arbitrarily long times become measurable. In contrast to the Hahn method the measurement is strongly dependent upon small readjustments, which makes the measurement of relaxation times less accurate.

STUDY OF PHTHALOCYANINE AND SOME OTHER PLANAR MOLECULES IN THE FIELD EMISSION MICROSCOPE, by A. J. Meimed. July 1958, 68p. incl. illus. diagrs. table, refs. (AFOSR-TN-58-646) (AF 18(600)672) AD 162178 Unclassified

Also published in Jour. Chem. Phys., v. 29: 1037-1041, Nov. 1958. (Title varies)

An improved technique for studying organic substances in the field emission microscope is described, in which the field emitter is kept at a low temperature during observations. Field emission patterns of organic molecules such as phthalocyanine or flavanthrene show improved stability when the tip temperature is lowered. No prior contamination or buildup is necessary for the production of typical quadruplet or doublet patterns. Upon heating or ion bombardment the molecule patterns may disappear in several distinct steps of size and intensity. On the average 13 phthalocyanine or 2 flavanthrene molecules must strike the tip to produce one pattern. These observations suggest that the substances

studied here evaporate and arrive at the tip as polymerized units consisting of two to six molecules. Field desorption and hydrogen ion images of Cu-phthalocyanine on tungsten and platinum are investigated. Finally, a mechanism for molecular image formation is proposed. (Contractor's abstract)

THEORETICAL AND EXPERIMENTAL TOTAL-ENERGY DISTRIBUTION OF FIELD EMITTED ELECTRONS, by R. D. Young. Dec. 1958, 44p. incl. diagrs. tables. (Technical rept. no. 9) (AFOSR-TN-58-1136) (AF 18(600)672) AD 208085 Unclassified

Also published in Phys. Rev., v. 113: 110-114, Jan. 1, 1959.

The energy distribution measurement was employed to study the electronic band structure in metals and semiconductors. When the energy analyzer was improved to carry out this study, the measured energy distribution was much narrower than predicted by the existing normal-energy distribution theory. Further investigation revealed that the retarding potential energy analyzer employed measures the total electron energy rather than the energy associated with the component of velocity normal to the surface. The Fowler-Nordheim equation was derived in a new way to preserve the distribution in total energy of field emitted electrons. A similar derivation was made for thermionic emission. A striking mirror image symmetry was found between the normal-energy thermionic emission and the total-energy field emission energy distributions. A similar symmetry was noted between the total-energy thermionic and normal-energy field emission energy distributions. Further analysis indicated that the widths of the energy distributions are the same. This means that field emission and thermionic emission are on an equal footing in cases where energy distribution contributes to vacuum tube noise or to chromatic aberration in electron optics. Energy distribution measurements at liquid hydrogen, liquid nitrogen and room temperature were found to agree with the new theory. (ASTIA abstract)

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 69, Jan. 29, 1958.

Low-temperature field evaporation of refractory metal tips produces the cleanest surfaces of atomically perfect smoothness. Unlike the heat of vaporization of neutral atoms, the work to remove ions from a surface depends upon the crystallographic orientation because of the variation of the thermionic work function. The habit of the end form of a field evaporating metal crystal is characterized by a rounded off shape with the radius of curvature varying in the same sense as the work function of the considered region. At practically zero temperature, the actual field strength for evaporation of tungsten ions from the 111 plane is measured to be 1 billion v/cm, and for the 110 plane, 800 million v/cm, in agreement with the image force theory. High resolution ion microscope pictures of field evaporated surfaces of tungsten, rhenium, iridium, platinum, and platinum-rhodium alloy with either perfect or imperfect structures are presented. The controlled evaporation at 21°K of individual atoms and single net planes of a platinum crystal will be shown in a short 16-mm movie film.

EXTREME STRESS CONDITIONS AT THE TIP CRYSTAL OF THE FIELD ION MICROSCOPE (Abstract), by E. W. Müller. [1958] [1]p. [AF 18(600)672] Unclassified

Presented at meeting of the Amer. Phys. Soc., Ithaca, N. Y., June 19-21, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 265, June 13, 1958.

The tip crystal in a field ion microscope is under a radial stress of 10^{11} dynes/cm² or more. If dislocations are absent, this stress does not exceed the strength of W, Re, Mo, Ta, Ir, Pt, Zr, Si, and C and perhaps a few other metals. The limitation for the observation in the FIM is set by field evaporation of individual ionized surface atoms, the rate of evaporation becoming rather fast towards the end of the foregoing list when He ions are used. Since the radial stress can also be considered as a negative pressure of 10^5 atm, regional phase transitions to a lower density lattice might occur. If dislocations are introduced, the gradient of stress towards the shank may cause slip, since in general the slip planes are inclined to the tip axis. This is not true for rhenium, where the basal plane as the only slip plane was always found to be parallel to the tip axis. Motion of dislocations and slip of parts of the crystal can be

observed continuously in high resolution while the stress is made alternating by superimposing an ac component to the dc field. This is a novel method for studying fatigue.

FIELD ION MICROSCOPE IMAGES OF PLATINUM SURFACES (Abstract), by E. W. Müller. [1958] [1]p. [AF 18(600)672] Unclassified

Presented at meeting of the Electron Microscope Soc. Amer., Santa Monica, Calif., Aug. 7-9, 1958.

Published in Jour. Appl. Phys., v. 29: 1625, Nov. 1958.

Although platinum is not a metal with a very high melting, the rate of field evaporation of Pt ions is relatively low because of its high ionization potential. It is therefore possible to obtain steady high-resolution helium ion images of perfect crystals and of surfaces with dislocations.

STUDY OF ATOMIC STRUCTURE OF METAL SURFACES IN THE FIELD ION MICROSCOPE, by E. W. Müller. Mar. 1957, 6p. incl. illus. diags. refs. (Technical rept. no. 3) (AFOSR-TN-57-120) (AF 18(600)673) AD 120474 Unclassified

Also published in Jour. Appl. Phys., v. 28: 1-6, Jan. 1957.

Details of the image formation in the low temperature field ion microscope are discussed. The hopping height of the rebounding gas atom, which depends on the atom's polarizability, the tip temperature, tip radius, and field, is significant for the resolution. Photographs of tungsten and rhenium surfaces with the atomic lattice resolved and in different states of disorder are presented. A color printing technique, which permits finding quickly a few displaced atoms among the many thousand that are visible, is described.

Published in Zeitschr. Krist., v. 109: 29-41, July 1957.

Crystals of pyridinium reineckate, $C_5H_5NH \cdot [Cr(NCS)_4(NH_3)_2]$, are monoclinic with space group A2/a. The unit cell has dimensions $a = 15.52 \text{ \AA}$; $b = 7.64 \text{ \AA}$; $c = 14.64 \text{ \AA}$; $\beta = 102.4^\circ$, and contains four formula units. The structure was determined by the use of two-dimensional Fourier syntheses. The chromium atom of the reineckate radical is at a center of symmetry. The pyridinium ion, which lies on the two-fold axis, is surrounded by twelve sulfur atoms. Four of the sulfur atoms coordinate to the pyridinium nitrogen, with two distances of 3.36 \AA and two of 3.80 \AA . Mean values of bond lengths in the reineckate ion are Cr - N, 1.95 \AA ; N - C, 1.15 \AA ; C - S, 1.76 \AA . Distances within the pyridinium ion are C - C, 1.40 \AA ; C - N, 1.35 \AA . The x-ray crystallography of a few other organic-base reineckates is reported. (Contractor's abstract)

X-RAY AND THERMAL STUDIES OF ORDER-DISORDER PHASE TRANSITIONS IN SOME COMPLEX-ION SALTS (Abstract), by N. [R.] Stemple, Y. Okaya and others. [Nov. 1957] [2]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(800)1556 and Signal Corps Engineering Labs. under DA 36-039-sc-72385) Unclassified

Presented at Pittsburgh Diffraction Conference, Pa., Nov. 6-8, 1957.

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 59, Jan. 29, 1958.

New order-disorder transitions have been found in the cubic crystals of $[Co(NH_3)_6](ClO_4)_3$, $[Co(NH_3)_6](BF_4)_3$, $[Co(NH_3)_6]SO_4Br$, and $[Co(NH_3)_5H_2O](ClO_4)_3$. In these, the large complex ion dominates the packing of the structures, and the smaller ions have some freedom in position and orientation. The transitions have been examined optically, by x-rays, and thermally. The ordered phase has a superstructure lattice with cell constant twice that of the disordered phase. Remaining short-range order in the disordered phase is studied by means of diffuse scattering in stationary-crystal photographs

taken with filtered $CuK\alpha$ radiation. The transitions are discussed thermodynamically. Similar studies are reported for other $[Co(NH_3)_6]^{+++}$ salts.

X-RAY ANALYSES OF SOME COMPLEX-ION STRUCTURES, by Y. Okaya, R. Pepinsky and others. [1957] 14p. incl. tables. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(800)1556, National Institutes of Health, and Office of Naval Research) Unclassified

Published in Acta Crystallographica, v. 10: 798-801, Dec. 10, 1957.

The crystal structures or symmetries of a variety of complex ion compounds are presented. The substances include: (1) Cr and Fe hexaurea complexes, (2) sodium cobaltinitrite and sodium nitroprusside dihydrate, (3) hexamminecobalt (III) salts, (4) the *cis* and *trans* dinitrobisethylenediamminecobalt (III) nitrate, (5) $K_3Co(CN)_6$ and related salts, (6) cupric and nickelous glycinate, (7) tetrahalogeno divalent-metal alkyl amines, (8) d-tris ethylenediamine cobalt (III)-halide-d-tartrate- $5H_2O$, and (9) "engineered" crystals. A table listing 20 engineered crystals is given and it is concluded that the packing in these crystals is controlled chiefly by the large complex ions and that the organic ions fill in spaces between these ions. Furthermore by properly matching the ionic sizes and shapes, charges, dipolar character, solubilities, etc. it is possible to exert a good deal of control over the arrangement of the organic ions within the crystal.

THERMAL AND X-RAY STUDIES OF ORDER-DISORDER PHASE TRANSITIONS IN SOME CUBIC HEXAMMINE-COBALT (III) SALTS, by N. R. Stemple. June 1957 [48]p. incl. illus. diagrs. refs. (Technical rept. no. 4) (AFOSR-TN-58-330) (AF 18(600)1556) AD 154234 Unclassified

New order-disorder transitions were found in the cubic crystals of the $[Co(NH_3)_6]^{+++}$ ion and the ions ClO_4 , BF_4 , and SO_4Br for which thermodynamic properties are discussed. These transitions are similar to those found in the "engineered" crystals of Pepinsky, and in AgI and Ag_2HgI_4 , where large ions also dominate the packings

PSU.07:012; PSU.08:010-012

of the structure and smaller ions have some freedom in their positions. The transitions were studied both by x-ray and thermal measurements. It is established that the ordered phase has a superstructured lattice with the cell constant twice that of the disordered phase. Remaining short-range order in the disordered phase is also studied by means of the maxima in the diffuse areas of Laue photographs taken with filtered $\text{CoK}\alpha$ radiation. The behavior of these maxima was found to be similar to that in binary alloys. (Contractor's abstract, modified)

SCHEME FOR MICROCHEMICAL IDENTIFICATION OF ALKALOIDS, PARTS I AND II, by F. Amelink, tr. by M. L. Willard, ed. by R. Pepinsky and J. Lombard. Feb. 1, 1957, 2v. incl. diags. tables, refs. (Technical rept. no. 3) (AFOSR-TN-58-331) (AF 18(600)1556) AD 154235 Unclassified

This work deals with the problem of identification of alkaloids and related synthetic medicinals by means of microchemical reactions. The presentation of a simple scheme for identification is a major contribution to the subject area. The description of reagents and 8 general reactions including methods of crystallization precedes the treatment of 95 alkaloids. A few applications to plant materials are found at the end of the book. The translation emphasizes the aspects of (1) x-ray and crystal-chemical investigations of salts of organic ions and complex ions and (2) application of the principle of "engineered crystals" for preparation of crystalline organic compounds particularly suited to x-ray structure analysis. An extensive bibliography is included.

A BRIDGE FOR ACCURATE MEASUREMENT OF FERROELECTRIC HYSTERESIS, by H. Diamant, K. Drenck, and R. Pepinsky. [1957] [23]p. incl. illus. diags. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)35] and Signal Corps Engineering Labs. under [DA 36-039-sc-63233]) Unclassified

Published in Rev. Scient. Instruments, v. 28: 30-33, Jan. 1957.

A new instrument was designed for the undistorted display of ferroelectric hysteresis loops even in the presence of relatively high conductivity. The electrical characteristics of a sample are determined directly from dial settings and meter readings. The basic circuit

of the bridge may be described as two parallel Sawyer and Tower circuits, one containing the sample and the other containing resistors and capacitors for the compensation of conductivity and dielectric constant at saturation. The compensated hysteresis loop is displayed on an oscilloscope with the aid of a calibrated differential amplifier. The spontaneous polarization and the applied voltage, as well as the coercive field, are read on an electronic peak-voltmeter. An important feature of the bridge is that measurements are independent of the frequency and waveform of the applied voltage. (Contractor's abstract)

Presented at Fourteenth Pittsburgh Diffraction Conf., Oct. 31-Nov. 2, 1956, Paper no. 44.

Published in Phys. Rev., v. 105: 856-860, Feb. 1, 1957.

The atomic positions of ferroelectric BaTiO_3 in its orthorhombic phase have been determined by a single crystal neutron diffraction analysis. Pillar-shaped crystals with their major axes along the cubic [110] direction were maintained as single domains by the application of an electric field. The structure deduced can be viewed as a framework of slightly distorted oxygen octahedra, in which the central Ti ions are displaced towards one of the octahedron edges (polar axis) by 0.13A. The Ba ions are also shifted in the same direction but by smaller amount of 0.07A. A comparison of this structure with that of the tetragonal phase suggests the essential role of Ti in the ferroelectricity of this crystal as treated by Slater. (Contractor's abstract)

X-RAY AND NEUTRON STRUCTURE ANALYSIS OF FERROELECTRIC RHOMBOHEDRAL $\text{Pb}(\text{Zr}_{0.75}\text{Ti}_{0.25})\text{O}_3$ AT ROOM TEMPERATURE (Abstract), by F. Unterleitner, G. Shirane and others. [1957] [1]p.

(Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35, Signal Corps Engineering Labs., and Atomic Energy Commission) Unclassified

Presented at meeting of the Amer. Phys. Soc., Philadelphia, Pa., Mar. 21-23, 1957.

Published in Bull. Amer. Phys. Soc. Series II, v. 2: 127, Mar. 21, 1957.

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Also published in Bull. Amer. Phys. Soc., Series II, v. 2: 220, Apr. 25, 1957.

The solid solution $\text{Pb}(\text{Zr}_{0.75}\text{Ti}_{0.25})\text{O}_3$ is ferroelectric and rhombohedral at room temperature, and is cubic (perovskite) at higher temperature. No ferroelectric rhombohedral structure had been completely established heretofore. A powder x-ray analysis established heavy atom positions in this rhombohedral phase; oxygen positions were determined from a neutron powder pattern. The space group is $R\bar{3}m$, with cell constants $a = 4.11\text{\AA}$, $\alpha = 89^\circ 41'$. Atomic coordinates are: Pb at (δ, δ, δ) , with $\delta = 0.575$; (Zr, Ti) at (ξ, ξ, ξ) , with $\xi = 0.040$; O at $(\gamma, 0, 0)$, $(0, \gamma, 0)$, $(0, 0, \gamma)$ with $\gamma = 0.520$. The oxygen octahedra surrounding the (Zr, Ti) atoms are only slightly distorted, and atomic displacements are of the same order as in tetragonal ferroelectric PbTiO_3 .

ON SOME OLD, NEW AND YET-UNDISCOVERED FERROELECTRICS AND OTHER INTERESTING DIELECTRICS (Abstract), by R. Pepinsky. [1957] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35, Signal Corps Engineering Labs., and Atomic Energy Commission) Unclassified

Presented at meeting of Special Technical Conf. on Solid-State Dielectric and Magnetic Devices, (AIEE and IRE), Catholic U. of America, Washington, D. C., Apr. 22-23, 1957.

Eleven crystal-chemical classes of ferroelectrics and antiferroelectrics are presently known. A very brief account is given of what is known of the structures and the structural mechanisms of transitions in these crystals. Directions of research for new ferroelectrics and antiferroelectrics are outlined. These include some crystal-chemical criteria and their application; reports of some old and some new crystal transitions; likely materials to be examined; some useful experimental techniques; and reasons why the search for new ferroelectrics must continue. Some other interesting dielectrics are discussed.

FERROELECTRIC BEHAVIOR OF $\text{NH}_4\text{Fe}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ (Abstract), by F. Jona, K. Vedam and others. [1957] [1]p. (AF 18(603)35) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

A re-investigation of the dielectric anomaly which occurs in ammonium iron alum at low temperatures has been carried out. The dielectric constant is about 6 at room temperature, and rises to a sharp peak, of approximately 60, at -185°C . A large ac field applied along the cubic [100] direction causes the appearance of double hysteresis loops above and close to the transition point, indicative of a first-order ferroelectric transition, as observed in the case of BaTiO_3 . In a 60 cps electric field of 20 kv/cm, the double loops can be observed within a range of about 2°C above the transition temperature. Ferroelectric loops appear at and below the Curie point, but can only be observed in a temperature range 1 to 2° below the transition. The spontaneous polarization P_s is of the order of 0.3 microcoulomb/cm², and the coercive field about 20 kv/cm. At about 2° below the Curie point, the hysteresis loop collapses suddenly to a narrow

PSU.08:016 - PSU.08:018

ellipse. This indicates that the motion of the domain walls is hindered and the coercive field is far larger than the breakdown field. The behavior of the crystal under a strong ac field applied along the cubic [111] direction is such that the crystal acts if the transition were of the second order.

FERROELECTRICITY AND STRUCTURE OF TRI-GLYCINE FLUOBERYLLATE AND ISOMORPHS (Abstract), by R. Pepinsky, T. Okaya, and F. Jona. [1957] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Signal Corps Engineering Labs.) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 220, Apr. 25, 1957.

Tri-glycine sulfate and selenate have previously been observed to be ferroelectric and now tri-glycine fluoberyllate which is isomorphous has also been observed to be ferroelectric. The crystal is piezoelectric below the Curie temperature $T_c = 75^\circ\text{C}$. Other data reported are: coercive field is 5 kv/cm; the spontaneous polarization is $P_s = 3.2 \times 10^{-6}$ cb/cm²; space group is found to be $P2_1$ below the Curie temperature and $P2_1/m$ above; and the unit cell dimensions and angles are similar for all three substances. The x-ray intensities from the sulfate are essentially unaltered above and below T_c and the fluoberyllate shows differences, but the selenate shows stacking disorder along a , immediately above T_c . The crystal structure above T_c is such that one glycine and the inorganic anion are on a mirror plane and two glycines are mirrored across the plane. H-bonds are found to be responsible for maintaining the structure. The mirror symmetry, chiefly of H's, disappears below T_c , producing polarization along b . Optically-active amino acids only, and acid-unstable inorganic anions, cannot form isomorphous crystals.

THERMAL, DIELECTRIC AND OPTICAL STUDIES OF SOME NEW FERROELECTRICS, by D. R. P. Eastman, May 13, 1957, 43p. incl. diagrs. refs. (Sponsored jointly

by Air Force Office of Scientific Research under AF 18-(603)35, Signal Corps Engineering Labs., and Atomic Energy Commission) Unclassified

The dielectric, crystallographic, optical, and thermal properties of $(\text{NH}_4)_2\text{Cd}_2(\text{SO}_4)_3$ were measured in order to establish the thermodynamic character of the ferroelectric transition and to estimate the order of magnitude of the entropy change at the Curie point. At room temperature the crystal is cubic with $a = 10.360\text{\AA}$ and apparently belongs to the langbeinite class. The space group is $P2_13$ and there are 4 formula units per cell. The Curie point is at $95 \pm 2^\circ\text{K}$ and the spontaneous polarization along the [100] direction is $0.50 \mu\text{c}/\text{cm}^2$ near the transition temperature. The direction of the polar axis in the ferroelectric phase is along the [100] direction. Saturated ferroelectric loops can only be observed in a temperature range of 4 to 5 degrees below the Curie temperature. The coercive field at 91°K in the [100] direction is 9.5 kv/cm and increases rapidly for decreasing temperatures until at 90°K it exceeds the breakdown field. The heat of transition at the Curie point is the order of 10^3 cal/mole. Measurements of the thermal expansion indicate a contraction along the original cube axis as the point is passed from above. The symmetry of the low-temperature phase is very probably monoclinic.

X-RAY, OPTICAL, AND DIELECTRIC STUDIES OF THE LOW-TEMPERATURE TRANSITION IN SODIUM NIOBATE, by J. F. Johns, May 13, 1957 [30]p. incl. diagrs. refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35, Signal Corps Engineering Labs., and Atomic Energy Commission under AT(30-1)1516) Unclassified

The crystallographic structure of NaNbO_3 is investigated in the temperature region from -167°C to room temperature in order to provide a crystal model for this substance which has been reported to be both ferro- and antiferroelectric. The room temperature structure is found to be orthorhombic. At -167°C the structure is monoclinic with probable space group Cm . The c axial length is twice that of the pseudo-cubic cell. If the doubling of the c axial length is disregarded, then the structure can be interpreted as rhombohedral. At about -25°C a discontinuity occurs in the cell axial parameters and cell volume. A similar discontinuity occurs in the dielectric constant as well as a discontinuity at about -100°C . A model for the low temperature phase of the NaNbO_3 is presented. A second room temperature phase of the crystal is reported.

SOME NEW X-RAY AND NEUTRON STUDIES OF HYDROGEN BONDING (Abstract), by R. Pepinsky. [1957] [5]p. incl. diagr. refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35, Signal Corps Engineering Labs., and Atomic Energy Commission) Unclassified

Presented at Symposium on Hydrogen Bonding, Internat'l. Union of Pure and Appl. Chem. and Union of Chem. Soc. of Yugoslavia, Ljubljana (Yugoslavia), July 29-Aug. 2, 1957.

The structure of ferroelectric Rochelle salt has been solved by means of a joint x-ray and neutron analysis. The neutron analysis involves the use of maps constructed from the neutron scattering from the regular compound and one in which the hydrogen has been replaced by deuterium. The complete hydrogen bond system is described and the contribution of the hydrogen on the second central hydroxyl group of the tartrate ion to the spontaneous polarization is confirmed. The hydrogen positions and the role of the H-bond in the anti-ferroelectric transition of the tetragonal phase of ammonium dihydrogen phosphate have been determined by means of neutron diffraction. Tri-glycine fluoberyllate, silver glycinate, and a low-temperature phase of methylammonium aluminum sulfate alum are found to be ferroelectric. Polarization mechanisms for the first two and the crystallographic structure of the latter are given along with H-bonds for all of the systems. A low-temperature phase of ammonium iodide is antiferroelectric for which the transition mechanism and bonding is described. X-ray methods in three dimensions have been used to determine the structures and H-bonding of zinc aspartate tri-hydrate, urea picosphate, and cycloserine hydrochloride.

DIELECTRIC AND THERMAL STUDY OF TRI-GLYCINE SULFATE AND TRI-GLYCINE FLUOBERYLLATE, by S. Hoshino, T. Mitsui and others. [1957] [4]p. incl. diagr. refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Signal Corps Engineering Labs.) Unclassified

Published in Phys. Rev., v. 107: 1255-1258, Sept. 1, 1957.

The small field dielectric constants measured along the b crystallographic axis of tri-glycine sulfate and tri-glycine fluoberyllate show a pronounced anomaly at the Curie temperature of 48°C and 70°C, respectively.

The dielectric constants measured along the a and c axes are practically temperature-independent. In the vicinity of the Curie point, the square of the spontaneous polarization increases linearly with decreasing temperature. The transition of both salts is of the second order. Measurements of the specific heat as a function of temperature yield $\Delta S = 0.48$ cal/mol degree for tri-glycine sulfate, and $\Delta S = 1.17$ cal/mol degree for tri-glycine fluoberyllate. The results are discussed on the basis of Mueller's thermodynamic theory for ferroelectric transitions. (Contractor's abstract)

FERROELECTRICITY IN GLYCINE SILVER NITRATE, by R. Pepinsky, Y. Okaya and others. [1957] [2]p. incl. diagr. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Signal Corps Engineering Labs.) Unclassified

Published in Phys. Rev., v. 107: 1538-1539, Sept. 15, 1957.

Glycine silver nitrate, $\text{NH}_2\text{CH}_2\text{COOH}\cdot\text{AgNO}_3$, is ferroelectric below -55°C. At -195°C the spontaneous polarization is 0.55×10^{-6} coulomb/cm², and the coercive field is 740 v/cm. The transition appears to be of second order. A differential thermal analysis does not reveal a specific heat anomaly. No dielectric anomalies appear between 4°K and -55°C. The spontaneous polarization here, as in triglycine sulfate and isomorphs, is attributed to disturbance of the planarity of the glycine ion by the crystalline field. (Contractor's abstract)

ANOMALOUS DIELECTRIC DISPERSION AND FERROELECTRICITY IN THE ALUMS (Abstract), by K. Vedam and R. Pepinsky. [1957] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Signal Corps Engineering Labs. under DA 36-039-sc-72385) Unclassified

Presented at Pittsburgh Diffraction Conf., Pa., Nov. 6-8, 1957.

The temperature dependence of the dielectric behavior of ammonium iron alum has been investigated at a number of frequencies between 1 kc and 50 mc. The temperature at which the dielectric loss reaches a maximum is frequency-dependent, and this anomalous absorption can be represented by the Debye theory of relaxation. In addition to this Debye absorption, abrupt changes in E' and E'' are observed in this alum at a temperature which is independent of frequency. This temperature corresponds to that of the phase transition, the low-temperature phase of the crystal being ferroelectric. Similar investigations of other ammonium and methylammonium alums are discussed.

SUPERSTRUCTURES AND TRANSITIONS IN K_2SO_4 -TYPE CRYSTALS (Abstract), by Y. Okaya and R. Pepinsky. [1957] [3]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Signal Corps Engineering Labs. under DA 36-039-sc-72385) Unclassified

Presented at Pittsburgh Diffraction Conf., Pa., Nov. 6-8, 1957.

The discovery of ferroelectricity in low-temperature phases of $(NH_4)_2SO_4$ and $(NH_4)_2BeF_4$ has prompted re-examination of the room-temperature structures of these crystals, and analysis of the ferroelectric phases as well. It is found that the room-temperature cells of both $(NH_4)_2SO_4$ and $(NH_4)_2BeF_4$ are not as reported in the literature, but show superstructures; and as the crystals become ferroelectric, the superstructures become more complex. The case of $(NH_4)_2BeF_4$ is given as an example:

(1) approximate (basic) cell and symmetry at room temperature: $a_1 = 7.64A$, $b_1 = 5.91A$, $c_1 = 10.44A$; space

group = Pnma (or, less probably, Pn2a). (2) true cell at room temperature: $a_2 = 2a_1$, $b_2 = 2b_1$, $c_2 = 2c_1$; space

group = Abma (or, less probably, Ab2a). Some stacking disorder along c_2 is observed in this phase. (3) approximate (basic) ferroelectric cell (below $-100^\circ C$):

$a_3 \approx 2a_1$, $b_3 \approx b_1$, $c_3 \approx c_1$, space group = Pna2₁. $c_3 =$

polar axis. (4) true ferroelectric cell (below $-100^\circ C$):

$a_4 \approx 2a_1$, $b_4 \approx 2b_1$, $c_4 \approx 2c_1$. Between $-135^\circ C$ and $+135^\circ C$

there is only the single (ferroelectric) transition at $\approx -95^\circ C$. The transition energy $\Delta Q = 0.14$ kcal/mol, and the entropy of the transition is 0.83 cal/mol-deg. The approximate (basic) cell of $(NH_4)_2SO_4$ at room temperature is isomorphous with that of $(NH_4)_2BeF_4$ at that temperature; the true room-temperature structure shows

superstructure, but this differs from one sample to another. The energy of the ferroelectric transition is $\Delta Q = 0.55$ kcal/mol, and the entropy of the transition is 2.5 cal/mol-deg. The shape of the $(NH_4)_2SO_4$ specific

heat vs temperature curve in the neighborhood of the transition point is of the λ -type; the curve for $(NH_4)_2BeF_4$ shows a broad maximum in the neighborhood of the transition, and the height of the maximum is very much less than that for $(NH_4)_2SO_4$. The latter crystal shows only the one transition in the temperature

range from $-135^\circ C$ to $+170^\circ C$. X-ray and thermal measurements have been made on a number of other members of the K_2SO_4 -type class, and on various mixed crystals in the class. The superstructure lines for $(NH_4)_2(BeF_4, SO_4)$ resemble maxima in a fiber diagram. $(NH_4, Rb)_2SO_4$

x-ray patterns show disorder in the (a,c) plane. The nature of transitions, superstructures and disorder in various other members and mixed crystals from the K_2SO_4 family are discussed.

INSTRUMENTATION FOR DIFFRACTION, MICRO-OPTICAL, MORPHOLOGICAL AND DIELECTRIC INVESTIGATIONS OF CRYSTALS (Abstract), by R. Pepinsky, K. Drenck and others. [1957] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35, Office of Ordnance Research, Signal Corps Engineering Labs., and Atomic Energy Commission) Unclassified

Presented at Congress of Internat'l. Union of Crystallography, Montreal, Que. (Canada), July 10-17, 1957.

Published in Acta Crystallographica, v. 10: 739, Dec. 10, 1957.

The following new instruments are described: a miniaturized Weissenberg camera, permitting a focal-spot to film distance of 4.3 cm, for use with a micro-focus x-ray

tube; a new Welssenberg for studies at liquid helium temperature; a new heating camera for the Unicam and Super Welssenbergs; a new heating chamber for powder and single-crystal studies on the G.E. XRD-3 instrument; a new servo-controlled miniaturized x-ray and neutron single-crystal counter goniometer; several new microscope stages for observations at liquid helium and liquid nitrogen temperatures, and a liquid-nitrogen dewar for studies on the Waldmann Chemists' microscope; a new two-circle photoelectric optical goniometer for morphological measurements, which automatically records stereographic projections; a new instrument for single-crystal piezoelectric measurements; new multiple-crystal holders for dielectric measurements at low and high temperatures; a self-balancing bridge and servo-driven recorder for automatic measurement and plotting of dielectric constants versus temperature; a new type of temperature controller and indicator, for use in thermostats at temperature from -196°C to $+500^{\circ}\text{C}$, with a control accuracy of $\pm 0.05^{\circ}\text{C}$; a system for electrode evaporative coating of hydroscopic crystals, for dielectric studies; and a new string saw for oriented crystal cutting.

OPTICAL, DIELECTRIC, DILATOMETRIC, THERMAL AND X-RAY STUDIES OF CRYSTAL TRANSITIONS (Abstract), by R. Pepinsky, F. Jona and others. [1957] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35, Signal Corps Engineering Labs., Atomic Energy Commission, and Office of Naval Research) Unclassified

Presented at Congress of Internat'l. Union of Crystallography, Montreal, Que. (Canada), July 10-17, 1957.

Published in Acta Crystallographica, v. 10: 835, Dec. 10, 1957.

Optical observations have revealed reversible low-temperature transitions in a large number of complex ion salts, divalent metal fluoborates and perchlorates, monovalent and divalent metal and amine hexafluorophosphates, urea and thiourea salts, basic beryllium acetate, various $\text{NH}_4\text{-Me}^{\text{II}}$ double sulfates, various

$\text{Me}^{\text{II}}(\text{Me}^{\text{II}})_2$ hexa-propionates, $\text{K}_3\text{Na}(\text{CrO}_4)_2$, etc, a variety of ammonium and substituted ammonium alums. Reversible high-temperature transitions have been observed in a large series of normal- and isoalkylamine phosphates and arsenates, various complex ion salts, tetraethylamine and other amine fluoborates, divalent metal fluoborates, etc. Dielectric measurements indicate anomalies in various of these, in $(\text{NH}_4)_2\text{S}_2\text{O}_3$ and many other ammonium salts, and in various perovskites and pseudoperovskites, including mixed crystals.

Dielectric hysteresis observations are reported for various new ferroelectrics, as are dilatometric and differential thermal analyses. X-ray diffraction studies are reported of the structures and transition mechanisms in various ferroelectrics and antiferroelectrics.

Also published in Zeltschr. Phys. Chemie, New Series, v. 13: 367-378, 1957.

The structure of the alum monomethylammonium aluminum sulfate dodecahydrate at room temperature has been redetermined. The CH_3NH_3^+ ions do not lie along the cube body diagonal, but are arranged statistically at an angle to this diagonal. The disordered arrangement of these ions does not appear to be of thermal origin. The $[\text{Al}(\text{H}_2\text{O})_6]^{+3}$ octahedra are slightly flattened, with trigonal symmetry, and with an Al - O separation of 1.88₆ A. The CH_3NH_3^+ ion is surrounded by a distorted octahedron of water molecules. The SO_4^{-2} ion possesses trigonal symmetry: three S - O separations are 1.49₄ A, and one is 1.47₃ A. The complex hydrogen-bond system, involving all types of oxygens, is described. The crystal becomes ferroelectric below -96°C . The low-temperature phase has symmetry $\text{P}2_1$. In order to understand the nature of the two transitions in Rochelle salt, at -18°C and $+23^{\circ}\text{C}$, between which points the crystal is ferroelectric, the structures of the two non-ferroelectric phases have been studied with x-rays, preparatory to neutron examination. Both non-ferroelectric phases are in space group $P2_12_12$. Multi-film Weissenberg data with $\text{CuK}\alpha$, and with specimens encased in pyrex, were obtained at temperatures -64°C , 0°C and $+35^{\circ}\text{C}$. Orthorhombic symmetry was assumed for all three phases, and six (001) projections were computed on X-RAC.

A NEW ROOM-TEMPERATURE FERROELECTRIC, by R. Pepinsky, K. Vedam, and Y. Okaya. [1958] [12]p. incl. diagrs. table, refs. (AFOSR-TN-58-217) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Signal Corps Engineering Labs. under DA 36-039-sc-72385) AD 234954 Unclassified

Also published in *Phys. Rev.*, v. 110: 1309-1311, June 15, 1958.

The neutral-salt complex with glycine, di-glycine manganous chloride dihydrate, $(\text{NH}_2\text{CH}_2\text{COOH})_2 \cdot \text{MnCl}_2 \cdot 2\text{H}_2\text{O}$, is found to be ferroelectric from low temperatures to $+55^{\circ}\text{C}$. Above the latter temperature the conductivity suddenly becomes excessive. At room temperature the spontaneous polarization is 1.3×10^{-6} coulombs/cm² and the coercive field is 5.6 kv/cm. A non-reversible surface change is observable optically above 72°C , probably due to loss of H_2O .

Thermal measurements indicate onset of water loss above 35°C ; electrical conductivity increases sharply and irreversibly above 55°C , and care must be taken to prevent dehydration even at room temperature. No Curie temperature can be observed. X-ray measurements of this hitherto unreported salt show space group $P2_1$, $a = 9.96 \text{ \AA}$, $b = 8.53 \text{ \AA}$, $c = 6.86 \text{ \AA}$, $\beta = 107 \pm 0.5^{\circ}$, density = 1.875_0 g/cc , and two formula units per cell. The ferroelectric axis is along b . The dielectric constants at room temperature are $\epsilon_a = 6.6$, $\epsilon_b = 8.1$, $\epsilon_c = 7.4$; and these decrease linearly and only very slightly as the temperature is lowered to 77°K . The corresponding neutral-salt complex of two glycines with MnBr_2 is not isomorphous, occurring as a tri-hydrate, and is not ferroelectric. It has not been possible to find any metal which will replace manganese and form an isomorphous crystal. (Contractor's abstract)

FERROELECTRICITY IN DI-GLYCINE NITRATE, $(\text{NH}_2\text{CH}_2\text{COOH})_2 \cdot \text{HNO}_3$, by R. Pepinsky, K. Vedam and others. [1958] 12p. incl. diagrs. table. (AFOSR-TN-58-219) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Signal Corps Engineering Labs. under DA 36-039-sc-72385) AD 154120 Unclassified

Also published in *Phys. Rev.*, v. 111: 430-432, July 15, 1958.

$(\text{Glycine})_2 \cdot \text{HNO}_3$ is ferroelectric below -67°C . The room-temperature phase is monoclinic, space group $P2_1/a$, with $a = 9.49_6 \text{ \AA}$, $b = 5.10_7 \text{ \AA}$, $c = 9.35_0 \text{ \AA}$, $\beta = 98.8^{\circ}$, $\rho_{\text{obs}} = 1.581_0 \text{ g/cc}$, and $Z = 2$. The nitrate groups must be disordered or rotating in this phase, since they are at centers of symmetry. The symmetry of the ferroelectric phase is Pa , as established from systematic absences and the fact that spontaneous polarization appears along the room-temperature [101] direction below -67°C . The dielectric constant $\epsilon_{[101]}$, at 10 kc and 5 v/cm, is 14 at room temperature, rises to a sharp peak of ~ 600 at -67°C , and falls to ~ 12 at -180°C . The transition appears to be of second order. At -77°C the spontaneous polarization is $0.60 \text{ \mu coul/cm}^2$, and the coercive field is 400 v/cm. A specific heat anomaly similar to that in $(\text{glycine})_3 \cdot \text{H}_2\text{SO}_4$ and $(\text{glycine})_3 \cdot \text{H}_2\text{BeF}_4$ is observed, with $\Delta E = 0.15 \text{ kcal/mol}$ and $\Delta S = 0.74 \text{ cal/mol deg}$. Examination of the results of Guillien and of Le Montagner on dielectric properties of alums reveals that the temperature T_m at which the dielectric loss

PSU.08:032 - PSU.08:034

reaches a maximum is frequency-dependent, and that this anomalous absorption can be represented by Debye's theory of relaxation. No anomaly could be detected by these investigators at the ferroelectric transition temperatures. Redetermination of the dielectric behavior of $(\text{NH}_4)_2\text{Fe}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ at a number of frequencies between 10 kc and 50 mc reveals small but reproducible anomalies in E' and E'' at 88° K. Similar anomalies have been detected at microwave frequencies by Griffiths and Powell. Deuteration of the alum increases the value of T_m , but does not alter the transition temperature.

Similar observations are reported for other ferroelectric alums.

Measurements of dielectric properties, specific heats and thermal expansions of the ferroelectric transitions in $(\text{NH}_4)_2\text{SO}_4$ and $(\text{NH}_4)_2\text{BeF}_4$ and mixed crystals of these have been performed under various conditions. It is found that the nature of the transition is affected by the previous history of the samples: i.e., heat treatment, application of electric fields, etc. For example, some samples of $(\text{NH}_4)_2\text{BeF}_4$ which do not show double ferroelectric hysteresis loops characteristic of a first-order transition exhibit this property after thermal annealing. A sample of $(\text{NH}_4)_2\text{SO}_4$ which was annealed at 75°C shows a typical lambda-type specific heat anomaly, while the sample without heat treatment shows quite different behavior. Results are discussed in the light of a parallel structural study.

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 44, Jan. 29, 1958.

$(\text{NH}_4)_2\text{SO}_4$ and $(\text{NH}_4)_2\text{BeF}_4$ become ferroelectric below -49.5°C and -97°C, respectively. Although these crystals were reported as isomorphous, reexamination by x-rays reveals differences in room-temperature symmetries and in directions of polar axes in the ferroelectric phases. Cell constants, in angstroms, are $a = 7.49$, $b = 10.39$, $c = 5.89$ for $(\text{NH}_4)_2\text{BeF}_4$ and $a = 7.729$, $b = 10.560$, $c = 5.951$ for $(\text{NH}_4)_2\text{SO}_4$. The room-temperature space group for both is Pnam if superstructuring is disregarded; superstructuring appears in all $(\text{NH}_4)_2\text{BeF}_4$ and some $(\text{NH}_4)_2\text{SO}_4$ samples, and doubles b and c , leading to space group Acam . Below its Curie point $(\text{NH}_4)_2\text{BeF}_4$ has a doubled, with symmetry $\text{Ac}2_1a$. Non-superstructured $(\text{NH}_4)_2\text{SO}_4$ shows neither dimensional doubling nor change in systematic absences at low temperature; the space group is $\text{Pna}2_1$. Polar directions observed dielectrically are b in $(\text{NH}_4)_2\text{BeF}_4$ and c in $(\text{NH}_4)_2\text{SO}_4$, in agreement with space-group requirements. X-ray, dielectric and thermal measurements are reported on $(\text{NH}_4)_2(\text{BeF}_4, \text{SO}_4)$ and other K_2SO_4 -type crystals.

SOME NEW X-RAY AND NEUTRON STUDIES OF HYDROGEN BONDING, by R. Pepinsky. [1958] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35, Signal Corps Engineering Labs., and Atomic Energy Commission) Unclassified

Presented at Internat'l. Conf. on Current Problems in Crystal Physics, Massachusetts Inst. of Tech., Cambridge, July 1-6, 1957.

Published in Rev. Modern Phys., v. 30: 100, Jan. 1958.

Three-dimensional refinement on the IBM 704 machine of x-ray analyses of cycloserine hydrochloride, zinc aspartate trihydrate, and urea phosphate has revealed interesting H-bond systems in these crystals. The

PSU.08:035 - PSU.08:037

cycloserine HCl analysis reveals six short intermolecular distances indicated O-H...O, N-H...O, and N-H...Cl bonds. A three-dimensional refinement of the structure of zinc aspartate trihydrate reveals H bonding which leads to the ring structure proposed by Steward and Thompson for a cyclic structure for asparagine. The structure of urea phosphate shows very strong H bonding throughout, indicating hydrogen sharing by two bonds in two cases. The structure of ferroelectric Rochelle salt has been solved, by a joint x-ray and neutron analysis. The contribution of the hydrogen (or deuterium) on the second central hydroxyl group of the tartrate ion to the spontaneous polarization is confirmed. Hydrogen positions have been found in the tetragonal phase of ammonium dihydrogen phosphate, by neutron diffraction. The interesting feature of the O-H...O bonds here is that the hydrogens do not lie on a line connecting the two O's. Very short intermolecular distances appear in the structure of the explosive HMX, cyclotetramethylene tetra-nitramine. Distances of 3.03 Å and 3.15 Å are found between one O of a nitro group and methylene C's of two adjacent molecules. It is demonstrable that H's are not involved in these remarkably short bonds. This compound must be a self-intermolecular-complex; and, if so, this is the reliable example of short intermolecular distances in such a complex. The structures of these organic intermolecular complexes, and the physical nature of the bonding, in which, in general, hydrogens are not involved, is a foremost problem in the modern valence theory; and further x-ray studies of these compounds are a pressing matter. Some problems in the stereochemistry of hydrogen bonds are described, as are problems of dielectric anomalies and other transition phenomena involving H bonds. The mechanisms of the ferroelectric transitions in the ammonium and organic amine alums, $(\text{NH}_4)_2\text{SO}_4$, $\text{Cd}_2(\text{NH}_4)_2(\text{SO}_4)_3 \cdot (\text{glycine})_3 \cdot \text{H}_2\text{SO}_4$ and isomorphs, and thiourea; the nature of the polarization in guanidinium aluminum sulfate hexahydrate and isomorphs, and the anomalies in the hydrogen halides, are of particular interest.

NON-ISOMORPHISM OF FERROELECTRIC PHASES OF AMMONIUM SULFATE AND AMMONIUM FLUOBERYL-LATE, by Y. Okaya, K. Vedam and R. Pepinsky. [1958] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35, Signal Corps Engineering Labs. under DA 36-039-sc-72385, and Atomic Energy Commission under AT(30-1)1516) Unclassified

Published in Acta Crystallographica, v. 11: 307, Apr. 10, 1958.

It is now reported that ammonium sulfate and fluoberylate crystals are not isomorphous in their low temperature (ferroelectric) phases even though the room

temperature phases are basically isomorphous. The room temperature phase of $(\text{NH}_4)_2\text{SO}_4$ sometimes shows super-structuring while the basic cell of $(\text{NH}_4)_2\text{BeF}_4$ is super-structured. The ferroelectric symmetry of the sulfate is $\text{Pn}2_1$ and that of the fluoberylate is $\text{Pn}2_1a$, while the directions of spontaneous polarization in the two crystals are oriented in directions which are 90 degrees with respect to each other. The dielectric and thermal studies of the crystals have been completed and the x-ray and neutron analyses are in progress. Other K_2SO_4 crystal types have also been studied.

A NEUTRON STRUCTURE ANALYSIS OF TETRAGONAL $\text{NH}_4\text{H}_2\text{PO}_4$, by L. Tenzer, B. C. Frazer, and R.

Pepinsky. [1958] [5]p. incl. diagr. tables, refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Atomic Energy Commission) Unclassified

Published in Acta Crystallographica, v. 11: 505-509, July 1958.

The structure of tetragonal $\text{NH}_4\text{H}_2\text{PO}_4$ has been determined in a single-crystal neutron-diffraction study. The N-H...O and O-H...O bond systems suggested in earlier x-ray investigations were confirmed. The H_2PO_4^- network is very similar to that found in KH_2PO_4 ; the only significant difference observed was in the angle between the P-O and O-H...O bonds. The ammonium ion was found to be only slightly distorted from a rectangular tetrahedral arrangement. Considerable distortion would be necessary for linear N-H...O bonds. The observed angle between the N-H bond and the line joining nitrogen and oxygen centers was about 14°. In order to achieve good agreement between calculated and observed data it was necessary to introduce anisotropic thermal vibration parameters. The final value of the discrepancy factor was 8.9%. THEORY OF THE FERROELECTRIC EFFECT IN ROCHELLE SALT, by T. Mitsui. [1958] [9]p. incl. diagr. refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35, Signal Corps Engineering Labs., and Atomic Energy Commission) Unclassified

Published in Phys. Rev., v. 111: 1259-1267, Sept. 1, 1958.

Mueller's phenomenological theory of Rochelle salt, $\text{NaKC}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$, has been generalized, and the properties of the clamped crystal described. A local field theory of the clamped crystal has been developed on the basis of the structure analysis of Frazer, Danner, and Pepinsky. A phase diagram is given which shows conditions for the occurrence of ferroelectricity. It has been shown that the difficulties of Mason and Devonshire's theories are the results of too simplified assumptions on the coefficients of the local field. Various quantities which appear in the theory have been calculated using the fact that the reciprocal susceptibility of the clamped crystal has a single zero value. The calculated coefficients which appear in the Taylor series expansion of Helmholtz free energy agree well with those predicted by the phenomenological theory. An explanation is given for the properties of the mixed crystal series, $\text{Na}[\text{K}_\alpha(\text{NH}_4)_{1-\alpha}]_2\text{C}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$. AMMONIUM HYDROGEN SULFATE: A NEW FERROELECTRIC WITH LOW COERCIVE FIELD, by R. Pepinsky, K. Vedam and others. [1958] [3]p. incl. diags. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35, Signal Corps Engineering Labs., and Atomic Energy Commission) Unclassified

Published in Phys. Rev., v. 111: 1508-1510, Sept. 15, 1958.

It has been found that $(\text{NH}_4)\text{HSO}_4$ is ferroelectric in the temperature range between -3°C and -119°C . The symmetry of the room-temperature phase is $P2_1/c$; the ferroelectric phase is monoclinic, with space group Pc ; and the lowest phase, which is piezoelectric has triclinic symmetry $P1$. All three phases are pseudo-orthorhombic. The coercive field is very low, about 150 v/cm at -13°C . The spontaneous polarization P_s is about $0.4 \mu\text{coul}/\text{cm}^2$ at that temperature, and rises to a maximum of about $0.8 \mu\text{coul}/\text{cm}^2$ just above -119°C . P_s falls to zero abruptly at the lower transition point. The higher transition is of second order, and the lower of first order. (Contractor's abstract)

ROOM-TEMPERATURE FERROELECTRICITY IN LITHIUM HYDRAZINIUM SULFATE, $\text{Li}(\text{N}_2\text{H}_5)\text{SO}_4$, by R. Pepinsky, K. Vedam and others. [1958] [2]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Signal Corps Engineering Labs.) Unclassified

Published in Phys. Rev., v. 111: 1467-1468, Sept. 15, 1958.

$\text{Li}(\text{N}_2\text{H}_5)\text{SO}_4$ is ferroelectric over the temperature range from below -15°C to above 80°C , and shows no dielectric peaks between -196°C and 140°C . No thermal anomalies are observed. The crystals are orthorhombic, space group $\text{Pbn}2_1$, with $a = 8.96_9 \text{ \AA}$, $b = 9.91_3 \text{ \AA}$, $c = 5.17_8 \text{ \AA}$, and the ferroelectric axis is, of course, along c ; $p = 1.996 \text{ g/cc}$, and there are 4 molecules per cell. The coercive field is about 320 volts/cm at room temperature, and the spontaneous polarization is $0.30 \text{ microcoulomb}/\text{cm}^2$. Beautiful large crystals can be grown from water by a variety of methods. After electroding, the crystal plates should be protected by silicone oil. Without such protection, reaction with normal atmosphere for prolonged time results in excessive conductivity.

CRYSTAL STRUCTURAL STUDIES OF SOME NEW FERROELECTRICS (Abstract), by K. Vedam and R. Pepinsky. 1958, 1p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Atomic Energy Commission under AT(30-1)1516) Unclassified

Presented at meeting of the Inorg. Chem. Div. of the Amer. Chem. Soc., Chicago, Ill., Sept. 7-12, 1958.

Published in 134th meeting of the Amer. Chem. Soc. Abstracts of Papers, 1958, p. 17-N.

Structural mechanisms of the transitions in the various new ferroelectric crystals under study are described, insofar as they are known. Results on extensive x-ray, dielectric, thermal and optical measurements are described for the following ferroelectrics: $(\text{NH}_4)_2\text{SO}_4$, $(\text{NH}_4)_2\text{BeF}_4$, the various ammonium and methylammonium alums, $\text{Li}(\text{N}_2\text{H}_5)\text{SO}_4$, $(\text{NH}_4)\text{HSO}_4$, $(\text{glycine})_3 \cdot \text{H}_2\text{SO}_4$, $(\text{glycine})_2 \cdot \text{MnCl}_2 \cdot 2\text{H}_2\text{O}$, $(\text{glycine}) \cdot \text{AgNO}_3$, and

(glycine)₂·HNO₃. It is shown that (NH₄)₂SO₄ and (NH₄)₂BeF₄ are not exactly isomorphous, as was thought heretofore; furthermore, the polar axes and the transition mechanisms for the two are markedly different. A detailed structure analysis of the important ferroelectric (glycine)₃·H₂SO₄ reveals that O-H...O and N-H...O bonds play a prominent role in the ferroelectric behavior. This appears to be the case for all of the above-listed ferroelectrics. The antiferroelectric transitions in NH₄PF₆·NH₄F and (NH₄)₃H(SO₄)₂ are also discussed.

DIELECTRIC AND THERMAL STUDY OF (NH₄)₂SO₄
AND (NH₄)₂BeF₄ TRANSITIONS, by S. Hoshino, K.

Vedam and others. [1958] [8]p. incl. diagrs. refs.
(Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35, Signal Corps Engineering Labs., and Atomic Energy Commission) Unclassified

Published in Phys. Rev., v. 112: 405-412, Oct. 15, 1958.

The behavior of the various dielectric properties, specific heat, and thermal expansion of (NH₄)₂SO₄ and

(NH₄)₂BeF₄ has been studied in detail under various experimental conditions, with particular reference to the ferroelectric transitions in these crystals. The curves of dielectric constant vs temperature follow a relationship other than the Curie-Weiss law. The shift of the transition temperature as reported in the literature could not be detected even under extreme experimental conditions. The transition energy and entropy change have been evaluated from a C_p vs T curve. The variation of the lattice parameters and the unit cell volumes with temperature has been measured by the x-ray method. The transition of (NH₄)₂SO₄ appears to be of first order, while that of (NH₄)₂BeF₄ is also of first but very close to second-order. Deuteration of these crystals does not affect the transition of (NH₄)₂SO₄; but in the case of (NH₄)₂BeF₄ the transition temperature is raised by 3°C by deuteration, and the transition energy is also increased. The phase diagram of (NH₄)₂SO₄-(NH₄)₂BeF₄ system is given. (Contractor's abstract)

EFFECT ON THE ENERGY OF INCREASED FLEXI-

BILITY IN THE SEPARABLE FACTOR OF HYLLERAAS-TYPE ATOMIC WAVE FUNCTIONS FROM H⁻ TO O VII, by L. C. Green, S. Matsushima and others. [1958] [5]p. incl. table, refs. [In cooperation with Haverford Coll., Strawbridge Observatory, Pa.] (Sponsored jointly by Air Force Office of Scientific Research under [AF 18-(600)660], National Science Foundation, and Office of Naval Research) Unclassified

Published in Phys. Rev., v. 112: 1187-1191, Nov. 15, 1958.

A number of wave functions of the form $f(r_1)f(r_2)g(r_1, r_2, r_{12})$ are applied to the two-electron systems from H⁻ to O VII. Various analytic expressions for f and g are employed. The values of the various parameters in f and g are chosen to yield the minimum energy. The wave functions, the values of the parameters, and the minimum energies are tabulated. Twenty of the twenty-six functions tabulated are presented here for the first time. For five of the remaining six functions the values of the parameters and the energies have been recomputed. The energies obtained with these wave functions as well as with functions investigated by others are examined to ascertain what improvement in the energy results from considering other functional forms for f(r) than the customary negative exponential. In the case of H⁻, it is clear that certain types of flexibility in f(r) can substantially improve the energies obtained with the simpler functions. For larger nuclear charge the improvement is definite but smaller. The functions obtained are of interest in themselves. Several of them give the lowest energies for H⁻ so far found for various specific numbers of parameters. Beyond Li II, no simple wave functions involving the interelectron distance were previously available.

ON THE HYDRODYNAMIC STABILITY OF CURVED LAMINAR LAYERS, by M. Lessen. [1958] [5]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)124] and General Electric Co.)

Unclassified

Published in Zeitschr. Angew. Math. Mech. (ZAMM), v. 38: 95-99, Mar./Apr. 1958.

The stability of curved laminar compressible flows is examined, and it is found that instabilities in the flow fields about bodies moving at high speed may exist under certain circumstances. The general disturbance equations are derived and simplified cases are discussed. Whereas in the case of incompressible flows, the instability is due to the kinematics of the flow field, for the compressible case, thermodynamic factors are also of importance. MEAN-L-STABLE SYSTEMS, by J. Auslander. June 1957, 48p. refs. (AFOSR-TN-57-460) (AF 18(600)1116) AD 136451
Unclassified

Also published in Illinois Jour. Math., v. 3: 566-579, Dec. 1959.

A study is made of the topological and measure theoretic properties of the discrete flow generated by a homeomorphism of a metric space onto itself. The metric space is usually assumed to be compact. An analysis is made of mean-L-stable systems by means of the ergodic theorem and the theory of Kryloff and Bogollouboff. Several results connecting mean-L-stability with various almost periodicity properties are obtained. A decomposition theorem for the systems is proved. Examples of the systems and open questions are discussed, with a detailed analysis being carried out of a modified version of a complicated example due to Floyd (Bull. Amer. Math. Soc., v. 55: 957-960, 1949). Statements and proofs of the results on upper density, lower density, and density, which are needed for the analysis of mean-L-stable systems are included in an appendix.

Also published in Proc. Amer. Math. Soc., v. 10: 637-643, Aug. 1959.

Let X be a separate uniform space, $C(X, X)$ the set of continuous functions of X into X , and $C(X)$ the set of real valued continuous functions on X provided with the topology of uniform convergence. For $f \in C(X)$ and $a \in C(X, X)$, fa will denote that element of $C(X)$ such that $(fa)(x) = f(ax)$ ($x \in X$). Let $f \in C(X)$ and $A \subset C(X, X)$. Then f is said to be almost periodic with respect to A if $fa = [fa \mid a \in A]$ is a relatively compact subset of $C(X)$. The behavior of A is studied by means of its almost period functions. In particular it is shown that if there are enough of these, then A is equicontinuous.

HOMOMORPHISMS OF TRANSFORMATION GROUPS, by R. Ellis and W. H. Gottschalk. [Oct. 1958] 38p. (AFOSR-TN-58-874) (AF 18(600)1116) AD 203914; PB 138147
Unclassified

Also published in Trans. Amer. Math. Soc., v. 94: 258-271, Feb. 1960.

Results of the study show that a transformation group with compact phase space and non-compact phase group gives rise to a compact topological group called its structure group. Let (X, T) be a transformation group with compact phase space X and with arbitrary phase group T . There exists least invariant closed equivalence relations S_d and S_e in X such that T is distal on $X|S_d$ and T is equicontinuous on $X|S_e$. If (X, T) is locally almost periodic, then the 4 relations of S_d and S_e with the proximal and regionally proximal relations coincide. Such transformation groups are partially classifiable according to their structure groups. (ASTIA abstract)

Also published in Rend. Circ. Matem. Palermo, Series II, v. 8: 241-270, Sept.-Dec. 1959.

A study is presented of periodic variation diminishing kernels. The problem is to determine those periodic frequency functions $\Omega(t)$ with the property that the convolution transformation, $g(t) = \frac{1}{2\pi} \int_0^{2\pi} \Omega(t-\pi)f(\pi)d\pi$, be variation diminishing in the following sense: for every real continuous function $f(t)$ of period 2π , the convolution transformation should imply the inequality $v_c(g) \leq v_c(f)$. A function $\Omega(t)$ of this kind is called a periodic variation diminishing function. (ASTIA abstract)

Also published in Pacific Jour. Math., v. 8: 295-334, 1958.

The de la Vallée Poussin means are shown to possess shape-preserving properties to a higher degree than certain Cesaro means because of their variation-diminishing character. The principal result states that the inequalities $v_c(V_n) \leq Z_c(V_n) \leq v_c(f)$ hold for an arbitrary integrable function $f(t)$. $Z_c(V_n)$ denotes the number of real zeros of $V_n(t)$ within a period including multiplicities; $v_c(f)$ is the number of cyclic variations of the sign of $f(t)$, a real-valued function of period 2π ; and $v_c(V_n)$ is the number of variations of sign of the de la Vallée Poussin means or V-means. The applications of the variation-diminishing property of V-means are discussed. Bernstein polynomials have shape-preserving properties relative to functions $f(x)$ defined in a finite interval which are analogous to that of the V-means for the functions of period 2π . A conjecture is presented on power series which represent a conformal 1-1 mapping of the unit circle onto a convex domain. (ASTIA abstract)

SPLINE FUNCTIONS, CONVEX CURVES AND MECHANICAL QUADRATURE, by I. J. Schoenberg. [1958] [6]p. [AF 18(600)1158] Unclassified

Published in Bull. Amer. Math. Soc., v. 64: 352-357, Nov. 1958.

By a spline function of degree $n-1$ is meant a function of the form

$$S_{n-1,k}(x) = P_{n-1}(x) + \sum_{v=1}^k C_v(x-\xi_v)^+_{n-1},$$

where $P_{n-1}(x)$ is a polynomial of degree $\leq n-1$ and $x^+_{n-1} = x^{n-1}$ for $x \geq 0$ and 0 if $x < 0$. In this research announcement a fundamental theorem of algebra is given for spline functions and applications are indicated to mechanical quadrature formulas of Gauss and Radau type. The determination of the knots (ξ_v) of a spline function with given zeros is made to depend upon a refinement of a theorem of Carathéodory on convex hulls. (Math. Rev. abstract)

SOME EXTREMAL PROBLEMS FOR POSITIVE DEFINITE SEQUENCES AND RELATED EXTREMAL CONFORMAL MAPS OF THE CIRCLE, by I. J. Schoenberg. [1958] [10]p. [AF 18(600)1158] Unclassified

Published in Nederl. Akad. Wetensch. Proc., Indag. Math., Ser. A, v. 61: 28-37, 1958.

Let $\sigma(t)$ be a positive mass distribution of total mass 1 on a circumference of radius 1, and let $\mu_v = \oint e^{ivt} \sigma(t)$ ($v = 0, \pm 1, \pm 2, \dots$). Suppose that σ has its entire mass contained in an arc $\alpha \leq t \leq \alpha + \lambda$ ($0 < \lambda < 2\pi$) and has moments $\tilde{\mu}_v$ such that $\tilde{\mu}_v = 0$ if $v = n_1, n_2, \dots$ ($1 < n_1 < n_2 < \dots$). Next let $\tilde{F}(z) = z + \sum_{v=1}^{\infty} \tilde{c}_{n_v} z^{n_v}$ map $|z| < 1$ onto a schlicht and convex domain \tilde{D} such that an arc $z = e^{it}$ ($\beta \leq t \leq \beta + \lambda$) maps onto a finite straight segment S in the boundary of \tilde{D} . The following two theorems are first proved: (1) For every distribution $\sigma(t)$ with the property $\mu_v = 0$ for $v = n_1, n_2, \dots$, the inequality $|\mu_1| \leq |\tilde{\mu}_1|$ holds, clearly with equality if $\sigma = \tilde{\sigma}$. (2) Let $F(z) = z + \sum_{v=1}^{\infty} c_{n_v} z^{n_v}$ map $|z| < 1$ onto a schlicht, convex domain D . Then D contains the circle $|w| < |\tilde{\mu}_1|$. For \tilde{D}_0 the segment S is tangent to the circle $w = \tilde{\mu}_1$ at some point of S between its end points. By specializing $\tilde{\sigma}$ several applications of the above theorems are given. For example, it is proved that the image of the unit circle under schlicht, convex mappings of the form $F(z) = z + c_2 z^2 + c_4 z^4 + c_6 z^6 + \dots$ covers the circle $w = 2^{-1}$. Similarly, under schlicht, convex mappings

PEN.11:001, 002; PEN.06:023, 024

of the form $F(z) = z + c_{k+1} z^{k+1} + c_{2k+1} z^{2k+1} + \dots + c_{v_{k+1}} z^{k+1} + \dots$, the image of the unit circle covers the circle $|w| < \Gamma^2((k+1)/\Gamma(k+2)/k)$.

ON THE SHEETED STRUCTURE OF COMPACT LOCALLY AFFINE SPACES, by L. Auslander. 1957, 10p. (AFOSR-TN-57-585) (AF 49(638)12) AD 136573 Unclassified

Also published in Mich. Math. Jour., v. 5: 163-168, 1958.

The following theorems are proved where M denotes an n -dimensional compact locally affine space, Γ the fundamental group of M , and $h(\Gamma)$ the holonomy group of

M . I. Let Z^s denote the direct sum of the integers taken s times, and assume that Z^s is the kernel of the homomorphism of Γ onto $h(\Gamma)$, $s \geq 1$, and that $h(\Gamma)$ contains no elements of finite order; then M is a fiber bundle over a compact locally affine space whose fundamental group is $h(\Gamma)$ and the fiber is the s -dimensional

torus. II. Let Γ/Z^s be isomorphic to $h(\Gamma)$, $s \geq 1$; and assume that $h(\Gamma)$ contains elements of finite order. Then there exists a mapping $p: M \rightarrow X$, where X is a compact space, which is not a manifold, with the following proper-

ties: (1) $p^{-1}(x)$, $x \in X$, is a compact s -dimensional manifold which can be given a Riemann metric with curvature and torsion zero, and (2) the mapping p satisfies the required hypothesis for applying the Fary spectral sequence. III. Let Γ be the fundamental group of a compact locally affine space M and assume that Γ has a nontrivial radical; then there exists a mapping $p: M \rightarrow X$, where X is a compact space, not necessarily a manifold, and the preimage of each point x under p is a compact manifold with a torus as covering space. An example is given of a locally affine manifold which shows that the conclusions of theorem II are essentially the best possible. (ASTIA abstract)

COMPACT LOCALLY AFFINE SPACES WITH ABELIAN HOLONOMY GROUPS, by L. Auslander. [1957] 16p. (AFOSR-TN-57-645) [AF 49(638)12] AD 136631 Unclassified

This mathematical study is divided into 2 parts. The main results in Part I are formulated in the following theorems: Theorem A. Let Γ be the fundamental group of a compact locally affine space with abelian holonomy

group $h(\Gamma)$. Assume further that $h(\Gamma)$ contains no elements of finite order. Then Γ is the fundamental group of a

compact solvmanifold S . Further S and R^n/Γ are homeomorphic. Theorem B. Let Γ_1 and Γ_2 be isomorphic and fundamental groups of compact locally affine spaces,

both of which have abelian holonomy groups. Then R^n/Γ_1 and R^n/Γ_2 are homeomorphic. In Part II the main results are formulated as follows: Theorem C. Given

$\Gamma \subset A(n)$, Γ the fundamental group of a compact solvmanifold with abelian holonomy group, there exists an n -dimensional solvable Lie group S , $S \subset A(n)$, whose component of the identity S_0 is simply connected, and such that Γ is a uniform subgroup of S . Further, (1) S is a split extension of S_0 by a finite group, and (2) there is a natural action of Γ on S_0/Γ^1 , where Γ^1 , acting on S_0 , and R^n/Γ are homeomorphic. It is shown

that the groups Γ which can be the fundamental groups of compact locally affine spaces with abelian holonomy groups must satisfy a relation analogous to the Jacobi identity for Lie algebras.

ENERGY CONTROL OF A 25-MEV BETATRON (Abstract), by K. N. Geller, J. Halpern and others. [1958] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)472] and Office of Naval Research) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 169, May 1, 1958.

To obtain precise information concerning photonuclear reactions, energy stability of the bremsstrahlung tip is often required to be better than ± 10 kev over an extended period. To this end a new energy control system has been designed. Integration of the voltage induced in a small pickup coil situated at the electron donut serves as the analog of the orbit flux density. Expansion of the electron orbit occurs when this analog voltage exceeds a preselected discriminator level. For increased energy resolution a faster method of expansion using a quadrupole sector coil is employed. The x-ray pulse has a full width at half-intensity of 0.3 μ sec. To maintain a fixed relation between orbit flux density and the voltage analog, the latter is clamped near ground for about 1200 μ sec before the field passes through zero. At this time, a zero-field trigger occurs which releases the clamp and allows the reference voltage to rise. Short term stability of better than ± 4 kev has been achieved. A drift of about 10 kev over a 10 hr interval is present. The over-all long term stability for a typical 5-wk interval is 15 kev. A preliminary calibration based on (γ, n) thresholds for D, Be⁹, Bi²⁰⁹, Pb²⁰⁷, Pb²⁰⁸, Cu⁶³, and P³¹ is linear on a momentum versus "helipot" setting plot. The calibration is known to about 50 kev. The apparent thresholds for O¹⁶, and B¹⁰ fall off this calibration line by approximately 200 kev.

THE THERMAL EXPANSION OF THE LITHIUM FLUORIDE LATTICE AND ITS COMPARISON TO THE LINEAR MACROSCOPIC THERMAL EXPANSION, by E. A. Abramson. June 1957, 40p. Incl. diags. tables, refs. (Technical note no. 4) (AFOSR-TN-57-319) (AF 18(600)-561) AD 132390 Unclassified

The thermal expansion of the lithium fluoride lattice has been measured by x-ray back reflection techniques. The measurements have been carried out on both single crystal and powdered samples. Although the results of previous investigators appear to indicate that the value of the thermal expansion obtained from single crystal diffraction experiments differs from that obtained with powdered diffraction techniques, no significant difference between the single crystal and powder values could be detected in the present experiments. The previously reported difference between the values of the macroscopic linear thermal expansion and the lattice thermal expansion of the alkali halides is again observed for the case of lithium fluoride. Our value for the relative thermal lattice expansion ($\Delta l/l$) in raising the temperature from 29 to 270 C is 9.5×10^{-3} . This is 0.6×10^{-3} less than the value for the relative macroscopic thermal expansion ($\Delta L/L$) in the same temperature range, obtained by Lin at this laboratory using dilatometric methods. Several

PEN.09:008, 009; PEN.10:005, 006

explanations for this observed difference are examined, and it is concluded that, being so large, the difference can only be accounted for by some macroscopic mechanism. (Contractor's abstract)

COMPLETE SET OF DISPERSION RELATIONS FOR A CLASS OF FIXED SOURCE MESON THEORIES, by R. E. Norton and A. Klein. Mar. 1957, 44p. incl. diags. refs. (Technical note no. 6) (AFOSR-TN-57-132) (AF 18(603)60) AD 120488 Unclassified

Also published in Phys. Rev., v. 109: 584-600, Jan. 15, 1958.

The structure of the transition matrices for all processes that can occur for a class of fixed source meson theories is studied. The model consists of scalar meson field coupled to an extended source in such a way that any finite number of quanta can be emitted or absorbed at a given time (multiple vertices), but that all interactions are restricted to be S-wave in nature. The general reaction matrix element for m incident and n emergent particles contains many terms describing sequences of independent processes, which must be removed before one obtains a proper object for studies of a dispersion theoretic nature. It is shown that the ratio of the residual matrix element to a suitable product of source functions possesses those analytic properties, as a function of the total energy of the system, which permit dispersion relations to be stated. Other than for the elastic scattering amplitude the latter make reference to values of the amplitude in a nonphysical energy region. In conjunction with a suitably generalized unitarity condition, however, the scheme, when viewed as a set of coupled integral equations, can be solved by successive approximations in terms of a number of arbitrary constants, essentially equal to the number of coupling

NUCLEAR RESONANCE SCATTERING OF 7-MEV PHOTONS BY LEAD (Abstract), by K. Reibel and A. K. Mann. [1958] [1]p. [AF 18(600)894] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 174, May 1, 1958.

The cross section for nuclear resonance scattering of 6.91- and 7.14-mev gamma rays by lead have been measured. The incident radiation is produced in the reaction $F^{19}(p,\gamma)O^{16}$; at proton energies of 2.05 and 2.40 mev, each of the lines has a Doppler broadened total width of about 130 kev and the ratios of the intensities of the 7.14- and 6.91-mev radiations are approximately 4.0 and 0.25, respectively. Preliminary measurements indicate that:

(a) $\sigma_{7.1}/\sigma_{6.9} \sim 3.5$, (b) $\sigma(\theta)_{7.1} \sim 1 + \cos^2\theta$, and (c) $\sigma_{7.1} \sim 18 \pm 4$ mb. Assuming electric dipole transitions, as suggested by the angular distribution, the ratio of level width to level spacing, ΓD , is found to be of order 10^{-4} , in agreement with the value obtained using brems-

PEN.10:007 - PEN.10:010

constants in the original Hamiltonian (actually one fewer). Nevertheless, it is pointed out that the scheme does not admit a unique solution, and this is illustrated physically by exhibiting an extended class of Hamiltonians which yield the same dispersion relations, but which, as a class, contain more coupling constants than make their appearance in the dispersion relations. Physically, these are connected with the occurrence of resonance scattering. (Contractor's abstract)

THE MANY BODY PROBLEM IN QUANTUM FIELD THEORY, by A. Klein and C. Zemach. Mar. 1957, 35p. incl. refs. (Technical note no. 7) (AFOSR-TN-57-133) (AF 18(603)60) AD 120489 Unclassified

Also published in Phys. Rev., v. 108: 126-138, Oct. 1, 1957.

A formalism for the covariant description of scattering processes involving composite particles is derived from first principles. Its basic ingredients are the Green's functions of quantum field theory combined with a physically sound formulation of the adiabatic hypothesis. Explicit expressions are presented for various examples of nucleon-nucleus and boson-nucleus collisions. It is shown that the impulse approximation can be formulated for such problems. A general method of obtaining electromagnetic moments of nuclei, based on the scattering formalism, is also derived. The normalization condition for covariant amplitudes is discussed and its application to bound-state problems reviewed. In particular, a method of carrying out perturbation theory for the discrete spectrum is suggested. (Contractor's abstract)

A DERIVATION OF A COMPLETE SET OF DISPERSION RELATIONS AND AN EXAMINATION OF THEIR PHYSICAL CONTENT, by R. E. Norton. June 1957, 86p. incl. refs. (Technical note no. 8) (AFOSR-TN-57-309) (AF 18(603)60) AD 132380 Unclassified

A study is made of the structure of transition matrices for all processes that can occur for a class of fixed-source meson theories. The model consists of a scalar meson field coupled to an extended source in such a way that (1) any finite number of quanta can be emitted or absorbed at a given time, and (2) all interactions are restricted to be S-wave in nature. The ratio of the residual matrix elements to a suitable product of source functions is shown to possess analytic properties (as a function of the total energy of the system) which permit dispersion relations to be stated. With a

suitably generalized unitarity condition, the scheme when considered as a set of coupled integral equations, can be solved by successive approximations in terms of a number of arbitrary constants, essentially equal to the number of coupling constants in the original Hamiltonian. Proof is given that the scheme does not, however, admit a unique solution. The solution which contains the fewest number of arbitrary constants is the solution for the Hamiltonian whose unperturbed part has a minimum of structure. The additional solutions correspond to the more complicated Hamiltonians and exhibit a resonant behavior. The case of 2 additional theories which can be solved exactly is calculated for verification.

DISPERSION RELATIONS FOR THE SCATTERING OF A NON-RELATIVISTIC PARTICLE BY A CENTRAL POTENTIAL, by A. Klein and C. Zemach. Oct. 1957, 14p. (Technical note no. 9) (AFOSR-TN-57-688) (AF 18(603)60) AD 136683 Unclassified

Dispersion relations analogous to those which hold in quantum field theory are established for an alternative pair of scattering amplitudes, one of which has not been investigated hitherto. The proofs are based on a study of the Born series and of the known properties of the Green's function, as the resolvent of a self-adjoint transformation, and require only that the potential be local and satisfy certain reasonable integrability conditions. The problem of continuation of the new amplitude into the non-physical region is even more acute than usual, but is solved by means of a power series in the momentum transfer. [THEORETICAL STUDIES IN MESON-NUCLEON INTERACTIONS AND QUANTUM ELECTRON DYNAMICS] Final rept. [1958] 1v. incl. diagrs. tables, refs. (AFOSR-TR-58-150) (AF 18(603)60) AD 265851 Unclassified

The work performed under this contract may be summarized as follows: Non-relativistic dispersion relations have been developed for general classes of fixed source meson theories. A theory of the static two-nucleon potential has been developed and compared with experimental results. A formalism for treating bound state problems in relativistic field theories and application of this theory to the problem of the photodisintegration of the deuteron are presented. Weak interactions have been studied with respect to the possible role of non-local interactions in μ meson decay. The results of these studies are described in the following publications: (1) Dispersion Relations For Fixed-Source Meson Theories, by A. Klein (item no. PEN.10-001); (2)

A new derivation of the two-nucleon potential proposed recently by the authors is given which avoids the ambiguous features of the scattering formalism employed previously. It is based on the reduction to a Schrödinger equation of a suitable covariant two-nucleon equation. An approximate evaluation of the fourth-order potential highlights the significant departure of the present proposals from past perturbation calculations, but represents a serious overestimate qualitatively of the additional contributions.

ON THE CONCEPT OF POTENTIAL IN QUANTUM FIELD THEORY, by A. Klein. [1958] 16p. incl. refs. (Bound with its AFOSR-TR-58-150; AD 205851) (AF 18(603)60) Unclassified

Also published in Prog. Theoret. Phys. (Japan) v. 20: 257-266, Sept. 1958.

This report contains two forms of the two-nucleon potential computed to fourth order in the coupling constant from the gradient coupling of the pi-meson to the nucleon field. These are commonly referred as the Taketani-Machido-Onuma (T.M.O.) and the Brueckner Watson (B.W.) potentials. The merits of the controversy surrounding this schism are reexamined from first principles starting from the covariant equation for two-nucleons, and it is concluded that the conditions for the applicability of the method leading to the T.M.O. potential are never satisfied in practice. On the other hand, the B.W. potential, suitably altered following recent suggestions by Miyazawa and the author may well yield a suitable approximation in the low energy region.

PHENOMENOLOGICAL ANALYSIS OF μ DECAY, by S. Bludman and A. Klein. [1958] [4]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)60] and Atomic Energy Commission) Unclassified

Published in Phys. Rev., v. 109: 550-553, Jan. 15, 1958.

The spectrum, asymmetry, and helicity of the electrons from μ decay are calculated from the most general form of the two-component neutrino theory with lepton-conservation. In addition to the non-local interactions considered recently by Lee and Yang, terms appearing phenomenologically as derivative couplings may occur. In particular, a spectrum that is, aside from a statistical factor, linear in momentum is possible with $p \neq 3/4$. This could be interpreted as evidence that fermions of baryonic mass are responsible for nonlocality.

BORN SERIES AND DISPERSION RELATIONS IN NON-RELATIVISTIC QUANTUM THEORY (Abstract), by A. Klein and C. Zemach. [1958] [1]p. [AF 18(603)60] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29- Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 68, Jan. 29, 1958.

Potential scattering of a nonrelativistic particle is examined with the aid of the Born series for the Green's function and the scattering amplitude. For a wide class of potentials, such series are shown to converge absolutely at sufficiently high incident energies and their values are approximated by their leading terms. These and related results provide a simple mathematical basis for the derivation and extension of previously given

SIGNIFICANCE OF THE REDUNDANT SOLUTIONS OF THE LOW-WICK EQUATION, by R. Norton and A. Klein. Oct. 14, 1957 [5]p. incl. diagr. refs. [AF 18-(603)60] Unclassified

Published in Phys. Rev., v. 109: 991-995, Feb. 1, 1958.

The content of the Low-Wick scattering formalism is studied, using the example of a class of exactly soluble meson theories with fixed-source interaction. The theories in question describe a set of harmonic oscillators with an arbitrary distribution of frequencies, coupled to a scalar meson field by means of their total dipole moment. The Low equation for scattering of a meson is shown to possess infinitely many solutions. These are compared with the exact, explicit solution of the same problem, and it is shown that there is one-to-one correspondence between a particular choice of theory (number of oscillators and their frequencies) and a given one of the aforementioned solutions of the Low equation. A similar situation is shown to obtain for symmetric pseudoscalar theory, and it is made plausible thereby that Chew and Low have chosen the particular solution appropriate to their Hamiltonian. PROOF OF DISPERSION RELATIONS IN FIELD THEORY (Abstract), by R. Prange and A. Klein. [1958] [1]p. [AF 18(603)60] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 170, May 1, 1958.

Recent proofs of dispersion relations for pion-nucleon scattering employ the device of continuing the amplitude with respect to the square of the pion mass. Dispersion relations are established first for negative values of this parameter. The passage back for the physical value is then rigorously justified. We have developed an alternative method which initially proceeds by keeping part of the energy dependence fixed. In a manner formally analogous to the proof for the forward scattering of light, the amplitude is then shown to satisfy a dispersion relation in the remaining energy dependence. The relation itself is unconventional, however, in that the absorptive part

refers solely (except for one point) to the nonphysical region. In order to convert to the more usual relation, the behavior of the amplitude as a function of the hitherto unused energy dependence has been studied. So far the proof has been completed only for the limit of infinite nucleon mass.

PERSISTENT PATTERNS OF WAKEFULNESS IN THE PRETRIGEMINAL MIDPONTINE PREPARATION, by C. Batini, G. Moruzzi and others. [1958] [3]p. incl. diagrs. (AFOSR-TN-58-564) (AF 61(514)1125) AD 158382 Unclassified

Also published in Science, v. 128: 30-32, July 4, 1958.

Of the two preparations (the "rostropontine" and the "midpontine pretrigeminal" cats, both connected to sensory receptors through the first two cranial nerves only), the former displays a permanently synchronized electroencephalogram, whereas the latter shows a clear-cut desynchronization. Thus, the critical factor is the injury or the integrity of a small amount of nervous tissue lying in the rostral part of the pons. The behavioral and electroencephalographic patterns of the "midpontine" animal do not appear to result from hypoventilation and consequent hypercapnia, as demonstrated by blood gas measurement before and after appropriate brain-stem transection. A synchronizing, or possibly sleep-inducing, influence exerted by some structure in the caudal brain stem can be tentatively envisaged.

STRENGTHS AND WIDTHS OF PRESSURE-BROADENED HCl INFRARED LINES (Abstract), by H. J. Babrov, G. A. Ameer, and W. M. Benesch. [1957] [1]p. (AF 18-(600)986) **Unclassified**

Presented at Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 10-14, 1957.

Published in Symposium on Molecular Structure and Spectroscopy. Abstracts, 1957, p. 38.

As part of an investigation of the various aspects of the pressure broadening of infrared absorption lines, the authors have undertaken the measurement of the line strengths and widths of several of the P-branch lines of fundamental vibration-rotation band of HCl. The value here obtained for the band absorption coefficient, $S_{1,0}^{\circ}$, is $143 \text{ cm}^{-2} \text{ atm}^{-1}$. This is based on a line strength for the P-1 line, S_{p-1}° , of $6.60 \text{ cm}^{-2} \text{ atm}^{-1}$ at 300°K . The line width of the P-1 line when broadened by nitrogen is $\sigma_{p-1}^{\circ} = .12 \text{ cm}^{-1} \text{ atm}^{-1}$ at 300°K . One of the favorable aspects of the present method is the use of a single large absorption cell into which are introduced easily reproducible mixtures of gases under moderate pressures. The resulting lines are large and easily planimeted. The resulting equivalent widths are treated in a manner indicated by the following equation:

$$\frac{W_{\sigma}^{35} S_{\sigma}^{37}}{W_{\sigma}^{37} S_{\sigma}^{35}} = \frac{f(\beta\chi)^{37}}{f(\chi)^{37}}$$

where $\chi = \frac{SL}{2\pi r}$, $\beta = \frac{\chi}{35}$, and the function $f(\chi)$ is well

known and tabulated. S is the line absorption coefficient, L is the optical path length, and σ is the line half-width produced by relatively large nitrogen pressures. The superscripts refer to the two isotopic lines of HCl. To obtain a large value of β , the less abundant isotope at very low HCl pressure and high (~ one atmosphere) N_2 pressure is used in one half of the experiment, while the more abundant isotope at higher HCl pressure and low (~ 1/6 atmosphere) N_2 pressure is used in the second half. It may be noted that this method is not inherently dependent on the presence of isotopes.

PROBLEM OF SPIN ARRANGEMENTS IN MnO AND SIMILAR ANTIFERROMAGNETS, by F. Keffer and W. O. Sullivan. [1957] [8]p. incl. diagr. refs. (AFOSR-TN-57-358) (Also bound in its AFOSR-TR-58-46; AD 228953) (AF 18(600)892) AD 132476 **Unclassified**

Also published in *Phys. Rev.*, v. 108: 637-644, Nov. 1, 1957.

The magnetic dipolar energy is computed for ordering of the second kind with the four antiferromagnetic sublattices of a face-centered cube making arbitrary spin directions with respect to one another, and this energy is shown to be of the same form in the sublattice direction cosines as is the calculated powder neutron-diffraction pattern. (The dipolar energy is also calculated for ordering of the third kind and shown to lead to a spin arrangement in disagreement with powder neutron-diffraction results on βMnS .) The observed neutron patterns in MnO and αMnS agree with minimum dipolar energy, but many spin arrangements can satisfy this, and the spins are constrained only to certain regions.

Other sources of anisotropy in Mn^{++} salts are shown to be much weaker. A model is introduced in which the spins are constrained by dipolar and exchange forces to point parallel to (111) planes and constrained by the weaker anisotropy to a threefold set of easy axes within these planes. Nagamiya's small-field approximation for the field dependence of the powder susceptibility of a uniaxial antiferromagnet is extended to all values of the applied field, and a similar calculation is made for the powder susceptibility of the MnO model. Comparison with experimental data indicates that the weak within-plane anisotropy is $3 \times 10^4 \text{ ergs/cm}^3$ which is to be contrasted with the theoretical out-of-plane dipolar anisotropy of 10^7 ergs/cm^3 . A rough theory of antiferromagnetic resonance for the model seems to explain the partial paramagnetic-like absorption observed below the Néel point.

Also published in Jour. Phys. Chem. Solids, v. 5: 34-43, 1958.

A discussion on conduction mechanism by motion of an extra-electron which is tightly bound to an ion in an ionic lattice is presented. It is assumed that the wave function of the electron is localized closely around an ion and motion of the electron is so slow that the lattice polarization is induced around the electron. In this case conduction mechanism may not be well explained by the usual band theory, but it might be better to use the Heitler-London picture and to understand the current as a result of wandering motion of the electron from ion to ion. This conduction mechanism was applied and explains the electronic current which appears in the NiO crystal or the LaMnO_3 crystal.

Unclassified

Also published in Jour. Chem. Phys., v. 27: 675-682, Sept. 1957.

The slight departure of wurtzite-type binary compounds from ideal c/a ratio and ideal sublattice displacement parameter u is accounted for by the forces arising from partial polar binding. These long-range forces are calculated in terms of a postulated charge $\pm fe$ per ion and certain lattice sums which were evaluated. When balanced against the lattice piezoelectric, and dielectric constants of the crystal, the forces account for both the direction and the order of magnitude of the distortion. The compounds AlN, BeO, and ZnO are considered in detail. An experimental value of 8.5 is given for the dielectric constant of AlN, but in the absence of precise values for elastic and piezoelectric constants only an order of magnitude check of the theory can be made at this time. Some remarks are appended on the general problem of finite lattice sums in complex lattices which have dipole and/or quadrupole moments in the unit cell.

PIT.02:019 - PIT.02:021

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 119, Mar. 21, 1957.

The Lorentz factor, $4\pi/3$, used in the derivation of the Lorentz-Lorenz formula relating the optical index of refraction of an ionic crystal to the electronic polarizabilities of the ions, assumes (a) no overlap between neighbor ions, and (b) tetrahedral symmetry. In the absence of (b), any difference between the dipole field factors along and perpendicular to the crystal axis may lead to double refraction. Anisotropy in neighbor-ion overlap, which may also cause double refraction, should be absent in wurtzite structures, which have tetrahedral symmetry out to next-nearest neighbors. A revised Lorentz-Lorenz formulation, introducing anisotropic field factors, leads to a pair of equations for the ordinary and extraordinary indices of refraction. Using measured values of the indices one may solve these equations for the electronic polarizabilities of both types of ions. Results for ZnS, ZnO, BeO, CdS, and AgI are in good agreement with the polarizabilities estimated by Tessman, Kahn, and Shockley from self-consistent calculations on simpler ionic crystals. Polarizabilities of the metallic ions tend to be slightly larger than the TKS values, indicating electron displacement towards these ions, a displacement required by the partial covalent bonding.

DOUBLE REFRACTION OF AXIAL CRYSTALS. II. RUTILE STRUCTURES (Abstract), by B. Smilowitz and F. Keffer. [1957] [1]p. [AF 18(600)892] Unclassified

Presented at meeting of the Amer. Phys. Soc., Philadelphia, Pa., Mar. 21-23, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 119-120, Mar. 21, 1957.

The theory outlined above for wurtzite structures has been applied to rutile structures. Here, since the nearest neighbors of any ion do not satisfy tetrahedral symmetry, overlap effects will be expected to contribute to double refraction. These effects should be small, however, in strongly ionic crystals. The dipole field factors were calculated for a rutile structure with $c/a = 0.67$, and applied to the determination of the electronic polarizabilities of the ions in MgF_2 and SnO_2 . The polarizabilities for Mg^{++} and F^{--} agree well with those quoted by Tessman, Kahn, and Shockley. The values obtained for Sn^{4+} and O^{--} differ from the TKS values to a greater extent than Mg^{++} and F^{--} , indicating, as the electronegativity values would lead one to expect, a larger degree of overlap for SnO_2 . Other compounds will be discussed in addition to those mentioned above. We have also used

the field factors to evaluate the magnetic dipolar fields at fluorine sites in paramagnetic and antiferromagnetic MnF_2 .

PROPOSED MODEL FOR THE ANISOTROPY IN ANTIFERROMAGNETIC MnO and αMnS (Abstract), by W. O'Sullivan and F. Keffer. [1957] [1]p. [AF 18(600)892] Unclassified

Presented at meeting of the Amer. Phys. Soc., Philadelphia, Pa., Mar. 21-23, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 118-119, Mar. 21, 1957.

According to Kaplan magnetic dipolar interactions in an antiferromagnetic FCC array with ordering of the second kind lead to a large anisotropy (4×10^6 ergs/cm³) aligning the spins parallel to ferromagnetic (111) planes; and recent Brookhaven neutron diffraction experiments on MnO , NiO , and αMnS confirm this alignment. This large anisotropy, however, disagrees with a much smaller anisotropy estimated by Nagamiya from the field dependence of xpowder in MnO . Our calculations of some other (weaker) sources of anisotropy possible for Mn^{++} ions in S states suggest a model in which, in addition to Kaplan's (111) plane constraint, a much weaker anisotropy selects preferred directions in those planes. The field dependence of xpowder, as calculated from this model, agrees with experiment if the weak anisotropy is $\sim 1.9 \times 10^4$ ergs/cm³ or possibly less. Furthermore, the presence of this weak anisotropy helps explain the strong spin-resonance absorption, well below the Curie point, observed in powdered MnS and MnO .

THE STUDY OF CRYSTAL AND MOLECULAR STRUCTURE BY NUCLEAR RESONANCE IN SINGLE CRYSTALS (Abstract), by C. Dean. 1957, 1p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)892 and National Science Foundation) Unclassified

Presented at meeting at the National Bureau of Standards, Washington, D. C., June 27, 1957.

Both in nuclear magnetic resonance and in nuclear quadrupole resonance the details of the spectrum from an individual nucleus depend on the relative strength and orientation of an externally applied magnetic field with

PIT.02:022 - PIT.02:025

respect to the internal magnetic and/or electric field at the site of that nucleus. With single crystal specimens the resonances from the atoms of one element at different unit cell sites can be distinguished. A sequence of spectra for different orientations of the crystal with respect to the external magnetic field can be analyzed to give the direction and magnitude of the internal field at the site of each nucleus of that element in the unit cell. These internal fields then constitute the basic data from which structural information is inferred with an accuracy and certainty which depends on the type of system under investigation. Specific cases will be described to illustrate different applications that have been made. The scope and limitations of these techniques will be discussed.

A NUCLEAR QUADRUPOLE RESONANCE AND X-RAY STUDY OF THE CRYSTAL STRUCTURE OF 1,2,4,5-TETRACHLOROBENZENE, by C. Dean, M. Pollak and others. [1958] [35]p. incl. diagrs. tables, refs. (AFOSR-TN-58-64) (Bound with its AFOSR-TR-58-46; AD 228953 (AF 18(600)892) AD 148107 Unclassified

Also published in *Acta Crystallographica*, v. 11: 710-718, Sept. 10, 1958.

The chlorine nuclear quadrupole resonance has been used to determine the C-Cl bond directions in a single crystal of 1,2,4,5-tetrachlorobenzene. With this data, the phases for the (0kl) structure amplitudes were determined directly and used in a Fourier projection. The results for the nuclear quadrupole resonance measurements and the two dimensional x-ray analysis agree within 1 to 2° in the bond orientations. The angle between adjacent C-Cl bonds in the molecule is $63 \pm 1^\circ$. The interpretation in terms of strained models is discussed in relation to the nuclear quadrupole resonance experiments.

ANISOTROPY ENERGY IN MnF_2 AT LOW TEMPERATURES, by T. Oguchi. [1958] 18p. incl. diagr. refs. (AFOSR-TN-58-99) (AF 18(600)892) AD 228953 Unclassified

Also published in *Phys. Rev.*, v. 111: 1063-1066, Aug. 15, 1958.

The anisotropy energy in MnF_2 is calculated by a spin-wave method. The magnetic dipole interactions and the interactions of individual ions with their surrounding crystalline fields give the anisotropy energy of $-4.9 \times$

10^6 erg/cc at 0°K. The experimental value extrapolated to 0°K by Foner is -5.0×10^6 erg/cc. The temperature dependence of the anisotropy energy is obtained as $E_{an}(T)/E_{an}(0) = [M(T)/M(0)]^{2.9}$, where $E_{an}(T)$, $M(T)$ are the anisotropy energy and the magnetization of the sublattice at 0°K, respectively, and $E_{an}(0)$, $M(0)$ are the corresponding values at 0°K. A CALCULATION OF THE VALENCE BAND STRUCTURE IN BeO (Abstract), by W. O'Sullivan. 1958, 1p. (AF 18(600)892; continued by AF 49(638)323) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in *Bull. Amer. Phys. Soc., Series II*, v. 3: 231, May 1, 1958.

The ICAO approximation is applied toward a description of the valence band in BeO, in which only the closed shell $Be(1s)^2 O(2p)^6$ configuration is considered. The treatment of closed shell systems, used by Löwdin in determining the cohesive energy in alkali halide crystals, is adopted for this calculation. Thus, no account is taken of the deformation of the oxygen valence electron distribution by the polarization field along the c axis of the wurtzite type crystal. The $O^{2-}(2p)$ radial function is used as calculated by Yamashita and Kojima for MgO and includes the correction for nonorthogonality of atomic orbitals centered on different lattice sites. The valence band width is found to be 18 eV and the maxima lie in the (k_x, k_y) plane rather than along the k_z axis.

The 18 ev width represents an overestimate, a result that follows reasonably from the use of the $\text{MgO O}^{--}(2p)$ function.

SUPPRESSING SIDE-BAND INTERFERENCE IN SUPERREGENERATIVE rf SPECTROMETERS, by C. Dean and M. Pollak. [1958] [3]p. incl. illus. diags. (AFOSR-TN-58-280) (AF 49(638)323; continuation of AF 18(600)892) AD 228953 Unclassified

Also published in Rev. Scient. Instruments, v. 29: 630-632, July 1958.

By slowly modulating the quench frequency, the side-band responses of a superregenerative spectrometer to a nuclear resonance can be prevented from appearing in a recorded spectrum. When searching for an unsplit Zeeman component in a nuclear quadrupole spectrum, an equivalent simplification of the recorded spectrum can be obtained by slowly modulating the magnetic field. Satisfactory spectrometers and the required modulation and compensation circuits are described. (Contractor's abstract)

THE VALENCE BAND STRUCTURE OF BeO, by W. J. O'Sullivan. May 1958, 78p. incl. diags. tables, refs. (AFOSR-TN-58-474) (AF 49(638)323) AD 158285; PB 135153 Unclassified

A determination is made of a representation of the

valence band of BeO for certain directions in the wurtzite brillouin zone (BZ) by using the tight binding approximation. Only the single configuration $\text{Be}(1s)^2\text{O}(2p)^6$ is considered in the calculation. The $\text{O}^{--}(2p)$ radial function from MgO is used to represent the oxygen-valence electron distribution in BeO. Free-ion radial functions are used for the tightly bound Be(1s) valence electrons and the oxygen(2s) core electrons. Because of the spherically symmetric nature of the $\text{Be}(1s)^2$ and $\text{O}(2p)^6$ charge distributions, no effort is made to construct orthogonalized atomic orbitals nor to form symmetry functions, but the correction is made for nonorthogonality of atomic orbitals centered about different lattice sites. The character tables for irreducible representations of the wurtzite single (space, no spin) group and compatibility relations between irreducible representations of the groups at different points of the BZ are determined. It is predicted from the BeO calculation that the valence band peaks, if located at some point of reciprocal space possessing more than general symmetry, lie in the (k_x, k_y) plane; possibly at the midpoint of the BZ faces intersecting this plane. The valence band width, as determined, is 18 ev.

FEEDBACK COHERENCE CONTROL FOR SUPER-REGENERATIVE SPECTROMETERS, by C. Dean. [1958] [1]p. incl. diagr. (AFOSR-TN-58-661) (AF 49(638)323) AD 228953 Unclassified

Also published in Rev. Scient. Instruments, v. 29: 1047, Nov. 1958.

PIT.05:006 - PIT.05:009

One disadvantage of a super-regenerative spectrometer is the need to adjust its quench rate (pulse repetition rate) frequently during searches through wide bands of radio-frequencies. This is done to restore the coherence and thus the gain of the spectrometer to a convenient level. However by stabilizing the gain through a feedback control of the quench rate it is possible to considerably broaden the rf bands that can be covered without manual readjustment. The feedback signal can be developed by selecting and rectifying a band of the noise from the audio-frequency output which does not contain an appreciable amount of the nuclear resonance signals. This noise may originate in the tuned circuit or in the oscillator tube. In any event the detected noise which is found in the audio output appears to have been amplified with the same gain as the nuclear resonance signals, and a feedback signal proportional to its amplitude furnishes a suitable control signal. A 30- to 45-mc self-quenched super-regenerative spectrometer incorporating this principle is described.

THEORY OF THE NUCLEAR MAGNETIC RESONANCE SHIFT IN PARAMAGNETIC CRYSTALS, by F. Keifer, T. Oguchi and others. [1958] 36p. incl. refs. (AFOSR-TN-58-947) (AF 49(638)323) AD 205100 Unclassified

Also published in *Phys. Rev.*, v. 115: 1553-1561, Sept. 15, 1959.

A theoretical study is made of the shift of the F^{19} nuclear resonance in paramagnetic and antiferromagnetic MnF_2 which has been observed by Shulman and Jaccarino. The problem is reduced to that of a single Mn-F pair. A net hyperfine interaction is shown to arise from overlap effects in the ground-state ionic configura-

tion $(3d)^5(2s)^2(2p)^6$ and from overlap and transfer effects to the configurations $(3d)^6(2s)(2p)^6$ and $(3d)^6(2s)^2(2p)^5$. These three configurations are equivalent to a single configuration involving bonding-type molecular orbitals. The results are in reasonable agreement with the experiment, the theoretical isotropic shift being slightly too small and the theoretical anisotropic shift (small non-dipolar part) being slightly too large. A re-appraisal is made of Tinkham's data on paramagnetic resonance Mn^{++} impurities in ZnF_2 , which Bleaney has shown to be closely related to the Shulman-Jaccarino data. It is found that there is no need to include, as did Tinkham, a large fraction of fluorine 3s and 3p functions into the bond. (Contractor's abstract)

TECHNIQUES OF NMR ACOUSTIC ABSORPTION (Abstract), by M. Menes and D. I. Bolef. [1958] [1]p. [AF 49(638)323] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Published in *Bull. Amer. Phys. Soc.*, Series II, v. 3: 144, Mar. 27, 1958.

The technique used in observing nuclear magnetic resonance acoustic absorption is a combination of conventional NMR technique with the composite resonator technique used in ultrasonic measurement. The composite resonator consists of the sample, which has been ground and polished to have flat and parallel faces, to which has been cemented a quartz transducer crystal. This composite resonator is coupled through an impedance matching and inverting network to a Pound-Watkins oscillator. This is followed by conventional synchronous detection equipment. At present the technique has been successful only in materials having small acoustic damping, and for nuclei

PIT.05:010; PLA.01:001;
PLA.02:001-003

having fairly strong quadrupole coupling to the lattice. A static quadrupole interaction is, however, not necessary. Under the test conditions, with a sample size of the order of a cubic centimeter, a sensitivity comparable to conventional NMR has been obtained.

PROPULSIVE PROPERTIES OF HIGH INTENSITY PLASMA JETS, by A. C. Ducati and G. L. Cann. Feb. 21, 1958, 138p. incl. illus. diagrs. tables. (Rept. no. GRL-TR-9) (AFOSR-TN-57-748) (AF 49(638)54) AD 136736 Unclassified

A continuously operating plasma generator has been developed, and experimental investigations of high intensity ionic propulsive jets have been conducted. A primary investigation of the propulsive properties indicated that specific impulses of 200 and 500 could easily be obtained for argon and helium, respectively, as a result of the direct transfer of electrical energy to the gas. Electrode and nozzle configuration was found to have a definite effect on the ratio of internal energy in the gas to ionization energy at the front exit area. Practically all of the energy in the form of nonequilibrium ionization can be assumed to be transferred to the random particle motion and direct kinetic energy of the gas. The radiated energy is to some extent included in the energy absorbed by the cooling system. The radiation measured externally to the generator was found to be approximately 5% of the input electrical energy. A limited number of mixing experiments have been performed. THE GENERALIZED OVERHAUSER EFFECT AND ITS APPLICATION TO FERRO- AND ANTIFERROMAGNETISM (Abstract), by T. Oguchi and F. Keffer. 1958, 1p. (AF 49(638)323) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 193, May 1, 1958.

The theory of the Overhauser effect may be formulated from general statistical-mechanical arguments, indicating that a forced statistical redistribution may be made to occur in any sub-system whose principal contact with a heat bath is indirectly routed through some other statistically distributed system. In particular we consider Overhauser nuclear polarization in ferro- and antiferromagnets. Here the main route of nuclear relaxation will generally be via the excitation and/or absorption of spin-wave quanta. At low temperatures multiple spin-wave processes should predominate over processes involving phonons. In order to conserve energy, at least one spin wave must be annihilated if a spin wave is created; this means that the nuclear relaxation rate depends strongly on the number of spin waves present. By resonance excitation of a large number, n_0 , of $k = 0$ spin waves, with $n_0 > \sum_k + 0 n_k$, (the number of thermally excited spin waves), we may force the nuclei to relax primarily to the $k = 0$ spectrum. We show that the resultant nuclear polarization is proportional to $\exp(-2\mu_N H-S \hbar \omega_0)/kT$, where ω_0 is the resonance frequency and S is the power saturation factor.

Argon has been passed through an arc and ejected as a jet through an orifice in one of the electrodes. Measurements were made to determine the total gas enthalpy and the proportion of the enthalpy in directed kinetic energy, random particle motion, and ionization energy. From these measurements it is postulated that the gas is initially in a non-equilibrium state on leaving the arc, but approaches equilibrium relatively quickly when confined to a constant diameter jet outside of the arc. The gas equilibrium temperature range in these experiments varies from 5,000 to 15,000°K. (Contractor's abstract)

Also published in Proc. Symposium on Advanced Propulsion Systems, Los Angeles, Calif. (Dec. 11-13, 1957), N. Y., Pergamon Press, v. 2: 33-41, 1959.

An experimental study of the thrust characteristics of a continuous, high-pressure, electrically heated jet has been carried out. Argon and helium were used as the working fluid. Equilibrium stagnation temperatures for the two gases varied from 5000 to 15,000°K with exit pressures of one atmosphere in all cases. At these temperatures real gas effects can become important in the analysis of the experiments. For instance, the measurements indicated a degree of ionization between about 0.5 and 15%, depending on the time available for the gas to reach thermodynamic equilibrium. The power input in the gas was measured directly and the fraction of this power in random motion of the particles (temperature), directed motion (thrust), and ionization was determined as a function of gas mass flow rate and chamber pressure. Original measured values of specific impulse were low by a factor of two or three when compared with expected values using real gas thermodynamics. When elongated nozzles were used to confine the jet, the values of the specific impulse were much larger and, within experimental error, equal to the calculated value. This behavior originally observed is attributed to the extreme thermal non-equilibrium which existed in the jet as it issued from the orifice. With the final configuration, specific impulses as high as 600 sec have been obtained and it is believed that values as high as 1000 sec can readily be produced with helium. (Contractor's abstract)

Presented at Second Annual AFOSR Astronautics Symposium, Denver, Colo., Apr. 1958.

Also published in Vistas in Astronautics, v. 2: 95-103, 1959.

Experiments have been run to determine the nature and magnitude of the thrust obtainable from plasma jet propulsors. The plasma jet is produced by an electric thrust device consisting of a chamber with a cylindrical electrode at the back and an annular electrode at the front. A dc power supply establishes a potential and maintains an arc between them. Working gas is heated and ionized passing through the arc and out of the orifice at high velocity. Consequently appreciable thrust is obtained. Addition of a nozzle produces a better distribution of energy in the jet. Detailed analysis revealed the following: (1) power absorbed in cooling the electrodes is 25 to 40% of total input; (2) power loss from radiation is not greater than 5% of total input; (3) power specifically concentrated in gas kinetic motion is 5 to 15%; and (4) the remaining 50% power is apparently stored in ionization of the gas. Results show that electric arc plasma generators yield sustained, high specific impulses. However, due to the thrust-to-weight ratio, the chief practical application of plasma rockets will be for certain space missions originating and terminating at satellites where the ratio can be < 1.

Presented at First Internat'l. Congress for the Aeronautical Sciences, Madrid (Spain), Sept. 8-13, 1958.

Also published in Advances in Aeronaut. Sciences, v. 2: 1111-1123, 1959.

Considerable experimental work has been conducted recently on the production of high velocity matter. In the course of this work, results have been obtained which may be of significance to those interested in the possibility of very high specific impulse thrust devices. A brief review is presented of two electrical systems for obtaining high velocity directed mass motion of plasmas ("thermal-plasma" and "magneto-plasma" systems). In thermal-plasma systems, the enthalpy of a gas is increased by conversion of electrical energy into random particle energy by means of internal ohmic heating. In magneto-plasma systems, plasma is accelerated by the interaction of currents in a gas with magnetic fields produced by currents in fixed external conductors. Experiments are described employing examples of each system.

THE "PUNCH" METHOD OF COMPRESSING, HEATING AND CONFINING OF A PLASMA, by H. G. Loos. Dec. 1958, 25p. incl. diagr. refs. (Rept. no. T-1TN128-335) (AFOSR-TN-58-1130) (AF 49(638)335) AD 207975; PB 139488 Unclassified

A method of compression, heating and confinement of a plasma by means of a suddenly applied magnetic field of external origin is explored. The basic cylindrical configuration does not show any instabilities in the hydrodynamic approximation. The no. of ions (N_i) per unit length along the tube is shown to be related to the amount of separation between plasma and field that is achieved in times small compared with the decay time of the field. Furthermore, N_i determines how many large angle

PLA.05:002; POL.01:016-018

collisions an ion will undergo with other ions during the decay time. Order of magnitude calculations have been made of the energy required for heating by isentropic compression and of the energy and voltage required for shock heating. (Contractor's abstract)

ACCELERATION AND CHANNELING OF PLASMA JETS BY MAGNETIC FIELDS (Abstract), by V. Blackman. [1958] [1]p. (Bound with its AFOSR-TR-58-125; AD 162274) (AF 49(638)335) Unclassified

Presented at Conf. on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

Previous experiments at the Giannini Research Lab. with the continuous arc-type plasma source as a thrust device have resulted in specific impulses up to 600 secs with helium as a working fluid. This value can be increased by a factor of two or three, but beyond this the practically attainable specific impulse of an arc jet is limited by rapidly increasing electrode erosion with increasing gas enthalpies. Likewise, the channeling of the very hot plasma by mechanical walls (conventional expansion nozzle) also becomes increasingly difficult. In order to increase the specific impulse by a large amount over the values already produced, i.e., to values above 3000 secs, one promising approach would be to accomplish both the acceleration and the channeling of the plasma by means of electromagnetic fields. Experimental work has been initiated on the creation and acceleration of plasmas by electromagnetic fields. An experimental geometry which has already been studied extensively is a gas-filled cylindrical pyrex vessel centrally girthed by a single-turn coil. A surge of current passed through the coil by the discharge of a low-inductance capacitor bank gives rise to a rapidly varying magnetic field, which in turn induces an electrodeless discharge in the gas. Ohmic heating of the resulting plasma and magnetomotive interaction between the eddy currents and the electromagnetic field transfer energy and some axial momentum to the gas. Thus, high Mach number shock waves are produced which travel along the tube away from the coil. The luminous front associated with these shock waves has been observed by high-speed photographic methods (rotating mirror camera). Exploratory experiments on the channeling effect of axially symmetric magnetic fields on a plasma jet were also undertaken. In these experiments 4000 joules of energy from a capacitor bank were discharged through a single-turn coil coaxially mounted with respect to the plasma jet. Attempts are being made to observe the resulting flow distortion effects by means of a high-speed drum camera. The experimental apparatus and data are discussed. In addition, a brief comparison between two types of plasma propulsors is presented.

The anodic and cathodic behavior of silver in perchlorate, nitrate and sulphamate solutions has been investigated by means of oscillographic recordings of the voltage-time curves, for very short rectangular current pulses. The influence of the anion, of the silver salt concentration and of the free acid content on the "maxima" and on the initial polarization capacities has been investigated and discussed. The activating influence of the sulphamate, nitrate and hydrogen ions has been confirmed. One explains the silver overvoltage as depending on crystallization processes.

ELECTROCHEMICAL BEHAVIOR OF NICKEL, by G. Serravalle. Dec. 1957, 29p. incl. diagrs. tables. (Technical note no. 11) (AFOSR-TN-58-237) (AF 61(514)733-C) Unclassified

The cathodic and anodic electrochemical behavior, the passivation phenomena and the passivity conditions of Ni in aqueous solutions of various nickel salts at different pH values, temperatures, and current densities have been investigated. Cathode overvoltages were measured at temperatures from 25 to 65°C and pH from 1.5 to 4.8. The electrode voltage has been found to depend on the current density as given by the Tafel relationship. The slope of the Tafel curves depend on temperature variations, but the effect of change of pH was slight. The current efficiency is found to increase with temperature for sulfate solutions and to a smaller extent for chloride and mixed sulfate-chloride solutions. The anodic behavior for carefully prepared electrodes of very pure Ni showed that hysteresis effects were small and no evidence was found of an ohmic contribution to the overvoltage.

RESEARCH ON ANODIC AND CATHODIC BEHAVIOR OF METALS, by R. Piontelli. Final rept. May 1958, 27p. Incl. refs. (AFOSR-TR-58-97) (AF 61(514)733-C) AD 162165 Unclassified

The measurement of electrode overvoltages of metals in solutions and fused salts was studied. The following were investigated: (1) structural characteristic of electrode material; (2) cell design with particular regard to current distribution on electrode surface, systematic errors involved by tensiometric devices, and elimination of concentration polarization; (3) contamination sources; and (4) choice of the electrical supply conditions and voltage measurement apparatus and practice. Results are discussed concerning the anode and cathode overvoltages of polycrystalline Au, Ag, Cu, Sn, Pb, Tl, Zn, Cd, In, Ni, Mg, Ti, and Fe. Thermodynamic, kinetic, and structural aspects are taken into account in the discussions on aspects of the metal electrode behavior. The anion influence on the kinetics of ionic exchange processes was considered. A glossary is proposed in order to attain sufficient order and agreement on general concepts and definitions in the study of passivation and passivity. The eventual anisotropy in the overvoltages of electrodes whose working surface corresponds to a well defined crystallographic orientation was determined. Systematic work was conducted on the electrode behavior of metals in fused salts, especially of Al in cryolite-alumina baths.

By the use of suitable singular functions fulfilling the equation of Tomotika and Tomada (Quart. Appl. Math., v. 9: 129, 1951) utilized as stream functions, a process is developed to construct motion fields around symmetrical wing profiles, with Mach numbers a little higher than one. The theoretical analysis is followed by a numerical calculation of a particular profile and the flow around it; a comparison is then made with the corresponding results relating to the case in which $M = 1$. On the basis of the statement of the problem, the conditions on the shock polar are fulfilled with a certain error which is explained. The solution obtained is not an exact solution in the strict sense, but it is the rigorous solution of a very similar problem, in which the flow upstream of the shock wave is not perfectly uniform but slightly distorted by these conditions.

ON THE DISSOCIATION RATE OF A DIATOMIC GAS,
by G. Jarre. July 25, 1957, 12p. incl. diagrs. tables,
refs. (Technical note no. 2) (AFOSR-TN-57-528)
(AF 61(514)1124) AD 136513 Unclassified

A discussion is presented of a reaction rate formula which is applicable in current studies on hypersonic flow of diatomic gases. The rate of a reaction of the type, $X_2 = 2X$, is taken as the difference between the rate of the unimolecular dissociation and the rate of bimolecular recombination, $R = \bar{k}n_{X_2} - \bar{k}n_X^2$ in molecules X_2/cm^3 -sec, where $\bar{k}(sec^{-1})$ and $\bar{k}(cm^3/mol$ -sec) are the reaction constants and n_1 the partial densities (mol/cm^3). The activation complex or the existence of an intermediate state between the molecule and the 2 atoms is postulated by the theory of absolute reaction rate; this complex determines the reaction rate. The final form which is derived for the reaction rate is

$$R = \frac{kT}{he} e^{-E/T} n_{X_2} - \frac{kT}{h\nu} n_X^2. \text{ The activated complex has the characteristics } (\Delta E \text{ (internal energy), } \Delta N \text{ (stoichiometric coefficient), } \Delta S^\circ \text{ (standard entropy)) which minimize the entropy source of the reaction.}$$

plex has the characteristics (ΔE (internal energy), ΔN (stoichiometric coefficient), ΔS° (standard entropy)) which minimize the entropy source of the reaction.

Also published in Zeitschr. Angew. Math. Phys., v. 9B: 389-403, Mar. 25, 1958.

A study of the dissociation of a pure diatomic gas behind a strong normal shock wave included: (1) an analytical discourse on the general expression of the dissociation rate; (2) the employment of simplified models of the dissociating gas and of the shock wave; (3) the analysis of heating and compression effects of the shock on the dissociation; and (4) the analysis of the space constant of relaxation. Results showed that the discontinuous transition through the shock is only controlled by the upstream Mach number, while the continuous relaxation behind the shock is only controlled by the heating effect and the compression effects. The compression effect mainly determines the space constant of relaxation or its asymptotic value. (ASTIA abstract)

The purpose of this work is the determination of the two-dimensional flow past an airfoil placed in a stream of inviscid fluid, uniform to the infinity, under the following conditions: (a) the stream at infinity, referred to a system of axes (x^* , y^*), has a speed U_∞ and a Mach number $M_\infty < 1$ which is sufficiently high so that a supersonic region exists; (b) the symmetrical airfoil starting from a given instant, which will be conventionally considered as initial, has a translatory motion [referred to the same system (x^* , y^*)] in the direction of its symmetry axis. By applying the transformation of Legendre, the study of the problem is transferred from the physical space to the hodographic space. The equation which the transformed potential must satisfy is not linear, but is analogous to the equation of Guderley which gives this potential in the three-dimensional steady flow problem.

POT.01:009, 010; PIB.11:001;
PIB.02:003

The ogive having minimum drag in hypersonic flow is determined for a given thickness, or for a given arc length, or for a given enclosed area. Fluid is assumed inviscid, the airfoil is assumed to be symmetric with zero incidence. Approximation of small disturbances is accepted, but not the linearized theory, assuming that the hypersonic similarity parameter could reach the value 2. Within these limits the flow behind the shock wave is a quasi-simple-wave, that is it may be approximate to a flow in which pressure is constant along the characteristics of one family; this is rigorously demonstrated in the proximity of the shock-wave and on the leading edge. As in these regions, the entropy gradient and rotationality are the greatest, it is assumed that the approximation has a general character over the whole field. (Contractor's abstract)

THE DISSOCIATION OF A PURE DIATOMIC GAS IN A LAMINAR BOUNDARY LAYER ON AN ADIABATIC FLAT PLATE, by G. Jarre. Sept. 1958 [18]p. incl. diagrs. tables. (Technical note no. 10) (AFOSR-TN-58-944) (AF 61(514)1124) AD 205082; PB 138057 Unclassified

The problem is discussed of the dissociation, produced by the friction heating, in a pure diatomic gas in a laminar boundary layer on an adiabatic flat plate at hypersonic Mach numbers. Two different and simplified methods are applied and give almost the same numerical laws describing the temperature-decay at the wall at the approaching of the chemical equilibrium state. Two numerical examples show that the considered case of dissociation is a very slow process.

PHOTOCONDUCTION IN SINGLE CRYSTALS OF ZnS, by J. J. Dropkin and F. G. Ullman. Final rept. Dec. 1, 1953-Aug. 31, 1958 [111]p. incl. illus. diagrs. tables, refs. (AFOSR-TR-58-126) (AF 18(600)692) AD 203331; PB 140850 Unclassified

Growth of ZnS crystals: Synthetic single crystals were grown by deposition of ZnS vapor obtained by sublimation of unactivated ZnS powder in an atmosphere of flowing He in a 2-zone furnace to produce crystals suitable for photoconduction measurement. The electrical behavior of single crystals of ZnS: The ac and dc photoconduction in nonluminescent natural and synthetic single crystals was investigated. Natural crystals exhibit persistent internal space charge polarization and show a Debye type of frequency dispersion in ac resistance and capacitance in the 3- to 50-c range. In synthetic crystals, dc polarization and ac dispersion effects are small, and the speed of response is slow. The differences in electrical behavior of these 2 crystal types result from the presence of deep traps in the natural crystals and their absence in the synthetic crystals. IR stimulation and quenching of photoconduction in single crystals of ZnS:Cu: The spectral response of photoconduction in the synthetic crystals was investigated from 0.5 to 2.0 μ . Two IR photocurrent peaks at 0.65 and 1.35 μ were found even in crystals not previously irradiated by UV. Photocurrents are also excited by 2537A and 3650A and each can be quenched by IR. In all crystals, and for all intensities, the sum of the UV and IR photocurrents, measured separately, is always greater than the photocurrent excited by simultaneous UV and IR. Excitation of IR photocurrent, IR absorption and quenching of UV photocurrent, IR absorption and quenching of fluorescence and excitation of IR emission have nearly identical spectral response; therefore, all probably arise from the same excitation mechanism.

STUDY OF PHASE TRANSITIONS IN WO₃ WITH A HIGH-TEMPERATURE X-RAY DIFFRACTOMETER, by J. A. Perri, E. Banks, and B. Post. July 12, 1957 [4]p. incl. diagrs. [Technical note no. 3] (AFOSR-TN-58-285) (AF 18(600)1193) AD 154189 Unclassified

Also published in Jour. Appl. Phys., v. 28: 1272-1275, Nov. 1957.

WO₃ undergoes a phase transformation from monoclinic to orthorhombic at approximately 320°C and from orthorhombic to tetragonal at 720°C. A detailed study of the variation of the unit cell dimensions over the range from room temperature to 1000°C has been carried out using high-temperature x-ray diffraction techniques.

PIB.02:004; PIB.04:007-009

Some unique features of the apparatus are described in this paper. Between the 320°C and 720°C transformations, the a and c axes increase uniformly in length while the b axis decreases. There is a marked increase in the volume of the unit cell below the orthorhombic to tetragonal transformation; the volume decreases sharply in the transformation and resumes its "normal" increase above 720°C. RARE EARTH METAL "DISILICIDES", by J. A. Perri, I. Binder, and B. Post. [1958] [10]p. incl. diagrs. tables. [Technical note no. 4] (AFOSR-TN-58-1054) (AF 18(600)1193) AD 206982 Unclassified

Also published in Jour. Phys. Chem., v. 63. 616-619, Apr. 1959.

Disilicides of Ce, Pr, Nd, Sm, Eu, Gd, Dy and Y have been prepared. The Ce, Pr and Nd compounds are tetragonal as previously reported; the Sm, Gd, Dy and Y compounds are orthorhombic, space group Imma. Their structures are slightly distorted versions of the tetragonal MeSi_2 structures. The magnitude of the distortion appears to increase with decreasing size of the metal atom. Chemical and x-ray diffraction studies of " GdSi_2 " indicate that the composition is close to

$\text{GdSi}_{1.4}$. EuSi_2 crystallizes in the tetragonal system apparently due to the anomalously large size of the metal atom. (Contractor's abstract)

A PHENOMENOLOGICAL THEORY OF THE FREE TURBULENT FLOW OF A NON-REACTING BINARY GAS MIXTURE, by L. G. Napolitano. Dec. 1956, 46p. incl. refs. (PIBAL rept. no. 317) (AFOSR-TN-57-39) (AF 18(600)693) AD 115077 Unclassified

Classical results of the kinetic theory of non-uniform gases are used to derive the basic equations describing the free turbulent motion of a non-reacting binary gas mixture. Upon extension of the Reynolds similarity concept, all conductive currents are neglected and the resulting equations are presented in curvilinear orthogonal coordinates. Turbulent transport fluxes are defined and their analogy with the corresponding molecular conductive currents discussed. These turbulent fluxes are subsequently related to pertinent mean gradients through phenomenologically defined eddy coefficients. Turbulent Prandtl (Pr^t), Schmidt (Sc^t) and Lewis (Le^t) numbers are introduced by means of non-dimensional grouping of these coefficients. The boundary layer approximation

to the basic equations is successively derived and the simplifications connected with the assumptions $\text{Sc}^t = \text{Pr}^t = 1$ investigated. First integrals of the diffusion and energy equations are found, which simply express linear dependence of mass concentration and total stagnation enthalpy of the mixture on the velocity ratio. TURBULENT MIXING OF TWO NON-REACTING GASES, by L. G. Napolitano. Jan. 1957, 49p. incl. table. (PIBAL rept. no. 323) (AFOSR-TN-57-41) (AF 18(600)-693) AD 115079 Unclassified

A preliminary investigation of two-dimensional free turbulent mixing of two non-reacting gases in the absence of axial pressure gradients is presented. A linear dependence on the velocity ratio of mass concentration and stagnation enthalpy of the mixture is proved to exist when the turbulent Prandtl and Schmidt numbers are both assumed to be one. The possibility of determining the combined effects of velocity, temperature, and concentration gradients by means of solutions of a single total differential equation is demonstrated. Two forms of the fundamental equation are derived under the hypothesis of constancy, along cross sections of the flow, of either the turbulent exchange coefficients or the mixing lengths. Several particular cases are examined and instances wherein the subject problem is reduced to well known solutions of turbulent mixing with uniformity in concentration are given. GENERALIZATION OF INTEGRAL RELATIONSHIPS WITH APPLICATIONS IN WING-BODY INTERFERENCE, WING THEORY, AND DIFFRACTION OF PULSES, by L. Ting. Apr. 1957 [44]p. incl. diagrs. refs. (PIBAL rept. no. 379) (AFOSR-TN-57-159) (AF 18(600)693) AD 126451 Unclassified

A theorem is proved concerning the integrated properties of the linearized pressure distribution on a cylindrical surface in a supersonic stream when the normal velocity on the cylindrical surface is prescribed. The theorem is a generalization of the integral relationships concerning certain properties of (1) the linearized pressure fields due to a planar source distribution in a supersonic stream; (2) extensions of these properties to a class of 3-dimensional problems which involve biplanes or cruciform wing arrangements; (3) the pressure integral along the line of intersection of a forward Mach

cone with a specified nonplanar surface which is a prismatic body of rectangular cross section mounted on a planar wing with supersonic edges; (4) the normal velocity prescribed on the side walls of the body; and (5) the cylindrical surface of the form of a stairway with a finite number of steps. The theorem is useful in the evaluation of total lift and drag of wing-body combinations when the linear dimensions of the cross section of the body are not small as compared to the chord length. The theorem is applied in the derivation for lift and drag of a rectangular wing with a constant zero thickness profile in supersonic flight without the use of Ervard's (NACA TN 1382) result. For the diffraction of a pulse or a weak shock over a rectangular notch, a pressure integral theorem is obtained. Its usefulness is demonstrated in reducing the labor of obtaining the mean pressure distribution along any depth inside the notch at different instants for various width-height ratios of the notch.

SOME REMARKS ON THE SOLUTION OF A SYSTEM OF EQUATIONS OCCURRING IN LAMINAR MIXING WITH AXIAL PRESSURE GRADIENTS, by L. G. Napolitano. Sept. 1957 [15]p. incl. diagrs. (PIBAL rept. no. 393) (AFOSR-TN-57-609) (AF 18(600)693) AD 136599 Unclassified

A fifth order system of equations with three-point boundary considerations is investigated from the point of view of obtaining solutions by means of high speed computing machine. The subject system occurs in the study of laminar mixing in the presence of axial pressure gradients. Two methods of solution are outlined: In the first one a suitable change of variables reduces the original equations to integro-differential equations defined over a finite interval of the independent variable. An iteration scheme is subsequently adopted and asymptotic solutions, as needed to compute the solution in the proximity of the end points, are presented. The second method considers the solution as an "initial value" problem. The four-fold indeterminacy which arises when the solution is started from the point $\sigma = 0$ is shown to be reducible to a two-fold one. The two parameters left are related to the attainment of the required asymptotic behavior of the solution. (Contractor's abstract)

INCOMPRESSIBLE MIXING OF A SHEAR FLOW WITH FLUID AT REST, by L. G. Napolitano. Nov. 1957 [44]p. incl. diagrs. refs. (PIBAL rept. no. 318) (AFOSR-TN-57-754) (AF 18(600)693) AD 136743 Unclassified

The laminar and turbulent mixing of a non-uniform free stream with fluid at rest is investigated. Laminar and turbulent vorticity numbers are defined, which indicate the relative importance of the free stream vorticity as compared to the average vorticity present in the wake. Solutions of the subject problem are given to a first approximation in the vorticity numbers. The quantitative analysis shows that the presence of vorticity in the outer stream can be used as a practical and efficient device to control the transfer of properties between two different streams. HIGH SPEED MACHINE SOLUTIONS FOR PLANE TURBULENT HOMOGENEOUS AND NON-HOMOGENEOUS MIXING, by L. G. Napolitano. Oct. 1957, 37p. incl. tables. (PIBAL rept. no. 399) (AFOSR-TN-57-755) (AF 18(600)693) AD 136744 Unclassified

Numerical values as obtained from high speed machine solutions of the total differential equation governing two-dimensional, plane, turbulent homogeneous and non-homogeneous mixing are presented for a parabolic variation of the density ratio with the velocity ratio. Each solution is identified by the values of three parameters characterizing flow properties and nature of the free streams. A total of 28 cases is given, covering a wide range of these parameters. The pertinent formulae relating the tabulated values to the essential physical quantities of the flow field are also presented. (Contractor's abstract)

TWO-DIMENSIONAL PLANE MIXING OF HOMOGENEOUS AND NON-HOMOGENEOUS STREAMS, by L. G. Napolitano. Nov. 1957 [48]p. incl. diagrs. tables, refs. (PIBAL rept. no. 400) (AFOSR-TN-57-756) (AF 18(600)-693) AD 136745 Unclassified

High speed machine solutions of isobaric turbulent mixing of two semi-infinite streams are analyzed. The solutions (based on unitary turbulent Prandtl and Schmidt number and on a parabolic density-velocity relationship) apply to (1) homogeneous mixing, and (2) heterogeneous mixing of: (a) gases having the same number of degrees of freedom; (b) gases having the same molecular weight but specific heat differences that are small compared to velocity differences; (c) gases having the same specific heats but molecular weight differences that are small compared to velocity differences; and (d) streams with differences in the molar heat capacities small compared to velocity differences. For all these cases a particular

PIB. 04:014-016; PIB. 05:007, 008

solution depends upon the values of three parameters describing nature and properties of the free streams. Velocity profiles in terms of the similarity variable $\sigma = y/x \epsilon^{1/2}$ have appeared to be substantially independent of the nature of the interacting gases, the free stream stagnation enthalpy ratio and the Mach number. Based on these results, explicit approximate solutions are presented which prove to be very satisfactory when compared with the available exact ones. (Contractor's abstract)

CRITICAL STUDY OF THE ADEQUACY OF INTEGRAL METHODS IN PLANE MIXING PROBLEMS, by L. G. Napolitano. Dec. 1957, 1v. incl. illus. tables. (PIBAL rept. no. 425) (AFOSR-TN-57-757) (AF 18(600)693) AD 136746. Unclassified

Solutions of plane isobaric homogeneous mixing by integral methods are presented. Incompressible and compressible, laminar and turbulent cases are shown to be reducible to the solution of a unique laminar-incompressible-type system of equations. The third boundary condition, to be imposed on the y-component of the velocity, is proved to be inessential. The solution is given in a transformed (ζ, η_1) plane wherein the streamline through the origin is taken to coincide with the ζ -axis. Solutions of plane mixing problems subject to arbitrary boundary condition on the y-component of the velocity are related to the previous one through simple transformation formulae. Sixth degree polynomials are assumed for the velocity profiles and the solution of the basic equations is made to depend upon a single algebraic quadratic equation when the flow fields are similar. The accuracy of the method is determined by comparison with some high speed machine solutions of the pertinent Blasius equation and it proves to be extremely satisfactory. Comparative study of the accuracy obtained (1) by integral methods with fourth, sixth and seventh degree polynomials, and (2) by series solution of the Blasius equation is also made. It appears that sixth degree polynomials are the most accurate velocity profiles and that their accuracy is comparable with that of the series solution for large values of the free stream velocity ratio, but it is definitely better for small values of the aforementioned ratio. FAVORABLE INTERFERENCE IN LIFTING SYSTEMS IN SUPERSONIC FLOW, by A. Ferri, J. H. Clarke, and L. Ting. Nov. 1957 [14]p. incl. diagrs. refs. (PIBAL rept. no. 430) (AFOSR-TN-58-19) (AF 18(600)694) AD 148058 Unclassified

Presented at Twenty-fifth annual meeting of the Inst. of Aeronaut. Sciences, New York, Jan. 28-31, 1957.

Also published in Jour. Aeronaut. Sciences, v. 24: 791-804, Nov. 1957.

Certain simple integral relations are applied to the qualitative assessment and calculation of the favorable interference effects arising in various spatial arrangements of wings and bodies in a supersonic stream. The arrangements include slender bodies in proximity to wings, wings with underslung pylons or other vertical surfaces, and wing-fuselage combinations. The elementary considerations used in these examples serve to demonstrate to the designer how the pressure drag due to volume and lift can be reduced by arranging the several components comprising the configuration so that they exhibit mutually advantageous shapes and orientations. Vertically antisymmetric modifications of the fuselage shape in the neighborhood of the midwing are suggested which reduce the drag due to lift of mid-wing-body systems. The considerations are different from those giving rise to the supersonic area rule, according to which vertically symmetric fuselage indentations are made in order to reduce the drag due to thickness or volume, and might have comparable significance. (Contractor's abstract)

derived in the present report. Furthermore, the integral of the pressure along the line of intersection of a Mach plane with the wing surface can be obtained from the integral of the prescribed normal velocity by the integral relationship derived in a previous report. With this information the pressure distribution on the wing can be represented by a function of 2 variables which assume the proper values along the Mach lines issuing from the vertex of the wings and along the line of intersection of the wings. The remaining arbitrary constants in the function are determined by the integral relationships corresponding to the Mach planes at various orientations. If the normal velocity on the wing surface is constant, the approximate solution with only one arbitrary constant, determined by one integral relationship, is in good agreement with the linearized conical solution. If in the approximate solution, there are 2 arbitrary constants, determined by 2 integral relationships, the result is in perfect agreement with linearized conical solution. When the normal velocity on the wing surface can be represented by a power series of 2 variables, the general procedure of obtaining an approximate solution is outlined and illustrated by an example. Finally, a partially swept-back wing with dihedral is chosen as a working example, and the detail pressure distribution on the wing is obtained.

PRESSURE DISTRIBUTION ON DIHEDRAL WINGS AT SUPERSONIC SPEED, by L. Ting. Jan. 1958, 46p. incl. diagrs. (PIBAL rept. no. 397) (AFOSR-TN-58-86) (AF 18(600)694) AD 148135 Unclassified

Also published in Jour. Fluid Mech., v. 6: 302-312, Aug. 1959.

For the problem of supersonic flow over wings with supersonic edges, with dihedral and with arbitrary twist, camber, and thickness distributions, the pressure distributions on and outside the Mach cone issuing from the vertex of the wing are equal to the corresponding solutions for planar wings. The pressure distribution along the line of intersection of the wings is obtained from the corresponding solution for planar wings by virtue of the averaging properties of solutions of wave equations

PIB.05:013-016; PIB.06:006

increase in the height-width ratio the lift-drag ratio of the favorably contoured wing-body configurations, with the same projected planform, decreases slightly while the volume increases linearly with the height-width ratio. The effect of contouring the vertical surface which does not support lift of the subject wing-body configurations, results in an increase of 5 to 10% in the lift-drag ratio depending on the height-width ratio and also the ratio of the area of the lifting (horizontal) surface to that of the non-lifting (vertical) surface. Calculations for a simple model of wing-body combination are made to study the effect of favorable interference at off-design conditions. For a given value of lift coefficient, the drag varies in the same manner as a planar wing when the Mach number deviates from the designed value.

The possibility of drag reduction of wing-body combinations at all practical values of the lift coefficient, by a proper distribution of the body volume, is explored. This is illustrated by modifying a midwing configuration, composed of a full circular cone, symmetrically disposed about the sweptwing of zero thickness, to a high-wing configuration, composed of the same wing, but two half cones of equal volume as the full cone, mounted beneath the wing. It is found that at $M = 3.0$ and lift coefficient = 0.1, for a cone of semi-vertex angle $\theta_c = 5^\circ$,

the high-wing configuration gives a drag reduction of 16% over that of the corresponding midwing configuration whereas there is found to be a drag reduction of 6.5% at $M = \sqrt{2}$. Similar comparison for the percentage increase in lift drag ratio for the above-mentioned configurations shows a maximum increase of 34% at

$M = 3.0$ for the high-wing configuration over the midwing configuration, whereas it is 22% at $M = \sqrt{2}$. Numerical results show that the high-wing configuration gives a significant reduction in drag as compared to a midwing configuration of equal volume and furthermore, greater reductions in drag are obtained at higher Mach numbers. SOLUTIONS OF SUPERSONIC INTERFERENCE PROBLEMS BY GENERALIZED INTEGRAL RELATIONSHIP. EXAMPLES FOR A CIRCULAR CYLINDRICAL BODY, by L. Ting. Oct. 1958 [43]p. incl. diagrs. (PIBAL rept. no. 465) (AFOSR-TN-58-1069) (AF 18(600)694) AD 207229; PB 145482

Unclassified

The generalized integral relationship is employed to solve the interference problem of wings and cylindrical bodies of arbitrary cross section. The procedure is to represent the pressure distribution of the body and the wing inside the interference region by a linear combination of a finite number of elementary functions of the surface variables. The combination fulfills the condition that the pressure is continuous inside the interference region and also across its boundary. The arbitrary constants in the combination are determined by the generalized integral relationship which will be reduced to a set of simultaneous linear algebraic equations. A numerical example is carried out for a circular cylindrical body mounted on a semi-infinite plate. The results are in agreement with those obtained by Nielsen by a different theoretical method. The inverse matrix of the simultaneous equation in the present numerical analysis is tabulated so that the labor of solving the problem with a different prescribed normal velocity is substantially reduced. ELASTIC ANALOG FOR PRIMARY CREEP, by N. J. Hoff. n.d., 7p. (AF 18(600)1381)

Unclassified

Elastic analogues are developed for the primary creep problem. The strain rate is assumed to be a function of the instantaneous values of the stress and the strain to the extent that an approximate mechanical equation of state can be assumed for the system. A power law is assumed for the stress-strain relationship, and an expression for the strain rate is obtained. A model is assumed in which surface tractions $T_1(x, t)$ and body forces $\phi(x, t)$ are applied to one section S_1 of the body, and the remaining section of the body S_2 is slowly displaced with given velocities $V_1(x, t)$. Boundary conditions are given relating the applied traction and body forces, strain rate tensor, and displacement velocities. Elastic analogues are established for two cases: (1) $V_1 = 0$ on S_2 and (2) $\phi_1 = 0$, $T_1 = 0$ on S_1 .

A theoretical and experimental investigation was made of the behavior of rectangular frames of 5052-O Al alloy subjected to loads at 500°F. The displacement velocities of the point of application of the load were measured and compared to the results of theoretical analyses. The agreement can be considered satisfactory considering that primary creep was disregarded. (ASTIA abstract)

Published in Aero. Quart., v. 8: 215-225, Aug. 1957.

This analysis shows that the higher-harmonic deflection components reduce the column lifetime significantly only when their initial amplitudes, as well as the initial amplitude of the first harmonic component, are very large. Furthermore, it is shown that second-harmonic components have a much smaller effect on the column behavior than do third-harmonic components. (Contractor's abstract)

Part I-Theoretical phase: Indications were that elastic and plastic analogs exist for both transient and steady creep conditions. Creep problems in column, beam, tube, truss, frame, and plate structures were solved. Experimental phase: Two types of creep experiments were performed. One involved rectangular frames subject to the 2 opposing loads in the plane of the frame. The experimental deflection rates obtained were in good agreement with theoretical predictions. The second type of test involved damped circular plates subject to uniform lateral pressure and to rapid creep. Part II: Abstracts of all technical reports published under the subject contract are presented with concise remarks relative to the significance of the results, and a comparison with the results of other applicable investigations.

This paper deals with the solution of some particular cases of non-homogeneous isobaric turbulent plane mixing. Momentum, energy, diffusion, continuity and state equations, are presented for the general case of non-isobaric free turbulent motion of a non-reacting binary gas mixture in curvilinear orthogonal coordinates. Two dimensional plane isobaric motion is considered in detail within the boundary-layer approximation. Assuming similarity and other given conditions, the basic equations are reduced to a single total differential equation for the non-dimensional stream function. In the resulting equation the density ratio appears as a rational function of the velocity ratio. Simple approximate so-

lutions of the subject flow fields are derived and density profiles are computed from approximate velocity profiles obtained by the integral method.

Also published in Jour. Acro/Space Sciences, v. 25: 444-450, July 1958.

The laminar and turbulent mixing of a nonuniform free stream with fluid at rest is investigated. Laminar and turbulent vorticity numbers are defined, which measure the relative importance of the free-stream vorticity as compared to the average vorticity present in the wake and which increase with the square root of x and with x , respectively. Solutions of the subject problem are given to a first approximation in the vorticity numbers. In comparing the characteristics of the mixing due to a non-uniform stream $u_1 = \omega y$ with those due to the uniform stream $u = u_0$, it is found that vorticity effects over a given length are nearly always negligible in the laminar case but became sizable in the turbulent case. This is due to the usually higher rate of increase with x of the turbulent vorticity number. Results of the analysis, as applied to streams having constant vorticity over finite y -length, indicate the practicability of the use of outer vorticity as a means to control the rate of transfer of properties between two different streams. Solutions of plane isobaric homogeneous mixing by integral methods are presented. It is first shown that, under some usually accepted restrictive hypotheses, incompressible and compressible, laminar and turbulent cases are reducible to the solution of a unique laminar-incompressible-type system of equations. The solution is then given in a transformed (ξ, η) -plane wherein the streamline through the origin is taken to coincide with the ξ -axis. Solutions of plane mixing problems subject to arbitrary boundary conditions on the y -component of the velocity are related to the previous one through

simple transformation formulas. Sixth degree polynomials are assumed for the velocity profiles and the solution of the basic equations is made to depend upon a single algebraic quadratic equation. The accuracy of the method is determined by comparison with some high speed machine solutions of the pertinent Blasius equation and it proves to be extremely satisfactory. Comparative study of the accuracy obtained: (1) by integral methods with fourth, sixth and seventh degree polynomials, and (2) by series solution of the Blasius equation is also made. It appears that the integral method with sixth degree polynomials yields the best overall accuracy and that the superiority of the present method increases as the free stream velocity ratio decreases.

An experimental investigation at a Mach number of 3.09 of a low-drag auxiliary body, zero lift system, has been conducted. The design of the body was carried out by nonlinear methods of flow analysis. The test Reynolds number per foot for the entire program was 3.37×10^7 . The body can be applied to the problem of external storage under a wing or as an auxiliary ramjet engine to be used, for example, during acceleration. A drag coefficient of 0.0094 based on a reference area (maximum cross sectional area) of 2.120 sq in. was determined experimentally for the body in the proximity of the wing. The capture area of the body is 3.53 sq in. and the Mach number at the minimum section is 1.6. The method of design, a description of the test setup, discussion of the test results and the possible applications of the system are presented. (Contractor's abstract)

With the employment of the techniques of boundary

layer theory, the proper third boundary condition for the mixing of two parallel streams is derived from the compatibility condition of the higher order approximation. It is shown that the commonly adopted third boundary condition of balancing of transverse momentum is correct only for the mixing problem of two semi-infinite incompressible streams. For the fulfillment of the proper third boundary condition, the possibility of introducing the similar solution of Blasius type is examined for various cases. (Contractor's abstract)

Also published in Jour. Aero/Space Sciences, v. 26: 63-64, Jan. 1959.

In recent years great use has been made of approximate methods for the determination of the pressure distribution on blunt-nosed bodies and afterbodies at high Mach numbers. For quasi-spherical bodies it has been suggested that modified Newtonian theory in combination with a Prandtl-Meyer expansion be used on the nose portion, the two laws being matched at the point where the pressure gradients are equal. No simple approximation, however, has been found for flat-nosed bodies. As for the pressure distribution on the afterbody, the blast-wave analogy has been suggested for general nose shapes but particular afterbody profiles. The purpose of this note

PIB.12:008 - PIB.12:011

is to compare these approximate estimates with a more accurate determination of the flow field about a hemisphere-cylinder in an ideal gas flow at $M = 20$.

THEORETICAL AND EXPERIMENTAL ANALYSIS OF A COWLING AS A MEANS OF DRAG REDUCTION FOR AN AXISYMMETRIC CENTER BODY, by M. Visich, Jr. and A. Martellucci. Aug. 1958 [35]p. incl. illus. diagrs. tables, refs. (PIBAL rept. no. 451) (AFOSR-TN-58-760) (AF 49(638)217) AD 162273 Unclassified

Also published in *ARS Jour.*, v. 29: 447-449, June 1959.

A theoretical and experimental investigation at $M = 3.09$ of an axisymmetric boat-tailed center body surrounded by a cowling ring was conducted. The design of the body was accomplished by the method of characteristics for axisymmetric irrotational flow for zero angle of attack. The test Reynolds number per foot for the entire program was 3.37×10^7 and the flight attitude for the tests was at zero angle of attack. The configuration studied can be used as an independent flight vehicle with a circular wing. It can also be used as an auxiliary ramjet engine or external storage system for long range vehicles. For the optimum configuration considered, a total drag reduction of 61.8% was measured over the center body alone. Comparison of the total drag of the optimum configuration to that of a cone with the same volume and length as the center body indicates a reduction of 47%. The method of design, a description of the experimental equipment, discussion of the test results, and the possible applications of the system are presented in this report. (Contractor's abstract)

THE THREE-DIMENSIONAL COMPRESSIBLE LAMINAR BOUNDARY LAYER, by M. Epstein. Oct. 1958 [77]p. incl. diagrs. table, refs. (PIBAL rept. no. 455) (AFOSR-TN-58-894) (AF 49(638)217) AD 204135; PB 143510 Unclassified

A method is presented for determining approximate solutions to the 3-dimensional compressible laminar boundary layer equations. The proposed method resembles the classical integral method, and is designed to overcome one of the principal difficulties in that method, namely the problem of choosing appropriate analytical representations of the boundary layer profiles. An iteration procedure was developed wherein improved approximations to the boundary layer profiles are gen-

erated from a set of simple initial profiles. The present method requires the satisfaction of 2 integral conditions by each of the improved profiles. The first iteration, for any given initial choice of profiles, should give an improvement over the standard integral method. A comparison of results predicted by the present method with known exact solutions of 2- and 3-dimensional problems indicates that one iteration is sufficient to obtain engineering accuracy for a wide range of problems. The application of the method to a more general 3-dimensional problem is illustrated by calculating the development of the boundary layer along the stagnation line of a wing with a curved leading edge. PRESSURE DISTRIBUTIONS ON A TWO-DIMENSIONAL BLUNT-NOSED BODY AT VARIOUS ANGLES OF ATTACK, by V. Zakkay and A. K. Fields. Oct. 1958, 22p. incl. illus. diagrs. (PIBAL rept. no. 461) (AFOSR-TN-58-1016) (AF 49(638)217) AD 162281; PB 145481 Unclassified

Pressure measurements have been made for a two-dimensional blunt-nosed body in order to determine the effect of angle of attack on the pressure distribution. It is shown that the Newtonian theory does not apply to bodies where the sonic point does not fall on the same radius of curvature as the stagnation point. A large reduction in stagnation point heat transfer was obtained as a result of increasing the radius of curvature of the body at the sonic point over that which exists at the stagnation point of constant radius of curvature models. RECENT WORK ON MIXING AT THE POLYTECHNIC INSTITUTE OF BROOKLYN, by I. G. Napolitano, P. A. Libby, and A. Ferri. [1958] [35]p. incl. illus. diagrs. table, refs. [AF 49(638)217] Unclassified

Published in *Combustion and Propulsion, Third Agard Colloquium: Noise, Shock Tubes, Magnetic Effects, Instability and Mixing*, Palermo (Italy) (Mar. 17-21, 1958), London, Pergamon Press, 1958, p. 118-152.

Recent theoretical and experimental work on mixing flows is reviewed. Two general problems are discussed: (1) the free mixing of semi-infinite streams, and (2) mixing in the presence of a wall. In the first problem there are considered the cases of uniform streams and of non-uniform streams involving separately streamwise pressure gradients and vorticity. The fully developed free

turbulent mixing of two different gases is discussed; in particular the governing equations for two different assumptions with respect to turbulent transport are derived. Solutions for unity values of turbulent Prandtl and Schmidt numbers and for a parabolic density-velocity relationship have been obtained by high-speed machine calculations. On the basis of the numerical results it is concluded that turbulent mixing velocity profiles are substantially independent of the nature of the gases, of the free stream density ratio and of the Mach numbers. Approximate solutions in these types of non-homogeneous turbulent mixing are presented. The possibility of one-parameter solutions of homogeneous compressible laminar mixing in the presence of streamwise pressure gradients is shown and the pertinent equations are derived. The influence of outer vorticity on the characteristics of the laminar or turbulent interaction of an incompressible, constant-vorticity stream with fluid at rest is determined. In the second problem, the various regions of the interaction between the mixing region and the boundary layer on the wall are discussed. For the first region, wherein an inviscid core between the two viscous regions exists, a solution is presented. Preliminary results of an experimental investigation of compressible, isoenergetic mixing in the presence of a wall are also presented. (Contractor's abstract)

A REVIEW OF SOME RECENT DEVELOPMENTS IN HYPERSONIC FLOW, by A. Ferri. [1958] [45]p. incl. illus. diagrs. tables, refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 49(638)-217 and WADC Aeronautical Research Lab. under AF 33-(616)3265) Unclassified

Presented at First Internat'l. Congress for the Aeronautical Sciences, Madrid (Spain) Sept. 8-13, 1958.

Also published in *Advances in Aeronaut. Sciences*, v. 2: 723-770, 1959.

This review indicates the following conclusions: (a) The results of theoretical work and of experiments involving simulation of flight conditions tend to indicate that in the approximation within which the physical quantities can be determined and for high flight Reynolds number real gas effects are of relatively small importance. (b) Pressure distributions and forces on simple boundary conditions can be obtained with simple rough approximations, with accuracy often sufficient for engineering applications. More appreciable progress is required in the development of approximate analyses for more complicated boundary conditions or of more precise analyses for simple problems. (c) The heat transfer on simple bodies can be obtained with good approximation for the laminar case from existing theories. Simple

theories for turbulent cases seem to give sufficient approximation. However, transition phenomena and the foundation of turbulent analysis require much further study. (d) Entropy gradients can affect heat transfer an appreciable amount and can be utilized to reduce aerodynamic heating at high speed.

TORSION OF CYLINDRICAL AND PRISMATIC BARS IN THE PRESENCE OF PRIMARY CREEP, by S. A. Patel and K. A. V. Pandalai. Apr. 1958 [7]p. incl. diagrs. (PIBAL rept. no. 417) (AFOSR-TN-58-303) (AF 49-(638)302) AD 154213; PB 134662 Unclassified

The creep problem treated in this article has been shown to reduce to the non-linear elastic problem where

the material is governed by the equation: $\epsilon_{ij} = DJ_2^a s_{ij}$

where ϵ_{ij} is the strain tensor, s_{ij} the stress-deviation

tensor, and D and a are material constants. The elastic solution for the torsion of cylindrical and prismatic bars is given by Patel, Venkatraman and Hodge (Torsion of Cylindrical and Prismatic Bars in the Presence of Steady Creep, presented at the annual meeting of the annual ASME Meeting, New York, Dec. 1957). The results for the angle of twist per unit length α for a given torque T are obtained for the case of a cylindrical bar of circular cross-section, as well as for cross sections which are regular polygons and triangles of unequal sides. By employing the principle of minimum total potential and the principle of minimum complementary potential, upper and lower bounds on α were obtained. However, an exact solution could be obtained for the case of circular cross-section for which the warping function vanishes. (Contractor's abstract)

ON ASYMPTOTIC NUMERICAL METHODS FOR PARABOLIC EQUATIONS, by J. R. M. Radok. Nov. 1958, 14p. [PIBAL rept. no. 485] (AFOSR-TN-58-1072) (AF 49-(638)302) AD 207241 Unclassified

Investigation of the roles played in the partial differential equations of physics by time and space derivatives leads to the conclusion that divided differences render suitable approximations to space derivatives, while the approximation of time derivatives may greatly benefit from more refined treatment. The formerly developed method of exponential extrapolation is applied to the diffusion equation for which explicit and implicit schemes are deduced. Based on certain assumptions, it is shown that the

PIB.13:003; PIB.07:006-008

stability range for the explicit scheme becomes infinite as the steady state is approached. This result may lead to considerable savings of machine time in practical applications of the method. (Contractor's abstract)

LIGHT INDUCED SPECTRAL SHIFT OF THE THIAZINE DYES IN THE BOUND STATE, by N. Wotherspoon and G. Oster. [1957] [4]p. incl. diagrs. table. (AF 18(600)1182) Unclassified

Published in Jour. Amer. Chem. Soc., v. 79: 3992-3995, Aug. 5, 1957.

The authors have found that thiazine dyes in the presence of polymethacrylic acid or polyacrylic acid undergo a spectral shift when irradiated with visible light. A combined recording spectrophotometer and irradiation apparatus was used to follow the reaction either at a fixed wave length or by scanning the spectrum repetitively. Two photo products are formed, one in the absence of oxygen and the second by the photooxidation of the first. The rate of formation of the second product is retarded by small amounts of paraphenylenediamine or by potassium iodide suggesting that long-lived excited states are involved. The final photoproduct is the same for all the thiazine dyes studied and is identical to thionine. The reaction requires a polyacrylic acid but does not take place in the presence of other high polymeric acids or of dibasic acids. (Contractor's abstract)

PHOTOREDUCTION OF METHYLENE BLUE BY ETHYLENEDIAMINETETRAACETIC ACID, by G. Oster and N. Wotherspoon. [1957] [3]p. incl. diagrs. refs. (AF 18(600)1182) Unclassified

Published in Jour. Amer. Chem. Soc., v. 79: 4836-4838, Sept. 20, 1957.

Methylene blue in the presence of ethylenediaminetetraacetic acid (EDTA) is reduced to the leuco dye on irradiation with red light. The rate of photoreduction depends upon pH in the same way as does the base titration of EDTA. EDTA is consumed in the reaction suggesting that it is oxidized although it does not normally function as a reducing agent. A number of nitrogen-containing chelating agents were tested but only those with secondary or tertiary nitrogens behaved as electron donors in the photochemical reaction. The photoreduction involves a long-lived excited state of the dye (10^5 times that of the first electronically excited state) and is retarded by small amounts of p-phenylenediamine. The rate of regeneration of the dye by near ultraviolet irradiation of the leuco form increases with increasing hydrogen ion concentration. (Contractor's abstract)

PHOTOREDUCTION OF ACRIDINE DYES, by F. Millich and G. Oster. [1958] [35]p. incl. diagrs. table, refs. (AFOSR-TN-58-836) (AF 18(600)1182 and AF 19(603)-3065) AD 202921 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 81: 1357-1363, Mar. 20, 1959.

A number of acridine dyes in the presence of allylthiourea are reduced to their leuco forms on irradiation with blue light. Those acridines which have amino substituents in both the 3- and 6-position undergo photoreduction rapidly. Another group of acridines undergoes photoreduction at one tenth the rate of the first and a third group exhibits no reactivity. A correlation exists between phosphorescence of the dyes and their ability to undergo photoreduction. The detailed kinetics of photoreduction of proflavin at its pH for maximum rate, namely, pH 4, coupled with fluorescence studies showed that: (a) the reduction proceeds through a long-lived excited state, (b) the transition from the first singlet excited state to the long-lived state is induced by dye molecules in the ground state, (c) the inductive forces of interaction act over distances of 500A. The kinetics of photoreduction of dyes in the presence of electron donors for the excited dyes has been studied in detail. The dyes examined include members of the fluorescein, thiazine, triphenyl methanes (bound to high polymers), and the acridines. In all cases it was established that long-lived excited states are involved. It is in this state that the dye abstracts electrons from the reducing agent to give the reduced (leuco) dye. The long-lived state has a life time about 10^5 times greater than the excited singlet state. Dyes in the bound state and proflavine in the free state show an increase in quantum yield with an increase in concentration of dye. This is accompanied by a self-quenching of fluorescence. These results are probably due to dye induced conversion of the singlet to the triplet (long-lived) states. The relation of photoreduction to dye-sensitized photooxidations is described. Applications of the work are outlined. (Contractor's abstract, modified)

PHOTOREDUCTION OF DYES IN RIGID MEDIA. I. TRIPHENYLMETHANE DYES, by G. Oster, J. Joussot-Dubien, and B. Broyde. [1958] [4]p. incl. diagrs. refs. (AFOSR-TN-58-1051) (AF 49(638)293) AD 206985
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 88: 1869-1872, Apr. 20, 1959.

Certain triphenylmethane dyes can be photoreduced when incorporated in glucose glasses, whereas the same dyes in aqueous solutions of glucose are unaffected by light. All triphenylmethane dyes become increasingly more fluorescent the greater the viscosity of the medium. In the case of the dyes which are photoreducible in glucose glass, however, superposed on room temperature fluorescence is an α -phosphorescence (delayed fluorescence). In the more rigid glasses the phosphorescence lifetime was found to decrease with increasing temperature but to be practically independent of viscosity. The rate of photoreduction of acid fuchsin in glucose as a function of temperature is maximal at about 60°. The kinetic and spectral data suggest that three processes must be considered: (1) the suppression of internal conversion of the single excited state to the ground state by increasing the viscosity of the medium, (2) the transitions from the metastable state to the ground state, (3) the reaction between dye molecules in the metastable state and glucose. The first process is

favored by lowering the temperature, whereas the reverse is the case for the latter two processes.

A NEW THEORY OF ELASTIC SANDWICH PLATES. ONE-DIMENSIONAL CASE, by Y.-Y. Yu. [Oct. 1958] 25p. incl. diagrs. table. [Technical note no. 1] (AFOSR-TN-58-896) (AF 49(638)453) AD 204133
Unclassified

The 1-dimensional case is presented of a new flexural theory of isotropic elastic sandwich plates deduced from the theory of elasticity. The theory includes the effects of transverse shear deformation and rotatory inertia in both the core and faces of the sandwich, and no limitations are imposed upon the magnitudes of the ratios between the thicknesses, material densities, and elastic constants of the core and faces of the sandwich. The method used is an extension of one used by Mindlin, and the results reduced to those of his for the corresponding homogeneous plates as special limiting cases. A final equation may also be simplified and reduced to the corresponding results of Reissner (NACA report 975, 1950), and Hoff (NACA Tech. note 2225, 1950) for the bending of ordinary sandwich plates that have thin faces. Results of the theory are applied to the problem of bending of a cantilever plate subjected to load at the unsupported end, and to the problem of propagation of straight-crested waves in an infinite plate.

SIMPLE THICKNESS-SHEAR MODES OF VIBRATION IN INFINITE SANDWICH PLATES, by Y.-Y. Yu. [Oct. 1958] 15p. incl. tables. [Technical note no. 2] (AFOSR-TN-58-897) (AF 49(638)453) AD 204132
Unclassified

Closed-form solutions are obtained for simple thickness-shear modes of free vibration of infinite sandwich plates from the exact elasticity theory. The antisymmetric mode is further solved according to the new flexural theory of sandwich plates presented in a companion paper. By matching the lower frequency calculated from the sandwich-plate theory with the corresponding fundamental frequency from the elasticity theory, the value of a shear coefficient in the sandwich-plate theory may be determined directly. It is shown that, for sandwich plates, the shear coefficient is not constant and may have a value very close to unity, in contrast to its constant value of $\pi^2/12$ for homogeneous plates given by Mindlin (Jour. Appl. Mech., v. 18: 31-38, 1951). (Contractor's abstract)

of these phenomena and their influence on efficiency and performance. This is of particular interest where space charge effects are pronounced as in high power tubes.

THE APPLICATION OF MAXIMUM-LIKELIHOOD TECHNIQUES TO SEVERAL PROBLEMS IN COMMUNICATION THEORY, by D. [C.] Youla. Oct. 23, 1956 [25]p. incl. diagr. (Research rept. no. R-524-56; PIB-454) (AFOSR-TN-57-28) (AF 18(600)1505) AD 115063

Unclassified

In this report the technique of "Maximum Likelihood" is applied to two distinct problems with engineering significance. The first problem may be stated as follows: Suppose that the received datum in $0 < t \leq T$ is given by $e(t) = \sigma x(t)$, where $x(t)$ is Gaussian, and σ is unknown but constant over the observation interval. Then it is shown that with probability one σ may be determined exactly from any one realization of $x(t)$ independent of T . The method requires an infinite sampling scheme. In addition, any method using N samples possesses a percentage inaccuracy $\approx \sqrt{2}/N$. An explicit representation is given for the sampling procedure which attains the lower bound. The results are applied to several cases involving power measurement. The second problem is concerned with the demodulation of information when both additive noise and fading (of a special type) are present. It is pointed out that the resulting integral equations imply a closed-loop type of servo-system with internal automatic gain control. Possible mechanization schemes are discussed.

SYNTHESIS OF ACTIVE RC TRANSFER FUNCTIONS, by I. M. Horowitz. Nov. 8, 1956, 85p. incl. diagrs. refs. (Research rept. no. R-507-56; PIB-437) (AFOSR-TN-57-74) (AF 18(600)1505) AD 120417

Unclassified

This report presents new methods of synthesis of stable active RC transfer functions in the form of unbalanced two terminal-pair networks. The philosophy leading to these methods is the representation of active RC networks by means of positive and negative RC elements. Modern passive synthesis procedures are thereby made available. The outstanding features of the synthesis techniques are: (1) they are exact in that the active elements are not idealized with respect to input and output impedance, (2) emphasis throughout is on methods and configurations which lead to practical structures involving transistors or tubes; and (3) the relations between

the gain, the sensitivity and the character of the transfer function are developed. The designer knows how to make the transfer function insensitive to circuit parameters and the price paid in gain and impedance level. The complex pole synthesis problem is divided into two classes. One class consists of those problems resolvable into separate RC and RL syntheses. The RL synthesis is achieved by means of resistors, capacitors and transistors or tubes. In many cases one transistor or tube suffices. The second class of complex pole functions involves the synthesis of a negative RC immittance. Several synthesis procedures are developed for this purpose. Two general synthesis techniques are presented for the unrestricted realization of transmission zeros. One of these is an active RC ladder development in canonical sections in the tradition of Brune, Darlington, and Dasher. The other method involves the realization of a transfer function with unrestricted zeros and negative real poles by means of an RC network in parallel with a transistor. The methods derived for pole and zero realization are combined for the general solution of transfer function problems. (Contractor's abstract)

THE SHEATH-HELIX PARAMETER KQ FOR $n = 1$ MODE, by I. Sugai. Feb. 7, 1957 [16]p. incl. diagrs. (Research rept. no. R-554-57; PIB-482) (AFOSR-TN-57-75) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1505, Office of Naval Research, and Signal Corps Engineering Labs.) AD 120418

Unclassified

For the modes with angular variation $\exp(-jn\theta)$ in a sheath-helix, the surface admittance presented to a thin hollow electron beam either inside or outside of the helix is derived for the general n -th mode in an exact form. Useful approximations are given for Pierce's K impedance. This approximation is very similar to previously obtained expressions. It has sometimes been thought that the values of KQ for $n = 1$ and $n = 0$ are equal. They are found to be fairly different for both positions of the electron beam except for $\nu_0 = 5$.

A TRANSIENT ANALYSIS OF A BISTABLE MAGNETIC AMPLIFIER, by A. Aronowitz. July 10, 1957 [44]p. incl. illus. diagrs. tables. (Rept. no. R-592-57; PIB-520) (AFOSR-TN-57-593) (AF 18(600)1505) AD 136579
Unclassified

The effect was investigated of the circuit parameters on the response time of a bistable magnetic amplifier. A detailed examination of the diode bridge is made, and from this all pertinent circuit equations are derived. From these equations, the core fluxes are solved as functions of time, for three half cycles of the transient. The relative magnitudes of the circuit parameters that minimize the transient time are then deduced. In conclusion, two relations for the circuit parameters are presented. When the first is satisfied, the transient time required to switch the amplifier from its "off" to "on" condition is minimized to two half cycles. When the second is satisfied, the transient time required to switch the amplifier from its "on" to "off" condition is minimized to three half cycles. (Contractor's abstract)

POWER GAIN AND PROPAGATION CONSTANTS IN

TRAVELING WAVE TUBES, by G. Mourier and I. Sugai. Mar. 1, 1957, 6p. (Rept. no. R-561-57) (AF 18(600)1505)
Unclassified

Though the existence of power gain in forward wave traveling wave tubes is generally believed to be associated with exponentially growing waves, it will be shown here that it is also obtained in conditions where each wave has a constant amplitude along the circuit. This tends to emphasize the importance of the phase relationship between the total electronic current and the total field rather than that of the nature of the propagation constants, as already indicated by the theory of the carcotrons, O-type as well as M-type. The "non-exponential gain" found here depends critically upon the initial conditions at the input of the circuit, but it is a wide band phenomenon and, in fact, it increases the bandwidth of tubes, especially of low gain tubes as the M-type amplifier has been so far. It can pose problems in applications where the filterlike properties of the tubes are used. The study is done here on the simplest case algebraically speaking, the M-type amplifier, but the nature of the results is believed to be more general. Cold attenuation is not taken into consideration.

SURFACE WAVES IN ELECTRONIC WAVEGUIDES, by G. Mourier. Mar. 25, 1957, 9p. (Rept. no. R-587-57; PIB-495) (AF 18(600)1505)
Unclassified

Electronic waveguides have been studied under the assumption that an infinite longitudinal magnetic field prevents transverse motion of the electrons. Considered here is the case of no focusing magnetic field. In practice, this new assumption is realistic only in very few cases: if the dc space charges were neutralized by positive ions trapped in the beam, no external focusing force would be needed, and, neglecting the ac motion of the ions in regard to their large mass as well as collisions, one would have to consider only the electron motion without magnetic force. In some cases too, a drift tube will be short and no magnetic field will be required. We consider a smooth waveguide of any cross section partly filled by an electron beam moving along the guide.

INSTABILITY IN THIN ELECTRON BEAMS, by G. Mourier. Apr. 3, 1957, 18p. (Rept. no. R-570-57; PIB-498) (AF 18(600)1505)
Unclassified

Space charge phenomena in electron beams have been studied in conditions where the transverse dimensions

of the beam are not negligible. A very simplified description of the phenomena that have been analyzed is that electrons oscillate inside the beam around some stable position which drifts with the electron stream. In practical tubes where these phenomena occur, the transverse dimensions of the beam are commensurate with the "waveguide" wavelength, itself of the order of $\lambda v/c$.

the constants C_r , α_r , β_r , and γ_r being linked together by the integral equation. It is precisely the labor involved in their determination that in practice often causes the problem to assume awesome proportions. By means of the results given herein, this labor is diminished to the irreducible minimum—the solving of a transcendental equation. (Contractor's abstract)

THE SOLUTION OF A HOMOGENEOUS WIENER-HOPF INTEGRAL EQUATION OCCURRING IN THE EXPANSION OF SECOND-ORDER STATIONARY RANDOM FUNCTIONS, by D. C. Youla. [1957] [7]p. incl. refs. (AF 18(600)1505) Unclassified

Published in I.R.E. Trans. of Professional Group on Information Theory, v. IT-3: 187-193, Sept. 1957.

In many of the applications of probability theory to problems of estimation and detection of random functions an eigenvalue integral equation of the type

$$\psi(x) = \lambda \int_0^T K(x-y)\psi(y)dy; \quad 0 < x \leq T,$$

is encountered where $K(x)$ represented the covariance function of a continuous stationary second-order process possessing an absolutely continuous spectral density. In this paper an explicit operational solution is given for the eigenvalues and eigenfunctions in the special but practical case when the Fourier transform of $K(x)$ is a rational function of ω^2 , i.e.,

$$K(x) = G(s^2) \frac{N(s^2)}{D(s^2)}, \quad s = i\omega,$$

in which $N(s^2)$ and $D(s^2)$ are polynomials in s^2 . It is easy to show by elementary methods that the solutions are of the form

$$\psi(x) = \sum_r C_r e^{-\alpha_r x} \cos(\beta_r x + \gamma_r),$$

ORTHOGONALITY PROPERTIES FOR MODES IN PASSIVE AND ACTIVE UNIFORM WAVEGUIDES, by A. D. Bresler, G. H. Joshi, and N. Marcuvitz. Dec. 5, 1957 [19]p. (Rept. no. R-625-57; PIB-553) (AFOSR-TN-58-29) (AF 18(600)1505) AD 148068 Unclassified

Also published in Jour. Appl. Phys., v. 29: 794-799, May 1958.

Orthogonality relations are given for the "four-vector" guided modes of anisotropic uniform waveguides and for the "six-vector" guided modes of uniform waveguides containing unidirectional electron beams with axially independent dc velocities. In general, these orthogonality relations involve both the modes of the given waveguide and those of an appropriate "adjoint" waveguide. A description is given for the adjoint waveguides associated with waveguides which contain media whose characteristics are restricted only by the requirement that they be axially independent and which, if bounded, are subject to a variety of boundary conditions arising from idealization of actual boundaries.

GENERAL ELECTRONIC WAVEGUIDES, by N. Marcuvitz. [1958] [25]p. incl. diags. (AF 18(600)1505) Unclassified

Published in Proc. Symposium on Electronic Waveguides, Polytechnic Inst. of Brooklyn, N. Y. (Apr. 8-10, 1958), N. Y., Interscience Publishers, 1958, p. 63-87.

Different analyses of propagation and diffraction problems in traveling-wave-tube, plasma, and other anisotropic structures are contrasted. Application of conventional guided wave theory to electron and ion beam loading in such electronic waveguide regions leads to an analysis in terms of the "cold modes" of the unloaded structure. Difficulties and advantages of this perturbation procedure are discussed. An alternative analysis in terms of orthogonal "hot modes", the use of transverse resonance techniques for hot mode determinations, and the relation to problems of diffraction at "hot discontinuities" is presented. SYNTHESIS OF OPTIMUM PHASE-LEAD COMPENSATED SECOND ORDER FEEDBACK CONTROL SYSTEM, by C. Davidson. Sept. 29, 1958 [17]p. incl. diags. (Rept. no. R-690-58; PIB-618) (AF 18(600)1505) Unclassified

The purpose of this report is to study the properties of phase-lead compensated second order feedback control systems and to show how to synthesize the closed-loop transfer function of the system, starting with specifications for bandwidth, maximum overshoot, and generalized error constants. These specifications are used in the Guillemin-Truxal synthesis. Attempt is made to find a pure synthesis approach; to construct "synthesis diagrams" from which all unknown parameters can be determined immediately, eliminating a trial and error procedure. Further, because an infinite set of parameter values always satisfies the specifications, if these can be

satisfied at all, the "optimum" configuration is desired. Attention is also given to the linear and nonlinear limitations of the system. Finally, the second step in the system design, the determination of open-loop transfer functions, is discussed briefly. (Contractor's abstract, modified)

PLASMA PROGRAM (Abstract), by N. Marcuvitz. [1958] [2]p. (Bound with its AFOSR-TR-58-125; AD 162274) (Sponsored jointly by Air Force Office of Scientific Research, Office of Naval Research, and Signal Corps under AF 18(600)1505; Air Force Office of Scientific Research under AF 49(638)340; and Air Force Cambridge Research Center under AF 19(604)2031) Unclassified

Presented at Conf. on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

The plasma program is directed both toward understanding the basic properties of plasmas in the low to medium density range and producing carefully controlled plasmas in these ranges. The effort is devoted on the one hand to the study of wave types and instabilities associated with relatively high current density electron beams in crossed fields and on the other to more direct investigations of electronic behavior and wave types in plasmas produced by high current discharges in Ne and H₂.

The experimental program is supplemented by related studies of transport processes in plasmas and wave phenomena resulting from electromagnetic field-charged particle interactions particularly in the microwave range.

SCATTERING MATRICES AND THE FOUNDATIONS OF LINEAR, PASSIVE NETWORK THEORY, by D. C. Youla, L. J. Castriota, and H. J. Carlin. Sept. 10, 1957 [72]p. incl. diags. refs. (Rept. no. R-594-57; PIB-522) (AFOSR-TN-57-581) (AF 18(603)105) AD 136569

Unclassified

This report is concerned with the construction of a rigorous theory of linear passive networks from the point of view of energy conservation and causality. It is shown that five postulates defining the physical nature of a network suffice to give all analytic properties of the network scattering matrix $S(z)$ (z is the complex frequency variable $\omega + i\beta$). These analytic properties define a bounded real scattering matrix, the possession of which is necessary and sufficient for an n -port network to satisfy physical realizability as stated by these postulates. A bounded real scattering matrix is analytic and bounded in the strict upper half of the z plane, and has an associated form $Q(z) = 1_n - \bar{S}^T(z) S(z)$ which is the matrix of a positive hermitian form in this region. An alternate formulation of the bounded real property is given which stresses boundary behavior of $S(z)$ and $Q(z)$. These analytic properties of $S(z)$ lead to a generalized formulation of a positive real immittance matrix. A theorem concerning the necessary and sufficient conditions for the existence of a Faltung-representation is proved and its implications discussed. The entire treatment is mathematical in nature and leans heavily on the theory of linear bounded operators.

ON THE THEORY OF M-TYPE TUBES WITH THICK BEAMS, by G. Mourier. Aug. 22, 1958, [16]p. incl. diags. refs. (Rept. no. R-680-58; PIB-808) (AFOSR-TN-58-926) (AF 49(638)340) AD 204738; PB 147446
Unclassified

The effects of space charge in crossed-field, M-type, tubes is considered qualitatively. The consideration of 2 surface waves associated respectively with the upper and lower boundaries of the beam make possible a broad understanding of the behavior of M-type tubes with thick, heavy-current beams. No systematic comparison of theory with experiments is made. However, the gain calculation seems to be in general agreement with experiment, as is the prediction of a minimum efficiency for intermediate values of beam current. The most serious restriction on this analysis is probably the assumption of laminar flow. (Contractor's abstract)

SEMIEMPIRICAL DETERMINATION OF MASS ABSORPTION COEFFICIENTS FOR THE 5 TO 50 ANGSTROM X-RAY REGION, by B. L. Henke, R. White, and B. Lundberg. [1957] [8]p. incl. diags. tables. (Bound with its AFOSR-TN-57-436; AD 136426) [AF 18(600)-1045] Unclassified

Also published in Jour. Appl. Phys., v. 28: 98-105, Jan. 1957.

A semlemprical method for the determination of mass absorption coefficients for the very soft x-ray region of 5 to 50A is described. A universal function for the absorption by K-shell electrons and another for absorption by L and extra-L shell electrons are given in table form to permit the calculation of mass absorption coefficients for elements of atomic number up to 36. Calculated and observed values from available absorption data are compared with those predicted by quantum theory. Tables are given for the mass absorption coefficients for nine useful wavelengths in the ultra-soft region, 8.34, 13.3, 17.6, 21.7, 23.7, 27.4, 31.6, 36.3 and 44A. (Contractor's abstract)

x-ray radiation for thin samples of materials have been outlined. An introduction is given to the diffraction, absorption and reflection methods of analysis available with long wavelength x-rays. A brief description is given of some of the sources, methods of producing monochromatic beams, and the detectors used in these long wavelength studies.

[PHYSICS OF SOFT X-RAYS] Interim final rept. Nov. 1958 [3]p. (AFOSR-TR-58-164) (AF 18(600)1045) AD 207831 Unclassified

This project has been concerned with the physics of ultrasoft x-radiations which lie in the wavelength region between conventional x-rays and the extreme ultraviolet. It has been an attempt to systematically investigate the important interactions of these radiations with matter, viz. (1) diffraction, (2) total reflection, (3) photoelectric absorption, (4) auger and photoelectron emissions. Because the cross sections for these interactions are large even for micromass thicknesses, a parallel investigation on the applications of ultrasoft x-ray interactions to micromass and microchemical analysis has been carried out. To date, these have included: (1) submicroscopic structure analysis by diffraction, (2) thin film analysis by total reflection, and (3) micromass and microchemical analysis by high resolution microradiography. Because relatively little work has been done previously in this field, an integral part of this program also has been the development of ultrasoft x-ray instrumentation.

MICRORADIOGRAPHIC ANALYSIS OF MICRON SYSTEMS (Abstract), by B. L. Henke. [1957] [1]p. [AF 18(600)1045] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 210, Apr. 25, 1957.

The "contact printing" of images of microscopic material which is laid upon ultra-fine grain photographic plates can yield micrograms which permit microscopic and microphotometric analysis of systems of micron dimensions. Sufficient absorption signal or contrast can be obtained for these systems when the contact microradiograms are made with the ultra-soft x-radiations in the 10 to 50A region. Standard absorption analysis techniques can be applied to the microradiograms for quantitative micromass and microchemical analysis provided that good mass absorption coefficient data for this radiation region are obtained, and provided that the proper design of the contact microradiographic camera, of the photographic emulsions, and of the microphotometric apparatus is employed. A first report on the work conducted at this laboratory on the theory and practice of contact microradiographic analysis for micron systems will be presented.

CALCULATION OF ULTRASOFT X-RAY DISPERSION COEFFICIENTS (Abstract), by J. C. Miller and B. L. Henke. [1958] [1]p. [AF 49(638)394] Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Los Angeles, Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 413, Dec. 29, 1958.

The semiempirical method described in a previous paper (item no. POM.02:004) for the calculation of atomic form factors in ultrasoft x-ray dispersion theory leads to the extensive application of numerical techniques, particularly in integrations involving singularities within the range of integration. In this case use has been made of the usual Cauchy's principal value definition and of a modified form of Simpson's rule applicable to a rational function for the integrand. A further difficulty is encountered in attempting to perform the integration under limiting conditions on certain parameters of the integrand. In these calculations assistance was rendered by the personnel and facilities of the Western

Data Processing Center of UCLA. A program for the calculation of transmission efficiencies of ultrasoft x-rays at grazing incidence through thin films forms an additional part of the present study. This work uses the standard two surface optics as given, for example, by Wolter. The latter calculation was performed on the computing facilities of the Millikan Laboratory, Pomona College, Claremont.

X-RAY DISPERSION IN THE 5 TO 50A WAVELENGTH REGION (Abstract), by B. L. Henke and J. C. Miller. [1958] [1]p. [AF 49(638)394] Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Los Angeles, Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 413, Dec. 29, 1958.

The complex atomic scattering factors for the light elements C_6 to Ge_{32} and for the long wavelength x-ray region have been calculated from mass photoelectric absorption coefficients using an integral relationship given by the quantum mechanical theory of dispersion. The anomalous scattering due to electron "resonances" at the K and the L critical absorption edge wavelengths has been found to be more extensive than that predicted by the older dispersion theories. The reflection efficiency as a function of both angle of reflection and of wavelength has been calculated for a quartz and an aluminum mirror from the atomic scattering coefficients. The predicted reflection curves are found to be in good agreement with those obtained experimentally. Ultrasoft x-ray interactions as absorption, diffraction, grazing incidence reflection, and transmission are being investigated as bases for the analysis of microscopic systems for structure, mass, and chemical information.

HIGH SPEED AERODYNAMICS AND JET PROPULSION. VOLUME VII. AERODYNAMIC COMPONENTS OF AIRCRAFT AT HIGH SPEEDS, ed. by A. F. Donovan and H. R. Lawrence. N. J., Princeton U. Press, 1957, 845p. incl. illus. diagrs. tables, refs. (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under [Nonr-03201]) Unclassified

The primary concern of this volume is to present aerodynamic knowledge that is of direct interest to the designers of high speed aircraft. The items deal primarily with aircraft components, i.e. wings (in both steady and nonsteady motion), bodies, interference effects, propellers, diffusers, and nozzles. The volume begins with a comprehensive treatment of the steady state aerodynamic theory of wings by R. T. Jones and D. Cohen. The tables of flow functions in this section should be particularly useful to the practicing aerodynamicist. C. Brown next presents a section on the aerodynamics of bodies at high speed, which is noteworthy for including bodies of noncircular cross section—a type which is usually given too little attention. Interactions between wings, body, tail, and propeller are treated in a section by C. Ferrari, who was aided in translation by R. Cramer. This section is notable for bringing together much information which otherwise can only be found scattered widely through the literature. Propellers at high speeds, including supersonic propellers, are covered in a section by C. B. Smith. A section on diffusers and nozzles by J. C. Evvard completes the treatment of the external aerodynamics of high speed propulsion systems. The basis for the treatment of aeroelastic problems is presented in a section by I. E. Garrick on nonsteady wing characteristics. Finally, a section by C. W. Frick on the experimental aerodynamics of wings clearly brings out the accomplishments of aerodynamic theory and the limitations imposed by assumptions.

AN ANALYSIS OF THE INTERACTION OF SHOCK WAVES WITH UNSEPARATED TURBULENT BOUNDARY LAYERS, by A. G. Hammit. Feb. 1957 [24]p. incl. illus. diagrs. refs. (Rept. no. 371) (AFOSR-TN-57-108) (AF 18(600)498) AD 120460 Unclassified

Analysis of the behavior of turbulent boundary layers through rapid pressure rises may be described by a modified shock wave theory based on average boundary layer parameters. This method may be applied to shock wave boundary layer interactions at pressure ratios insufficient to cause separation. The results show that the properties of a boundary layer behind a discontinuous pressure rise may be considerably different than the ones measured in mild pressure gradients.

UNSTEADY LAMINAR BOUNDARY LAYER OVER A FLAT PLATE IN THE DOWNSTREAM REGION, by S.-I. Cheng and I. D. Chang. Mar. 1956 [24]p. incl. diagrs. refs. (Rept. no. 339) (AFOSR-TN-57-180) (AF 18(600)498) AD 126475 Unclassified

The unsteady motion of a flat plate in an incompressible viscous fluid is studied by using Rayleigh's method. Formulas for calculating velocity profiles and skin friction are presented together with many examples to show their application. These results are applied to the problem of a moving plate, and the relationship between the velocity of the plate and the force applied is discussed. The chief implication of such a study is due to the fact that in the unsteady motion of a plate, a dominating portion of the flow field belongs to the Rayleigh type and hence for common engineering applications, the present analysis affords a good approximation. In general, the approximation holds good from downstream up to the point lying at the middle point between the instantaneous and the original leading edge position. In computing the velocity profiles and skin friction, it was found that the analytical representations for the final results were

PRI.04:018 - PRI.04:021

generally very lengthy and did not usually give a numerical result. Therefore in the practical applications, general solutions presented in this paper may very often be more conveniently used by direct numerical integration. Some general properties of these solutions are also contained in the analysis and may serve as a general guide to the final results. (Contractor's abstract)

ON THE MIXING THEORY OF CROCCO AND LEES AND ITS APPLICATION TO THE INTERACTION OF SHOCK WAVE AND LAMINAR BOUNDARY LAYER. PART I. GENERALS AND FORMULATION, by S.-I. Cheng and K. N. C. Bray. May 1957, 1v. incl. diagrs. tables, refs. (Rept. no. 376) (AFOSR-TN-57-283) (AF 18(600)498) AD 132354 Unclassified

The mixing theory of Crocco and Lees is reviewed briefly, and three semiempirical functions are evaluated, in terms of which the theory treats the growth of a boundary layer. A description is given of how the theory may be applied to laminar and turbulent boundary layer shock wave interactions. Three simple approximate solutions of the equations are developed, and finally, an exact solution is found numerically for a laminar boundary layer at a Mach number of 2 and an initial Reynolds number of 10^5 . Five shock strengths, giving deflection angles between 2° and 4.2° , are considered. This set of sample calculations illustrates how the theory may be applied to determine the flow configuration of the interaction between shock wave and laminar boundary layer in general. The procedure is then applied to the following specific problem, the determination of the critical strength of the shock wave required to produce incipient separation of a laminar boundary layer on a flat plate for the Reynolds number and Mach number range in which the laminar boundary layer usually occurs. Simple correlations are obtained for (1) the pressure rise at the separation point in excess of the undisturbed free stream pressure as a function of Mach number and Reynolds number, and (2) the critical strength of the shock to produce incipient separation of a laminar boundary layer over a flat plate as a function of the Reynolds number and Mach number in question. According to the mixing theory, the separation pressure rise is independent of the flow configuration downstream of the separation point in agreement with the experimental data available. This part of the result is, therefore, not restricted to the case of incipient separation. (Contractor's abstract)

AN ANALYSIS OF THE EFFECT OF SHOCK WAVES

ON TURBULENT BOUNDARY LAYERS, by A. G. Hammitt, I. E. Vas, and S. Hight. July 1957 [39]p. incl. diagrs. refs. (Rept. no. 396) (AFOSR-TN-57-297) (AF 18(600)498) AD 132368 Unclassified

An analysis of boundary layer surveys in the region of the interaction of shock waves with turbulent boundary layers is presented. By this analysis, it is possible to determine the order of magnitude of the static pressure gradients across the boundary layer and changes of mass and momentum in the boundary layer. The results indicate that the static pressures across the boundary layer in the interaction region are far from constant and that shear forces have only a secondary effect on the total momentum in the boundary layer. (Contractor's abstract)

ON THE MIXING THEORY OF CROCCO AND LEES AND ITS APPLICATION TO THE INTERACTION OF SHOCK WAVE AND LAMINAR BOUNDARY LAYER. PART II. RESULTS AND DISCUSSION, by S.-I. Cheng and I. D. Chang. Nov. 1957 [47]p. incl. diagrs. tables. (Rept. no. 376, pt. 2) (AFOSR-TN-58-3) (AF 18(600)-498) AD 148042 Unclassified

The procedure developed in Part I (item no. PRI.04:018) is used to determine the critical strength of the incident shock wave required to produce incipient separation of a laminar boundary layer over a flat plate for the range of Re from $1-15 \times 10^5$ and for the range of free stream Mach number M from 1.5 to 4.0. Nineteen cases have been integrated. Simple correlations of the results for the separation pressure ratio and the critical pressure ratio are obtained as $C_p = \Delta p/p_o = a(M-b) \cdot [Re_g \times 10^{-6}]^{-c}$. Comparison with two sets of available experimental data shows agreement in general but no quantitative conclusions can be affirmed without the guidance of more detailed and extensive experimental information. It is suggested that this form of correlation may be obtained for the non-flat plate problems according to the mixing theory. (Contractor's abstract)

ON THE MECHANISMS OF ATMOSPHERIC ABLATION, by S.-I. Cheng. Apr. 1958 [31]p. incl. diagrs. table, refs. (Rept. no. 427) (AFOSR-TN-58-649) (AF 18(600)-498) AD 162181; PB 144042 Unclassified

Also published in Proc. Ninth Internat'l. Astronaut. Congress, Amsterdam (Holland) (Aug. 25-30, 1958), Austria, Springer-Verlag, 1959, p. 252-264.

The problem of ablation of meteoric objects entering the atmosphere is considered. Existing theory of meteoric ablation due to Lindemann and Dobson from the continuum point of view and that due to Sparrow-Opik from the particle point of view requires some modification. The deceleration of the meteor and the presence of a molten layer over the meteoric body results in an unstable liquid-gas interface that leads to the direct loss of mass as liquid droplets flying away from the meteoric surface. The feasibility of this mechanism is analytically shown and demonstrated with typical examples. By incorporating the present mechanism, the irregularity of the meteoric luminosity when compared with the calculated results of Opik's theory may be qualitatively explained and the occasional "burst" or "flare" of some meteors may be visualized. Several other observations of the meteoric phenomena also tend to verify the plausibility of the proposed mechanism. (Contractor's abstract)

INVESTIGATION OF THE INTERACTION OF A TURBULENT BOUNDARY LAYER WITH PRANDTL-MEYER EXPANSION FANS AT $M=1.88$, by K. R. A. Murthy and A. G. Hammit. Aug. 1958 [34]p. incl. illus. diags. (Rept. no. 434) (AFOSR-TN-58-839) (AF 18(600)498) AD 203081; PB 144580 Unclassified

The interaction of expansion fans with a 2-dimensional supersonic turbulent boundary layer at a free stream $M=1.88$ was investigated. The angle of expansion was varied from 5° to 30° . Schlieren photographs of the flow pattern were taken to obtain an over-all picture of this type of interaction. Static pressure and total head tube measurements were made to study the interaction in detail. The method of rotational characteristics was applied to the boundary layer velocity distribution as it expands about a convex corner to construct the flow field and to calculate the inviscid pressure distribution near the convex corner as a better approach to the problem than the classical Prandtl-Meyer flow. A turbulent boundary layer was found to affect the wall pressure distribution caused by a supersonic expansion around a convex corner for about 5 boundary layer thicknesses. The effect of the boundary layer can be predicted to a first approximation by considering the distorted profile ahead of the corner and considering the boundary layer flow inviscid through the expansion region. A region of high shear is created behind the corner which, in some respects, has the appearance of a new boundary layer originating from the corner. (ASTIA abstract)

EXPERIMENTAL STUDIES AT MACH NUMBERS 12 TO 19 OF CONICAL AND BLUNTED BODIES AT ZERO ANGLE OF ATTACK, by S. M. Bogdonoff and I. E. Var. Sept. 1958 [56]p. incl. illus. diags. (Rept. no. 435) (AFOSR-TN-58-841) (AF 18(600)498) AD 203181; PB 143655 Unclassified

An experimental study on the conical and blunted bodies was carried out at Mach numbers between 12 and 19 using the Princeton University Helium Hypersonic Tunnel. Pressure distributions and Schlieren photographs were obtained for bodies with cone half angles varying from 10° to 45° . Comparison with the theoretical inviscid and Newtonian pressures corrected for normal shock losses were made. The pressures on a body without corners can be predicted quite well. A corner at the junction of the nose section and conical afterbody results in large

variations between the measured values and predicted ones. The pressures on the conical bodies were not affected by the nose shape for that part of the body downstream of a station located at $1\frac{1}{2}$ times the nose bluntness diameter. (Contractor's abstract)

A CLASS OF EXACT SOLUTIONS OF THE MAGNETO-HYDRODYNAMIC NAVIER-STOKES EQUATIONS, by C.-S. Wu. Sept. 1958 [51]p. incl. diags. tables. (Rept. no. 436) (AFOSR-TN-58-895) (AF 18(600)498) AD 204134 Unclassified

A class of similarity solutions of the magnetohydrodynamic Navier-Stokes equations have been found in this paper so that the original differential system may reduce to two ordinary differential equations. The equation governing the velocity field appears to be of first order but with a non-linear interaction term of the magnetic field. On the other hand, the magnetic induction equation is of second order. Solutions similar to those obtained by Landau and Squire for non-magnetic case are found by using a perturbation expansion of small σ (σ is the ratio of kinematic viscosity and magnetic viscosity). Throughout the analysis, the fluid is assumed to be incompressible, viscous and electrically conducting. The physical properties are also postulated to be constant. (Contractor's abstract)

THE INTERACTION OF SHOCK WAVES AND TURBULENT BOUNDARY LAYERS, by A. G. Hammit. [1958] [12]p. incl. illus. diags. tables, refs. (AF 18(600)498) Unclassified

Published in Jour. Aeronaut. Sciences, v. 25: 345-356, June 1958.

A theory of shock-wave boundary-layer interaction consistent with available experimental data can be formulated on the basis of no external mixing and no skin friction. For shock waves not strong enough to cause separation, the boundary-layer properties behind the interaction can be calculated. For strong interactions where large separated regions exist, the possibility of the different types of interactions which have been observed can be demonstrated by using the appropriate flow models and describing the boundary layer as a one-parameter family. For all configurations, the pressure ratio at which separation occurs can be correlated by a boundary-layer form factor. (Contractor's abstract)

THE KINETICS AND MECHANISM OF ETHYLENE OXIDE DECOMPOSITION AT HIGH TEMPERATURES, by L. Crocco, I. Glassman, and I. E. Smith. Apr. 10, 1958 [19]p. incl. diagrs. refs. (Rept. no. 416) (AFOSR-TN-58-273) (AF 18(600)1527) AD 154174; PB 131932

Unclassified

Also published in Jour. Chem. Phys., v. 31: 506-510, Aug. 1959.

A flow reactor has been built to study combustion processes in rocket motors and for systems that have reaction times from 1 to 100 msec. This reactor has been evaluated by means of this study of the kinetics of the decomposition of ethylene oxide in the temperature range from 900°K up to its decomposition temperature. The experiments were conducted with N as the inert carrier gas, but Ar and CO₂ were also used. A wide range of flow velocities were used in order to spread the reaction zone over a suitable distance. The overall reaction rate constant was evaluated assuming first order kinetics and a free radical mechanism for the decomposition process. The data were also evaluated with 0.5, 3/2, and second-order determinations to establish the sensitivity of the procedure. The calculated activation energy of the reaction was 42 ± 2 kcal/mol. Experiments conducted with various inerts as the carrier gas in the flow reactor indicated that the overall decomposition characteristics of the ethylene oxide are independent of the flow rate, concentration, and the variety of the inert used.

Also published in Jet Propulsion, v. 27: 1266-1267, Dec. 1957.

A flow reactor is described which was designed for the study of reaction kinetics of propellants at high temperatures. The reactor consists of a stainless steel tubular duct in which a high-temperature stream of inert gas flows. A cold stream of monopropellant or fuel-oxidizer mixture is mixed rapidly with the inert gas. The reaction begins downstream of the injection point and continues until all components are consumed. By introducing only a small quantity of the reactants compared with the mass flow of carrier, the temperature decrease resulting from the mixing of the 2 streams and the temperature increase due to the exothermic reaction are small. The rate of decomposition of ethylene oxide with either N or He as the carrier gas was determined. The tubular duct was heated electrically to maintain a constant temperature. The inert gas was heated to the same temperature. The test fuel injection section of the duct consisted of a sharply convergent section followed by a parallel throat 0.75 in. in diameter and about 1.3 in. long. Four small-bore injection tubes branching from a common manifold carried the fuel. They were arranged so that the streams issuing from them impinged on one another to create a region of high turbulence. The gas mixture was brought back to the duct by a 15° diffuser. The course of the reaction was followed by an axially transverse probe with a Pt-Pt/Rh thermocouple. The temperature record covered the range from 1020° to 1100°K. The mean velocity of the gas stream was 1520 cm/sec or 66 msec/meter of duct. The activation energy of the ethylene oxide reaction was 42 to 44 kcal/mol.

A research program was undertaken to study the details of the combustion processes which occur within the liquid propellant rocket motor. The aim of the program is to gain information on the relationship of the physical and chemical properties of the propellant combination to (a) the problem of scaling rocket motor designs, and (b) the problem of instability of the powerplant. The experimental method which will be used to implement this program consists of injecting a monopropellant fuel into the hot products of combustion formed by the fuel itself in a slave rocket motor. The study will be expanded to include the bipropellant case of fuel and oxidizer after some experience is gained with the more simple monopropellant case. The

A STUDY OF THE KINETICS OF THE HYDROGEN-OXYGEN REACTION IN A NEW FLOW REACTOR, by R. J. Swigart. Aug. 15, 1958 [79]p. incl. illus. diagrs. table, refs. (Rept. no. 432) (AFOSR-TN-58-823) (AF 18(600)1527) AD 202907 Unclassified

A study of the kinetics of the hydrogen-oxygen reaction in the presence of large concentrations of nitrogen was made in a new type flow reactor under conditions which yielded data applicable to combustion processes in a rocket motor or ramjet combustor. The investigation was carried out over a temperature range from 900 to 1000°K. Initial hydrogen molar concentrations varied from 0.00826 to 0.0166 and initial oxygen molar concentrations varied from 0.0075 to 0.1975. A global reaction

$$\text{rate equation, } \frac{dC_{H_2}}{dt} = k \frac{C_{H_2}}{(C_{O_2})^2}$$

[where C = concentration in mol/l and k = specific reaction rate constant], was found to correlate the data over the temperature, velocity, and concentration ranges studied. The specific reaction rate constant increased and the activation energy and ignition lag times decreased as duct diameter decreased. Thus, a strong catalytic reaction on the reactor walls was indicated. Evidence of a chain breaking wall reaction was observed. Activation energies of 34.2 kcal/mol, 33.4 kcal/mol and 25.2 kcal/mol were obtained for the 2 in., 1-1/2 in., and 1 in. duct respectively when air was used as the oxygen source. The activation energy of the reaction in the 2 in. duct decreased when part of the excess oxygen was replaced by nitrogen. (Contractor's abstract)

THE SHOCK TUBE AS A TOOL FOR SOLID PROPELLANT IGNITION RESEARCH, by M. Summerfield and R. F. McAlevy III. [1958] [4]p. incl. illus. diagrs. (AFOSR-TN-58-957) [AF 49(638)411] AD 162276 Unclassified

Also published in Jet Propulsion, v. 28: 478-481, July 1958.

The fundamental problem of the solid propellant ignition process is to clarify the mechanism by which the solid surface begins to burn. The relative roles in ignition initiation of heat transfer, chemical reaction at the surface and radiation absorption are still unknown. By means of a shock tube it is possible to ignite a solid propellant under controlled conditions to study the purely thermal process. This paper describes the design and operation of a shock tube being used for this purpose and presents some preliminary results. (Contractor's abstract)

ON THE FLOW OF GASES UNDER NEARLY FREE MOLECULAR CONDITIONS, by D. R. Willis. Dec. 1958, 1v. incl. diagrs. tables, refs. (Rept. no. 442) (AFOSR-TN-58-1093) (AF 49(638)465) AD 207594; PB 149677 Unclassified

Boltzmann's equation is transformed into an integral equation, and an iterative method of solving for the distribution function is proposed. This method is shown to give the correct solution for the problem of linearized Couette flow, in contrast to several other proposed methods which are also examined. If the iteration commences with the free molecular distribution function, it appears that one iteration is sufficient to give the distribution function for nearly free molecular conditions. The method of first collisions is shown to be an approximate method of calculating this iterate. It is valid when the free stream Mach number is high and the body temperature is comparable to the free stream stagnation temperature. The method is applied to various geometries and results presented for the corrections to the free molecular macroscopic quantities at the body. There is found to be a marked effect of both body temperature and free stream Mach number. (Contractor's abstract)

A NOTE ON THE PRESSURE DISTURBANCE AT GROUND LEVEL CAUSED BY HIGH-FLYING SUPERSONIC AIRCRAFT, by N. C. Freeman and S. H. Lam. Dec. 1958 [11]p. incl. diagr. (Rept. no. 444) (AFOSR-TN-58-1127) (AF 49(638)465) AD 207781

Unclassified

The pressure disturbance or bang produced on the ground by a high-flying supersonic aircraft is studied. The main interest is (1) to assess the effect of the non-uniformity of the atmosphere in attenuating the waves from the aircraft, and (2) to relate this to some gross parameters of the aircraft. The linear supersonic flow theory is used to compute the pressure disturbance at a large distance from the aircraft and the attenuation of this disturbance through a Rand standard atmosphere is computed by a simple application of Whitham's theory. Formulas for either a lift-controlled or shape-controlled bang are given as a function of the gross parameters of the aircraft such as flight Mach number, altitude, size, slenderness ratio, lift coefficient, and certain design factors which depend on rather detailed knowledge of the aircraft. TRANSITION PROBABILITIES FOR THE MORSE OSCILLATOR WITH A CUBIC DIPOLE MOMENT, by D. Garvin. Feb. 17, 1958, 7p. (Technical note no. 2) (AFOSR-TN-58-146) (AF 18(603)134) AD 152173; PB 135074

Unclassified

A series of formulae are recorded for transition probability matrix elements for the non-rotating Morse oscillator suitable for use with linear, quadratic and cubic dipole moment expressions. These represent a re-formulation of the results obtained by Heaps and Herzberg for the case of the quadratic dipole moment expression, and an extension to the cubic integral. These formulae were derived using the factorization technique developed by Infeld and Hull and used by them to obtain the linear integral. A direct extension of the procedures explained by them yields the quadratic and cubic integrals. The expression for the quadratic integral yields the same specific formulae for particular transitions as those obtainable from the work of Heaps and Herzberg. The cubic integral has been checked, for several specific cases, against the results of Herman and Rubin. The principal advantage of the expressions is that the computational labor involved in the evaluation of transition moments for the higher 'overtone' bands is markedly reduced from that required when the other sets are used. In addition, certain approximations permit rapid computation with little loss in accuracy. (Contractor's abstract)

Presented at meeting of the Phys. and Inorg. Chem. Div. of the Amer. Chem. Soc., Miami, Fla., Apr. 7-12, 1957.

Abstract published in 131st meeting of the Amer. Chem. Soc. Abstracts of Papers, 1957, p. 15-R.

Also published in Jour. Amer. Chem. Soc., v. 81: 3173-3179, July 5, 1959.

The vibrational-rotational spectrum of the hydroxyl radical in its electronic ground state was determined in the visible and near infra-red region. Line systems in twenty-seven vibrational bands have been identified. Intensities of lines in eighteen bands are reported. No evidence of a Boltzmann distribution of rotational energies among these chemically produced radicals was found. The vibrational band intensities show an inter-relationship that is not consistent with prediction based on the Morse Oscillator transition moment expressions. Further developments are needed in the theoretical models used for the interpretation of high "overtone" vibrational transitions. (Contractor's abstract)

GENERALIZED SECOND ORDER DIFFERENTIAL OPERATORS AND THEIR LATERAL CONDITIONS, by W. Feller. [1957] [10]p. [AF 18(600)1379] Unclassified

Published in Illinois Jour. Math., v. 1: 459-504, Dec. 1957.

Let m be a (finite or infinite) regular positive measure

on a real interval I , vanishing on no subinterval, and let x be an everywhere positive continuous function.

The author studies the operator $A_m f = \varphi^{-1} D_m \varphi^2 D_m \varphi^{-1} f$, continuing the work on second-order operators that he originally undertook in connection with diffusion processes (Ann. Math., v. 61: 90-105, 1955). The differentiation D_m is in the sense of Radon-Nikodym. The

operator A_m is considered to be densely defined either on the space $L^2(m, I)$ of m -square-integrable functions, or else on the space $C(I)$ of continuous functions. In L^2 , when m is finite, Feller allows the end-points of I to carry positive weights, and in so doing defines conditions on A_m from which the classical boundary conditions are

obtained as a degenerate limiting case. For particular absolutely continuous m and suitable function-multipliers and changes of variable, Feller's operator represents locally the most general classical ordinary linear second-order differential operator $D_x^2 + gD_x + h$. And for singular or discontinuous m it includes various non-classical cases previously treated singly by ad hoc methods. The theory of A_m contains in a simple and elegant form the essentials of the traditional Sturm-Liouville and Weyl-Stone second-order theory.

ON THE INTRINSIC FORM FOR SECOND ORDER DIFFERENTIAL OPERATORS, by W. Feller. [1958] [18]p. [AF 18(600)1379] Unclassified

Published in Illinois Jour. Math., v. 2: 1-18, Mar. 1958.

Let I be an open interval, and for each open subinterval J let A_J be a non-trivial linear operator with domain and range both contained in the space $C(J)$ of all continuous functions on J . Suppose also that if K is an open subinterval of J and if $g \in C(K)$ is the restriction of some f in the domain of A_J , then g belongs to the domain of A_K and A_{K_g} is the restriction of A_{J_f} (but allow the domain of A_K to be perhaps larger than the restriction of the domain of A_J). This coherent collection of A_J defines an operator A of local character. Example: An ordinary linear differential operator with continuous coefficients (and, say, leading coefficient nowhere zero). Among these classical operators the "pure" second-order ones, $aD + bD^2$, have a characteristic minimum property: If f in the domain of A has a local minimum at x , then $(Af)(x) \geq 0$. In a definitive sequence of papers (Ann. Math., v. 61: 90-105, 1955; Comm. Pure. Appl. Math., v. 8: 203-216, 1955; Proc. Conf. on Differential Equations, Univ. of Maryland, 1956, p. 251-270; Illinois Jour. Math., v. 1: 459-504, 1957), Feller has invented and studied the

PRI.66:008; PRI.18:001-003

operator $D_m^2 D_x$ that naturally generalizes $aD^2 + bD$.

(The functions m and x are strictly monotone and intrinsically determined by the operator. Although m may have jumps, x is continuous and can thus serve to parametrize I .) In § 1-6 of the present paper, it is proven that any operator A of local character with the minimum property (has an extension that) equals some $D_m^2 D_x$, provided only that A has (on each subinterval) a 2-dimensional nullspace. And in each such interval a that A is $D_m^2 D_x$ on the open set of "regular" points of I ,

but degenerates to a first-order operator at the "singular" points. In § 7-9, there is characterized by means of a weaker minimum property the operator

$a^{-1} D_m^2 D_x a^{-1}$ (a any nowhere-zero element of the nullspace) that naturally generalizes $aD^2 + bD + c$. In § 10

three examples are provided that are of great help in understanding his fivefold classification of singular points. (Math. Rev. abstract)

A SPECIAL INTEGRAL TRANSFORMATION IN EUCLIDEAN SPACE, by S. Bochner and T. Kawata. [1958] [19]p. [AF 18(600)1379] Unclassified

Published in Ann. Math., v. 68: 150-158, July 1958.

The authors consider limits of the form

$$\lim_{T \rightarrow \infty} \int_{E_k} f(x_1, \dots, x_k) K(Tx_1, \dots, Tx_k) dx_1 \dots dx_k,$$

where E_k is the k -dimensional Euclidean space, and the kernel K is of the form

$$K(x_1, x_2, \dots, x_k) = K_0(x_1 + \dots + x_k) \prod_{j=1}^k K_j(x_j),$$

each K_j ($j = 0, 1, \dots, k$) being the Fourier transform of a bounded function in $L_1(-\infty, \infty)$. A typical result is

that the above limit has the value $C_k (2\pi)^k f(0, 0, \dots, 0)$, where C_k is a constant depending on k , if f is continuous

and in $L_1(E_k)$ and if the Fourier transform of f is in $L_1(E_k)$. The techniques of proof are fairly standard

Fourier transformation techniques. The authors also consider generalizations of those results to kernels whose dependence on T is more complex. (Math. Rev. abstract)

COHOMOLOGY OPERATIONS AND OBSTRUCTIONS TO

EXTENDING CONTINUOUS FUNCTIONS, by N. E. Steenrod, Colloquium Lecture, Aug. 1957, 60p, incl. diags. (AFOSR-TN-57-548) (AF 18(600)1494) AD 136532 Unclassified

A discussion is presented of the extension problem and methods of finding solutions in special cases. The problem is described and by the homology theory, transformed into an algebraic problem. Among the examples of extension problem solutions are the Urysohn lemma, the use of the cohomology ring to arrive at a decision, and a retraction problem solved by the squaring operations. To explain the geometric aspects, the concept of homotopy is studied. Lifting problems are illustrated by the solution of the monodromy theorem. The classification theorems of Hopf and Hurewicz are pointed out as certain restricted situations where homology and cohomology are adequate to solve the homotopy classification problem. A method to prove these results is the obstruction theory introduced by Eilenberg. The methods of constructing cohomology operation are described with particular attention to the cup product which gives the ring structure. The squaring operations are defined with their properties and reduced power operations given. Another approach to cohomology operations is the use of the Eilenberg-MacLane complexes. A brief review of the research done on the semi-simplicial complexes is presented. The theorem of Dold and Thom brings together the 2 methods of obtaining cohomology operations. Spaces with 2 nonzero homotopy groups are discussed; the Postnikov systems take in spaces with 3 or more such groups.

ON THE HOMOLOGY OF $K(\pi, n)$, by J. C. Moore. [1957] [3]p. (AF 18(600)1494) Unclassified

Published in Proc. Nat'l. Acad. Sciences, v. 43: 409-411, May 1957.

A definition is given of some little constructions in the fashion of Cartan which enable the computation of the homology of the complexes $K(\pi, n)$ of Eilenberg and Mac Lane for finitely generated groups π . Using these constructions, some properties of the homology and cohomology of $K(\pi, n)$ can be derived. One of the main points about these constructions is that they are constructions over the ring of p -adic integers, Z^p , and not, as usual in topology, constructions over the integers Z , or the integers modulo n , Z_n .

ON c.s.s. CATEGORIES, by D. M. Kan. [1957] [13]p. incl. refs. (AF 18(600)1494) Unclassified

PRI.18:004 - PRI.18:007

Published in Bol. Soc. Mat. Mexicana, Series II, v. 2: 82-94, Oct. 1957.

The purpose of this paper is to obtain for c.s.s. categories (described in item no. PRI.18:004) analogues of (1) the homotopy extension and/or covering theorems, and (2) a theorem of J. H. C. Whitehead. The Whitehead theorem asserts that a map is a homotopy equivalence if and only if it induces isomorphisms of all homotopy groups. The main tool in these investigations is a functor from the c.s.s. category C^V to the usual category of c.s.s. complexes, which allows one to transfer most of the old definitions to the new context.

ON THE HOMOTOPY RELATION FOR c.s.s. MAPS, by D. M. Kan. [1957] [7]p. (AF 18(600)1494)

Unclassified

Published in Bol. Soc. Mat. Mexicana, Series II, v. 2: 75-81, Oct. 1957.

A c.s.s. complex is a collection of sets together with a collection of maps between the sets satisfying certain identities. A c.s.s. group is a collection of groups together with a collection of homomorphisms between the groups satisfying certain identities. Let C be any category and V the category consisting of the simplexes of the simplicial theory and the c.s.s. maps between them; then C^V denotes the category whose objects are contravariant functions $K:V \rightarrow C$ and that for two objects $K, L \in C^V$ a map $f:K \rightarrow L$ is a natural transformation. The function category, C^V , is called the c.s.s. category over C . If C allows a notation of sum (generalizing the idea of union), then the C^V notion of homotopy can be defined. The following sufficient condition is established: let C and D be categories with sums and let $\Theta:C^V \rightarrow D^V$ be a c.s.s. functor. Then Θ maps the homotopic maps over C into maps homotopic over D .

COHOMOLOGY OPERATIONS DERIVED FROM THE SYMMETRIC GROUP, by N. E. Steenrod. [1957] [24]p. incl. diagrs. refs. (AF 18(600)1494)

Unclassified

Published in Commentarii Mathematici Helvetici, v. 31: 195-218, 1957.

A full account is given of a new method by Steenrod of defining the reduced pth power cohomology operators and illustrating the relations in the basic properties of these operators. If G is any permutation group, then each homology class of G determines a cohomology operation. There are relations of dependence between various cohomology operations so obtained, and in the present paper two specific relations are discussed. If G is of degree n , then a homology class of G gives the same operation as does its image in the full symmetric group of degree n . It is also shown that the totality of cohomology operations based on the full symmetric group of degree n is generated by a subset consisting of those operations based on cyclic permutation groups of prime orders and degrees.

COHOMOLOGY OPERATIONS, by N. E. Steenrod. [1956] [21]p. incl. refs. (AF 18(600)1494)

Unclassified

Published in Internat'l. Symposium on Algebraic Topology, Mexico City (Aug. 1956), Mexico City, National U. of Mexico, 1958, p. 165-165.

An exposition is given of some of the basic properties of primary cohomology operations. It is based on the work of Steenrod, Thomas, Eilenberg and MacLane, Serre, and Cartan. Proof is also given of the following reduction theorem for cohomology operations of several variables. Let C denote the family of cyclic groups each of whose orders is either infinite or a power of some prime. Then every cohomology operation whose coefficient groups are finitely generated can be expressed as a composition of the following ones: addition, coefficient homomorphisms, cup products with coefficient groups in C , and cohomology operations of one variable with coefficient groups in C . Also there is a discussion of the problem of finding generators and relations for the cohomology operations of one variable with coefficient groups in C . (Math. Rev. abstract)

A COMBINATORIAL DEFINITION OF HOMOTOPY GROUPS, by D. M. Kan. [1958] [31]p. incl. refs. (AF 18(600)1494) Unclassified

Published in Ann. Math., v. 67: 282-312, Mar. 1958.

A definition of the homotopy groups of a simplicial complex (or more general: c.s.s. complex) using only the simplicial structure is given. It involves free groups where the corresponding definition of the homology group involve free abelian groups. The results are stated in terms of the c.s.s. complexes of (S. Eilenberg and J. A. Zilber). Semi-simplicial complexes and singular homology, Ann. Math., v. 51: 499-513, 1950). In Chapter I, several definitions and results on c.s.s. complexes and homotopy groups are reviewed. Chapter II contains the new definition of the homotopy groups. In Chapter III, it is shown in what precise sense the homology groups are "abelianized homotopy groups". Chapter IV, contains miscellaneous results on the construction G. It should be noted that in several definitions either the first or the last face or degeneracy operator plays a special role and that another definition could be obtained by using the other extremal operator. Both definitions, however, are essentially equivalent and it is mainly a matter of convenience which one is chosen.

ON HOMOTOPY THEORY AND c.s.s. GROUPS, by D. M. Kan. [1958] [16]p. (AF 18(600)1494) Unclassified

Published in Ann. Math., v. 68: 38-53, July 1958.

If A and B are topological groups, two homomorphisms $f_0, f_1: A \rightarrow B$ are called loop homotopic if there is a homotopy f_t between them such that each $f_t, 0 \leq t \leq 1$, is

a homomorphism. Homotopy need not imply loop homotopy. For c.s.s. groups and homomorphisms, the analogous definition requires existence of a c.s.s. homotopy $f_t: I \times A \rightarrow B$ such that $f_t(\alpha, \sigma \cdot \tau) = f_t(\alpha, \sigma) \cdot f_t(\alpha, \tau)$

for $\alpha \in I$ and $\sigma, \tau \in A$ (I is the c.s.s. complex of a 1-simplex); loop homotopy need not be an equivalence relation on c.s.s. homomorphisms, although of course it is in the topological case. A c.s.s. group A is called free (with distinguished basis) if (a) for every n, A_n is freely generated, and (b) for every generator $\sigma \in A_n$ and degeneracy operator η^1 on σ , $\sigma \eta^1$ is a generator of A_{n+1} .

For c.s.s. groups, free groups play a role similar to that played for c.s.s. complexes by Kan complexes (=complexes with extension condition); for example, if A is free, loop homotopy is an equivalence relation for c.s.s. homomorphisms $A \rightarrow B$. On the category of reduced complexes (K is reduced if it has only one 0-simplex) the author has defined a functor G to the category of free c.s.s. groups; conversely, on the category of c.s.s. groups is defined a functor \bar{W} (essentially the Eilenberg-MacLane construction) to the category of reduced Kan complexes. Restricting G to reduced Kan complexes and \bar{W} to free c.s.s. groups, the author shows that they induce an equivalence between homotopy theory (relative to the base point) in the one category and loop homotopy theory in the other. An example is given of two free c.s.s. groups of the same homotopy type but not the same loop homotopy type. (Math. Rev. abstract)

AN AXIOMATIZATION OF THE HOMOTOPY GROUPS, by D. M. Kan. [1958] [19]p. [AF 18(600)1494] Unclassified

Published in Illinois Jour. Math., v. 2: 548-566, Dec. 1958.

In the present paper an axiomatic characterization of homotopy groups on c.s.s. (complete semi-simplicial) complexes is given which is essentially different from the ones given by Serrin, Milnor, Kuranishi, Hu, and others. A theory of homotopy groups on a subcategory S of the category of all c.s.s. complexes with base point is a collection of functors $\pi_n, n > 0$, from S to the category of groups, together with a natural boundary homomorphism for each fiber space $F \rightarrow E \rightarrow B$. The axioms are: (1) weak homotopy equivalences induce isomorphisms on homotopy groups; (2) exactness of the homotopy group sequence of a fiber space; (3) π_1 of a wedge product of two complexes is the free product of π_1 of each of the

PRI. 18:012, 013; PRI. 19:001

complexes; (4) $\pi_n(K) \neq 1$ for some K and n . Uniqueness is proved on the category of c.s.s. complexes weakly homotopy equivalent to countable c.s.s. complexes. Uniqueness is also proved for the category of all c.s.s. complexes when axiom (3) is strengthened to include infinite wedge products and the theory is extended to include π_0 . Finally it is shown that axioms (1) and (2) imply that $\pi_1(K(Z, 1))$ is torsion-free and abelian and hence that an arbitrary coefficient group cannot be introduced into the theory. A somewhat unfortunate feature of this axiomatization is that it requires for its statement, namely axiom (1), the definition of the usual homotopy groups on a c.s.s. complex. One wonders if axiom (1) could not be replaced by a homotopy axiom. (Math. Rev. abstract)

MINIMAL FREE c.s.s. GROUPS, by D. M. Kan. [1958] [11]p. incl. diags. [AF 18(600)1494] Unclassified

Published in Illinois Jour. Math., v. 2: 537-547, Dec. 1958.

A subset S of a free c.s.s. group F (Kan, Ann. Math., v. 68: 38-53, 1958) is said to be a basis of F if it is closed under degeneracy and freely generates F . F is called a free product of subgroups G_1 and G_2 if there are free bases S_1 of G_1 such that $S_1 \cap S_2 = \emptyset$ and $S_1 \cup S_2$ is a basis of F . F is minimal if it has no contractible free factors (except the trivial one). The main theorems of this paper are that any free c.s.s. group F with trivial F_0 and finitely generated homotopy groups is the free product of a contractible subgroup and a minimal subgroup M , M and F are homotopy equivalent and M is determined up to isomorphism by the homotopy type of F (homotopy means homotopy in the category of c.s.s. groups). ON MONOIDS AND THEIR DUAL, by D. M. Kan. [1958] [10]p. [AF 18(600)1494] Unclassified

Published in Bol. Soc. Mat. Mexicana, v. 3: 52-61, 1958.

Let C be a category with products. A monoid structure on an object $A \in C$ is defined to be a map m of $A \times A$ into A satisfying appropriate axioms. A co-monoid structure is defined by reversing all the arrows in the above. It is shown that in the category of groups, a group is free if and only if it admits a co-monoid structure and a group

is abelian if and only if it admits a monoid structure. A simplified proof is given for the lemma in [Illinois Jour. Math., v. 2: 548-566, 1958] above which states, roughly, that a functor from countable groups to groups which preserves short exact sequences and finite free products is either trivial or equivalent to the inclusion functor. Finally, it is shown that the F construction of Milnor [Mimeographed notes, Princeton U., 1956] is an isomorphism of the category of c.s.s. complexes onto the category of c.s.s. groups with co-monoid structure. GENERALIZED SECOND ORDER OPERATORS AND THEIR LATERAL CONDITIONS, by W. Feller. [1957] [46]p. (AFOSR-TN-57-141) (AF 18(603)24) AD 120500 Unclassified

Also published in Illinois Jour. Math., v. 1: 459-504, Dec. 1957.

Let m be a (finite or infinite) regular positive measure on a real interval I , vanishing on no subinterval, and let x be an everywhere positive continuous function. The operator $A f = \varphi^{-1} D_m \varphi^2 D_x \varphi^{-1} f$ is studied. Taking the differentiation D_m in the sense of Radon-Nikodym, the operator A is considered to be densely defined either on the space $L^2(m, I)$ of m -square-integrable functions or else on the space $C(I)$ of continuous functions. In L^2 , when m is finite, the endpoints of I carry positive weights and define conditions on A_C from which the classical boundary conditions are obtained as a degenerate limiting case. For particular absolutely continuous m and suitable function-multipliers and changes of variable, the operator represents locally the most general classical ordinary linear second-order differential operator $D_x^2 + gD_x + h$. For singular or discontinuous m it includes various non-classical cases previously treated. The endpoints of I are "active," "semi-active," or "natural" according to the behavior there of functions in the null space of A_C . The main shortcoming of A_C is that it cannot represent all second-order classical operators globally, but only the "pure" operators $D_x^2 + gD_x$. It is shown that the theory of A_C can be reduced to that of $A_1 = D_m D_x$. (Math. Rev. abstract, modified)

Also published in Illinois Jour. Math., v. 2: 1-18, Mar. 1958.

Also published in L'Enseignement Math., Series II, v. 3: 226-235, July-Sept. 1957.

Let I be an open interval, and for each open subinterval J let A_J be a non-trivial linear operator with domain and range both contained in the space $C(J)$ of all continuous functions on J . Suppose also that if K is an open subinterval of J and if $g \in C(K)$ is the restriction of some f in the domain of A_J , then g belongs to the domain of A_K and A_{Kg} is the restriction of A_{Jf} (but allow the domain of A_K to be perhaps larger than the restriction of the domain of A_J). This coherent collection of A_J defines an operator A of local character, which with the minimum property (has an extension that) equals some $D_{m \times m}$ provided only that A has (on each subinterval) a 2-dimensional null space. A is $D_{m \times m}$ on the open set of "regular" points of I , but degenerates to a first-order operator at the "singular" points. (Math. Rev. abstract, modified)

Let $S_n = X_1 + X_2 + \dots + X_n$ where the X_j 's are independent and assume the values ± 1 with probability $\frac{1}{2}$. The author derives for this symmetric random walk explicit formulas for the probability distribution of the number of changes of sign and other related quantities. The derivations are of a very elementary nature and the paper is self-contained. (Math. Rev. abstract, modified)

MICROWAVE ABSORPTION AND MOLECULAR STRUCTURE IN LIQUIDS. XIX. THE EFFECT OF INTERNAL FIELD UPON MOLECULAR RELAXATION TIMES IN LIQUIDS, by R. C. Millar and C. P. Smyth. [1957] [14]p. incl. diag. table. (AFOSR-TN-57-30) [AF 18(800)1331] AD 115065
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 3310-3313, July 5, 1957.

The effect of the internal field in a liquid upon the dielectric relaxation times of its molecules is examined by comparing the macroscopic relaxation times of a highly polar liquid with that of a liquid consisting of molecules of the same size and shape as those of the polar liquid, but with very small dipole moment. The comparison is made alternatively between the pure polar liquid and its dilute solutions in a nonpolar solvent. After correction for viscosity differences in most cases, the assumption is made that the macroscopic relaxation time of the pure liquid of low polarity or of the dilute solutions of the polar liquid is equal to the molecular relaxation time of the highly polar liquid. The molecular relaxation times thus obtained are compared graphically with those calculated by means of the various available equations. It becomes evident that the relation of the molecular relaxation time to the macroscopic relaxation time is dependent not only upon the dielectric constant of the liquid, but also, to some extent, upon the molecular shape. As a result, no equation thus far proposed for calculating the molecular relaxation time from the directly measured macroscopic relaxation time of a polar liquid is wholly adequate, but that proposed by Powles (Jour. Chem. Phys., v. 21: 633, 1953) and obtained by

Also published in Jour. Math. Pures. Appl., v. 38: 301-345, Oct.-Dec., 1959.

The theory of the birth and death process is explained with emphasis on analytical methods; probabilistic interpretations and applications are briefly discussed. In analytic terms, the theory reduces to the construction of Markovian matrices such that each column satisfies an infinite system of differential equations and each row satisfies the adjoint system. The problem is treated by elementary methods without the benefit of any known results. A pair of adjoint diffusion equations are used which are analogous to the matrix form of the differential equations, and methods developed for second order differential operators are applied. A metric is introduced in the space E of states $0, 1, 2, \dots$, and the distance is used as the natural scale; a canonical measure is also introduced in E . Examples are cited for some cases, and probabilistic interpretations are given.

THE DIPOLE MOMENT AND DIELECTRIC RELAXATION TIME OF ACEPLEIADYLENE, by D. A. Pitt, A. J. Petro, and C. P. Smyth. May 27, 1957 [2]p. incl. tables, refs. (AFOSR-TN-57-234) (Sponsored jointly by Air Force Office of Scientific Research under AF 18-(600)1331 and Office of Naval Research under [Nonr-185809]) AD 128531 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 5633-5634, Nov. 5, 1957.

The dipole moment and dielectric relaxation time of acepleiadylene have been measured in dilute benzene solution at 30°. The values were found to be $\mu = 0.49 \times 10^{-18}$ esu-cm and $\tau = 20.7 \times 10^{-12}$ sec, respectively. The moment is 50% of the value predicted by quantum mechanical calculations. Possible reasons for the low moment are discussed. The relaxation time is comparable to other aromatic compounds of similar size.

MICROWAVE ABSORPTION AND MOLECULAR STRUCTURE IN LIQUID. XX. DIELECTRIC RELAXATION TIMES AND MOLECULAR SHAPES OF SOME SUBSTITUTED BENZENES AND PYRIDINES, by A. J. Petro and C. P. Smyth. July 1, 1957 [6]p. incl. tables, refs. (AFOSR-TN-57-331) (AF 18(600)1331) AD 132405 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 6142-6147, Dec. 5, 1957.

Measurements of dielectric constant and loss at wave lengths of 1.25, 3.22 and 10.0 cm and 300 m have been carried out at 20, 40 and 60° on toluene, styrene, ethylbenzene, isopropylbenzene, o-xylene, m-xylene, p-chlorotoluene, α -picoline, 2- and 4-vinylpyridine, and 2- and 4-ethylpyridine in the pure liquid state and on solutions of p-chlorotoluene in benzene, p-xylene and p-dichlorobenzene. The relaxation times and viscosities are examined in relation to molecular size and shape. A regular increase in relaxation time with increasing size of the substituted group is observed for the benzene derivatives with the exception of styrene. The anomalous values for the latter are attributed to planarity of the molecule. The slightly polar hydrocarbons are compared with the polar pyridines after suitable internal field and viscosity corrections have been applied to the latter. The ratios of the molecular relaxation times and viscosities at constant temperature, or equivalently, the molecular relaxation times at constant viscosity, are found to be adequate in most cases for correlation of compounds of different polarity but similar size and shape. A similar correlation is made for p-chlorotoluene between the pure liquid and its solutions in non-polar solvents whose molecular sizes and shapes are similar to the solute. Activation energies for viscous flow and dielectric relaxation are compared on the basis of molecular size and shape and the mechanism of each process. The difference between the two quantities is found to be a maximum for the nearly planar molecules and to decrease with increasing bulk and irregularity of the substituted group.

at five wave lengths have been measured for the pure liquids benzene, toluene, o-xylene, m-xylene, p-xylene, ethylbenzene, styrene and isopropylbenzene at 20, 40, and 60°. The electronic polarizations have been calculated by the Lorentz-Lorenz and Cauchy relationships and the total polarizations by the Clausius-Mosotti equation. The electronic polarizations have been found to be density dependent, but a plot of the difference between total and electronic polarizations against the reciprocal of absolute temperature has been found to yield a straight line whose intercept is the atomic polarization and whose slope is proportional to the dipole moment. Values obtained by this method using the Debye equation agree well with those obtained by microwave dielectric constant measurements for all except o-xylene and compounds of higher moments. The liquid and vapor dipole moments have been correlated with the asymmetry of the molecules. (Contractor's abstract)

Dielectric constant and loss measurements at wave lengths of 577 m and 10.0, 3.22 and 1.25 cm have been carried out at 20, 40, and 60° upon dilute benzene solutions of phenyl isocyanate, phenyl isothiocyanate, p-tolyl isocyanate, tolylene-2,4-disocyanate, 1-naphthyl isocyanate and 2-biphenylene isocyanate. The densities, viscosities and refractive indices of the solutions have also been measured. The molecular dipole moments calculated from these data indicate that the direction of the bond from the ring to the linear isocyanate group is close to, if not coincident with, that of the axis of the group. The dielectric data have been used to construct arc plots, from which the dielectric relaxation times and their almost negligibly small distribution parameters have been calculated. The rather large molecular relaxation times resulting from the considerable protrusion of the polar group from the ring are found to vary in the expected manner with the direction of the molecular dipole relative to the molecular axes. MICROWAVE ABSORPTION AND MOLECULAR STRUCTURE IN LIQUIDS. XXV. MEASUREMENTS OF DIELECTRIC CONSTANT AND LOSS AT 3.1-MM WAVELENGTH BY AN INTERFEROMETRIC METHOD, by R. W. Rampolla, R. C. Miller and C. P. Smyth. Aug. 29, 1958, 27p. incl. diagrs. tables, refs. (AFOSR-TN-58-763) (AF 18(600)1331) AD 201862 Unclassified

Also published in Jour. Chem. Phys., v. 30: 566-573, Feb. 1959.

The theory and apparatus for an interferometric method for the measurement of the dielectric constant and loss of a liquid at 3.1-mm wavelength are described. The 3.1-mm wave is obtained as the fourth harmonic from a K-band reflex klystron. The probable error of the dielectric constant measurements is 0.5%, while that of the loss measurements is 2-5% for high loss liquids. For very low losses, only an upper limit can be obtained because of the small amount of harmonic energy obtainable. Four tetrahalogenated methanes, three substituted benzenes, two methylquinolines, three alcohols, and water have been measured and the results examined in the light of measurements at lower frequencies. All of the liquids but the three alcohols give 3-mm points lying satisfactorily on Cole-Cole arc plots drawn through points previously obtained at lower frequencies. The losses observed at 3-mm are, however, somewhat higher than that calculated indicating the probable presence of overlapping absorption regions at still higher frequencies. The apparent optical dielectric constant value 6.0

PRL 08:018; PRL 09:038, 039

found for water evidences further absorption at much shorter wavelengths. Methyl, ethyl, and n-octyl alcohols show absorption regions at frequencies too high to be attributable to molecular dipole orientation. The critical or maximum absorption wavelengths found for these additional high-frequency absorption regions are 0.57 cm for ethyl alcohol and 0.50 cm for n-octyl alcohol. (Contractor's abstract)

SHORTENING OF DIELECTRIC RELAXATION TIMES. AROMATIC METHOXY COMPOUNDS (Abstract), by D. M. Roberti and C. P. Smyth. [1958] [2]p. [AF 18(600)-1331] Unclassified

Presented at meeting of the Amer. Chem. Soc., Philadelphia, Pa., Feb. 5, 1958.

Dielectric relaxation studies on polar molecules have been extended to include molecules with rotating polar groups. Dielectric constant and loss were measured for a series of methoxy-substituted aromatic compounds over a range of temperatures and microwave frequencies. Data were used to calculate relaxation times, which were corrected for viscosity and internal field effects. These reduced relaxation times are compared with values for rigid molecules of similar size. Anisole, o-dimethoxybenzene, m-dimethoxybenzene, p-dimethoxybenzene, 1-methoxynaphthalene, and 2-methoxynaphthalene were studied as pure liquids, and the appropriate methyl- or ethyl-substituted compound used for comparison. In all cases, except for 1-methoxynaphthalene, the relaxation time is considerably shorter than would be expected, probably because of contribution to relaxation by an alternate mode of orientation, methoxy group rotation. With 1-methoxynaphthalene, a molecular model shows the methoxy group restricted in its rotation by the δ -hydrogen. With o-dimethoxybenzene, the data will not fit a Cole-Cole plot, and there is clear evidence for more than one dispersion region. Energies of activation for relaxation and for viscous flow are given and compared. High frequency intercepts on the Cole-Cole plots were used to calculate dipole moments.

FORCE AND MASS BALANCES OF THE INCOMPRESSIBLE, ISOTHERMAL, PLANAR LAMINAR JET ISSUING FROM A FINITE SOURCE, by A. L. Thomas. Dec. 1955, 17. Incl. illus. diagrs. tables, refs. (Technical note no. 31) (AFOSR-TN-57-21) (AF 33(038)23976) AD 115055. Unclassified

A mathematical solution to the velocity and concentration distributions of an incompressible, isothermal,

planar laminar jet issuing from a long rectangular slot into quiescent surroundings of the same density is presented. The features of the solution are: concentration and velocity distributions remain finite back to the orifice; the orifice is finite in dimensions; the change in concentration distribution (which is flat at the orifice), and the change in the velocity distribution (from the Poiseullian form at the orifice) are taken into account. The present solution for velocity distribution is a modification of that of Okabe who solved for the velocity distribution in a viscous jet for flow from a nozzle which provides a uniform velocity profile at the throat. Previous analyses of the planar, laminar jet assumed the jet to originate from a line source. Andrade reported experimental velocity distribution measurements of a laminar jet issuing from a nozzle under conditions similar to those specified by the theoretical studies of Okabe. The results of these two investigations are compared here after extension of numerical values of the essential parameters beyond those originally published. The solution for concentration distributions in the planar, laminar jet appears to be an initial one. A few experimental diffusion measurements have been performed along the centerline of the jet. The measurements indicate agreement with theory in the region of the orifice. The data were obtained from an ethylene-into-air jet. (Contractor's abstract)

A RELATIONSHIP BETWEEN SOME BOND PROPERTIES OF DIATOMIC MOLECULES AND THE IONIZATION POTENTIALS OF THEIR CONSTITUENT ATOMS, by B. Stevens. Mar. 1957 [16]p. Incl. tables, refs. (Technical note no. 34) (AFOSR-TN-57-194) (AF 33(038)23976) AD 126489 Unclassified

Also published in Spectrochimica Acta, v. 12: 154-161, Sept. 1958.

The relationship $kr_o^2/2 = N(I_A + I_B)$ between the force constant k , bond length r_o and bond order N of the diatomic molecule AB in its ground state, and the first ionization potentials I_A and I_B of atoms A and B , is examined. For covalent molecules with 8, 10, or 11 valence shell electrons, the relationship is satisfactory, but for molecules with 2, 12, or 14 electrons in the valence shell the expression must be modified by the introduction of 2 constants. For molecules of this type the agreement between calculated and experimental bond lengths is as good as that obtained by Gordy, and the proposed expression has the theoretical advantage of equivalent dimensions. Also published in Seventh Symposium (Internat'l.) on Combustion, Oxford U., London (Gt. Brit.) (Aug. 28-Sept. 3, 1958), London, Butterworths Scientific Publications, 1959, p. 621-632.

The work concerns flame blow-off limits at a 5 mm od cylindrical flame holder as the velocity of a premixed propane-air stream of different compositions is caused to increase to the condition of flame blow-off within a rectangular combustion chamber. Conditions are experimentally perturbed by gas and geometric changes to explore the blow-off process. Auxiliary combustible gases are found to raise the blow-off limit substantially for lean mixtures of the main premixed gas stream; O_2

acts in a like manner for rich mixtures. Inert gases tend to depress blow-off limits. The experiments indicate that a stabilizing ignition zone in a laminar flame is resident in the region near the burner lip in which streams of premixed combustible gases join and mix with convective streams of gas surrounding the burner. The resulting intermediate gas composition is characteristic only of the local zone and not of the adiabatic combustion wave farther distant.

CHEMILUMINESCENCE IN THE SYSTEM ATOMIC SODIUM PLUS ATOMIC HYDROGEN, by J. D. McKinley, Jr. and J. C. Polanyi. [1958] [7]p. incl. diagr. table, refs. (AF 33(038)23976) Unclassified

Presented at Symposium on the Structure and Reactivity of Electronically-Excited Species, Ottawa U. (Canada), Sept. 5-6, 1957.

Published in Canad. Jour. Chem., v. 36: 107-113, Jan. 1958.

When atomic sodium is diffused into a mixture of atomic and molecular hydrogen, a weak chemiluminescence is observed in the gas phase. Visible emission consists of the sodium D lines. The total intensity of the emission, $\sim 5 \times 10^{11}$ photons/sec, indicates that only one in 5×10^4 of the sodium atoms entering the reaction vessel is involved in luminescent reaction. In order to account for the rapid fall-off in intensity of the flame away from the nozzle it is necessary to suppose that some non-luminescent reaction is removing sodium atoms in the gas phase. Preliminary experiments suggest that the non-luminescent reaction is $Na + H + H_2 \rightarrow NaH + H_2$, and the luminescent reaction either $Na + Na + H \rightarrow NaH + Na^*$ with collision yield 4×10^{-3} or $Na + H + H \rightarrow H_2 + Na^*$ with collision yield 1×10^{-5} . QUENCHING AND VIBRATIONAL-ENERGY TRANSFER OF EXCITED IODINE MOLECULES, by J. C. Polanyi. [1958] [10]p. incl. illus. diagr. table, refs. (AF 33(038)-23976) Unclassified

Presented at Symposium on the Structure and Reactivity of Electronically-Excited Species, Ottawa U. (Canada), Sept. 5-6, 1957.

Published in Canad. Jour. Chem., v. 36: 121-130, Jan. 1958.

Quenching of I_2^* ($^3\Pi_{0u}^+$) ($\nu^* = 26$) is shown to take place to the exclusion of vibrational-energy transfer in iodine at pressures up to 19 mm. A possible quenching mechanism involving sensitized predissociation of the collision partner is described. Vibrational transfer in collisions with H_2 and D_2 is found to occur at less than every gas kinetic collision. Arguments on general grounds are put forward to support this result, which conflicts with that of earlier workers. Increase in the mass of the isotope is found to bring about increased efficiency of vibrational transfer.

CONDUCTIVITY AND THERMOELECTRIC POWER OF FeO (Abstract), by A. B. Kuper. [Mar. 1957] [1]p. (AF 18(600)967) Unclassified

FeO polycrystals were made by complete oxidation of 99.95 iron in hydrogen-water vapor followed by homogenization in the same atmosphere and rapid quench. Four compositions spanning the phase range at high temperature were used: Fe_{0.916}O to Fe_{0.951}O corresponding respectively to 4.9% to 8.4% Fe⁺⁺ vacancies. Measurements were made from 77 - 360°K. The alloy tends to decompose at somewhat higher temperature. The thermoelectric power (Q) is positive. QT increases with T with plateaus which depend on composition at roughly .007 and .02 ev. Assuming $QT = E_F$ the Fermi energy, then the number of holes changes relatively little over the T range. The conductivity, $\sigma \approx \sigma_0 \exp\left(\frac{-0.1 \text{ ev.}}{RT}\right)$ and shows some composition dependence. σ at room temperature $\approx 1 \text{ (ohm-cm)}^{-1}$. The number of acceptors is assumed to be one per Fe⁺⁺ vacancy since each such vacancy is neutralized at low temperature by two localized holes. At room T the mobility is $10^{-3} \text{ cm}^2/\text{v-sec}$. It is assumed that conduction takes place by diffusion of holes between localized Fe d-levels.

NON-LINEAR INTERACTIONS IN A VISCOUS HEAT CONDUCTIVE COMPRESSIBLE GAS, by B.-T. Chu and L. S. G. Kovaszny. June 1957, 51p. Incl. table, refs. (Proj. Squid technical rept. no. JHU-15-P) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1121, Office of Naval Research under N6ori-10503, and Bureau of Ordnance under NORD-15872) AD 133051 Unclassified

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

Also published in Jour. Fluid Mech., v. 3: 494-514, Feb. 1958.

The linearized equations of motion show that 3 basic modes of fluctuations exist in a viscous, heat-conductive, compressible medium. The nonlinearity of the governing equations can be interpreted as an interaction among 3 basic modes. These interactions are classed as "mass-like", "force-like", or "heat-like" effects. A system evolving interactions of an arbitrary order is presented, and the second-order (bilateral) interactions are investigated in detail. A method of estimating the relative importance of the different second-order interactions is illustrated by means of an example, and some predictions are made about the general behavior of the flow. ON THE FINE STRUCTURE OF TURBULENT FLOWS, by R. Betchov. [1957] [12]p. incl. diagrs. refs. (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) Unclassified

Published in Jour. Fluid Mech., v. 3: 205-216, Nov. 1957.

The turbulence produced by a multiplicity of small air jets has been investigated and comparisons are made with other turbulent flow. The eddy Reynolds number is large ($R_\lambda = 250$). The energy spectrum was measured, as well as the skewness and kurtosis of $\partial u/\partial x$. The effect of the finite length of the hot wire is considered, and the corrected results indicate that the spectrum follows the law of Kolmogoroff in an intermediate range and appears to fall off with the (-6)-power of the frequency in the viscous range. This range is limited at the upper end of the frequency range by electrical noise. Special precautions reduced this noise to the level of thermal agitation in the hot wire. The ultimate limit to spectral analysis is imposed by the molecular agitation of the gas. This limit is evaluated and compared with the spectrum of turbulence. It appears that the spectrum of $\partial^3 u/\partial x^3$ merges with the spectrum of molecular agitation without a distinctive separation. (Contractor's abstract)

SHOCK, by C.-T. Chang. [1958] [7]p. incl. diagrs.
(Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) Unclassified

Published in Jour. Aeronaut. Sciences, v. 25: 317-323, May 1958.

A problem of unsteady interaction between a weak upstream temperature disturbance and a plane oblique shock is investigated. The shock is assumed to be located at the concave corner of a wall. The temperature disturbance is taken as a layer of hot air of constant strength — namely, a step function. Its wave front is inclined at a definite angle with respect to the upstream unperturbed flow. It is found for such a configuration that, even for weak upstream disturbance, mixed flow (a supersonic region outside and a subsonic region inside a sonic circle, respectively) usually occurs downstream of the shock. Using a general concept of conical flow, the qualitative nature of the flow field downstream is predicted. Subsequently, a method for its quantitative investigation is presented. Based on the concept of constant states, the flow in the supersonic region is determined by the method of characteristics; the flow in the subsonic region is determined by following a procedure similar to the one used by Lighthill in his investigation about the diffraction of blast waves. VORTICITY PRODUCTION IN ISOTROPIC TURBULENCE, by R. Betchov. [1957] [9]p. incl. refs. (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) Unclassified

Published in Proc. Ninth Internat'l. Congress of Appl. Mech., Brussels (Belgium) (Sept. 5-13, 1956), v. 3: 405-413, 1957.

An essential aspect of turbulence is the presence of vorticity fluctuations. In isotropic, homogeneous and incompressible flow, they are tied to the energy dissipation and the rate of deformation of small fluid spheres. In a suitable non-dimensional form, the time derivative of the mean square of the vorticity is given by:

$$\frac{d}{dt} \overline{\omega^2} = \frac{35}{8} S - D^2$$

where the skewness S represents non-linear inertial effects and where D^2 represents viscous effects. Ex-

Princeton U. James Forrestal Research Center, N. J.
(Project SQUID)

perimentally S is found positive. With Helmholtz theorem, this indicates concentration of vorticity in narrow regions. S has been measured accurately and found to be equal to 0.4 ± 0.05 , irrespective of the turbulence Reynold's number. Under the usual assumptions of isotropy, homogeneity and incompressibility and using only first derivatives of the velocity, the following has been found:

$$-0.436 \gamma^{1/2} < S < 0.436 \gamma^{1/2}$$

where γ is a kurtosis. With $\gamma = 4$ a kinematic maximum $S = 0.87$ has been found. The dynamic equations involve second derivatives and they tend to lower the maximum value of S . Thus the observed value should correspond to a dynamic maximum. Other kinematic considerations show that when S is positive, the mean rate of deformation of small fluid spheres corresponds to squashing and not stretching of the spheres. Consequently the stretching of the vorticity occurs along the two minor principal axis of the rate of strain tensor. (Contractor's abstract)

PERFORMANCE, by H. C. Hottel, G. C. Williams, and A. H. Bonnell. June 1957, 27p. illus. (Proj. Squid technical rept. no. MIT-15-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 135111 Unclassified

Also published in Combustion and Flame, v. 2: 13-34, Mar. 1958.

The implications of well-stirred reactor kinetics in the prediction of combustion-chamber performance were examined. The gross performance characteristic of a combustion chamber can be simulated by models which are built up from interactive, well-stirred reactor elements. Three models which were examined analytically show (1) the effect of pressure interaction; (2) the effect of recirculation interaction; and (3) the effect of a non-uniform distribution of fuel-air ratio. Instability phenomena in a simple combustion system were experimentally investigated; preliminary results indicate that models which are based on the well-stirred reactor are capable of providing a basis for models of high-output combustion.

THERMAL CONDUCTIVITY OF PURE LIQUIDS, by W. J. Scheffy and E. F. Johnson. Aug. 1957, 19p. illus. tables, refs. (Proj. Squid technical rept. no. PR-71-M) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 142428 Unclassified

Efforts are being directed toward predicting empirically thermal conductivity in its variation with molecular weight, density, and temperature. A general correlation of thermal conductivity is described which is based on limited theoretical and inadequate experimental data, but which has advantages of simplicity and ease of application. A cylindrical apparatus was constructed for reasonably accurate determinations of thermal conductivity of liquids between room temperature and their boiling points. Temperature profiles were obtained without simultaneous longitudinal gradients on the heater tube and the wall separating the test section and the sand bed. By using the known conductivities of H_2O and CCl_4 ,

the following equation was obtained for the thermal conductivity of a test liquid for a temperature of 25°C in the cooling jacket: $k_L = \frac{26.24}{m} + 0.314$, where m is the

slope of the curve of ΔT_L versus ΔT_S for the test

liquid at various heat fluxes. Results of runs on MeOH, benzene, chlorobenzene, and allyl alcohol are compared.

Princeton U. James Forrestal Research Center, N. J.
(Project SQUID)

The apparatus appeared to be capable of yielding reliable results with fairly good reproducibility. A high-temperature apparatus was developed to obtain data on Me_2CO , benzene, ETOH, *tert*-BuOH, glycerol, and 2 silicone fluids; thermal conductivity data are tabulated.

Presented at Diamond Jubilee annual meeting of the Amer. Soc. Mech. Engineers, Chicago, Ill., Nov. 13-18, 1955.

An experimental investigation was conducted for determining the convection and radiation heat-transfer coefficients for pure dry air and pure gaseous carbon dioxide flowing turbulently through a small-diameter, water-cooled tube. The experimental results are correlated with an average deviation of $\pm 8\%$ by the following equation:

$$j = 0.035 Re^{-0.23}$$

wherein all physical properties are evaluated at the average film temperature. Data were obtained over a static gas pressure range of 50 to 250 psia, an average gas bulk temperature range of 597 to 1778F, and a Reynolds number range of 8300 to 140,000. The total heat-transfer coefficients for carbon dioxide, which contain both radiation and convection components, are shown to be numerically less than the pure convective coefficients for air at the same conditions of temperature, pressure, and Reynolds number. The total coefficients for CO₂ are shown to be affected by pressure at high bulk temperatures. For example, the total coefficient decreased 9% when the pressure was increased from 50 to 200 psia. Also published in Phys. Rev., v. 110: 1478-1479, June 15, 1958. (Title varies)

In analogy with the proposed self-interacting conserved vector current used to explain the almost precise equal-

ity of the vector coupling strengths in β and μ decay, a self-interacting conserved axial vector current has been proposed to explain the near equality of the axial vector strengths in the same two decays. In order to explain the decay of strange particles a strangeness non-conserving current has also been proposed. It is shown that both the axial vector current and the strangeness non-conserving current are ruled out on experimental grounds.

Also published in Phys. Rev., v. 112: 642-665, Oct. 15, 1958.

The electromagnetic structure of the nucleon is studied using dispersion relation techniques. Contributions to the magnetic moments and mean-square radii from the two pion intermediate state are studied exhaustively. It is shown that the electromagnetic structure of the meson itself may play an important role. The structure of the meson is also discussed. The two pion state seems to account reasonably for the isotopic vector magnetic moment and magnetization mean-square radius, but the charge density radius appears to be much smaller than the currently accepted experimental value. As regards the isotopic scalar properties of the nucleon, study is made of the contributions from intermediate states with two K-mesons and nucleon-antinucleon pairs (more generally baryon pairs). The K-meson state is treated by perturbation theory and found to have a small effect. Using an argument based on the unitarity of the S-matrix it is shown that the pair contributions must be small.

PRO.20:004; PRO.01:003, 004
PRO.02:001, 002

A SOLUBLE PROBLEM IN DISPERSION THEORY, by M. L. Goldberger and S. B. Treiman. [1958] [7]p. (AFOSR-TN-58-1017) (AF 49(638)304) AD 162282

Unclassified

Published in Phys. Rev., v. 113: 1663-1669, Mar. 15, 1959.

The Lee model is modified by addition of a new field θ' and a weak coupling $N + \theta \rightarrow N + \theta'$, which leads to instability of the V particle: $V \rightarrow N + \theta \rightarrow N + \theta'$. The decay amplitude is calculated to lowest order in the weak coupling by dispersion relation methods. In effect we are required to study a set of simultaneous dispersion relations. The problem is completely soluble and serves to clarify the essential structure of dispersion methods. The results agree with what one obtains, more easily in the present case, by direct methods. The streamsurface characteristics method for supersonic flow mentioned in item no. PRO.01:002 has been programmed for the IBM-650 digital computer. As a result, the isentropic supersonic flow between two close surfaces of arbitrary but regular shape, subject to proper boundary conditions, can be determined at a speed of about 1 3/4 minutes per point. The IBM-650 computer was found to be somewhat too small for the present problem. The numerical examples involving internal supersonic flow problems are given. (Contractor's abstract)

Various ducted fans driven by closed cycle gas turbines were studied. For chemical fuels, two arrangements were considered for the combustion chamber containing the closed cycle gas heater: (a) as part of a separate turbojet engine ("external heat source"), and (b) as an afterburner in the ducted fan air flow ("self contained closed cycle engines"). For nuclear fuels the high-temperature gas-cooled reactor was considered the most likely heat source ("single loop system"). One closed cycle power-plant with external gas heater was fairly completely designed. The component weights of this engine were used as a basis for weight estimates of the other engines. Two other closed cycle applications were briefly investigated: a high altitude secondary power-plant, and a boundary layer suction fan drive system. The closed cycle ducted fans using chemical fuels were found to be too heavy and complicated to be competitive with open cycle engines. The gas-cycle nuclear engine looked promising for subsonic and possibly for low supersonic propulsion. Further work on this was initiated. As secondary powerplants for future high altitude flight vehicles, closed cycle turbines promise to have a definite field of application. (Contractor's abstract)

aircraft has been summarized and evaluated. This study dealt with closed cycle turbine-ducted fan powerplants suitable for a gas-cooled reactor heat source. The reactor-gas turbine loop would use helium, at a turbine inlet condition of about 70 atm and 1800°F. Cycle calculations with and without a regenerator show a potential heat consumption at sea level static conditions of

7.5 - 12.2 x 10³ Btu/hr - 1 lb thrust (equivalent to an sfc of 0.42 - 0.68 for hydrocarbon fuels), and an air specific impulse of about 30 with a 1.6:1 pressure ratio fan. The regenerator would be extremely compact, about 1.6 cu ft/hp, the cooler rather bulky, about 30 cu ft/hp, but not excessively heavy. The cooler and regenerator together would weigh about 0.13 lb/hp. The closed cycle turbomachinery would be extremely small, favoring the design of larger power units (above 15,000 hp). The high speed capabilities of these engines as well as mechanically advantageous arrangements and overall weight estimates are currently being worked on. (Contractor's abstract)

Also published in Proc. Symposium on Advanced Propulsion Systems, Los Angeles, Calif. (Dec. 11-13, 1957), N. Y., Pergamon Press, v. 2: 117-134, 1959.

Closed gas-cycle nuclear power plants for aircraft applications are currently being re-evaluated in view of recent advances in refractory metals and ceramic fuel element technology. With high-pressure helium as the primary loop working fluid, the chief advantages of the closed-cycle gas-cooled systems are (1) compact reactor, (2) high cycle efficiency, (3) freedom from corrosion, and (4) high physical and nuclear stability of the working fluid. Heat exchanger sizes, weights and tightness, together with the possibility of fission product leakage into the helium, are currently considered as the most severe problems. Neither the size, weight, nor performance of the helium turbomachinery is expected to pose any serious difficulties. The performance of a subsonic-supersonic dash airplane with chemical fuel augmentation, was calculated using material temperatures compatible with present day technology. Two other airplanes, which were all supersonic and which used a nuclear power plant system during their entire mission, were studied. A preliminary study of the possible space vehicle applications of closed gas-cycle systems has also been started. (Contractor's abstract)

LOCAL A-SETS, B-SETS, AND RETRACTIONS, by C. J. Neugebauer. Apr. 1957, 20p. (Technical note no. 8) (AFOSR-TN-57-250) (AF 18(600)1484) AD 126548

Unclassified

Also published in Illinois Jour. Math., v. 2: 386-395, Sept. 1958.

A concept of retraction of a Peano space onto one of its B-set is introduced with the complement of the B-set mapped into a dendrite. A local A-set of a Peano space is introduced and a local A-set B is an A-set relative to a connected open set G of P, i.e., B is a non-degenerate compact subset of P such that every component of G-B has a single frontier point relative to G. A natural retraction from G onto B suggests itself, i.e., the one that sends each component of G-B into its frontier relative to G. It is asserted that this retraction t can be extended to P so as to map P-B into a dendrite. The composition of two retractions is analyzed. It is seen that every local A-set is a B-set, and if the underlying Peano space is of finite degree of multicoherence, every B-set is a local A-set.

LEBESGUE AREA ZERO, DIMENSION, AND FINE CYCLIC ELEMENTS, by R. F. Williams. June 1957, 13p. (Technical note no. 10) (AFOSR-TN-57-422) (AF 1: (600)1484) AD 136411 Unclassified

Surfaces are treated as maps f from general two-dimensional spaces X into a Euclidean space E_n . Three theorems are demonstrated which show that the surface has zero Lebesgue area only if it is essentially one-dimensional. It is stated as a corollary that Lebesgue area zero is a topological property. These theorems hold in quite general circumstances. Theorem 1 requires only that X be a bi-compact Hausdorff space, and theorems 2 and 3 require that X be a continuous curve of finite degree of multi-coherence. Theorem 3 characterizes Lebesgue area zero via fine cycle elements using results of Neugebauer, and generalizes a theorem of Radó.

THE DIRECT METHOD IN THE CALCULUS OF VARIATIONS, by L. H. Turner. Aug. 1957, 124p. incl. refs. (Technical note no. 11; rept. no. 1203) (AFOSR-TN-57-462) (AF 18(600)1484) AD 136453 Unclassified

In the present study, integrals on curves and surfaces are studied in relation to the direct method of the calculus of variations based on lower semicontinuity. An investigation is made in Chapter I of the convexity properties of integrand functions of the type used in the calculus of variations. In Chapter II, parametric curves and integrals on such curves are studied. Conditions for lower semicontinuity for integrals on curves are given in Chapter III. Chapter IV contains 3 existence theorems giving minima for nonparametric integrals. In Chapter V, parametric surfaces and corresponding integrals are studied. Sufficient conditions for lower semicontinuity are given for surface integrals in Chapter VI. These represent new proofs of theorems by L. Cesari. These proofs differ from his in that the proofs are given in terms of arbitrary representations and convexity conditions are substituted for conditions using differentiability of the integrand. PRIME ENDS FOR OPEN SUBSETS OF TWO DIMENSIONAL MANIFOLDS I, by R. E. Fullerton. Aug. 1957, 23p. incl. diagrs. refs. (Technical note no. 13) (AFOSR-TN-57-590) (AF 18(600)1484) AD 136476 Unclassified

This investigation was carried out in order to obtain basic topological results necessary for the study of surfaces defined over two-manifolds. Considerable use is made of the theory of prime ends of plane domains in building up locally a prime end theory for open subsets of manifolds. Admissible ends and prime ends are defined and certain of their properties studied. It is shown that for simple Jordan regions these two concepts give equivalent results. It is expected that the data obtained from this study will be used in the future for the investigation of contours for surfaces defined on two-manifolds, and, in particular, for proving the Cesari-Cavalleri type inequality for such surfaces.

GENERALIZED LENGTH AND AN INEQUALITY OF CESARI FOR SURFACES DEFINED OVER TWO-MANIFOLDS, by R. E. Fullerton. Aug. 1957, 21p. (Technical note no. 14) (AFOSR-TN-57-591) (AF 18(600)1484) AD 136577 Unclassified

The theory of contours has been generalized so that the domain space of a mapping which defines a surface is a two-dimensional manifold rather than the restricted domain of the subsets of a plane. The prime end theory for open subsets of two-manifolds has made possible a treatment of mappings of open subsets on compact two-manifolds. The Cavalleri inequality of Cesari has been shown to be valid in this more general case and should be useful in developing theorems similar to those

PRF.01:016 - PRF.01:018

Involving mappings defined on planar sets. Let T be a mapping from a manifold M into E_n , let $[S]$ denote the set of points in E_n occupied by the surface S , let there be a real valued continuous function $f: [S] \rightarrow \text{Reals}$ defined on $[S]$, let t be a parameter $t_1 \leq t \leq t_2$ where $t_1 = f_{\max}$ and $t_2 = f_{\min}$, let σ be a segment of ends and prime ends of $A \subset S$, and let $\gamma\sigma$ be the set of points of the boundary γ which are end points of the ends and prime ends in σ . The following theorems have been proved: (1) $T(\gamma\sigma) \subset E_n$ is a continuous curve of length

additivity theorem for Lebesgue area, which is analogous to Morrey's and Radó's cyclic additivity theorem, and states that the Lebesgue area of a surface is equal to the countable sum of the areas of its fine-cyclic elements. Also, the fine-cyclic elements are characterized as retractions of a given surface, having particular maximal-minimal properties. (Contractor's abstract)

SMOOTHING METHODS FOR CONTOURS, by L. Cesari and R. E. Fullerton. [1957] [11]p. (AF 18(600)1484) Unclassified

Published in Illinois Jour. Math., v. 1: 395-405, Sept. 1957.

In connection with his work on Cavalieri's inequality and its applications, Cesari devised a first smoothing method for contours [Rend. Matem. e Appl., v. 15: 341-365, 1956], roughly as follows: Given a map T from the closure of a simply-connected plane domain A , the sum of the continua of constancy of T which meet a set E constitute the corresponding "shaggy set" E''' ; further, by the join of two sets in a continuum K , i.e., an irreducible subcontinuum which meets both; and the shaggy set which corresponds to this join may be termed shaggy join. This being so, let C be a portion of the boundary of A determined by an interval of prime ends $< 2\pi$ between two distinct prime ends ω_1, ω_2 , and let E''' be a shaggy join of ω_1, ω_2 in C''' . Then the first smoothing operation consists in replacing C by a corresponding portion of the boundary of the set $A - E'''$. A second and a third smoothing process are now considered, the former of which turns out to be fully equivalent to the first, and the latter partially so. (Math. Rev. abstract)

A NEW PROCESS OF RETRACTION AND THE DEFINITION OF FINE-CYCLIC ELEMENTS, by L. Cesari. [1957] [7]p. incl. refs. (AF 18(600)1484) Unclassified

Published in Anais Acad. Brasileira Ciências, v. 29: 1-7, Mar. 31, 1957.

It is the purpose of this paper to refer to a new concept of retraction for continuous mappings $S = (T, A)$ from a finitely connected Jordan region $A = J$ (mappings, or surfaces, of the type ν , where ν is the connectivity of J , $0 < \nu < +\infty$). New features have been observed for $\nu \geq 1$ which have no analogy in the case where J is a simple Jordan region ($\nu = 0$). It may for instance occur that a surface of type $\nu \geq 1$ presents a system of leaves linked together to form a unique cyclic element of a rather complex type, while each leaf may be of an extremely simple type, namely of the disc. To account for these simple elements of a surface, the new concept of fine-cyclic element σ of a mapping $S = (f, J)$ of the type ν has been introduced as a retraction of S , according to the new concept of retraction. The concept of fine-cyclic element has been discussed in great details. The fine-cyclic elements may be actually finer than the usual cyclic elements of the same mapping when $\nu \geq 1$, while they coincide with the usual cyclic elements when $\nu = 0$, i.e., when J is a simple closed Jordan region. The theory has been developed independently of the usual cyclic element theory, and is self-contained, based as it is on known properties of Elementary Topology of the Euclidean plane. The theory comprehends a fine-cyclic

PRF.01:019 - PRF.01:022

$V(A, T) - \Sigma V(\pi, \tau, T) < \epsilon$, where Σ ranges over all $\pi \in [\pi]$. Theorem IV of the present paper allows the replacement of the above inequality of theorem I with $V(A, T) - \Sigma v(\pi, \tau T) < \epsilon$. It is proved that analogous relations subsist between theorem III and theorem V. With either theorem III or V one can prove theorem II which implies the basic equality $L = V = P$. Theorem II states that there is another continuous mapping (T^*, A) with $V(A, T^*) < + \epsilon$ such that $d(T, T^*, A) < \epsilon$, T^* maps a finite collection $[q]$ of disjoint squares $q \subset A$ onto squares $Q \in E_3$, and $V(A, T) + \epsilon > V(A, T^*) \Sigma |Q| > V(A, T) - \epsilon$, where Σ ranges over all $q \in [Q]$.

ON THE CONCEPT OF SURFACE INTEGRAL, by L. Cesari and L. H. Turner. [1958] [2]p. [AF 18(600)1484] Unclassified

Published in Proc. Nat'l. Acad. Sciences, v. 44: 42-43, Jan. 1958.

By a surface $S = (T, A)$ is meant a continuous mapping T from an admissible set A of E_2 into E_3 . Cesari [Ann. Scuola Norm. Sup. Pisa, v. 13: 77-117, 1944] has defined the surface integral

$$J(T, A, \Omega) = \int_{\Omega} f(p, t),$$

for any surface of finite area and for any f on $T(A) \times S^2$ to the reals, which is uniformly continuous, S^2 being the unit sphere $t_1^2 + t_2^2 + t_3^2 = 1$ in E_3 . Here $p = T(w)$ for $w \in A$. This definition has since been fundamental for problems of the calculus of variations for parametric surfaces. It generalized, for example, the Tonelli integral

$$I(T, A, \Omega) = \int_A f(T(w), J(w)) dw,$$

where $J(w)$ is the generalized Jacobian at w , to the general situation in which the latter does not exist. In the present paper the authors construct, from the Cesari variation functions, a measure ν and new set functions V_1, V_2, V_3 . The Radon-Nikodym derivatives $\theta_r = dV_r/d\nu$ exist always, and $\theta_1^2 + \theta_2^2 + \theta_3^2 = 1$ almost everywhere. The integral

$$H(T, A, \Omega) = \int_A f(T(w), \theta(w)) d\nu,$$

where $\theta(w) = (\theta_1(w), \theta_2(w), \theta_3(w))$, then exists for every surface of finite area and every f bounded and B-measurable in $T(A) \times S^2$. The principal theorem is that then $J(T, A, \Omega) = H(T, A, \Omega)$. H thus gives a definition of surface area and an integral representation of J valid for every surface of finite area. (Math. Rev. abstract)

SURFACE INTEGRAL AND RADON-NIKODYM DERIVATIVES, by L. Cesari and L. H. Turner. [1958] [12]p. [AF 18(600)1484] Unclassified

Published in Rend. Circ. Matem. Palermo, Series II, v. 7: 143-154, May-Aug. 1958.

(T, A) is considered to be ac.BV mapping (a continuous surface of finite area) from an admissible set $A \subset E_2$ into E_3 : $p = T(w)$, $w = (u, v) \in A$, $p = (x, y, z) \in E_3$. \mathcal{B} is taken as a finite set of nonoverlapping simple polygonal regions $\sigma \subset A$ and σ^* is the oriented boundary of σ . A mapping T_r maps σ^* onto a closed oriented curve C_{σ^*} in E_{2r} . The topological index $O(p; C_{\sigma^*})$ of points of C_{σ^*} is Borel measurable and integrable over E_{2r} . A set \mathcal{B} is defined by indices d, m, μ and such that $d = \max \{ \text{diam } T(\sigma) : \sigma \in \mathcal{B} \}$, $m = \max \{ |T_r(\mathcal{L}\sigma^*)| : r = 1, 2, 3 \}$ where the absolute value sign denotes 2 dimensional Lebesgue measure, and the sum ranges over all $\sigma \in \mathcal{B}$ and $\mu = \max \{ |V(T, A) - \Sigma u(\sigma, T), V(T_r, A) - \Sigma u(\sigma, T_r)|, r = 1, 2, 3 \}$, where $V(T, A)$ is the Geöcze area of (T, A) , and $V(T_r, A)$ the Geöcze area of (T_r, A) .

RECTIFIABLE CURVES AND THE WEIERSTRASS

INTEGRAL, by L. Cesari. [1958] [16]p. incl. diags. (AF 18(600)1484) Unclassified

Published in Amer. Math. Monthly, v. 65: 485-500, Aug.-Sept. 1958.

This brief exposition intends to emphasize those parts of the theory for rectifiable curves which are of greater interest because of their recent extensions to surfaces. Those areas of interest presented in this report are parametric curves, the Jordan length, the Jordan theorem, lower semicontinuity of the Jordan length, the function $s(u)$, the Tonelli theorems, the Noebbling theorem, Lebesgue and Fréchet equivalences, Fréchet distances of two curves, the representation theorem, and the line integral as a Weierstrass integral.

is analyzed is a single-stage device which uses a simple RC differentiating network, followed by an infinite clipper and a simple RC smoothing filter. Negative feedback is used around the clipper and smoothing filter to insure that the filter output is always directly proportional to the derivative of the input signal. The noise reduction obtained from such a device is found to be rather poor compared with linear filters. Next, an analysis is made of a 2-stage nonlinear filter made up of a simple RC differentiating network followed, successively, by an idealized dead-zone symmetrical clipper, a lead network, and a simple RC smoothing filter. This filter uses the same type of feedback that was used in the single-stage case. The two-stage nonlinear filter is capable of a great amount of noise reduction and a small settling time, especially if the input S/N ratio is small. (ASTIA abstract)

AN INVARIANT PROPERTY OF CESARI'S SURFACE INTEGRAL, by L. H. Turner. [1958] [6]p. (AF 18(600)1484) Unclassified

Published in Proc. Amer. Math. Soc., v. 9: 920-925, Dec. 1958.

The author gives a modified definition for Cesari's surface integral and shows that it is equivalent to the original one [L. Cesari, Surface area, Princeton Univ. Press, Princeton, N. J., 1956]. The new definition is in terms of the vector-valued set-function $\mathcal{V} = (\mathcal{V}_1, \mathcal{V}_2, \mathcal{V}_3)$, where $\mathcal{V}_r = V_r^+ - V_r^-$, V_r^+ and V_r^- being defined, as by Cesari [loc. cit.], as the signed variations of partial plane transformations, $r = 1, 2, 3$. Then the coordinates of \mathcal{V} change covariantly under rotations of 3-space, from which Cesari's surface integral is invariant under such rotations. (Math. Rev. abstract)

ON SEMI-NORMAL OPERATORS, by C. R. Putnam. July 1957, 5p. (Technical note no. 3) (AFOSR-TN-57-89) (AF 18(603)139) AD 120437 Unclassified

Also published in Pacific Jour. Math., v. 7: 1649-1652, 1957.

Investigation is made of the spectrum of seminormal operators and of the associated self-adjoint operators defined by $J_\theta = \frac{1}{2}(A_\theta + A_\theta^*)$, where $A_\theta = Ae^{-i\theta}$ and θ is real. A is a seminormal bounded linear operator in a Hilbert space H . J_θ becomes the real or the imaginary part of A as $\theta = 0 = \pi/2$. A number λ belonging to the spectrum of A ($sp(A)$) is accessible if there exists a sequence of numbers λ_n not belonging to $sp(A)$ for which $\lambda_n \rightarrow \lambda$ as $n \rightarrow \infty$. If M is any self-adjoint operator, $\max M$ and $\min M$ denote the greatest and the least points, respectively, of the set $sp(M)$. The following theorems are proved: (1) Let A be semi-normal with $H \geq 0$ and $\lambda = re^{i\theta}$ (r is real and ≥ 0) be an accessible point of the spectrum of A ; then $(\max J_\theta)^2 \geq \min AA^*$ and $|r - \max J_\theta| \leq ((\max J_\theta)^2 - \min AA^*)^{1/2}$ where J_θ is defined as above. (2) Let A be seminormal and let $J = J_\theta$ have the spectral resolution $J = \int \lambda dE$; then if $S = S_\theta$ is any measurable set for which $\int_S dE = I$, the inequality $\|H\| \leq 4 \|A\|$ holds. NONLINEAR DIFFERENTIATING FILTERS, by G. R. Cooper and J. E. Kemmerly. Final technical rept. Feb. 1, 1956-May 5, 1958, 78p. incl. diags. tables, refs. (AFOSR-TR-58-56) (AF 18(600)1588) AD 162106 Unclassified

Two nonlinear filters, using negative feedback are considered. The filters incorporate a so-called infinite clipper and an idealized symmetrical clipper containing a dead zone. The statistical properties of the outputs of these 2 nonlinearities are then described, and it is shown that the mean value of the output can be made directly proportional to the mean value of the input under certain conditions. The autocorrelation functions of the outputs are also derived. The first nonlinear filter which

Also published in Jour. London Math. Soc., v. 34: 23-28, Jan. 1959.

A few facts are collected concerning the numerical ranges W_C of commutators $C = AB - BA$, where A and B are bounded linear operators on a Hilbert space of elements x . W_C is defined as the (closed, convex) set consisting of the closure of the set of complex numbers (Cx, x) where $\|x\| = 1$. A complex number z will be said to be in the interior of W_C if one of the following holds: (1) W_C consists of z alone, (2) W_C is an interval and z is an interior point, or (3) W_C is two-dimensional and z is an interior point. If z belongs to W_C but is not an interior point, z will be called a boundary point of W_C .

COMMUTATORS AND NORMAL OPERATORS, by C. R. Putnam. May 1958, 4p. (Technical note no. 8) (AFOSR-TN-58-116) (AF 18(803)139) AD 152024
Unclassified

Also published in Portugal. Math., v. 17: 59-62, 1956

The following theorems are proved: (1) Let A be normal with the Cartesian representation $A = H + iJ$, $H = \frac{1}{2}(A + A^*)$ and $J = \frac{1}{2i}(A - A^*)$; let B be arbitrary, and let $C = AB - BA$. Then 0 is in the interior of the convex closed set W_C (consisting of the closure of the set of numbers (Cx, x) when $\|x\| = 1$), whenever $\liminf_{\delta \rightarrow 0} \dots$

$[f(H, \delta) f(J, \delta)/\delta] = 0$. (2) If A satisfying $\liminf_{\delta \rightarrow 0} \dots$

$[f(H, \delta) f(J, \delta)/\delta] = 0$ is normal and if $\text{meas}(sp(H)) = 0$ and J has a pure point spectrum, then 0 is in the interior of W_C . The notation is as follows: A and B are bounded linear operators on a Hilbert space of elements x . Let D be self-adjoint and let $\{\Delta_k\}$ denote any covering of $sp(D)$, the spectrum of D , by a finite number of intervals Δ_k of length d_k . For $\delta > 0$, the positive numbers $f(D, \delta)$ and $g(D, \delta)$ are defined by $f(D, \delta) = \inf(\sum_k d_k)$, where $d_k \geq \delta$, and $g(D, \delta) = \inf(\sum_k d_k)$, where $d_k = \delta$.

AN ANNULAR JET PUMP, by W. H. Haak and F. Vrátný. Oct. 1958, 2p. diagr. (AFOSR-TN-58-937) (AF 18(603)-45) AD 205089; PB 137842 Unclassified

Also published in Rev. Scient. Instruments, v. 30: 296-297, Apr. 1959.

The need for a fast pump, capable of attaining a high ultimate vacuum and functioning over extended periods of time, led to the design of a two stage annular jet pump. Tests of the design demonstrated two advantages over the design suggested by Bull: (1) the extent of mercury diffusion was significantly reduced, and (2) the consumption of liquid nitrogen was likewise appreciably diminished. The annular spacing between the concentric cones and the distance between the bottom of the first and second stage jets are considered critical dimensions in the construction of the pump.

SEPARATION OF METAL IONS UTILIZING 1,10-PHENANTHROLINE COORDINATION KINETICS (Abstract), by D. W. Margerum and J. O. Frohlicke. [1957] [2]p. [AF 49(638)60] Unclassified

Presented at meeting of the Analyt. Chem. Div. of the Amer. Chem. Soc., New York, Sept. 8-13 1957

Published in 132nd meeting of the Amer. Chem. Soc. Abstracts of Papers, 1957, p. 24-B-30-B.

Coordination kinetics presents a new approach to obtaining metal ions in separable forms. By utilizing differences in coordination rates, it is possible to place

metal ions in significantly different chemical states and separate them from one another before the system reaches equilibrium. Hence a new variable - the coordination rate - can be used for possible separations in addition to the usual variables such as solubility, equilibrium state, oxidation potential, etc. This paper illustrates how separations can be achieved using 1,10-phenanthroline as the coordinating group. Various metal ions of the transition group elements have markedly different reaction rates in chelation with 1,10-phenanthroline. Advantage is taken of differences in rates of formation and of dissociation of these complexes to form separable species. It is possible to have in solution for short periods of time two metal ions bonded to dissimilar coordination groups, even though at equilibrium both metal ions are similarly complexed. For example, the phenanthroline complexes of nickel(II) and the aquo complex of copper(II) can be made to exist in solution simultaneously for an appreciable time interval. The coordination rate can lead not only to such differences as these (one metal ion bonded to large organic molecules and the other bonded to small water molecules) but also to changes in the charge of the complex. For example, the positive iron(II)-phenanthroline complex and the negative copper(II)-EDTA complex can exist simultaneously. Once such temporary differences in the coordination of the metal ions have been achieved, the problem becomes rapid separation by taking advantage of the marked differences in chemical and physical properties of the complexes. The separations discussed are achieved by extraction and fast flow adsorption and ion-exchange columns. The use of silica gel, charcoal and Dowex 50 columns is discussed. Separations involving the phenanthroline complexes of vanadium, chromium, iron, cobalt, nickel, copper, and zinc are presented.

COORDINATION KINETICS OF THE EDTA-NICKEL(II) COMPLEX (Abstract), by W. Margerum and J. F. G. Clarke, Jr. [1958] [1]p. [AF 49(638)60] Unclassified

Presented at meeting of the Phys. and Inorg. Chem. Div. of the Amer. Chem. Soc., San Francisco, Calif., Apr. 13-18, 1958.

Published in 133rd meeting of the Amer. Chem. Soc. Abstracts of Papers, 1958, p. 48-Q.

Special injection and spectrophotometric recording techniques were used to follow the dissociation rate of the nickel(II) ethylenediaminetetraacetic acid complex, NiY^{2-} . The reactions were followed after a 5 to 15-sec mixing time of the complex with acid. At the highest acidity used, 0.70M hydrochloric acid, the dissociation was virtually complete after 30 sec. The dissociation rate increases greatly with acidity. A 20-fold increase in acidity (0.035 to 0.700M hydrochloric acid) causes a 500-fold increase in dissociation rate. All kinetics were measured at 25° and at an ionic strength of 1.3. Spectrophotometric evidence confirms the formation of a protonated complex above 0.01M acid, presumably NiHY^- . Above 1M hydrochloric acid additional shifts in absorbance suggest the existence of another complex, perhaps NiH_2Y . The high dependence of the dissociation rate on $[\text{H}^+]$ indicates a more rapid dissociation of the protonated forms of the complex. The hydrogen ion dependence is higher than first order. A thousandfold excess of zinc(II) at 0.035M hydrochloric acid does not increase the dissociation rate.

HETEROGENEITY AS A FACTOR IN THE ALKYLATION OF AMBIDENT ANIONS: PHENOXIDE IONS, by N. Kornblum and A. P. Lurie. [1958] [43]p. incl. diagrs. tables, refs. (AFOSR-TN-58-939) (AF 49(638)324) AD 205087 Unclassified

Presented at meeting of the Inorg. Chem. Div. of the Amer. Chem. Soc., San Francisco, Calif., Apr. 13-18, 1958.

Abstract published in 133rd meeting of the Amer. Chem. Soc. Abstracts of Papers, 1958, p. 14-N-15-N.

Also published in Jour. Amer. Chem. Soc., v. 81: 2705-2715, June 5, 1959.

Sodium and potassium salts of phenol and p-tert-octylphenol have been alkylated with benzyl and allyl halides in a variety of solvents. Quantitative yields of the ether (oxygen alkylation) are obtained whenever the

reaction is conducted in solution. In addition, it is demonstrated that the truly heterogeneous reaction gives exclusively carbon alkylation. Reactions carried out with the phenolic salt present as a solid phase ordinarily give both carbon and oxygen alkylation, but this result is clearly a consequence of incursion by the homogeneous process. The factors, other than heterogeneity, which may influence the course of phenoxide alkylations are briefly discussed. An explanation is offered for the fact that heterogeneity confers an essentially irresistible preference for carbon alkylation. (Contractor's abstract)

ASYMPTOTIC FORMS FOR THE WHITTAKER FUNCTIONS WITH BOTH PARAMETERS LARGE, by N. D. Kazarinoff. 1957 [20]p. incl. diagrs. refs. (AFOSR-TN-58-576) (AF 18(600)1481) AD 142763 Unclassified

Also published in Jour. Math. and Mech., v. 6: 341-360, May 1957.

Certain solutions of the differential equation

$$\frac{d^2 w}{dx^2} + \left\{ -1/4 + k/x + \frac{1/4 - m^2}{x^2} \right\} w = 0$$

are called Whittaker functions and are customarily designated $W_{k,m}(x)$ and $M_{k,m}(x)$. Their asymptotic behavior is different accordingly as 1, 2, or 3 of the quantities $|x|$, $|k|$, and $|m|$ are large. An examination of the literature reveals that least is known of the structure of the Whittaker functions if both k and m are unbounded. When $|x|$ is also large, such information as is available applies only to nearly real values of x and k and nearly real or pure imaginary values of m and is subject to the further limitation that the ratios x/k and x/m be nearly fixed. In this study, the asymptotic behavior of the Whittaker functions with x , k , and m real or complex is obtained for both $|k|$ and $|m|$ large and x unrestricted

PUR. 10:003; PUR. 02:002-004

under the hypothesis that $(m^2 - k^2)/k$ be bounded, so that $\lim m/k = \pm 1$. The results are stated in theorems. $|k| \rightarrow \infty$

The analysis to be given is based upon the methods of asymptotic solution of ordinary differential equations containing a large parameter developed by R. E. Langer. In the present study, particular reference is made to the work of R. McKelvey. (Trans. Amer. Math. Soc., v. 67: 461-490, 1959).

ASYMPTOTIC SOLUTIONS WITH RESPECT TO A PARAMETER OF ORDINARY DIFFERENTIAL EQUATIONS HAVING A REGULAR SINGULAR POINT, by N. D. Kazarinoff. [1957] [14]p. (AFOSR-TN-58-577) (AF 18(600)1481) AD 158399 Unclassified

Also published in Mich. Math. Jour., v. 4: 207-220, 1957.

The asymptotic behavior is examined for large complex λ of solutions of the differential equation

$$\frac{d^2 u}{dz^2} + \sum_{i=-2}^{\infty} f_i(z) \lambda^{-i} u = 0$$

where the sum is assumed convergent for $|\lambda| > N$, and $f_{-2}(z), z f_{-1}(z), z^2 f_1(z)$ ($i = 0, 1, 2, \dots$) are analytic in a closed simply-connected region D containing the origin in its interior. The investigation generally follows the pattern established by R. E. Langer. The asymptotic forms of the solutions are expressed in terms of Bessel functions when $\xi = \lambda \int_0^z [f_{-2}(t)]^{1/2} dt$ is bounded, and in terms of elementary functions when ξ is large. The work is motivated partly by its potential applications to special functions, and partly by a desire to progress towards completion of the asymptotic theory of differential equations with turning points. This paper considers the spaces of bounded sequences

$c = \{c_n\} = \langle c_n \rangle$, such that

$$\text{l.u.b.} \sum_N |c_{n+1} - c_n| = M < \infty,$$

where \sum_N is extended over $2^N \leq |n| \leq 2^{N+1}$, $N =$

$0, 1, 2, \dots$, and introduces the norm $\|c\| = \|c_n\|_{\infty} + M$.

According to a theorem of Marcinkiewicz (Studia Math., v. 8: 78-91, 1939) if a_n are the Fourier coefficients of a function f in L^p , $1 < p < \infty$, then the a_n are the Fourier coefficients of a function Tf in L^p . The author proves that $\omega(c) = \sigma(T) = \sigma(c)$, where $\omega(c)$ is the closure of the set $\{c_n\}$, $\sigma(T)$ and $\sigma(c)$ are the spectra of T and c respectively. He further shows that $\|c\|_{\infty} \leq \|T\|_p \leq k_p \|c\|$. (Math. Rev. abstract)

SPECTRAL INVARIANCE OF CONVOLUTION OPERATORS ON L^p ($-\infty, \infty$), by G. L. Krabbe. May 9, 1957, 18p. incl. refs. (Technical note no. 2) (AFOSR-TN-57-238) (AF 18(603)44) AD 126535 Unclassified

Also published in Duks Math. Jour., v. 25: 131-142, Mar. 1958.

For a given bounded Radon measure A on $G = (-\infty, \infty)$, convolution operators A^*f defined by the integral $\int_G f(\theta - \sigma) dA(\sigma)$ are studied as mappings from L_p into L_p . It is shown under certain restrictions on A that the spectrum of the convolution is independent of p and is the same as the spectrum of A , which is the closure of the range of the Fourier transform of A . An appendix contains the referee's proof that this result is true if G is an arbitrary locally compact Abelian group and A is a bounded Radon measure on $L^p(G)$. Among others, results are obtained concerning the point spectrum which generalize those proved by H. Pollard in the case $p = 2$. (Math. Rev. abstract)

VAGUELY NORMAL OPERATORS ON A BANACH SPACE, by G. L. Krabbe. Mar. 5, 1956, 15p. incl. refs. (Technical note no. 3) (AFOSR-TN-58-183) (AF 18(603)44) AD 152180; PB 140156 Unclassified

Also published in Arch. Rational Mech. Anal., v. 3: 51-59, 1956.

Properties of normal (Hilbert space) operators are

extended to Banach space operators. If β is the Haar measure of a locally compact abelian group G , then the relation $(x|y) = \int_G x(\lambda) \cdot y(\lambda) \cdot \beta(d\lambda)$ for all (x, y) in $L^p(G) \times L^{p'}(G)$ defines the inner product in the space $L^2(G)$ when $p = 2$. If $R[L^p(G)]$ is the set of all operators T on $L^p(G) \cup L^{p'}(G)$ such that $(Tx|y) = (x|Ty)$ for all (x, y) , then $N[L^p(G)]$ denotes the set of all operators of the form $T_1 + iT_2$, where T_1 and T_2 are in $R[L^p(G)]$. An operator is called vaguely normal if it is a bounded operator on $L^p(G)$ that has an extension in $N[L^p(G)]$; $G = \{0, \pm 1, \pm 2, \dots\}$. Consider a certain algebra A_{*p} of convolution operators on $l_p = L^p(G)$. A_{*p} consists of vaguely normal operators and is included in the weak closure of the algebra generated by the Hilbert transformation $x \rightarrow Hx$, for a suitably defined Hx . To each T in A_{*p} there corresponds an operator-valued measure E^T and a function f such that the relation $T = \int \lambda E^T(d\lambda)$ holds in a certain sense. When $p = 2$, $T = f(H)$. If $p \geq 2$, then the resolvent set of T is void and thereby extends another property of normal operators.

SPECTRAL THEOREM, by G. L. Krabbe. May 15, 1958, 28p. incl. refs. (Technical note no. 6) (AFOSR-TR-58-65) (AF 18(603)44) AD 158260; PB 139564
Unclassified

Also published in Math. Zeitschr. v. 70: 446-462, Mar. 1959.

Let $[X]$ be the Banach algebra of all bounded operators on a Banach space X . Sufficient conditions are given for which the following occur: (1) T belongs to the class of C_0 of all members T of $[X]$ which have a pass E_Δ^T such that $K(E_\Delta^T)$ is included in the point-spectrum of T ; (2) T belongs to the class C_S of all operators T in C_0 such that the relation $T = \int \lambda E_\Delta^T(d\lambda)$ holds in the weak topology; (3) T belongs to the class C_U of all operators T in C_0 that have the properties: (a) the residual spectrum of T is void and E_Δ^T is a weakly continuous function of rectangles, (b) the set $K(E_\Delta^T)$ of all complex λ such that $E_\Delta^T(\lambda) \neq 0$ coincides with the point-spectrum of T . The algebra L of Laurent operators and an algebra F of functions are discussed. L is the image $p(F)$ of F under an isomorphism $F \rightarrow pF$.

CONVOLUTION OPERATORS WHICH ARE NOT OF SCALAR TYPE, by G. L. Krabbe. Apr. 30, 1958, 8p. (Technical note no. 5) (AFOSR-TN-58-396) (AF 18(603)44) AD 154305; PB 140155
Unclassified

Additional motivation for extending the scope of the spectral theorem beyond Dunford's class of scalar type operators is presented. Let $G = \{0, \pm 1, \pm 2, \dots\}$ and let T be a bounded operator on $l_p = L^p(G)$, $1 < p \neq 2$. T is said to be of the scalar type if it is a spectral operator satisfying the relation $T = \int \lambda E(d\lambda)$, where E is the resolution of the identity for T . To any uniformly bounded transformation, there corresponds a family $\{E_\lambda\}$ of projectors. Set $\alpha = \pm 1$ and let $\tau_\alpha x$ be the translate $x_n + \alpha n \in G$ of the sequence $x = \{x_n\}_{n \in G}$. The operator $x \rightarrow \tau_\alpha x$ defined on l_p is not a scalar type operator, although it is a uniformly bounded transformation of the simplest kind. The Hilbert transformation H defined on l_p is not of the scalar type. Both H and τ_α belong to a class of convolution operators T .

Also published in Ann. Math. pura et appl., v. 44: 93-104, 1957.

According to a paper by K. Krickeberg [Ann. Math. pura et appl., v. 44: 105-133, 1957] the concepts of "gradient" of a function $f(x)$, $x = (x_1, \dots, x_k)$, with a compact support (say a fixed cube $K \subset R^k$) and whose first partial derivatives $\phi = (\mu_1, \dots, \mu_k)$ are Radon measures in R^n and of "track of a closed generalized surface" are proved to be equivalent. In the present paper a new proof of this equivalence is given in terms of L. C. Young's theory, together with the result I. below. Let \mathcal{F} be the collection of all functions f as above and put $I(f) = V(\phi)$, the total variation of ϕ (thus $I(f) < +\infty$); let \mathcal{F}_N be the subcollection of all $f \in \mathcal{F}$ with $I(f) \leq N$. If E is any measurable set $E \subset K$, and f_E the characteristic function of E , then $P(E) = I(f_E)$ is a sort of "measure" of the boundary of E . Thus $P(E)$ is said to be the perimeter of E . Let $\mathcal{E}, \mathcal{E}_N$ be the collections of all measurable sets $E \subset K$ with $P(E) < +\infty$, $P(E) \leq N$ (Caccioppoli sets). With the usual

PUR.11:002, 003; PUR.03:07:008

l_1 topology \mathfrak{F}_N is a compact convex space and hence the convex closure of its extreme points (theorem of Krein-Milman). Also, by a result of G. Choquet, each element of \mathfrak{F}_N has an integral representation in terms of a measure carried by the set of extreme points. I. If $k = 2$ or 3 , and f is an extreme point of \mathfrak{F}_N , then there is a set $E \subset \mathfrak{G}_N$ with $f_E = \pm N^{-1} P(E)f$. For $k = 2$, E is a simple Jordan region, $E \subset K$, whose boundary is a rectifiable (simple closed) curve of Jordan length $L = P(E)$. (Math. Rev. abstract)

NONDEGENERATE SURFACES AND FINE-CYCLIC SURFACES, by W. H. Fleming. Nov. 1957, 18p. incl. refs. (Technical note no. 3) (AFOSR-TN-57-788) (AF 49(638)18) AD 136756 Unclassified

Also published in Duke Math. Jour., v. 26: 137-146, Mar. 1959.

A fine-cycle decomposition of surfaces in E_N space ($N \geq 2$) has been carried out for surfaces which are defined from finitely connected Jordan regions. Even if the fine-cycle elements are not nondegenerate, the surface S becomes nondegenerate if cuts are introduced in S at a finite number of points. A representation theorem for fine-cycle surfaces has been obtained for these not necessarily nondegenerate surfaces. A new proof is given of the equality of the Lebesgue area $L(S)$ and the Geöcze area for fine-cycle surfaces if $L(S)$ is finite.

IRREDUCIBLE GENERALIZED SURFACES, by W. H. Fleming. Nov. 1957, 42p. incl. refs. (Technical note no. 2) (AFOSR-TN-57-767) (AF 49(638)18) AD 136757 Unclassified

Also published in Riv. Matem. Univ. Parma, v. 8: 251-281, 1957.

Two main innovations are applied to the problem of irreducible generalized surfaces. First, conformal mapping for polyhedra of higher topological types was applied in a way similar to the author's recent extension of Morrey's theorem to 2-manifolds (Trans. Amer. Math. Soc., v. 90: 323-335, 1959). Second, the set of generalized surfaces of given topological type which admit a given set Γ of curves in space as boundary in the sense presented by L. C. Young (Memoirs Amer. Math. Soc. no. 17, 1955) is enlarged to include those which admit Γ as boundary in a certain limiting sense.

General conditions (irreducibility) are given under which an element of the larger set necessarily belongs to the smaller set and possesses a microrepresentation. Various improvements are made in the results of Young. Boundary identifications are pointwise and piecewise linear, instead of merely arcwise. Less restrictive assumptions are made about the set Γ of boundary curves.

PARITY EXCHANGE SCATTERING, by D. C. Peaslee. Dec. 28, 1956, 3p. (AFOSR-TN-57-6) (AF 18(600)1579) AD 115037 Unclassified

The features of intrinsic parity exchange on nuclear scattering of K mesons existing as parity doublets is discussed. The elastic K-nucleon scattering amplitude has the (non-relativistic) form:

$$a = \alpha + \beta \sigma - n + \beta' \sigma \cdot t$$

where σ refers to nuclear spin. This form has certain interesting implications. The absence of any spin-independent pseudoscalar term α' means that parity exchange scattering should effectively be absent in K encounters with heavy nuclei, where $\langle \sigma \rangle \approx 0$. If parity exchange scattering is the dominant process in K-nucleon interactions, then K scattering on heavy nuclei would be relatively weak in comparison with K-nucleon scattering. It is suggested that polarization measurements on the recoil proton from K-p scattering would supply an unequivocal test of the parity doublet hypothesis.

ISOTOPIC SPIN SELECTION RULE $|\Delta I| = 1/2$ FOR DECAYS OF STRANGE PARTICLES, by M. Kawaguchi. Mar. 15, 1957 [16]p. incl. diagrs. tables, refs. (AFOSR-TN-57-131) (AF 18(600)1579) AD 120487 Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 191, Apr. 25, 1957.

Also published in Phys. Rev., v. 107: 573-576, July 15, 1957.

Decay processes of strange particles are re-examined under the assumption of the selection rule $|\Delta I| = 1/2$, when all particles concerned have isotopic spins, but parity is not necessarily conserved. Some of the results obtained before still hold as they are, even if parity nonconservation is taken into consideration. However, the relation between the branching ratio

$(\Sigma^+ - p + \pi^0)/(\Sigma^+ - n + \pi^+)$ and the ratio of lifetimes $\tau(\Sigma^-)/\tau(\Sigma^+)$ is changed by parity nonconservation. The experimental results on Σ particles may be interpreted as indicating comparable magnitudes for parity-conserving and parity-nonconserving terms. Some results based on $|\Delta I| = 1/2$ and $3/2$ are also discussed for these particles. (Contractor's abstract)

PHOTOPRODUCTION OF K MESONS FROM SINGLE NUCLEONS, by M. Kawaguchi and M. J. Moravcsik. [1957] 17p. (AFOSR-TN-57-246) (AF 18(600)1579) AD 126544 Unclassified

Also published in Phys. Rev., v. 107: 563-569, July 15, 1957.

The lowest order perturbation calculations are carried out for K meson photoproduction from single nucleons. Results are given for scalar and pseudoscalar mesons, with or without anomalous magnetic moments for the nucleons and hyperons, and with scalar, pseudoscalar, vector, and pseudovector couplings. Numerical results are given assuming unity for the coupling constant. The difference between the present results and those carried out for pion photoproduction is due to the mass difference of the nucleons and hyperons, the larger ratio of the mesons mass to the nucleon mass, and the different values for the anomalous magnetic moments. The last of these effects is particularly striking and might be of practical significance when sufficient experimental information is available. (Contractor's abstract)

POLARIZATION MEASUREMENTS AND THE UNIVERSAL FERMI INTERACTION, by D. C. Peaslee. June 27, 1957, 12p. refs. (AFOSR-TN-57-389) (AF 18(600)1579) AD 132464 Unclassified

Two possibilities are considered for maintaining the notion of a universal Fermi interaction (UFI) among the processes of (1) μ -e decay, (2) nuclear β -decay, (3) nuclear μ -capture, and (4) $K_{\mu 3}(K_{e 3})$ decay. If the 2-component neutrino with lepton conservation is adopted, the UFI must involve predominantly (VT) for nuclear β -decay, and there is a discrepancy of a factor of 2 in the magnitude of the coupling constant C_V as compared with μ -e decay: the coefficient C_T is arbitrary, and $C_S = C_P$ is small. The slight preliminary evidence available on $K_{\mu 3}$ and $K_{e 3}$ does not favor a dominant V

term. If the 2-component neutrino with lepton conservation is abandoned, an interaction of the (STP) form can be written which fits all present polarization measurements. This interaction can be definitely excluded in μ -e decay only by an absolute measurement of the μ -polarization direction or by observing 2 separate electron polarization terms in the μ -e process. In nuclear β -decay the most direct approach seems to be search for (VT) interference effects, either in a Fierz-type $1/W$ term in first forbidden spectra of allowed shape, or in the transverse polarization of electrons from oriented nuclei in allowed transitions containing both Fermi and Gamow-Teller parts. These 2 interference terms reflect respectively the real and imaginary parts of the (VT) interference. Further comments are made on similar measurements for processes 3 and 4. Under favorable circumstances, the assumption of a UFI might specify the intrinsic in parity of the K relative to the π .

ON THE PION-ELECTRON DECAY, by M. Kawaguchi and K. Nishijima. [1957] 4p. (AFOSR-TN-57-628) (AF 18(600)1579) AD 144783 Unclassified

Also published in Phys. Rev., v. 108: 905-907, Nov. 1, 1957.

Attempts are made to calculate the branching ratio of π^+ into the e^+ and μ^+ modes. Experimentally the π^+ to e^+ decay has not been observed, but an experimental upper limit of 5×10^{-5} sec has been given for the branching ratio. The $\pi^+ \rightarrow e^+ + \nu + \gamma$ process with V and T couplings is used to find a lifetime for the tensor coupling of 8.6×10^{-4} sec, which leads to a branching ratio which is not inconsistent with the experimental upper limit. The γ decay of π^0 is studied and a lifetime of 0.5×10^{-15} sec is calculated.

BETA DECAY MATRIX FROM THE QUASI- α MODEL. (Abstract), by D. W. Dorn and R. W. King. [1957] [1]p. [AF 18(600)1579] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc. Series II, v. 2: 26, Jan. 30, 1957.

Allowed beta decay transition probabilities provide a rigid test for low energy nuclear models. The

PUR.03:013 - PUR.03:016

supermultiplet formalism has remained the only means of obtaining qualitative accord with the experimental evidence on beta decay. In general, the predictions of j-j coupling models have been considerably worse. Since the quasi- α model in j-j coupling does bear some resemblance to the supermultiplet formalism in L-S coupling, it is conceivable that a strong spin-orbit coupling description can be maintained with improved beta decay matrix elements. Specific matrix elements in the d 5/2 and f 7/2 shells have been calculated; the improvement obtained suggests that wave functions constructed from the quasi- α model afford a better description of nuclei than those derived from the use of a "seniority" quantum number.

Λ -NUCLEON FORCE WITH $S\Sigma = 3/2$ (Abstract), by M. T. Vaughn and D. C. Peaslee. [1957] [1]p. [AF 18(600)1579] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 39, Jan. 30, 1957.

Pion exchange Λ -N forces are estimated in accordance with the possibility that the spin of the intermediate Σ state may be 3/2. The Λ is taken to have $S = 1/2$ and the same parity as the Σ , and a phenomenological interaction operator ($S \cdot \nabla$) assumed with matrix elements proportional to Clebsch-Gordan coefficients for vector addition $1 + 1 = 3/2$. The term corresponding to V_2 in ordinary nuclear forces does not operate directly but only through mixing in Σ states. Its effect is therefore dependent on the structure of the nuclear core in a hyperfragment, but this structure dependence appears negligible in the present case. The Λ -N potential $(V_2)^2 + V_4$ in the region $ur = 1$ is attractive but only quite weakly spin-dependent.

PHOTOPRODUCTION OF K-MESONS (Abstract), by M. Kawaguchi. [1957] [1]p. [AF 18(600)1579] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 39, Jan. 30, 1957.

The processes $\gamma + p \rightarrow K^+ + \Lambda^0$ and $\gamma + p \rightarrow K^0 + \Sigma^+$ are investigated in terms of the lowest order perturbation calculation, on the assumption that the nucleon-hyperon pair coupling is relatively weak. The $K + \Lambda$ cross sections are obtained straightforwardly by simple modifications of the results of photo-pion production. For example, (i) with $\Lambda = 1/2^+$ and $K = 0^+$, or $\Lambda = 1/2^-$ and $K = 0^-$, the result of $s(s)$ meson theory is available, and (ii) $ps(ps)$ theory for $\Lambda = 1/2^+$ and $K = 0^-$, or $\Lambda = 1/2^-$ and $K = 0^+$. The former shows a peak at forward laboratory angles and the latter does not. Therefore, if experiment could distinguish between a single one of these angular distributions and a superposition of the two, it would in principle be possible to decide whether or not the Λ, K are parity doublets. For production of $K + \Sigma$ the treatment is more complicated if the Σ spin is taken as 3/2.

QUASI- α NUCLEAR SUBSTRUCTURE IN j-j COUPLING (Abstract), by R. W. King and D. W. Dorn. [1957] [1]p. [AF 18(600)1579] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 28, Jan. 30, 1957.

Empirical evidence on complex nuclei reveals, in addition to large spin-orbit forces, a tendency for two neutrons and two protons to form a particularly stable ("quasi- α ") structure. The j-j coupling shell model provides a description of strong spin-orbit effects; however, in all but a few simple nuclei, the model does not lead to uniquely determined wave functions. We have chosen to remove the nonuniqueness of j-j coupled wave functions by imposing the maximum amount of quasi- α structure permitted by strong spin-orbit coupling. The α -like structure is associated with two neutrons and two protons in an $S = T = 0$ substate; the antisymmetry of the total wave function assures that the substate is completely space-symmetric. The procedure of maximizing this α structure thus demands that the dominant parts of nuclear wave functions be formed by pairs of nucleons in relative $T = 1, S = 0$ and $T = 0, S = 1$ states with symmetrical space coupling. This type of pairing appears more realistic than that imposed by the "seniority" quantum number.

SIGMA-NUCLEON $T = 3/2$ FORCE (Abstract), by M. T. Vaughn. [1957] [1]p. [AF 18(600)1579] Unclassified

PUR.03:017 - PUR.03:020

Presented at meeting of the Amer. Phys. Soc., St. Louis, Mo., Nov. 29-30, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 353, Nov. 29, 1957.

The sigma-nucleon force in the $T = 3/2$ state is computed in the static approximation for one- and two-pion exchanges. The resulting singlet and triplet central potentials satisfy $V^1 \approx 3V^3 < 0$; the tensor force is relatively weak. The V^1 is very similar to the 1S nucleon-nucleon potential but is about 10% larger in magnitude if the π coupling is equivalent to $\pi - N$, because of differences in the two-pion term. Sigma-nucleon binding is further enhanced by the increased mass of the sigma (relative to nucleon-nucleon); these two features are sufficient to yield an $n - \bar{\nu}$ - binding of order 1 mev.

If the $n - \bar{\nu}$ - binding exceeds 1/2 mev, the $p - \bar{\nu}^+$ should also be bound. For a cutoff radius of order 0.35μ the K-exchange forces are negligible if $G_K^2/4\pi \approx 1$.

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 3: 222, May 1, 1958.

Also published in Phys. Rev., v. 111: 1314-1318, Sept. 1, 1958.

The transverse polarization of the outgoing proton from the photodisintegration of the deuteron is calculated in the angular momentum representation, without assuming any detailed interaction among particles. General formulas for the polarization as well as for the angular distribution are given in terms of the Racah coefficients. If we write the angular distribution in a form

$$a + b \sin^2 \theta (1 + 2c \cos \theta),$$

the polarization is given in terms of a, b, c, and the nucleon-nucleon scattering phase of the S, P, and D states under reasonable assumptions. By using experimental values of a, b, and c, and scattering phase shifts as much as available and also some theoretical estimates of the phase shifts, 20 to 30% polarization is expected for up to 40-mev gamma rays and 10 to 20% for 140-mev gamma rays over a wide range of angles in the center-of-mass system. INVERSE BETA DECAY AND THE TWO COMPONENT NEUTRINO (Abstract), by R. W. King and J. F. Perkins. [1958] [1]p. [AF 18(600)1579] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 205, May 1, 1958.

The discrepancy between the experimental cross-section for neutrino absorption by protons as determined by Cowan and Reines and that predicted by the two component theory of the neutrino has usually been dismissed as due to the uncertainties involved in determining the spectrum of antineutrinos from fission products. From a complete summary of the known decay schemes of the fission products, we are able to establish a firm lower limit for the average cross-section per antineutrino $\bar{\sigma}_p = 7 \times 10^{-44} \text{ cm}^2$ (based on the two-component theory) which exceeds the experimental upper limit. We furthermore, offer a "best value" for the cross-section $\bar{\sigma}_p = 17 \times 10^{-44} \text{ cm}^2$ that is several times larger than that found experimentally ($\bar{\sigma}_p = 2.8 \pm 1 \times 10^{-44} \text{ cm}^2$).

Various improvements made on previous estimates of the antineutrino spectrum have served to widen rather than remove the discrepancies. Thus, it can be concluded that the existence of the disagreement between the two component theory and experiment is quite real and independent of the uncertainties in the spectrum of antineutrinos.

WEAK DECAYS AND ISOTOPIC SPIN (Abstract), by D. C. Peaslee and M. Kawaguchi. [1958] [1]p. [AF 18(600)-1579] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 216, May 1, 1958.

Consequences are considered of expressing weak interactions in terms of the two independent isotopic spins characterizing baryons. There are then four independent coupling constants g for each class of charged lepton decays. Under this assumption the lepton decay of K mesons implies lepton decay of at least some baryons besides n and p , though these may still be slightly below presently observed levels with a suitable choice of the g 's. The absence of $\pi \rightarrow e + \gamma$ can be interpreted simply by saying one of the four g 's is zero; the absence of $K \rightarrow e + \gamma$ implies a similar rule which is less simple if the K -baryon interaction is not universal (as the π -baryon interaction is assumed). For weak pion emission the present scheme readily reproduces the $\Delta I = \frac{1}{2}$ results for Λ decay while at the same time allowing $\Delta I \geq \frac{1}{2}$ for Σ decay; it also predicts the Ξ lifetime directly from the known Λ lifetime. The slowing of $K^+ \rightarrow 2\pi$ relative to $K^0 \rightarrow 2\pi$ appears at least superficially fortuitous; but a wide range of charged neutral $K^0 \rightarrow 2\pi$ ratios (including the experimental value) can readily be encompassed.

K_{e3} AND $K_{\mu 3}$ DECAY MODES, by M. Sugawara. [1958] 1p. [AF 18(600)1579] Unclassified

Published in Phys. Rev., v. 112: 2128, Dec. 15, 1958.

A viewpoint is presented in which some boson pairs are included among members which are exerting universal weak interactions on each other. The inclusion of K -meson-pion pairs leads to direct terms responsible for K_{e3} and $K_{\mu 3}$ decay modes. It is shown that these direct terms may result in too rapid decays of K_{e3} and $K_{\mu 3}$ if one assumes the universality of the weak-coupling constant, while the branching ratio of these decay modes is quite consistent with the data. GENERALIZED VARIATIONAL APPROACH TO THE OPTIMUM THRUST PROGRAMMING FOR THE VERTICAL FLIGHT OF A ROCKET. PART I. NECESSARY CONDITIONS FOR THE EXTREMUM, by A. Miele. Mar. 1957 [47]p. incl. diagrs. refs. (Rept. no. A-57-1) (AFOSR-TN-57-173) (AF 18(603)69) AD 126467 Unclassified

Also published in Zeitschr. Flugwissensch., v. 6: 69-77, Mar. 1958.

The burning program for the vertical flight of a rocket-powered vehicle is analyzed. The results of previous theories are extended to cover the general problem of

PUR.04:003 - PUR.04:006

minimizing the difference $\Delta G = G_f - G_i$ between the final and initial values of an arbitrarily specified function $G(t, m, V, h)$ of time, mass, velocity and altitude. By using the indirect methods of the Calculus of Variations, it is shown that the totality of extremal arcs is composed of zero-thrust sub-arcs, sub-arcs to be flown with maximum engine output and variable-thrust sub-arcs. An explicit solution is determined for the optimizing mass flow of the rocket engine as a function of the local coordinates of the missile. Closed form solutions are obtained for the relationships between time, mass, altitude and velocity for the following particular cases: flight in vacuum, flight in a uniform atmosphere and flight in an isothermal atmosphere. The boundary value problem is investigated. Several numerical examples are included, having the object of illustrating the general procedures developed in the present report. (Contractor's abstract)

GENERALIZED VARIATIONAL APPROACH TO THE OPTIMUM THRUST PROGRAMMING FOR THE VERTICAL FLIGHT OF A ROCKET. PART II. APPLICATION OF GREEN'S THEOREM TO THE DEVELOPMENT OF SUFFICIENCY PROOFS FOR PARTICULAR CLASSES OF SOLUTIONS, by A. Miele and C. R. Cavoti. Aug. 1957 [35]p. incl. diagrs. table. (Rept. no. A-57-2) (AFOSR-TN-57-652) (AF 18(603)69) AD 136638
Unclassified

Also published in Zeitschr. Flugwissensch., v. 6: 102-109, Apr. 1958.

The vertical flight of a rocket is analyzed in connection with the problem of determining the burning program which extremizes an arbitrary function of the final values of time, mass, altitude and velocity. The minimal or maximal character of the solutions is investigated. It is shown that the Legendre-Clebsch condition does not provide any information at points of the constant thrust sub-arcs and variable-thrust sub-arcs forming one extremal arc. An identical difficulty is encountered when applying the more stringent Weierstrass condition at points of the variable-thrust sub-arcs. By the use of a new and hitherto unexploited technique, based on Green's theorem, the afore-mentioned difficulties can be overcome. Rigorous sufficiency proofs can be developed for particular classes of solutions, in connection with linear variational problems of both the simplest type and the isoperimetric type. The cases of flight in a uniform atmosphere and flight in a vacuum are investigated. Concerning the latter, analytical proofs are supplied for both single-stage and multi-stage rockets. Presented at the ASME-ARS Aviation Conf., Dallas, Tex., Mar. 17-20, 1958.

Also published in Proc. Fourth annual meeting of the Amer. Astronaut. Soc., New York (Jan. 29-31, 1958), N. Y., Amer. Astronaut. Soc., 1958, p. 6-1 - 6-17.

Also published in Astronautica Acta, v. 4: 167-181, 1958.

A variational analysis of the theory of the thrust programming is presented for the case where a variable mass body is moving along an arbitrarily inclined rectilinear path. It is shown that the totality of extremal arcs is composed of zero-thrust sub-arcs, maximum thrust sub-arcs, and variable thrust sub-arcs. The optimum acceleration law is determined and some numerical example is presented emphasizing the engineering aspects of the present theory in connection with the flight analysis of rockets.

MINIMALITY FOR ARBITRARILY INCLINED ROCKET TRAJECTORIES, by A. Miele. [1958] [7]p. incl. diagr. (AFOSR-TN-58-202) (AF 18(603)69) Unclassified

Also published in Jet Propulsion, v. 28: 481-483, July 1958.

The problem of arbitrarily inclined rectilinear paths is analyzed by applying the Euler-Lagrange equations and the Legendre-Clebsch condition. The minimal properties of functional forms of the linear type are investigated by a new technique based on Green's theorem. While the Legendre-Clebsch condition alone is only indicative of the local behavior of the solution with respect to weak variations, this new technique supplies a complete, integral proof of necessary and sufficient conditions for the extremum.

PATHS OF ROCKET-POWERED AIRCRAFT, MISSILES AND SATELLITE CARRIERS, by A. Miele. Jan. 1958, 57p. incl. diags. refs. (Rept. no. A-58-2) (AFOSR-TN-58-246) (AF 18(603)69) AD 154148 Unclassified

Presented at Ninth Internat'l. Astronautical Congress, Amsterdam, Holland, Aug. 25-30, 1958.

Also published in *Astronautica Acta*, v. 4: 264-288, 1958.

Presentation of a basic theory for analyzing the optimum flight paths of rocket-powered aircraft, missiles, and satellites. The problem with three degrees of freedom is considered; it consists of the simultaneous optimization of the time history of lift, thrust modulus, and thrust direction. Special problems involving either one or two degrees of freedom are investigated by the introduction of additional constraining equations. For some of these problems closed form expressions are derived for the optimizing conditions. Furthermore, a complete formulation of the boundary conditions is supplied by means of the general transversality condition of the calculus of variations.

TOPICS IN DYNAMIC PROGRAMMING FOR ROCKETS, by A. Miele and J. O. Cappellari, Jr. July 1958 [65]p. incl. diags. (Rept. no. A-58-5) (AFOSR-TN-58-685) (AF 18(603)69) AD 162218 Unclassified

Also published in *Zeitschr. Flugwissensch.*, v. 7: 14-21, Jan. 1959.

Topics associated with the programming of optimum trajectories for rocket-powered vehicles are investigated. Attention was devoted to stationary conditions for problems involving time associated with vertical trajectories. A simple approximate relationship was computed between altitude and Mach number which holds for all drag functions, regardless of the end-conditions and of the analytical configuration of the functional form to be extremized. For the Legendre-Clebsch condition for level flight, a discussion is presented of the second variation in connection with the optimization of the thrust modulus for constant altitude flight. Methods of programming thrust direction with aerodynamic forces, and thrust modulus in vacuum flight were investigated. Maximum range in vacuum flight was determined for the case where both the initial and final path inclinations are free and the velocity modulus at final point is also free. (Contractor's abstract)

STATIONARY CONDITIONS FOR PROBLEMS INVOLVING TIME ASSOCIATED WITH VERTICAL ROCKET TRAJECTORIES, by A. Miele. Mar. 15, 1958, 6p. (AF 18(603)69) Unclassified

Published in *Jour. Aero/Space Sciences*, v. 25: 467-469, July 1958.

PUR.05:023-025; PUR.06:004, 005

This paper extends an earlier investigation by the author of trajectories of minimum propellant consumption involving time. Due to detection of a first integral for an isothermal atmosphere involving time variants, a simple approximate relationship is noted between altitude and Mach number. This relationship holds (with a precision of 3-4%) for all drag functions, regardless of end-conditions and of the analytical configuration of the functional form to be extremized.

A NEW AND SELECTIVE METHOD OF OXIDATION, by N. Kornblum, J. W. Powers and others. [July 16, 1957] 3p. incl. table. (AFOSR-TN-57-794) (AF 18(600)310) AD 148026 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 6562, Dec. 20, 1957.

A method is described for oxidizing alkyl bromides to the corresponding aldehyde, ketone or acid. The oxidation is achieved by dissolving the halide in dimethyl sulfoxide at room temperature. As an example an 84% yield of p- $\text{BrC}_6\text{H}_4\text{COCHO}$ was obtained from the reaction with p-Bromophenacyl bromide. The simple procedure described cannot be satisfactory with benzyl bromides. However, by raising the temperature, and using acetonitrile as a solvent, pure p-nitrobenzaldehyde has been obtained in 48% yield from p-nitrobenzyl bromide.

DIFFUSION PHENOMENA IN PRESSURE WELDING, by A. G. Guy and A. L. Eiss. Apr. 15, 1957, 1v. incl. illus. diags. tables, refs. (Rept. no. 6) (AFOSR-TN-57-225) (AF 18(600)1463) AD 126523 Unclassified

Also published in Welding Jour. Research Suppl. 1-8, Nov. 1957.

A study was made of the pressure welding of "sandwich" specimens and of the diffusion processes that occur during subsequent heating of these specimens. Conventional wire markers were unnecessary since impurity particles at the weld interfaces served this purpose. Sandwich specimens were made using several combinations of copper and brass, various surface preparations, welding pressures and welding temperatures. Several characteristics of the weld interfaces were studied such as width, straightness, and parallelism. Welded specimens were given diffusion heat treatments under various conditions to obtain information on the transport of zinc along the weld interface. "Extra" interfaces were observed in many of the specimens. (Contractor's abstract)

PUR.06:006 - PUR.06:008

Also published in *Trans. Metall. Soc. AIME*, v. 212: 107-112, Feb. 1958.

A study was made of the effects of a prolonged flux of zinc atoms through the α solid solution of zinc in copper. The experimental arrangement consisted essentially of a copper disk about 0.01 in. thick, at one of whose surfaces a gaseous atmosphere containing zinc atoms was maintained, and at the other surface a gaseous atmosphere with a minimum of zinc atoms was maintained. During prolonged exposure at high temperatures the zinc content of the copper disk gradually built up to the steady-state concentration and then remained at this value. The concentration distribution curves for various conditions were determined by chemical analyses. The results showed that the condition of steady-state diffusion was achieved. The diffusion coefficients calculated from the experimental data, although not of high precision, agreed with the values obtained by other workers using unsteady-state methods. Relatively slight porosity developed in the specimens in the course of diffusion. (Contractor's abstract)

EFFECT OF PRESSURE ON THE DIFFUSION OF ZINC IN ALPHA BRASS, by A. G. Guy and C. Spineiti. Jan. 15, 1958, 6p. incl. diags. tables, refs. (Rept. no. 7) (AFOSR-TN-58-85) (AF 18(600)1463) AD 148134
Unclassified

Also published in: *Welding Jour.*, v. 37: 524s-526s, Nov. 1958.

It has been reported that the diffusion of zinc in brass changes radically as the pressure is varied over a range of relatively low pressures. In an attempt to duplicate this work, sandwich diffusion specimens of copper between brass were heated to 850°C under uniaxial compression for 7 hrs. No difference in diffusion behavior was observed for pressures of 9 or 142 psi. It is suggested that the conflicting results can be explained by transport of zinc along weld interfaces in specimens welded and diffused at lower pressures. (Contractor's abstract)

DIFFUSION OF ZINC FROM THE VAPOR PHASE INTO

COPPER-ZINC AND SILVER-ZINC ALLOYS, by A. G. Guy. Jan. 31, 1958 [17]p. incl. diags. table, refs. (Rept. no. 8) (AFOSR-TN-58-282) (AF 18(600)1463) AD 154184
Unclassified

Diffusion measurements were performed using heated samples of copper-zinc and silver-zinc alloys exposed to a cooler zinc vapor reservoir. Natural markers at the initial surfaces of the specimens were "trapped" under a thin electroplate and their depth of burying was measured after diffusion. The ratio of diffusivities of the two components determined from these data and the chemical diffusion coefficient calculated by the Matano method agreed with previously reported results. The line of markers was found to be irregular and was often discontinuous as grain boundaries were crossed.

Steady-state diffusion was produced in a substitutional solid solution (item no. PUR.06:005). Two theoretical studies were important preliminaries to this research: (1) consideration of the mathematics of diffusion prior to and during steady-state diffusion (item no. PUR.06:002) and (2) devising an approximate method of calculation which permits a correction to be made for the variation of the diffusion coefficient with concentration (item no. PUR.06:003). The study of the Kirkendall effect in sandwich specimens was devoted principally to the welding phenomena involved in producing the specimens. A comprehensive study (item no. PUR.06:004) was made of the pressure welding of specimens and of the diffusion processes that occur during subsequent heating of these specimens. An alternative experimental technique to the usual sandwich specimen was studied for use in obtaining reproducibility and precision in measuring the Kirkendall shift in diffusion specimens; the technique was that of vapor-phase diffusion (item no. PUR.06:007). Three special pieces of equipment were built in connection with the research: a laboratory vacuum furnace; a precision, measuring metallurgical microscope; (item no. PUR.06:001) and special apparatus for welding studies.

ON THE EMISSION MECHANISM OF COLD CATHODE ARCS, by K. G. Hernqvist. [1958] [11]p. incl. illus. diags. tables, refs. (AFOSR-TN-57-521) [AF 18(600)-1239] AD 136651
Unclassified

Also published in *Phys. Rev.*, v. 109: 636-646, Feb. 1, 1958.

A new theory for the electron-emission mechanism of cold-cathode arcs is proposed in which excited atoms play a predominant role as a source for ion generation in the vicinity of the cathode surface. The processes of resonance ionization of excited atoms at the cathode surface are considered. Special emphasis is given to the dispersed (or D-type) arc, which operates with a relatively low emission-current density. An analysis of the D-type of arc is given based on the proposed theory. The rapid decrease of electron plasma temperature and population of excited atoms during arc-current interruption offer an explanation for the short extinguishing time of cold-cathode arcs. An equation of motion for the linear bending vibration of a thin plate of a visco-elastic material of Maxwell's type as derived previously by the authors is solved for transient motions of simply-supported and clamped rectangular plates. The deflection can then be expressed as the linear combination of a set of time functions and a set of space functions. The time functions have the same forms for both cases and are in terms of the roots of a cubic algebraic equation for each mode. The space functions are those for the corresponding problems of free vibrations of purely elastic plates in vacuum and have been solved exactly for a simply-supported plate and approximately for a clamped plate by other authors.

Damped oscillation is possible only when the cubic equations have complex roots. Then the natural frequencies depend on the natural frequencies of the corresponding purely elastic plate of the same size and same boundary conditions in vacuum, on the elasticity constants, viscosity coefficients, area density and thickness of the plate and on the densities and wave velocities of the surrounding fluid media. When the cubic equations have real roots only, the motion is simply damped out without oscillation. (Contractor's abstract)

TRANSLATION OF A DISCUSSION BETWEEN E. MOHR AND E. FUES AND CRITICAL REMARKS ON THIS DISCUSSION, by J. Martinek. Mar. 15, 1957, 1v. incl. diagrs. refs. (AF 18(603)104) Unclassified

Four papers from German technical journals are translated and critically reviewed by J. Martinek. They are: I. On the Navier-Stokes Stress Tensor for Viscous Fluid Flow, by E. Mohr. Luftfahrt-Forschung, v. 18:

327⁺, 1941. An examination of the equations of Navier-Stokes are made in the light of Maxwell's concept of friction. In this connection, the possibility of a different equation is indicated. II. Is There Any Vortex Friction?, by E. Fues. Zeitschr. für Physik, v. 118:

409⁺, 1941-1942. In repetition of a well-known gas kinematic derivation, it is demonstrated that internal friction is connected with the correlation of the velocity components for the secondary motion. A typical example is presented showing why there is distortional friction, but not vortex friction. III. Remarks on the Paper by E. Fues, Is There Any Vortex Friction?, by E. Mohr. Zeitschr. für Physik, v. 119: 575-580, 1942. By means of simple flows, a "few further reasons" are presented indicating an asymmetric stress matrix. Also, an attempt is made to show that the stresses which have been computed by Fues belong to a symmetric matrix; however, these stresses are negligible in first approximation when compared to those stresses created by the transport of macroscopic order of magnitudes of motion, and which evolve from an asymmetric matrix. IV. Is There Any Vortex Friction? II. Reply to the Criticism of E. Mohr, by E. Fues. Zeitschr. für Physik, v. 121, 1943. In this reply, the "further reasons" enumerated by Mohr for an asymmetric stress tensor in fluids are repudiated.

ON TURBULENT FLOW AND EDDY HEAT TRANSFER DIFFUSIVITY IN A PIPE, by R. R. Hunziker and J. S. Florio. [1957] [3]p. incl. diagr. refs. (AF 18(603)104) Unclassified

Published in Jour. Aeronaut. Sciences, v. 24: 782-784, Oct. 1957.

In his analysis of the flow in a circular pipe or between parallel plates, Pai considers simplifying hypotheses which allow him to write the Reynolds equations in the form first given by Kampé de Fériet for parallel plates. As in the case of the parallel plates, the equations for the circular pipe reduce to a pair of independent equations which are insufficient to determine uniquely the five related dynamical magnitudes charac-

terizing the flow. The use of Pai's polynomial distributions allows a consistent determination of the eddy diffusivity for heat $\epsilon_H = \alpha \epsilon_M$ on the basis of the "momentum transfer theory" and with a minimum of assumptions.

HEAT TRANSFER AND REYNOLDS' ANALOGY IN A TURBULENT FLOW WITH HEAT RELEASE, by R. R. Hunziker. [1958] [9]p. incl. refs. (AF 18(603)104) Unclassified

Published in Zeitschr. Angew. Math. Phys., v. 9A: 307-315, Nov. 25, 1958.

A mathematical study was made of heat transfer in a turbulent fluid flowing in a circular pipe in which sources of heat are present in the fluid. The solution of the boundary value problem is indicated, and it is shown that Reynolds' analogy, relating heating transfer and momentum in turbulent flow, can be extended to a heat-releasing flow, allowing a series solution approximation to the problem.

AN ELECTRIC-TANK ANALOGY SOLUTION OF A LINEARIZED THEORY FOR THE NORMAL-FORCE ON A SLENDER CLOSED BODY-OF-REVOLUTION, by W. B. Brower, Jr. Feb. 8, 1957, 49p. incl. illus. diagrs. table, refs. (Rept. no. TR-AE-5701) (AFOSR-TN-57-43) (AF 18(600)499) AD 115081 Unclassified

The problem considered is the determination of the normal-force on a slender closed body-of-revolution slightly inclined to the main stream. A theory is formulated which represents the mechanism of normal-force generation by a vortex sheet in the wake. The magnitude and distribution of vorticity is determined by imposing a new boundary condition on the body tangential velocity along the zero-meridian line due to the combined effects of the transverse-flow and the vortex sheet. The electric-tank analogy is employed to obtain the solution for one body configuration, that of a paraboloid of revolution, fineness-ratio 5. In addition, the case of the body in a classical Munk-flow is computed. Results for the loading coefficient, normal-force distribution and integrated normal-force coefficient are given. Comparisons are made with wind-tunnel results for slender bodies and with an unpublished theory of von Kármán. It is concluded that the slope of the normal-force-curve depends mainly on two parameters of the stern geometry, the stern-fineness-ratio and the shape of the stern meridian-line.

A brief review is presented of the Theodorsen theory which describes the origin and basic structure of turbulence. The experimental procedure used and results obtained in attempting to find the basic structure occurring when a flow is transformed from a laminar to a turbulent nature by the use of artificial disturbances, and verification of results obtained by other investigators are given. From the investigation conducted, it was found that the horseshoe-shaped vortex does exist in laminar pipe flow, for the range of Reynolds numbers investigated, when the flow is suddenly interrupted by an artificial disturbance. The sequence of events following the formation of this system of vortices to transition compares with that given by Theodorsen. The inverse relation between the disturbance Reynolds number and transition Reynolds number as predicted by Theodorsen was found to exist. From visual observations, the basic structure of the vortices formed when a flow is transformed from a laminar to a turbulent state without artificial disturbances present appears to be similar to that obtained with artificial disturbances. The above results agree favorably with those found by other investigators. (Contractor's abstract)

The deflection of two streams possessing different velocities when a curved surface is inserted into one of the streams was studied. The analysis is based on the

assumption that the two streams, both of finite width, will always be in contact. The main interest is in the location of the "separation points" R and S, i.e., how they will be affected by the presence of a second stream II. Results are given showing the qualitative effect upon the location of the "separation points" and the flow patterns when a second stream II is introduced. A complete solution of the problem is not attained because of mathematical difficulties. Lighthill's problem and results are summarized.

(Rept. no. TR-AE-5601) (AFOSR-TN-57-107) (AF 18-
(600)992) AD 120459 Unclassified

The induction problem in a duct is studied in this report. In Part I, attention is directed to the effect of change in pressure and flow patterns caused by the deflection of the inducing stream. Potential theory for an incompressible flow is used and the compressibility effect is corrected by the Kármán-Tsien method. The mass flow rate ratio is shown to depend on two parameters -- the width ratio of the inducing stream and the induced stream, and the deflection angle of the jet. Qualitative agreement with experimental results is obtained. In Part II, a comparison is made between a constant pressure and a constant area mixing duct, for the optimum induction effect. In addition, a method is proposed which may be used to correct the mass flow rate ratio, as obtained in Part I, for the diffuser efficiency. (Contractor's abstract)

ON A SMALL PERTURBATION TECHNIQUE FOR COMPRESSIBLE ROTATIONAL FLOWS, by K.-T. Yen and A. V. Farmer. Mar. 1957, 25p. diagr. (Rept. no. TR-AE-5702) (AFOSR-TN-57-160) (AF 18(600)992) AD 126452 Unclassified

A small perturbation technique for compressible inviscid flows has been developed using generalized coordinates. Application has been made to some simple compressible flow problems, both irrotational and rotational. The effect of a vorticity distribution of a specific form on the pressure distribution has been determined. Only subsonic flows have been considered. Further extension of this study to supersonic and more general types of flow problems is recommended. (Contractor's abstract)

VIBRATIONAL RELAXATION PHENOMENA IN A SHOCK TUNNEL, by W. Lick and T.-Y. Li. June 1957, 21p. illus. (Rept. no. TR-AE-5704) (AFOSR-TN-57-346) (AF 18(600)1591) AD 132419 Unclassified

Investigation is made of the effect of the vibrational heat capacity lag on the steady flow in a shock tunnel of gas in which specific heats are assumed to be a function of temperature and time. The investigation is restricted to temperatures below about 5000°R where the vibrational degrees of freedom are the only inert degrees of freedom. The energy content and the adjustment to equilibrium of the various degrees of freedom are discussed. The basic equations of state, energy, momentum, continuity, and relaxation are simplified. Three types of flow are considered: equilibrium, relaxed, and frozen flow. Conditions behind the incident shock and before expansion are assumed identical in all cases. A numerical example is worked out to compare the properties of an imperfect gas in the 3 cases for a particular shock tunnel. The resulting calculations show that the vibrational heat capacity lag has a considerable effect on the temperature and Mach number in the test section. The irreversibility of the process increases the final temperature several hundred degrees and decreases the Mach number considerably from that predicted by equilibrium flow. However, the final temperatures and Mach numbers have little meaning when the relaxation times are long compared with the time required for passage through the test section. To minimize the effect of heat capacity lag, a lower expansion rate should be used.

ASYMPTOTIC INTEGRATION OF SHOCK TUBE BOUNDARY LAYER EQUATIONS, by W. Lick. July 1957, 13p. incl. table. (Rept. no. TR-AE-5705) (AFOSR-TN-57-610) (AF 18(600)1591) AD 136600 Unclassified

The compressible boundary layer equations for the case of a shock wave propagating into a stationary fluid bounded by a wall are integrated by an asymptotic method first introduced by Meksyn (Proc. Roy. Soc. (London), A, v. 231: 274, 1955) for the usual case of a compressible boundary layer on a semi-infinite plate. Arbitrary constant Prandtl number and viscosity proportional to the temperature are assumed. Simple algebraic equations are obtained from the momentum and energy equations. The results of comparatively rapid calculations for skin friction and heat transfer agree closely with previous numerical calculations made by the NACA. (Contractor's abstract)

SHEAR FLOW PAST A CIRCULAR CYLINDER IN AN INCOMPRESSIBLE FLUID OF SMALL VISCOSITY, by R. Duffy and T.-Y. Li. Oct. 15, 1957, 29p. incl. diagrs. (Rept. no. TR-AE-5707) (AFOSR-TN-57-715) (AF 18(600)1591) AD 136708 Unclassified

The boundary layer characteristics about a circular cylinder in an incompressible fluid stream of symmetrical velocity distribution have been examined. Boundary layer results are expressed in the form of an infinite series expansion in terms of the free stream velocity distribution and the distances normal to and along the body surfaces. Preliminary results indicate that small free stream vorticity acts in a manner similar to induced pressure gradients along the body surface and as such have pronounced effects on boundary layer separation, boundary layer growth and shear stress. INVISCID FLOW FIELD AROUND A BLUNT BODY AT HYPERSONIC SPEEDS. PART I. THE STAGNATION POINT REGION, by T.-Y. Li. Sept. 7, 1957 [64]p. incl. diagrs. (Rept. no. TR-AE-5706) (AFOSR-TN-57-758) (AF 18(600)1591) AD 136747 Unclassified

RPI.05:008 - RPI.05:010

The inviscid hypersonic flow in the stagnation point region on a blunt body of revolution was studied, with particular emphasis on finding out the effects of the body curvature. Geometrical considerations led to the conclusion that the blunt nose could be treated as essentially spherical. In the blunt nose region, the differential equation for the stream function was derived. A stagnation point approximation solution was obtained, which, for small values of the density ratio ($k < 0.10$), yielded numerical results in excellent agreement with the exact solution. The results were compared with the simple theory of Li-Geiger, which neglected the body curvature effects. The major effects were to (1) increase the shock detachment distance over the theoretical value predicted by Li-Geiger, (2) provide a pressure relief on the body surface as predicted in the Newtonian-plus-centrifugal force formula, (3) increase the value of the nondimensional velocity gradient at the stagnation point over the value obtained by Li-Geiger, and (4) modify the velocity distribution within the shock layer. Numerical results of velocity distribution, surface pressure distribution, vorticity distribution, streamlines, detachment distance, and nondimensional velocity gradient at the stagnation point were obtained. STAGNATION POINT OF A BLUNT BODY IN HYPERSONIC FLOW, by T.-Y. Li and R. E. Geiger. [1957] [8]p. incl. diagrs. [AF 18(600)1591] Unclassified

Published in Jour. Aeronaut. Sciences, v. 24: 25-32, Jan. 1957.

Whereas Hayes ["Hypersonic flow fields at small density ratio" Ramo-Wooldridge Corp., May 1955] has treated the hypersonic flow about blunt bodies, the present authors consider the stagnation point region in more detail. Specifically, the density in this region is assumed to be constant, and the ratio of free stream to local density is small but not negligible. The pressure coefficients near the stagnation point are calculated for blunt two-dimensional and axially symmetric bodies. These results agree with experiments and with Hayes' results within the limits of applicability of his theory. Shock detachment distances are also predicted, but with slightly less accuracy.

INVISCID HYPERSONIC FLOW AROUND SPHERES AND CIRCULAR CYLINDERS, by E. D. Martin. Apr. 1956, 70p. incl. diagrs. refs. (Rept. no. TR-AE-5807) (AFOSR-TN-58-448) (AF 18(600)1591) AD 158254 Unclassified

Also published in Jour. Aero/Space Sciences, v. 26: 529-530, Aug. 1959.

An approximate method is presented for calculating the flow around spheres and circular cylinders in steady hypersonic flow; the results are in terms of simple closed form analytical expressions. The method is applicable to flows in the hypersonic regime and increases in accuracy with increase in Mach number. The effects of viscosity and heat conduction in the flow outside the boundary layer in the region behind the detached shock wave are neglected. The equations of motion can then be integrated exactly if the approximation is made that the density in the shock layer is nearly constant, which is valid for sufficiently high Mach numbers. An additional approximation, that the shock wave is concentric with the body surface, was also made to simplify the application of the boundary conditions known at the shock wave. The integration of the equations of motion was accomplished by the introduction of an unknown function, which was proportional to the stream function, and a third order ordinary differential equation was obtained. The solution for the sphere is a polynomial, while the 2-dimensional solution is found in terms of Bessel functions. Some important properties of the flow that can be found from this solution are shock detachment distance, velocity, stagnation point velocity gradient, vorticity, stream function, pressure coefficient and M_1 , a parameter defined in the analysis, which may be identified and compared with Mach number. The results (except for M_1) are given completely in terms of the shock density ratio. In general the results are found to agree fairly well with those obtained in other theoretical and experimental investigations.

INVISCID FLOW AROUND A BLUNT BODY OF A REACTING MIXTURE OF GASES. PART A. GENERAL ANALYSIS, by W. Lick. May 1956, 52p. incl. diagrs. refs. (Rept. no. TR-AE-5810) (AFOSR-TN-58-522) (AF 18(600)1591) AD 158335; PB 136214 Unclassified

A description is presented of a general numerical procedure whereby the details of inviscid flow about a blunt body of a mixture of perfect gases, including the effects of chemical reaction and relaxation, may be calculated. The fundamental equations and boundary conditions for the inviscid, nonheat conducting flow of a mixture of perfect gases are presented. The effects of vibrational relaxation and finite dissociation and recombination rates are included. An inverse method is described whereby if the form of the detached shock wave is known or is assumed, the flow field behind the shock and the corresponding shape of the body may be found. The method of solution and an iteration procedure to increase the accuracy of the computation are discussed. A method

RPL 05:011-013; RPL 08:001

of characteristics for 2-dimensional flow is developed including effects of vibrational relaxation and finite dissociation and recombination rates; the speed of sound is also briefly discussed. A rough analysis of dissociation and recombination rates is made in order to perform numerical computations using the methods presented, and to obtain reasonable qualitative effects of finite reaction times.

ance designs significantly. The present method should provide means of accurate determination of the following quantities: (1) the rate of change of lift coefficient with angle of attack, and (2) the rate of change of moment coefficient with angle of attack; both quantities are important in stability evaluation.

ON A POWER SERIES METHOD OF SOLUTION OF A BODY OF REVOLUTION AT AN ANGLE OF ATTACK IN HYPERSONIC INVISCID FLOW, by T.-Y. Li. Aug. 1958 [27]p. incl. diags. (Rept. no. TR-AE-5812) (AFOSR-TN-58-956) (AF 18(600)1591) AD 205349 Unclassified

A method of systematic solution of the aerodynamic problem of hypersonic inviscid flow past a body of revolution at a small angle of attack is presented. The equations of motion and the boundary conditions on the body surface and at the shock wave are examined. For a small angle of attack, ϵ , it is shown that the solution can be expressed as an ascending power series of ϵ . A sequence of differential equations with appropriate boundary conditions corresponding to various degrees of approximation is obtained. The approximation of the zero order corresponds to the case of the axisymmetric flow past the body of revolution. Higher order approximation equations are linear equations, the first order approximation equations are studied here. The aerodynamic stability of rocketcraft presents some unusual problems which can influence both structure and guid-

To determine the effects of chemical non-equilibrium on the flow about a blunt body, a detailed analysis of the flow field is necessary. The present paper describes an inverse method for the computation of the subsonic shock layer region. Results for three examples for the flow of air and one for the flow of pure oxygen through a prescribed shock shape at a Mach number of 14 and for free stream density and temperature corresponding to those at 100,000 ft altitude are presented. For air, three shock radii are chosen so that they represent three classes of flows: (1) an equilibrium flow, (2) a non-equilibrium flow and (3) a chemically frozen flow. These results show appreciable effects on the flow quantities due to chemical non-equilibrium. The limitations and methods of improving the accuracy of the numerical integration are discussed. A comparison of the results with Freeman's non-equilibrium theory, other equilibrium theories and experimental results is also given. (Contractor's abstract)

ON A BOUNDARY LAYER APPROXIMATION TECHNIQUE, by K.-T. Yen. Apr. 1, 1958, 34p. incl. refs. (Rept. no. TR-AE-5802) (AFOSR-TN-58-403) (AF 49-638)23) AD 158206 Unclassified

The problem of two-dimensional steady viscous flow is formulated using the streamlines and their orthogonal trajectories as generalized coordinates. Based on this, two boundary layer approximations are then developed. The first one, called the P-approximation, applies to boundaries with surface curvature equal to zero. This approximation is essentially equivalent to Prandtl's boundary layer theory. The second boundary layer approximation, called the C-approximation, is developed for the study of the effect of surface curvature. The conditions under which similar solutions exist for the C-approximations are obtained. Because of the complexity of the differential equations, high speed computing machines will have to be used to obtain solutions of the C-approximation. (Contractor's abstract)

STUDY OF SOME SUPERSONIC ROTATIONAL FLOW PROBLEMS BY A PERTURBATION TECHNIQUE, by C. Thyagarajan and K.-T. Yen. Apr. 1958, 37p. incl. diagrs. (Rept. no. TR-AE-5803) (AFOSR-TN-58-624) (AF 49(638)23) AD 162154; PB 138976 Unclassified

A small perturbation technique using generalized coordinates formed by streamlines and their orthogonal trajectories is applied to the analysis of some supersonic rotational inviscid flows. With a properly prescribed pressure distribution on a body surface in generalized coordinates, the body shape and the pressure field in the physical plane can be determined. Using a conveniently chosen initial Mach number distribution two examples have been studied in some detail. The first one is concerned with a linear surface pressure distribution which gives a nearly wedge-shaped body in the physical plane. It is shown that the wedge angle should be negative or positive depending on the slope of the vorticity distribution to create the pressure distribution prescribed. To examine the phase shift of the pressure distribution for a supersonic rotational flow over a periodically wavy wall, a sinusoidal pressure distribution is chosen as the second example. It is shown that the phase shift also depends on the slope of the vorticity distribution. (Contractor's abstract)

STANDARD ELECTRODE POTENTIALS IN NON-AQUEOUS SOLVENTS, by H. Taniguchi, S. S. Danyluk, and G. J. Janz. Final rept. Nov. 1956, 15p. (AFOSR-TR-57-4) (AF 18(600)333) AD 115060 Unclassified

The standard reference electrodes, hydrogen and silver, silver chloride, have been the subject of an exact investigation. A best procedure for the preparation of stable and reproducible electrodes for precision investigations has been developed. In acetonitrile, emf measurements with these electrodes were impossible owing to electrode instability and poisoning. The conductance of hydrogen chloride was investigated at 25°C to interpret the behavior of this solute in the light of the interionic attraction theory. In absolute ethyl alcohol the determination of the standard potential for the silver, silver chloride electrode and the thermodynamics of hydrogen chloride have been completed at 25°C. The theoretical problem of the concept of the absolute electrode potential, and the experimental attempts to measure absolute potentials have been critically examined. The problem of the relation of the electromotive force series in various non-aqueous solvents to that in water has also been discussed. A need exists for sound electrode potential data in non-aqueous media to advance the theoretical aspects of the subject. (Contractor's abstract)

STUDY OF EFFECT OF DEFORMATION ON THE THERMAL EXPANSION OF METALS, by H. B. Huntington. Apr. 2, 1957, 5p. (AFOSR-TR-57-60) (AF 18(600)649) AD 136528 Unclassified

The study of the effect of deformation on the thermal expansion of metals is reviewed. The effects of steady stress on various materials (Mg, brass, Cu, and Al) were first investigated in an attempt to understand the basic causes for the phenomena. A temperature-regulated box with stations for 8 specimens was installed. Each station consisted of a long quartz tube closed at one end. The specimen is pushed against the end by pressure from a long quartz rod, and the differential motion of the ends of the tube and rod as observed well

outside the box gives a measure of the thermal expansion of the specimen. Unaccountable variations in single runs and larger variation in level from one run to another were attributed to possible variations in the specimens themselves. Metallographic examination confirmed this in part, and more care was devoted to the pretreatment anneal. For Mg, a count of the twin boundary abundance correlated well with the mechanical history and could be used as a sensitive index of the completeness of the initial anneal. Methods for improving the contact between specimen and quartz rod were developed, and attention was given to reducing the temperature dependence of the part of the system which remains at room temperature.

UTILIZATION OF ENERGY STORED IN THE UPPER ATMOSPHERE, by P. Harteck and R. R. Reeves, Jr. Final technical rept. July 15, 1957, 61p. incl. diagrs. tables. (AFOSR-TR-57-50) (AF 18(600)1336) AD 135421 Unclassified

This work has been divided into two parts. First, an investigation to develop a flying missile, now called the HARE. The HARE is to fly through the upper atmosphere within the region where oxygen atoms are present and most dense. The HARE is to be propelled by energy obtained by recombination of these atoms on a catalytic surface placed inside. The atmosphere would be scooped in, heated, and rush out the tail, pushing the missile forward. The investigation included determination of a catalyst for the recombination, materials of construction, and various calculations indicating the feasibility of such a missile. Further equipment has been obtained to test various models of the HARE under simulated flight conditions. As a second, more recent, part of the work a study has been started to determine more precisely the maximum oxygen atom concentration in the upper atmosphere. Several reactions must be considered of importance in consuming these atoms such as

The results from experiments undertaken indicate that the rate coefficient for the second reaction involving the formation of ozone is equal to $5.7 (\pm 0.2) \times 10^{-34}$. (Contractor's abstract)

CONSTITUTION OF MOLTEN SALTS, by G. J. Janz.

RPI.12:002 - RPI.12:005

May 1957 [55]p. incl. diags. tables, refs. (Technical note no. 1) (AFOSR-TN-57-239) (AF 49(638)50)
AD 126536 Unclassified

The constitution of molten salts is reviewed with particular interest on the contributions gained from Raman and x-ray spectroscopy and physicochemical investigations based on electrical conductance and cryoscopy. The scope is limited to the more simple inorganic salts; the structure of slags and silicates is not treated, as these systems may be regarded as macro-molecules and highly polymerized forms of molten salts. TRANSFERENCE NUMBERS IN MOLTEN SALTS, by M. R. Lorenz and G. J. Janz. May 1957, 1v. incl. diags. tables. (Technical note no. 2) (AFOSR-TN-57-240) (AF 49(638)50) AD 126537 Unclassified

Also published in Jour. Phys. Chem., v. 81: 1683-1684, Dec. 1957.

A detailed description of previous work on transport numbers in molten salts is presented, with special consideration given to the most recent work published in this field. The applicability of a moving indicator bubble method to molten silver chloride was studied. A transport furnace, control circuit for constant temperature, a constant current dc power supply, silver chloride purification system and electrolysis cells were designed and constructed. A transference number equation, applicable to the system investigated, was derived. A basic study was undertaken with respect to mobility, sensitivity, reversibility, reproducibility and current leakage of air indicator bubbles in aqueous and molten salt media. It follows that the experimental methods based on air indicator bubbles or electrode displacements, described in the most recent studies of lead chloride, cannot be applied to determine the transport numbers of silver chloride. Analysis of the experimental and theoretical problems of the properties of molten inorganic salts has led to criteria for evaluation of results reported in this field. The great discrepancy in the values for the transport number of the lead ions in molten lead chloride is resolved in the light of the present investigation. (Contractor's abstract)

A RECORDING BECKMAN THERMOMETER AND DIFFERENTIAL POTENTIOMETER, by C. Solomons and

G. J. Janz. Aug. 1957, 6p. diags. (Technical note no. 3) (AFOSR-TN-57-497) (AF 49(638)50) AD 136487
Unclassified

An apparatus is described by means of which accurate measurements and records of changing electromotive forces can be made. The apparatus is normally used to measure and record changes of temperature of 1 to 5°C. The principle of operation is such that small differences in emf between a test source such as a thermocouple and a standard source such as a potentiometer is amplified by means of a stable dc microvolt amplifier. A continuous-balance stripchart potentiometer recorder is used with the device.

A CRYOSOPIC ASSEMBLY FOR PRECISE MEASUREMENTS UNDER CONTROLLED ATMOSPHERES AT TEMPERATURES UP TO 500°C, by C. Solomons and G. J. Janz. Aug. 1957 [12]p. incl. diags. tables. (Technical note no. 4) (AFOSR-TN-57-526) (AF 49(638)50) AD 136510 Unclassified

Also published in Rev. Scient. Instruments, v. 29: 302-304, Apr. 1958.

A cryoscope is described which was designed for the accurate measurement of freezing points of molten salts under controlled atmospheres. It possesses several advantages over apparatus in the published literature, especially when used with solutions which attack or embrittle the glass container. The ancillary apparatus used with the cryoscope is also described, and the features of the apparatus are discussed. Examples are given to show how several problems of molten salt cryoscopy under controlled atmospheres have been satisfactorily overcome. (Contractor's abstract)

CRYOSCOPY AND CONSTITUTION OF MOLTEN SALT MIXTURES IN THE LITHIUM CHLORIDE-POTASSIUM CHLORIDE EUTECTIC AND MERCURIC BROMIDE, by J. Goodkin and G. J. Janz. Aug. 18, 1958, iv. incl. diagrs. tables, refs. (Technical note no. 8) (AFOSR-TN-58-736) (AF 49(638)50) AD 162269; PB 151171 Unclassified

A calorimeter was developed which was capable of measuring heats of fusion of inorganic salts to an accuracy of $\pm 2\%$. The heats and entropies of fusion and the cryoscopic constant were determined for the $LiCl-KCl$ eutectic mixture, $AgNO_3$, and $HgBr_2$. The values were $3200 \pm 60 \text{ cal mol}^{-1}$, 5.1 EU, and $13.6 \text{ deg mol}^{-1}$ 1000 g^{-1} for the mixture; $2890 \pm 60 \text{ cal mol}^{-1}$, 5.9 EU and $27.2 \text{ deg mol}^{-1}$ 1000 g^{-1} for $AgNO_3$; and $4280 \pm 80 \text{ cal mol}^{-1}$, 8.4 EU, and $43.8 \text{ deg mol}^{-1}$ 1000 g^{-1} for Hg_2Br_2 . The cryoscopy of the alkali halides in the $LiCl-KCl$ eutectic mixture was extended to include LiF and KF solutes. The Temkin model adequately described the properties of $NaCl$, NaF , and KF in the chloride eutectic.

THERMAL ASPECTS OF GALLING OF DRY METALLIC SURFACES IN SLIDING CONTACT, by F. F. Ling and E. Saibel. [1957] [12]p. incl. diags. table, refs. (Sponsored jointly by [Air Force Office of Scientific Research under AF 49(638)67] and Office of Ordnance Research) Unclassified

Published in *Wear*, v. 1: 80-91, Oct. 1957.

The phenomenon of galling or seizing of metals is believed to be, in general, a function of the thermal and mechanical conditions under which the metallic surfaces are rubbed together. For polished surfaces, under ideal dynamic conditions, i.e., conditions where the surfaces are devoid of appreciable oscillations in the direction normal to the surfaces, thermal aspects of galling predominate. Galling due to thermal conditions is viewed as that condition where the tips of surface asperities weld together and are then sheared apart according to the weld-junction or adhesion theories. Welding may be achieved when the melting temperature is reached; also when surface asperities, which are under a high degree of strain, are in sliding contact. Welding may be achieved by recrystallization recovery. The latter process is taken as the governing condition for thermal galling since the recrystallization temperature is only a fraction of the melting temperature. The galling criterion, relating normal load, velocity, and time of rubbing, is established theoretically. The result compares favorably with experience. (Contractor's abstract)

ON KINETIC FRICTION BETWEEN UNLUBRICATED METALLIC SURFACES, by F. F. Ling and E. Saibel. [1957] [6]p. incl. diags. (Sponsored jointly by [Air Force Office of Scientific Research under AF 49(638)-67] and Office of Ordnance Research) Unclassified

Published in *Wear*, v. 1: 167-172, Dec. 1957.

A theory of friction between unlubricated metallic surfaces in sliding contact is proposed. For sliding conditions for which "hot" or "cold" welding of asperities is possible, the present weld-junction theory leads to a simple formulation of the coefficient of friction under idealized conditions. This result differs from that of Bowden and Tabor in that the coefficient of friction is found as the ratio of the shear strength to the yield pressure multiplied by a factor in which additional effects of load, relative velocity, temperature, and other physical properties appear. In arriving at this factor, the process of welding and fracturing of surface asperities is postulated to be a unimolecular reaction. (Contractor's abstract)

ADHESION, "PURE-SHEAR" AND FRICTION MEASUREMENTS AND WELDING ASPECT OF FRICTION, by F. F. Ling. Jan. 30, 1958 [29]p. incl. illus. diags. tables, refs. (Technical note no. 2) (AFOSR-TN-58-281) (AF 49(638)-67) AD 154183; PB 133966 Unclassified

This paper proposes a mechanism of recrystallization recovery for the welding mode of adhesion in contrast to the surface-tension mode of adhesion. Qualitatively, the resulting formulation is supported by data of Bowden and Rowe (*Proc. Roy. Soc. (London)*, v. 233A: 429, 1956). Also, a new relationship is proposed between adhesion, "pure-shear" and friction. "Pure-shear" refers to the shear force required to cause sliding after normal load is removed. It is believed that the relationship further elucidates the role welding plays in

the friction process. Moreover, measurements of adhesion, "pure-shear" and friction on lead specimens in limited quantity seem to substantiate the proposed theory. (Contractor's abstract)

A QUASI-ITERATIVE METHOD FOR COMPUTING INTERFACE TEMPERATURE DISTRIBUTIONS, by F. F. Ling. Oct. 1958, 22p. incl. diagr. (Technical note no. 3) (AFOSR-TN-58-1004) (AF 49(638)67) AD 206147 Unclassified

Also published in Zeitschr. Angew. Math. Phys., v. 10: 461-474, Sept. 1959.

A simple model of sliding contact is proposed for the experimentalist who is interested in the wear distribution, which is dependent on the temperature distribution of the interface. A relative simple method is developed for calculating the interface temperature distribution for the proposed model. The method is iterative in nature; the quasi-iterative method developed here reduces drastically the number of quasi-iterations to no more than one in most cases. An example is given to illustrate this point. The method may be extended to more complex models. Although the present method is iterative in nature, the actual labor involved is less than that required for numerical solution of the problem given a degree of computational accuracy. Results show that the interface temperature model can be used as an analogue problem for inverting a class of singular integral equations of the first kind. (Contractor's abstract)

ON MODEL STUDIES OF METALLIC SURFACE ASPERITIES, by F. F. Ling and R. C. Lucek. Dec. 1958, [26]p. incl. illus. diagrs. table, refs. (Technical note no. 4) (AFOSR-TN-58-1134) (AF 49(638)67) AD 208083; PB 138734 Unclassified

Also published in Jour. Appl. Phys., v. 30: 1559-1563, Oct. 1959.

An apparatus for measuring two components of the force generated at the tips of two cones throughout the sliding-contact life-cycle is described. The cones are used to simulate a class of surface asperities. Test results under atmospheric conditions show: (1) That for cones with 90° internal angles the ratio of the integrated value of the horizontal component over the length of the life-cycle to that of the vertical component, a measure of coefficient of friction after Green [Proc. Royal Soc.

(London) v. 228A: 191-204, Feb. 22, 1955], is not sensitive to the presence of lubricants for the case where the cone tips are in line or nearly in line with the direction of relative motion, direct-hit modes. But the ratio is substantially lowered in the presence of lubricants when the cone tips are far from in line with the direction of relative motion, slide-swipe modes. Direct-hit modes are always accompanied by the formation of macroscopic wear debris while side-swipe modes are usually not accompanied by an macroscopic debris; and (2) That by increasing the internal angle of cones, the ratio defined above is decreased, but its value does not seem to approach 0 for the angle approaching 180°. On the basis of the above, the mutual inclusiveness of the classical interlock theory and the popular adhesion theory of friction is discussed. Moreover, the coefficient of friction for a pair of idealized surfaces with asperities in the form of 90° cones and randomly distributed is calculated from considerable amount of test data. A PRINCIPLE OF VIRTUAL DISPLACEMENTS FOR REAL FLUIDS, by P. Lieber, K.-S. Wan, and O. Anderson. July 1957, 21p. incl. diagrs. tables. (AFOSR-TN-57-476) (AF 18(800)1704) AD 136488 Unclassified

Also published in Proc. Ninth Internat'l. Congress of Appl. Mech., Brussels (Belgium) (Sept. 5-13, 1956), v. 1: 106-113, 1957.

A principle of virtual displacements for incompressible viscous flows is formulated with the Navier-Stokes equations rendered as the Euler equations for the generating function. This variational principle asserts that the work done by the forces applied to an arbitrary surface at which the velocities are assigned, is stationary for the real motion or path. As in the case of the principle of virtual displacements in mechanics, only the displacements are subjected to the variation and the forces are kept constant under the variation. The principle is applied to the calculation of the skin friction coefficient, velocity profile, and thickness of rotational regime for a flat plate under the restrictions of the boundary layer theory. The results are in good agreement with the Blasius solution and experimental data.

A PRINCIPLE OF MINIMUM DISSIPATION FOR REAL FLUIDS, by P. Lieber and K.-S. Wan. Aug. 1957, 52p. incl. diagrs. tables. (AFOSR-TN-57-477) (AF 18(800)-1704) AD 136469 Unclassified

RPI.14:003 - RPI.14:006

Also published in Proc. Ninth Internat'l. Congress of Appl. Mech., Brussels (Belgium) (Sept. 5-13, 1956), v. 1: 114-126, 1957.

The principle of minimum dissipation is introduced as a hypothesis which asserts that consistent with the constraints imposed by the conservation laws and boundary conditions, the observable flow patterns minimize the time rate of dissipation of energy. The principle is applied to 2-dimensional incompressible viscous flows to establish that the admissible flow patterns are governed by the biharmonic equation for the stream function which satisfies the continuity equation. The necessary and sufficient general conditions, under which flows admissible by this variational principle are also admissible by the Navier-Stokes equation, are established for incompressible viscous flows. This requirement gives an auxiliary differential equation governing the transport and distribution of vorticity which is interpreted to show that flows which are everywhere time-independent can occur only under special conditions. This principle is applied to a circular cylinder and a flat plate, and between 2 parallel flat plates.

ON A STATISTICAL THEORY FOR ONE-DIMENSIONAL REAL GAS FLOWS, by P. Lieber and K.-S. Wan. Sept. 1957, 23p. incl. diagr. (AFOSR-TN-57-478) (AF 18-(600)1704) AD 136470 Unclassified

A set of mathematically tractable governing conditions are obtained for compressible-viscous flows. The equations are formulated in terms of physical parameters which describe the behavior of a gas in its most primitive and yet essential aspects. The parameters are the mass density, the mass flow velocity, and the root mean square of the velocity fluctuations relative to the mean velocity. A characteristic length is introduced which represents the mean free path. The flow field is regarded as made up of discrete regions, and the state in each region, relevant from a gas-dynamic point of view, is assumed to be well represented by the parameters. The theory yields a relation across a normal shock wave which is in agreement with the Rankine-Hugoniot theory. The developed theory shows that downstream flow conditions depend upon the disturbance as well as upon the inflow Mach number. The expansion compression wave may, according to the theory, be produced in an initially subsonic flow when the disturbance has a critical range determined by the Mach number. The relationship of this theory to the Navier-Stokes theory is discussed.

A PROOF AND GENERALIZATION OF THE PRINCIPLE OF MINIMUM DISSIPATION, by P. Lieber and K.-S. Wan. Sept. 1957 [20]p. (AFOSR-TN-57-479) (AF 18-(600)1704) AD 136471 Unclassified

The principle of stationary dissipation and the L variational principle for real fluids are used to calculate the flow fields produced under various boundary conditions. The modified Couette flow is considered and extended to include the free surface problem. The L principle is used to obtain both the temporal mean and time-dependent flow for the Couette case and for the modified Couette flow. The preliminary results indicate the possibility of obtaining real vortices when the L principle is employed to calculate flows about closed bodies. The curvature at the boundary appears to be fundamental in the production of real vortices.

A STUDY LEADING TO THE BOUNDARY CONDITIONS AT A FREE SURFACE JOINING AN IRRATIONAL-ROTATIONAL FLOW REGIME, by P. Lieber and K.-S. Wan. Sept. 1957 [11]p. incl. diagr. (AFOSR-TN-57-480) (AF 18(600)1704) AD 136472 Unclassified

A theoretical demonstration is given that the curvature of the interface is necessary, as a consequence of the boundary conditions assigned at the interface, for terminating the rotational regime. Therefore, the mechanisms which terminate the rotational regime are related to the mechanism which produces the curvature called for at the interface. In investigating these mechanisms, a number of elementary flow configurations calculated according to the principle of stationary dissipation are considered. The problem of a two-dimensional viscous incompressible flow produced by a circular cylinder is investigated in three stages. The first consists of obtaining a solution to the classical problem treated by Stokes; the second encloses the cylinder by two fixed boundaries and calculates the resulting flow; the third frees the portions of the boundaries arbitrarily fixed in the second stage.

APPLICATIONS BASED ON VARIATIONAL PRINCIPLES FOR REAL FLUIDS, by K.-S. Wan and P. Lieber. Sept. 1957 [36]p. incl. diagrs. (AFOSR-TN-57-481) (AF 18-(600)1704) AD 136473 Unclassified

Application was used of the "L" principle to the

RPI.14:007; RPI.07:004-007

calculation of a real flow field about a circular cylinder in a manner which will include the determination of the extent of the rotational regime. The differential equation governing the time dependent steady state motion according to the "L" principle and the compatibility condition is investigated. This investigation relates the temporal mean flow to the temporal fluctuations. It thereby suggests a connection with turbulent flow. The coupling of the time dependent motion and the temporal mean flow suggests the possibility of calculating inhomogeneous turbulent flows from this point of view.

Feb. 27, 1958 [11]p. incl. diagrs. (Math. rept. no. 12) (AFOSR-TN-58-126) (AF 18(600)1586) AD 152153

RIA. 01:001

theories yield the same results regardless of which approach is adopted, but anisotropic theories, such as those using Prager's kinematic hardening law, may not. This paper treats a specific plane stress problem, the bending of a rigid-plastic simply-supported circular plate by a uniform load, from a three-dimensional point of view, using Prager's hardening law. This more elaborate theory predicts displacements less than half as large as those obtained for the same loads from the two-dimensional theory. The dependence of the post-yield stresses and displacements on the magnitude of the initial yield stress is also examined. (Contractor's abstract)

AN IMPACT TESTING MACHINE FOR PLASTICS AND RUBBER-LIKE MATERIALS, by E. Volterra and C. S. Barton. [June 1957] 14p. illus. diags. tables. (AFOSR-TN-57-347) (Sponsored jointly by Office of Naval Research under Nonr-59105 and Air Force Office of Scientific Research under AF 49(638)19) AD 132420
Unclassified

A testing machine for studying dynamic properties of plastics and rubber-like materials under impact loadings is described. The cylindrical specimens to be tested are placed on the plane end of a short steel bar hung as a ballistic pendulum. Another bar, also hung as a ballistic pendulum, is made to impinge upon the specimen. The force acting on the specimen during the time of impact is measured by an accelerometer fixed to the impacted bar. From the acceleration-time diagram, which is recorded on an oscilloscope, the force acting on the specimen during impact is measured. The length of the specimen during impact is determined by integrating twice the acceleration-time diagram. This accelerometer method represents a considerable improvement in experimental accuracy as compared with the optical method (drum camera method), which has been described in a previous paper, and in which method the dynamic parameters of the specimen were obtained by photographing the distance between the two bars during impact. Experiments conducted using this accelerometer method under different conditions of temperatures and impact loadings are described and the results compared with those obtained by the drum camera method. An experimental attempt was made to prove the Hertz theory of impact as applied to the impact of a hemispherical end of a short rod against the plane end of an infinitely long rod. Modern instrumentation and electric strain gages mounted on the long bar and on the short bar enabled the study to be made of the time of contact (pulse length) and the stress as a function of time. The principle of the conservation of momentum of the bars was used as a basis for evaluating the accuracy of the experimental as well as the theoretical pulses. Little difference was noted in magnitude of stress, peak time, and pulse length for all bar lengths and impact velocities between the round end and flat end bars. The shapes of the experimental and theoretical curves compared favorably in the pulse rise and fall regions. Large differences exist between the theoretical and experimental pulses except in the case of the long impacting bars. The fact that a limiting value of stress was almost reached when the longer impacting bars were used also permitted good agreement in the peak time values between the theoretical and experimental pulses. Results indicated that the Hertz theory of impact as applied in the theoretical approach expressed the loading phenomena fairly well but failed to do so as soon as the pulse returned to the contact end.

CONTINUITY PROPERTIES OF DERIVATIVES OF SEQUENCES OF FUNCTIONS, by G. R. MacLane. [1957] [2]p. (AF 18(600)1135) Unclassified

Published in Proc. Amer. Math. Soc., v. 8: 897-898, Oct. 1957.

A supplement to Dvoretzky's generalization of a theorem of Walsh [Proc. Amer. Math. Soc., v. 7: 363-386, 1958] is presented here. The theorem states: There exists

a sequence of functions $\{f_n\}_{n=1}^{\infty}$, $f_n \in C^1(-\infty, \infty)$, with

$\lim_{n \rightarrow \infty} f_n(x) = 0$, such that: if N_1 is any subsequence of the natural numbers with the property that there exists a sequence x_{n_1} , $n_1 \in N_1$, satisfying

$$f_{n_1}(x_{n_1}) = 0, \text{ and } \lim_{n_1 \rightarrow \infty} x_{n_1} = 0,$$

then the sequence N_2 complementary to N_1 (i.e., N_2 contains exactly those natural numbers omitted by N_1) is infinite and

$$\limsup_{n_2 \rightarrow \infty} \int_0^h |f_{n_2}(x)| dx = -$$

for every $h > 0$.

EFFECT OF VIBRATIONS ON THE YIELD STRENGTH OF A LOW-CARBON STEEL, by G. E. Nevill, Jr. and F. R. Brotzen. Apr. 15, 1957, 12p. illus. diagrs. tables, refs. (Technical rept. no. 1) (AFOSR-TN-57-170) (AF 49(638)78) AD 126463; PB 131260 Unclassified

Also published in Proc. Amer. Soc. for Testing Materials, v. 57: 751-758, 1957.

Experimental results show that, when a specimen is subjected to vibration in the frequency range from 15 kc to 80 kc, the steady stress necessary to cause plastic deformation is appreciably reduced. This reduction is examined under different conditions of vibrational

amplitude, frequency, strain, and temperature. It is found to be proportional to the vibrational amplitude, but independent to the frequency of vibration, prior strain, and temperature. Several possible explanations for this decrease in yield strength have been considered on the basis of dislocation theory. A discussion and a detailed picture of the responsible mechanisms are included. (Contractor's abstract, modified)

THE EFFECT OF VIBRATIONS ON ORDERING IN A COPPER-GOLD ALLOY, by H. C. Burghard, Jr. and F. R. Brotzen. Oct. 1, 1958 [28]p. incl. diagrs. table, refs. (Technical rept. no. 2) (AFOSR-TN-58-915) (AF 49(638)78) AD 204584 Unclassified

Also published in Trans. Metall. Soc. AIME, v. 215: 863-868, Oct. 1959.

Experiments were performed to determine the effects of mechanical vibrations on ordering in CuAu. The effects of 5, 10 and 15 kc vibrations were investigated over a range of ordering temperatures of 280° to 380°C. A decrease in the rate of ordering was observed at all frequencies and ordering temperatures. This retarding effect is attributed to the interference of moving dislocations with growth of ordered domains. (Contractor's abstract)

REACTION BETWEEN METHANOL AND BORON CONTAINING GLASSES, by R. P. Porter. May 27, 1957, 2p. (AFOSR-TN-57-262) (AF 18(600)1528) AD 126560
Unclassified

Also published in Jour. Phys. Chem., v. 61: 1260, Sept. 1957.

The presence of B in methanol stored in Pyrex was verified by measuring the emission caused by B at 548 m μ with a model D. U. Beckman spectrophotometer and its flame photometer attachment. The presence of trimethyl borate was verified by means of the consolidated mass spectrometer model 21-620. The mass spectrogram of a sample of anhydrous methanol which had been in contact with Pyrex was in agreement with that obtained from a sample of trimethyl borate obtained from the Pacific Coast Borax Company, purified by distillation, and that obtained from a sample of methanol in which boric acid was dissolved. The comparison of mass spectrograms was made on the basis of 18 peaks whose ratios of mass to charge are greater than the largest ratio caused by methanol. The most prominent peaks lie at 104, 103, 73, 72, and 43. The flame photometer showed that alcohol stored for several months in soft glass bottles contained 0.01 mol-% B while that stored in Pyrex contained 0.04 mol-%. The mass spectrometer showed that methyl alcohol distilled over Na in a Pyrex distilling flask contained as much as 1 mol-% of trimethyl borate. Anhydrous methanol vapor in contact with Pyrex produced varying amounts of trimethyl borate. The concentration reached as high as 12 mol-% in the course of 10 hr. When such alcohol was photolyzed with a H discharge tube, varying amounts of products were formed. Mass spectrograms of a sample of methanol which contained trimethyl borate to which small amounts of water were added showed that as the water content increased, the trimethyl borate content decreased.

THE LIQUID PHASE PHOTOLYSIS OF DIETHYL KETONE AND METHYL ETHYL KETONE, by P. Ausloos. June 15, 1957, 18p. Incl. diagrs. tables, refs. (AFOSR-TN-57-320) (AF 18(600)1528) AD 132391; PB 132306
Unclassified

Also published in Canad. Jour. Chem., v. 36: 400-409, Feb. 1958.

The liquid phase photolysis of diethyl ketone has been studied in the temperature range from -35 to 95°C. The CO quantum yield at 95°C was found to be close to unity. At 28°C decrease in intensity and addition of heptane led to a substantial increase of the CO and the ethane yield. The methyl and ethyl ketone liquid phase photolysis at temperatures between 5 and 75°C led to the same observations. Arrhenius plots of $R_E/R_B^{1/2}$ (K) gave for both compounds a value of 5 kcal/mole. Gas phase studies in the temperature range 0 to 60°C confirmed the low CO quantum yield reported previously and showed evidence for disproportionation and recombination reactions between ethyl and propionyl radicals. A review was made of the reactions of excited ketone molecules, with Me₂CO, biacetyl, and Et₂CO as examples. Mention was made of the methods of dissociation of the molecules and the importance of knowing the 2 quantities α , the fraction of initially excited molecules which dissociate and ϕ , the primary quantum yield. Me₂CO, biacetyl, Et₂CO, and ketone were studied in the consideration of the fraction of ϕ which is due to α . For all of them, the over-all quantum yield (and probably the primary quantum yield) increases with temperature although the effect with Et₂CO is small. The effects of added O in this study were also included.

ROC.02:010 - ROC.02:013

An attempt has been made to determine the primary processes in the gas and liquid phase photolysis of simple alkyl esters. The liquid phase photolysis of methyl, ethyl, n-propyl and n-butyl formate has been briefly investigated. Besides the dissociation processes, two intramolecular rearrangements were found to occur:

Process I takes place with approximately the same quantum yield for all the formates studied. Process II occurs only when there is a β hydrogen in the alkyl group. An investigation of the gas and liquid phase photochemical decomposition of esters other than formates showed the existence of the following primary processes:

Processes VI and VII require β and γ hydrogens, respectively in the Y and X alkyl groups. It was found that processes I and X occur mostly at short wavelength, while the other processes take place at long wavelengths as well. (Contractor's abstract)

At 35°C, mixtures of 0.4 ml iodine with EtI, PrI, sec-BuI, and iso-PrI which were illuminated with a high-pressure mercury arc lamp produced alkenes in the ratios of 1:5:21:22; the filter was 3 mm Corning glass 3484 which absorbed wavelengths below 5070Å. MeI yielded no detectable products. Only negligible amounts of hydrocarbons were formed in thermal blanks upon irradiation of the pure alkyl iodide. Propylene was formed by the illumination of I-iso-PrI mixtures with radiation filtered for 4000 to 5510Å or for 5790Å. The ratio of butene-2 to butene-1 from sec-BuI was 3.4 and 3.7:1. The butene-2 was at least 85% the trans isomer. The rate of propylene formation was unaffected by the presence of 75 mm of dry air. The photochemical decomposition of iso-PrI was studied. H, CH_4 , and 2, 3-dimethylbutane were not products of the propylene yield in the absence of Hg at constant intensity. The rates showed a decrease only after extended photolysis. C_3H_8 was greatly decreased in the presence of added iodine, especially at the longer wavelengths, but increased after long photolysis.

REACTIONS OF METHYL RADICALS WITH WATER ON QUARTZ AND PYREX SURFACES, by P. Ausloos and J. Paulson. Nov. 20, 1957, 5p. incl. table. (AFOSR-TN-57-740) (AF 18(600)1528) AD 136725; PB 135691 Unclassified

ROC.02:014 - ROC.02:017

Also published in Jour. Phys. Chem., v. 62: 501-502, Apr. 1958.

The photolysis and radiolysis of acetone-d₆ have been investigated in the presence of water. The experiments indicate that: (1) CD₃H is only formed when water is present, with as little as 0.1 mole percent of water sufficient to cause the reaction; (2) the ratio of CD₃/CD₄ is independent of water concentration; (3) CD₃H/C₂D₆ is practically independent of the water and acetone concentrations and the ratio increases with temperature; (4) the CD₃H/CD₄ ratio falls off drastically at temperatures above 100°C in the radiolysis experiments but does not in the photolysis experiments even at temperatures up to 195°C; and (5) flaming out the pyrex and quartz cells results in a substantial decrease of the CD₃H/CD₄ ratio. These results indicate that the CD₃H is formed on the surface. Result (3) above shows that all CD₃ radicals reach the wall and that abstraction on the surface and recombination are two competing reactions.

THE PHOTOCHEMISTRY OF 2-HEXANONE VAPOR, by V. Brunet and W. A. Noyes, Jr. Oct. 30, 1957, 10p. incl. table. (AFOSR-TN-57-741) (AF 18(600)1528) AD 136727
Unclassified

Also published in Bull. Soc. Chim. (France), no. 1: 121-123, 1958.

The photochemical dissociation of 2-hexanone was studied to determine whether this reaction occurs from the upper singlet or triplet state. At room temperature and at temperatures up to 100°, propylene, and acetone quantum yields were about equal when no O was present. At temperatures above 100°, there were additional reactions to produce propylene but the acetone quantum yields remained constant up to 300°. In the presence of O, the yields of acetone and propylene were equal at all temperatures. Both yields were the same as in the absence of O up to 100°; at 150°, the acetone yield was the same in both the presence and absence of O. The fact that O did not inhibit the nonfree radical dissociation of 2-hexanone into propylene and acetone together with the independence of the quantum yields on temperature indicated that the dissociation occurs from an upper singlet state.

THE PHOTOLYSIS OF POLYMETHYLVINYL KETONE AND POLYMETHYLISOPROPENYL KETONE, by K. F. Wissbrun. July 9, 1958 [18]p. incl. diagrs. tables, refs. (AFOSR-TN-58-588) (AF 18(600)1528) AD 162111 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 81: 58-62, Jan. 5, 1959.

The photolysis of polymethylvinylketone (PMVK) and polymethylisopropenyketone (PMIK) was studied by using thin films of these materials. In both cases the effect of irradiation is one of depolymerization. For low dosages the effect on the mol wt of PMVK is independent of temperature, incident intensity, and film thickness. At higher dosages, however, the amount of

degradation appeared to be affected by film thickness. The results indicate formation of a double bond conjugated with the carbonyl group. The quantum yield is calculated to be 0.02. Upon photolysis at 80°C for 16 hrs, the products were determined by mass spectrometric analysis to be acetaldehyde, carbon monoxide, and methane with quantum yields of 0.06, 0.003, and 0.0006, respectively. Photolytic degradation of PMIK at 150° and 177°C yields essentially the pure monomer. A clear understanding of the mechanism of this process is complicated by dependence on temperature, mol wt, and on diffusion-controlled termination reactions.

OXYGEN EFFECTS IN PHOTOCHEMICAL SYSTEMS, by W. A. Noyes, Jr. [1958] 24p. incl. tables, refs. (AFOSR-TN-58-591) (AF 18(600)1528) AD 162115

Unclassified

Presented at Internat'l. Congress of Radiation Research, Burlington, Vt., Aug. 11-15, 1958.

Also published in Radiation Research, Suppl., v. 1: 164-176, 1959.

Oxygen effects in photochemical systems have been surveyed briefly as regards the following points: (1) reactions of radicals with oxygen; (2) reactions of excited molecules with oxygen. Many radicals react rapidly with oxygen, but radicals which retain excess kinetic or vibrational energy from the primary process may undergo certain reactions which are not completely inhibited. These effects will be most easily observed with light atoms or radicals if the energy is mainly kinetic. Molecules in triplet states may react directly with oxygen without dissociating. In this case oxygen may change profoundly the nature of the primary process. (Contractor's abstract)

THE PHOTOLYSIS AND FLUORESCENCE OF ACETONE AND ACETONE-BIACETYL MIXTURES, by J. Hecklen and W. A. Noyes, Jr. Sept. 12, 1958 [24]p. incl. diagrs. tables, refs. (AFOSR-TN-58-845) (AF 18(600)1528) AD 203335 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 81: 3858-3863, Aug. 5, 1959.

The photolysis of acetone vapor has been redone at 3130A to very low conversions and the fluorescence and photolysis of acetone-biacetyl mixtures have been studied. If biacetyl is present during the photolysis of acetone at 3130A, an energy transfer occurs between

ROC.02:022 - ROC.02:025

excited acetone molecules and biacetyl, the acetone photodecomposition and phosphorescence are diminished, and biacetyl phosphorescence is observed. Since biacetyl is a reaction product of acetone photolysis, the quantum yield of acetone decomposition decreases as the time of irradiation increases. The ratios of reaction products also change with time of irradiation. A detailed mechanism is presented for the primary process in acetone and for the energy transfer between acetone and biacetyl. The fluorescence and phosphorescence of biacetyl have been studied at 40° as a function of pressure and incident wavelength from 4358A to 3020A. A mechanism is proposed which explains both the light emission and the photochemistry. With incident radiation of 3020A or 3130A the absorption is into a second electronic state. This state is converted to the first singlet and triplet states, and the same fluorescence is observed as with incident radiation of longer wavelengths. This paper is combined with item no. ROC.02:023 and published as cited above. (Contractor's abstract)

Light emission from acetone has been studied with incident radiation from 2800A to 3130A. The fluorescence efficiency is independent of pressure and nearly independent of exciting wavelength. The phosphorescence increases markedly with wavelength and with pressure at short wavelengths. With incident radiation of 3130A and 40°, the phosphorescence decreases slightly as the pressure increases. At 63° the quench is more pronounced. A complete mechanism is presented. This paper is combined with item no. ROC.02:022 and published as cited above. (Contractor's abstract)

The principal products of the photochemical decomposition of methanol vapor at wave lengths below 2000A are hydrogen, formaldehyde, ethylene glycol together with small amounts of carbon monoxide and methane. By use of scavengers and by study of deuterated methanol, CD₃OH, at least two primary processes must occur:

CH₃O + H. Other primary processes, including the formation of hot methoxy radicals and hot hydrogen atoms, may occur but conclusive evidence for or against them could not be obtained. Secondary reactions are discussed. Methoxy radicals must, by abstraction, form CH₂OH radicals, and CH₂OH radicals must also be formed by the reaction H + CH₃OH = CH₂OH + H₂. (Contractor's abstract)

PHOTOISOMERIZATION PROCESSES IN CYCLIC KETONES. I. CYCLOPENTANONE AND CYCLOPENTANONE-2,2,5,5-d₄, by R. Srinivasan. Nov. 12, 1958 [13]p. incl. tables, refs. (AFOSR-TN-58-998) (AF 18(600)1528) AD 206141
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 81: 1546-1549, Apr. 5, 1959.

4-Pentenal has been identified as one of the products of the vapor phase photolysis of cyclopentanone at 3130A. Quantum yields for the formation of 4-pentenal have been obtained at various temperatures and in the presence of added oxygen and carbon dioxide. The photolysis of cyclopentanone-2,2,5,5-d₄ has been found to give

tetradepro 4-pentenal, the structure of which is most probably CD₂ = CHCH₂CD₂CHO. On the basis of these results, it is deduced that the photoisomerization of cyclopentanone to 4-pentenal involves a direct transfer of a hydrogen atom from a β-carbon to the carbonyl group in an excited state of the ketone molecule. RADIOLYSIS OF $\text{CH}_3\text{COOCH}_3$ AND $\text{CH}_3\text{COOCD}_3$ BY COBALT-60 GAMMA-RAYS, by P. Ausloos and C. N. Trumbore. Dec. 2, 1958, 22p. incl. tables, refs. (AFOSR-TN-58-1067) (AF 18(600)1528) AD 207227
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 81: 3866-3871, Aug. 5, 1959.

Results of studies on the radiolysis of liquid and gaseous $\text{CH}_3\text{COOCH}_3$ and $\text{CH}_3\text{COOCD}_3$ by cobalt 60 gamma radiation are reported. Yields of the volatile radiation decomposition products have been studied as a function of temperature, dose and the presence of added radical scavengers. A comparison of the isotopic hydrogen, methane, ethane and dimethyl ether species present in these products provides information about possible primary processes, hot radical effects and radical disproportionation and recombination reactions within the liquid "cage." Recombination of methyl radicals originating from the same parent molecule as well as abstraction reactions between radicals in the same cage are postulated to explain the non-statistical yields of CH_3CD_3 and the high yields of CH_3D and CH_3OCD_3 in the liquid phase. PHOTOISOMERIZATION PROCESSES IN CYCLIC KETONES. II. CYCLOHEXANONE AND 2-METHYLCYCLOHEXANONE, by R. Srinivasan. Dec. 20, 1958 [13]p. incl. table, refs. (AFOSR-TN-58-1128) (AF 18(600)1528) AD 207973; PB 139862
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 81: 2601-2604, June 5, 1959.

5-Hexenal has been identified as one of the products of the vapor phase photolysis of cyclohexanone at 3130A. Quantum yields for the formation of 5-hexenal have been obtained as a function of temperature and pressure and in the presence of oxygen or carbon dioxide. The photoisomerization also occurs in the pure liquid phase and in methylpentane solution. The photolysis of 2-methylcyclohexanone as a pure liquid apparently gives rise to only one isomeric product, which is most probably trans-5-heptenal. The photoisomerization of these two ketones closely resembles the corresponding process in cyclopentanone and probably proceeds by the same mechanism. (Contractor's abstract)

THE CLOSE-PAIR EFFECT IN COSMIC RAY STARS AT 92,000 FEET, by M. E. Matsis and M. F. Kaplon. n.d. 3p. incl. diagrs. [AF 18(600)380] Unclassified

A study of the close-pair correlation of cosmic ray induced stars in a nuclear emulsion has been carried out with inconclusive results. The stars produced by the decay of thorium which is present in the emulsion has been used as a comparison. A plot of the difference of close-pair expected values and observed values shows a larger than expected occurrence for the star center separation of less than 600μ . If the thorium graph can be accepted as a criterion for randomness, then no close-pair effect is observed in the cosmic ray stars.

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 23-24, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 1: 320, Nov. 23, 1956.

Also published in Phys. Rev., v. 105: 278-284, Jan. 1, 1957.

The proportions of the various decay modes of K^+ -mesons produced by the 2.9 bev proton beam of the Brookhaven Cosmotron have been investigated in two emulsion stacks separately exposed at different distances from the target. An analysis of the observed ratios of different decay modes has been made in order to determine the various partial lifetimes using the $K_{\mu 2}$ and $K_{\tau 2}$ lifetimes as a secondary standard. The results indicate that within experimental error all the partial lifetimes are consistent with a unique value.

jointly by Atomic Energy Commission under AT(30-1)-
875 and Air Force Office of Scientific Research under
AF 18(600)380) AD 134725 Unclassified

Also published in Phys. Rev., v. 107: 1698-1708,
Sept. 15, 1957.

A systematic study of the scattering of 1173 definitely
identified K_L^+ -mesons and 279 τ (including τ') mesons
has been made in the energy interval 30-65 mev using
photoemulsion exposed to the Berkeley K^+ -meson beam.

All scatters of K^+ -mesons having a projected angle
greater than 2° on the emulsion plane were recorded and

analyzed. The results of analysis are the following:
(1) the interaction properties of the K_L^+ and τ -mesons
are essentially indistinguishable; (2) the coherent nuclear
scattering of K^+ -mesons interferes constructively with
the Coulomb scattering; (3) in terms of the optical model,
the best fit for coherent scattering corresponds to a real
potential of $\sim +15$ mev, and the inelastic scattering
gives an imaginary potential of ~ 3.6 mev; and (4) charge
exchange is rare in this energy region: $\sigma(\text{charge ex-}$
 $\text{change})/\sigma(\text{incoherent}) < 1/10$. A tentative interpretation
of the results in terms of isospin $T = 0$ and $T = 1$ states
is presented. A discussion is also given on the charac-
teristic features of K^+ -stars. (Contractor's abstract)

SCATTERING OF K_L^+ AND τ MESONS (Abstract), by
T. F. Hoang, M. F. Kaplon, and R. Cester. [1957] [1]p.
(Sponsored jointly by Atomic Energy Commission and Air
Force Office of Scientific Research under [AF 18(600)-
380]) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York,
Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 20,
Jan. 30, 1957.

A systematic study of the scattering of 1175 K_L^+ mesons
and 242 τ and τ' mesons has been made in the energy
region of 20 to 80 mev using Bevatron K^+ mesons re-
corded in Ilford G5 emulsions. All scatters of K meson
having a projected angle greater than 2° in the emulsion
plane were analyzed. A scattering is accepted as elastic
if no energy loss can be detected on the basis of ioniza-
tion and range. The same differential cross section of
elastic scattering was observed for K_L^+ and τ mesons.

An attempt was made to separate nuclear scattering
from coulomb scattering by means of an energy-dependent
cutoff. The elastic nuclear scatterings thus found gave a
mean free path of $44(+6, -4)$ cm for the K_L^+ meson and
 $43(+12, -8)$ cm for the τ meson; their angular distribution
shows the characteristic features of a diffraction scat-
tering. The ratio of inelastic to elastic ($\Delta E/E < 10\%$)
scatterings of K_L^+ and τ mesons was found to be $\sim 1/11$.

ON THE FLUX OF COSMIC-RAY PARTICLES WITH
 $Z \geq 2$ AT $\lambda = 41^\circ N$ (Abstract), by A. Engler, M. F.
Kaplon, and J. Klarman. [1957] [1]p. [AF 18(600)380]
Unclassified

Presented at meeting of the Amer. Phys. Soc.,
Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2:
192, Apr. 25, 1957.

A stack of nuclear emulsions has been exposed to the cosmic radiation under $\sim 8 \text{ g/cm}^2$ of matter at $\lambda = 41^\circ \text{N}$. Since at this latitude all incoming particles are nearly relativistic, ionization measurements are sufficient to determine their charge. Blob-and-gap measurements were made on the tracks of α particles, and δ -ray counts on those of particles with $Z \geq 3$. The obtained fluxes were presented and compared with those of other authors.

balloon flight. The identification of α -particles was based on 'blob-gap' measurements while those of elements with $Z \geq 3$ were based on δ -ray densities. The charge resolution obtained was satisfactory. To calculate the fluxes at the top of the atmosphere an extrapolation procedure was used. Two sets of parameters which account for the interactions in the residual atmosphere, differing considerably as far as their influence on the fluxes of light elements is concerned, were used. The results (in particles/ $\text{m}^2 \text{ sec sterad}$) are:

	Set I	Set II
$Z = 2$	90.9 ± 8.0	89.2 ± 8.0
$3 \leq Z \leq 5$	1.68 ± 0.32	0.45 ± 0.36
$6 \leq Z \leq 9$	5.60 ± 0.58	6.05 ± 0.56
$Z \geq 10$	2.19 ± 0.38	2.19 ± 0.38

K^+ -MESON INTERACTIONS IN NUCLEAR EMULSIONS (Abstract), by D. F. Davis and M. F. Kaplon. [1958] [1]p. [AF 18(600)380] Unclassified

Presented at meeting of the Amer. Phys. Soc., Ithaca, N. Y., June 19-21, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 270, June 19, 1958.

The interactions of K^+ -mesons of energies up to 250 mev are being studied. A stack of emulsion consisting of 80 pellicles, each 400 μ thick and 25 cm x 9.3 cm in area, was exposed to the "separated" K^+ -meson beam at the Berkeley Bevatron. The stack has the advantage that it is large enough to stop K^+ mesons of 250 mev. This allows the stopping particles to be identified by their characteristic decay modes. The energy dependence of the cross section and of the ratio, charge exchange/inelastic scatter, are presented. These results are based on the data from about 30 meters of track.

THE STRUCTURE OF THE M DWARF STARS. I, by D. N. Limber. [1958] [24]p. incl. diagrs. tables, refs. [AF 49(638)52] Unclassified

Published in *Astrophys. Jour.*, v. 127: 363-386, Mar. 1958.

The problem of the internal structure of the middle and late M dwarf stars is considered, and the discrepancy between theory and observation that had been found by Osterbrock for these stars is reexamined. A rediscussion of the observations that relate to the masses, luminosities, and radii for the stars whose spectral types range from M4 V to M8 V is carried out on the basis of what are believed to be the best and most recent data; and revised values and probable errors for these observational quantities are determined. The evidence is found to indicate rather strongly that the bolometric corrections that are usually quoted in the literature should be reduced by at least 0.3 or 0.4 mag. for the stars of spectral type M4 V and by correspondingly larger values for the still later spectral types. Some indication is also found that the effective temperatures of the middle and late M dwarfs are actually higher than the values usually quoted. These suggested corrections act to reduce significantly the discrepancy between Osterbrock's theory and the observations and lend support to the view that the middle and late M dwarfs are completely convective insofar as their interiors are concerned. (Contractor's abstract)

THE STRUCTURE OF THE M DWARF STARS. II, by D. N. Limber. [1958] [41]p. incl. diagrs. tables, refs. [AF 49(638)52] Unclassified

Published in *Astrophys. Jour.*, v. 127: 387-427, Mar. 1958.

The theory of completely convective models is developed specifically for application to the middle and late M dwarfs in such a way that the effects of electron degeneracy are taken into account, and the restrictions that are set upon the realm of applicability of these models by the effects of radiative transport and of electron conduction are determined. Under rather general

assumptions, the results of the theory can be expressed in analytical form. The required formulae and equations that describe these models and that give the criteria for their applicability are derived for an arbitrary chemical composition in terms of rather general expressions for the rate of energy production and for the radiative opacity. The corresponding convective models have been constructed for the relevant range of values for the masses and radii and for what appear to be the best present estimates for the chemical composition, rate of energy generation, and radiative opacity. The effects of the atmospheres for these models are examined insofar as they determine the mass-luminosity relation and enter into the comparison of the theory of the interiors with the observations. The models that have been constructed have been compared with the observational values for the masses, luminosities, and radii for Krüger 60 A (M4 V) and Krüger 60 B (M6 V) that were obtained from the rediscussion of the observations in Paper I, and theory and observation have been found to be consistent. Spectral response measurements have been made on Eastman Kodak lead sulfide photocells in the wavelength range 0.2 - 2.0μ. The quantum sensitivity is roughly constant for wavelengths greater than 0.6μ, and rises linearly with photon energy at shorter wavelengths. The increase in quantum yield is attributed to secondary internal photoemission. (Contractor's abstract)

ANISOTROPY OF EDGE LUMINESCENCE IN CADMIUM SULFIDE, by D. Dutton. Jan. 1958 [6]p. incl. diagr. (Technical note no. 12) (AFOSR-TN-58-56) (AF 18(600)193) AD 148097
Unclassified

Also published in Jour. Phys. Chem. Solids, v. 6: 101-102, July 1958.

Observations were made on the luminescence produced with polarized light to obtain additional evidence for an indirect excitation mechanism and to provide some information on the anisotropy of the luminescence centers and their distribution within the crystal. The observations were made in connection with an investigation of the optical absorption spectrum of CdS. The specimen which was a single crystal in the form of a thin platelet was maintained at 90°K and illuminated by monochromatic polarized light. The intensity and polarization of the luminescence were measured as functions of wavelength and polarization of the exciting radiation. The results showed that the emission at 5205Å was strongly polarized, and the component with E vector perpendicular to the c-axis was 6.3 ± 0.2 times as intense as the parallel component. This ratio was independent of the polarization of the exciting radiation, implying that the excitation and emission processes are only directly related and may occur in different states or in different parts of the crystal. The excitation spectrum showed pronounced peaks coincident with absorption maxima, indicating that the luminescence efficiency was appreciably higher near the surface.

THE FUNDAMENTAL ABSORPTION EDGE IN CADMIUM SULFIDE, by D. Dutton. June 1958, 20p. diags. refs. (Technical note no. 14) (AFOSR-TN-58-545) (AF 18(600)193) AD 158362 Unclassified

Also published in Phys. Rev., v. 112: 785-792, Nov. 1, 1958.

The absorption and reflection spectra of CdS have been determined in the temperature range 90°-340°K by photoelectric measurements on single crystals, using polarized light. The temperature and frequency dependence of the absorption coefficient in the edge, over a substantial range of absorption magnitudes, are well described by expressions of the form $\alpha(\nu) = \alpha_0 \exp\{-\beta(E_{00} - CT - h\nu)/kT\}$, where the energy $(E_{00} - CT)$ is closely associated with the position of an absorption peak. For light polarized with E vector parallel to the crystalline c-axis, there is one such peak, at $\lambda 4844\text{\AA}$ at 90°K; for light polarized with E vector perpendicular to the c-axis, the 4844\text{\AA} absorption is again present in about equal strength and a stronger line appears at $\lambda 4874\text{\AA}$, shifting the absorption edge toward longer wavelengths by a corresponding amount. These absorption lines, or sharp bands, are observed in the reflectance spectrum, and correspond to absorption lines observed photographically by Gross and others. These results are discussed in the light of the present theoretical picture of absorption in insulating crystals, and it is noted that an exponential absorption edge of this kind, characteristic also of other ionic crystals, cannot be adequately explained in terms of existing models. A SIMPLE PULSED ULTRAVIOLET LIGHT SOURCE, by R. F. Weeks. Sept. 1958 [18]p. incl. illus. diags. (Technical note no. 15) (AFOSR-TN-58-615) (AF 18(600)193) AD 162143 Unclassified

Also published in Jour. Opt. Soc. Amer., v. 49: 429-433, May 1959.

A pulsing circuit to permit the use of a conventional low pressure "Nester" hydrogen arc as an ultraviolet stimulating source for luminescence studies is described. The pulse duration may be varied from 4 msec to 30 μ sec with a repetition rate of 60 per sec. There is no perceptible variation of the light form from pulse to pulse. The rise time of the pulses is 20 μ sec and the fall time, 0.3 μ sec. The pulsing circuit is assembled from conventional electronic components and contains no critical high frequency circuits. The inherent spectral range and reliability of operation of the Nester lamp are maintained and the unit may be easily switched to dc operation. The use of this source in kinetics measurements is discussed briefly. (Contractor's abstract)

RESEARCH ON OPTICAL AND ELECTRICAL PROPERTIES OF SOLIDS, by D. Dutton. Final rept. Sept. 1958, 8p. (Technical note no. 16) (AFOSR-TN-58-100) (AF 18(600)193) AD 162214 Unclassified

The research carried out during this contract is summarized and abstracts of the reports and publications issued under the contract are presented. The work was initially directed toward investigation of intergrain potential barriers in polycrystalline lead sulfide photocells, using a microbeam scanning technique, with a view to establishing the properties of such barriers. The scope of the project was later broadened to include experimental studies of photoconductivity, luminescence, and optical absorption in various materials including the alkali and silver halides, the thallous halides, cadmium sulfide, lead sulfide, and lead selenide. RESISTIVITY OF INTERSTITIALS IN COPPER, by R. J. Potter and D. L. Dexter. June 1957 [23]p. incl. diagrs. tables, refs. (Rept. no. 18) (AFOSR-TN-57-327) (AF 18(600)688) AD 132399 Unclassified

Also published in Phys. Rev., v. 108: 677-682, Nov. 1, 1957.

The residual resistivity of copper per atomic percent of interstitial atoms is computed in several different models. It is found that the contributions from the defect itself and from the associated lattice strain are of comparable magnitude and that the interference between them tends to reduce the resistivity. A shielded Coulomb potential, Blatt's computed phase shifts, and an electron-lattice interaction constant are variously used to calculate the scattering amplitudes. The necessary parameters are determined from high-temperature resistivity data. Values of about 2 $\mu\text{ohm cm}$ per atomic percent are obtained. (Contractor's abstract)

ANISOTROPIC EFFECTS IN OPTICAL EXCITATION OF EXCITONS IN MOLECULAR CRYSTALS, by D. Fox and S. Yatsiv. Sept. 1957, 41p. incl. refs. (Rept. no. 19) (AFOSR-TN-57-597) (AF 18(600)688) AD 136583 Unclassified

Also published in Phys. Rev., v. 108: 938-945, Nov. 15, 1957.

The expression for the energy of an exciton state contains certain dipole lattice sums. These sums are strongly dependent on the direction of the propagation vector of the exciton, even when the magnitude of this vector is very small. As a result, the energy of an optically-excited exciton may depend strongly on the direction of propagation of the absorbed radiation, if the excitation takes place coherently over a region whose linear dimensions are comparable with or much larger than a wavelength. The behavior of the lattice sums may also introduce a dependence of the exciton polarization and of the absorption coefficient on the direction of propagation. The magnitudes of these effects were calculated for the cases of the first and second transitions of naphthalene and of anthracene. Experimental observations of the extent to which these effects occur could provide information on the dimensions of excitation of the exciton.

ON EXCITON MODELS IN THE ALKALI HALIDES, by D. L. Dexter. Apr. 1957 [23]p. incl. diagrs. refs. (Rept. no. 17) (AFOSR-TN-57-198) (AF 18(600)688) AD 126493 Unclassified

Also published in Phys. Rev., v. 108: 707-712, Nov. 1, 1957.

The common models for excitons in the alkali halides are criticized as to their goodness as zero-order models. Some new calculations on energies, oscillator strengths, and charge distributions are made with the models as they are commonly used. It is shown that the customary use of an LCAO (linear combination of atomic orbitals) method with the electron transfer model gives qualitatively incorrect results, particularly for the wave functions and charge distributions, results which are not even internally consistent with the model. It is argued that the other model, an excitation model, gives at least semiquantitatively correct results, and is a satisfactory zero-order approximation. Finally, it is shown that in the alkali halides the LCAO method must inevitably be an inconvenient one for finding accurate charge distributions and wave functions for localized centers. EXCITON STATES IN SOLID ARGON, by R. S. Knox. Apr. 1958, 292p. incl. diagrs. tables, refs. (Technical note no. 23) (AFOSR-TN-58-370) (AF 18(600)688) AD 154276 Unclassified

The ground and lowest excited states of a rare gas crystal are treated in the tight-binding approximation. Frenkel exciton states constructed from symmetrically-orthogonalized states of localized excitation are used and intermediate coupling of singlet and triplet states is carried out in order to include atomic spin-orbit

interaction. Expressions for energies, effective masses, and integrated absorption cross sections associated with the lowest optically interesting states are obtained in an approximation which considers overlapping of atomic wave functions through terms of order equal to the square of the overlap in the integration and which neglects perturbations by single exciton states other than the 12 belonging to the lowest configuration. Lattice vibrations are not explicitly taken into account. The formalism is applied to solid argon using atomic Hartree-Fock wave functions. Exciton bands built from certain atomic $J = 2$ states have appreciable perturbing effects on the optically interesting bands, and certain interaction terms which depend explicitly on overlap integrals are decisive in determining the sign of the exciton effective masses. The model predicts two absorption lines in the vicinity of 9 ev (± 1 ev) with a separation of 0.2 ev and a combined integrated absorption cross section of the order of 10^6 ev cm^{-1} . The estimated computational error in excitation energy arises in part from difficulties in evaluating 2- and 3-center integrals in the presence of large overlap and in part from the natural inaccuracy of the atomic Hartree-Fock functions. Exciton effective masses are relatively insensitive to the direction of the momentum vector k and are of the order of 5 electron masses.

EXCITED STATE WAVE FUNCTIONS, EXCITATION ENERGIES, AND OSCILLATOR STRENGTHS FOR

Ne ($2p^5 3s$), by A. Gold and R. S. Knox. Sept. 1958, 20p. incl. tables, refs. (Technical rept. no. 1) (AFOSR-TN-58-885) (AF 49(638)432; continuation of AF 18(600)688) AD 204101; PB 137156 Unclassified

Also published in Phys. Rev., v. 113: 834-839, Feb. 1, 1959.

Solutions of the Hartree-Fock equations for the $3P$ and $1P$ terms of neon ($2p^5 3s$) have been obtained. Wave functions are tabulated and results of computations of excitation energies and oscillator strengths are presented. The former fall within 10% of experimental values. It is found that enlarging the size of the "invariant core" used to compute the excited state wave functions has only a small effect on the predicted energies. The predicted oscillator strength of the 736A transition is 0.11, which is in reasonable agreement with available experimental data considering the large uncertainties in the measurements. The computed diamagnetic susceptibility of the ground state is $-7.4 \times 10^{-6} \text{ cm}^{-3} \text{ mol}$, in good agreement with experiment. (Contractor's abstract)

TRAPPED CHARGE AND THE LOW TEMPERATURE LUMINESCENCE OF UNDOPED KI, by K. Teegarden and R. F. Weeks. Nov. 10, 1958 [17]p. incl. diags. (Technical note no. B-1) (AFOSR-TN-58-918) (AF 49-638)433) AD 204562; PB 137845 Unclassified

Also published in Jour. Phys. Chem. Solids, v. 10: 211-216, July 1959.

New data is presented on the previously reported low temperature blue luminescence of undoped KI. It is shown that the emission previously observed during irradiation in the fundamental bands can also be stimulated by irradiation in the F. and F'-bands formed by exposure to ultraviolet light at 93°K. The crystals display a burst of red luminescence when warmed after irradiation with light absorbed in the fundamental bands at 93°K. No emission occurs upon irradiation in the F-band at 93°K if the F-centers have been formed at a temperature somewhat above that of the thermal burst of red luminescence. It is suggested that the red luminescence occurs when holes are released from V-centers during warming and the blue luminescence is due to the recombination of electrons with trapped holes at 93°K. AN EXACT SOLUTION FOR FREE RECTANGULAR PLATES Laterally Loaded, by L. Broglio. Aug. 1958, 116p. incl. diags. tables. (Technical note no. 2; SIARgraph no. 8) (AFOSR-TN-57-288) (AF 61(514)888) AD 132359 Unclassified

The general problem of the rectangular free plate of constant thickness, under whichever load-distribution, is considered in this paper. It is firstly shown that (1) any given load distribution can be reduced to boundary loads and (2) that the complete solution is reached when six particular problems (symmetric or antisymmetric, moments or reactions, be prescribed by the boundary condition) are solved. The solution of each one of the six particular problems is then developed. A new procedure is here introduced. It consists in satisfying exactly one of the boundary conditions on the four sides; and then the other one by means of a system of linear equations, by methods of successive approximations of very good convergence. A numerical example developed for three plates of different aspect ratio shows the adequacy of the method, and the trend in the stress-distribution as aspect ratio increases. (Contractor's abstract)

SOME CONTRIBUTIONS TO THE HEAT CONDUCTION AND THERMAL STRESSES ANALYSIS IN AIRCRAFT AND MISSILE STRUCTURES, by L. Broglio. [1958] [48]p. incl. diags. refs. [Technical note no. 4; SIARgraph no. 40] (AFOSR-TN-58-1006) (AF 61(514)888) AD 206149; PB 139815 Unclassified

Presented at meeting of the First Internat'l. Congress in Aeronaut. Sciences, Madrid (Spain), Sept. 8-13, 1958.

Also published in *Advances in Aeronaut. Sciences*, v. 1: 213-235, 1959.

The analysis of temperature distribution for bodies subjected to kinetic heating and heat losses by radiation is discussed along with the case of boundary conditions, depending upon the time and upon surface temperature distributions. The simple solution for the concentrated heat source in a heterogeneous body of whatever shape is found is presented first. By considering a surface layer of timewise and spacewise variable heat sources, the so-called Q-solution is obtained. By combining the Q-solution with the boundary conditions, an integrodifferential equation with respect to time is obtained, which can be easily integrated step-by-step, despite its non-linear nature. The application of the theory to the hollow hemisphere and to the hollow semicylinder is then presented. It also contains, for sake of comparison, the solution of a classical two-dimensional problem, of rather difficult analytical solution, and an evaluation of thermal stresses. (Contractor's abstract)

HEAT CONDUCTION IN SOLIDS AT HYPERSONIC SPEED, by L. Broglio. Oct. 1958 [27]p. incl. diags. table. (Technical note no. 5; SIARgraph no. 45; NATO AGARD rept. no. 209) (AFOSR-TN-58-1132) (AF 61(514)888) AD 207977; PB 142980 Unclassified

Presented at Eighth meeting of the AGARD Structures and Materials Panel, Copenhagen (Denmark), Oct. 20-25, 1958.

A simple formula is obtained which relates directly each series coefficient of the temperature to the

RCS.01:001 - RCS.01:003

corresponding series coefficient of the heat flow. In the field of nonlinear problems, special attention is paid to the heat conduction problem for a body whose thermal properties are changing with temperature. Such a problem, by means of a suitable change of variables, is reduced to a similar problem for the same body with constant thermal properties and whose solution is obtained. The results are applied to the problem of heat conduction at hypersonic speeds. An exact expression is found for the trajectory of the body in the atmosphere for the case in which gravity and centrifugal forces are neglected. (ASTIA abstract)

A DIRECT METHOD OF USING THE HODOGRAPH PLANE IN FLUID DYNAMICS, by A. G. Mackie. [1957] 21p. (In cooperation with St. Salvator's Coll., St. Andrews (Scotland)) (AF 61(514)1170) Unclassified

Also published in Proc. Edinburgh Math. Soc., v. 11: 107-114, 1958/59.

A number of problems in 2-dimensional incompressible flow in which either the magnitude or the direction of the velocity is constant on sections of the bounding streamlines can be solved by means of the conformal mapping of the hodograph plane. In this study, these are regarded as real boundary value problems for the stream function Ψ as a function of the velocity variables. In many cases the solution can be found with much less work than is involved in the use of the Schwarz-Cristoffel transformation. Further, this direct method can be extended immediately to solve analogous problems in compressible flow, whether the exact or approximate (transonic) equations of motion are used. General formulas are given for the position coordinates and for the drag. (Contractor's abstract)

TWO-DIMENSIONAL SUBSONIC AND SONIC FLOW PAST THIN BODIES, by J. B. Helliwell and A. G. Mackie. Oct. 1957 [17]p. incl. diagrs. (Technical note no. 1) (AFOSR-TN-58-111) (AF 61(514)1170) AD 152019 Unclassified

Also published in Jour. Fluid Mech., v. 3: 93-109, Oct. 1957.

Hodograph methods are applied to determine the flow at high subsonic and sonic velocities past two-dimensional, thin, symmetrical bodies. The boundary value problem for the determination of the stream function ψ , which in the present theory is a solution of Tricomi's equation, is simplified by the assumption of a free stream breakaway at sonic velocity from the shoulder of the body. A solution is obtained in terms of Bessel functions. The flow past a wedge of small angle is discussed and expressions are obtained for the pressure on the nose, the drag coefficient and the width of the wake. A comparison with the corresponding results in the case of sonic velocity derived by the more complex analysis of Guderley and Yoshihara (1950) shows that the present simpler theory yields very similar values for the pressure over the nose. The flow at sonic velocity past a profile which is a first-order perturbation upon a wedge profile is analyzed on the basis of the same free streamline theory. The flow pattern is obtained past an arbitrarily specified body by an application of the Hankel inversion theorem, and an expression is deduced for the drag. (Contractor's abstract)

TWO-DIMENSIONAL FLOW PATTERNS AT HIGH SUBSONIC SPEEDS PAST WEDGES IN CHANNELS WITH PARALLEL WALLS, by J. B. Helliwell. Sept. 6, 1957 [22]p. incl. diagrs. (Technical note no. 2) (AFOSR-TN-58-294) (AF 61(514)1170) AD 154203
Unclassified

Also published in Jour. Fluid Mech., v. 3: 385-403, Jan. 1958.

Investigations are made of the plane flow of an inviscid isentropic gas at high subsonic and sonic speeds past a finite wedge of small angle set at zero incidence in a channel with parallel walls. Hodograph methods are applied to the determination of the stream function, which, under the usual transonic approximation, is a solution of Tricomi's equation. A brief summary is given of the derivation of the fundamental solution of this equation in terms of Bessel functions. Two models of the flow pattern are discussed. The model of Cole is examined with the sonic line from the shoulder extending completely across the channel at right angles to the wall. The Helliwell-Mackie model is taken in which there is a free stream breakaway at sonic velocity from the shoulder of the wedge and the velocity far downstream may be either uniformly subsonic or sonic. Values are obtained for the drag coefficient in both cases and a high degree of both qualitative and quantitative agreement is found. On the basis of the free streamline theory explicit formulas are given relating, in terms of the channel width and upstream Mach number, the drag of the wedge in the channel to that of the same wedge in the free stream.

AN APPLICATION OF THE WEBER-ORR TRANSFORM TO THE PROBLEM OF TRANSONIC FLOW PAST A FINITE WEDGE IN A CHANNEL, by J. B. Hellweil. [1958] [5]p. incl. diagrs. [Technical note no. 4] (AFOSR-TN-58-1037) (AF 61(514)1170) AD 206486
Unclassified

Also published in Proc. Cambridge Philos. Soc., v. 54: 391-395, July 1958.

The flow around an angle placed symmetrically in a channel of constant width is treated, and the length of the sides of the angle is taken as finite. It is assumed that the flow line which follows one of the sides of the angle is continued by a jet line at constant velocity. The flow is subsonic everywhere, but the angle is small; and the velocities, at the upper infinity and at the lower infinity, are related to the critical velocity. It is possible to make a study legitimately within the framework of the theory of small perturbations of a transonic flow: one ought to look for a solution of a Tricomi equation in the plane of the hodograph suiting conditions with suitable limits. This method of solution is related to that of an integral equation that can be explicitly resolved in this case. (Math. Rev. abstract)

THE SOLUTION OF BOUNDARY-VALUE PROBLEMS FOR A GENERAL HODOGRAPH EQUATION, by A. G. Mackie. [Aug. 1958] 23p. refs. (In cooperation with St. Salvator's Coll., St. Andrews (Scotland)) (AF 61-(514)1170) Unclassified

Published in Proc. Cambridge Philos. Soc. (England), v. 54: 538-553, Oct. 1958.

In this mathematical study, the solution is found for certain boundary-value problems appropriate to the flow of an inviscid, compressible fluid past a wedge-shaped profile. The most general hodograph equation in the form

$$\frac{\partial^2 \Psi}{\partial \sigma^2} + k(\sigma) \frac{\partial^2 \Psi}{\partial \theta^2} = 0$$

is used. Expressions are found for

the position coordinates and the drag. The resulting solutions are then discussed for functions $k(\sigma)$ appropriate to Chaplygin's equation, Tricomi's equation, and the equation of Tomotik and Tamada. The case of Helmholtz flow past a wedge with sonic velocity upstream is treated in detail, and the resulting expressions for the drag enable an estimate to be made of the error which results in using approximations to Chaplygin's equation. EARLY DETECTION OF MICROCRACKS, by J. J. Slade, Jr. and A. Szrajer. Progress rept. no. 5, Dec. 1, 1957-Feb. 28, 1958. Mar. 14, 1958, 11p. diags. (AFOSR-TN-58-252) (AF 49(638)17) AD 154155 Unclassified

A general expression is given for the rocking curve associated with the $\vec{n} = [h, k, l]$ family of planes:

$$r(\vec{\beta}, \vec{n}) = A / (\beta_1^2 + \beta_2^2) (\beta_2^2 + \beta_3^2) (\beta_3^2 + \beta_1^2).$$

Errors in the locations of the atoms are cumulative and are usually not known a priori. A scheme of computation is presented for expressing β_1 in terms of measurable quantities associated with the rocking curves. Elements of the Cauchy function are related to the moments of the truncated rocking curve. Finally, Ag single crystals, showing no substructure by the Lane method, have been selected for a preliminary investigation of rocking curves. They are being examined by a double crystal diffractometer.

UNIQUENESS OF MULTIPLE TRIGONOMETRIC SERIES, by V. L. Shapiro. Jan. 31, 1957, 22p. (AFOSR-TN-57-51) (AF 18(600)1595) AD 115090 Unclassified

Also published in Ann. Math., v. 66: 467-480, Nov. 1957.

Two theorems are proved on the uniqueness of multiple trigonometric series. I. Given the multiple trigonometric series $(P) = \sum_m a_m e^{i(m,x)}$ where the a_m are arbitrary complex numbers; suppose that (1) $\sum_{R-1 < |m| \leq R} |a_m| =$

$o(R)$ as $R \rightarrow \infty$, (2) $f^*(x)$ and $f_*(x)$ are finite for all x , (3) $\bar{a}_m = a_{-m}$, and (4) $f_*(x) \geq A(x)$ where $A(x)$ is in L^1 on T_n ; then $f^*(x)$ is in L^1 on T_n and (P) is its Fourier series. II. Given the same series, let W be a set of measure zero on T_n and let q be a point on T_n not in W ;

suppose that (1) $\sum_{R-1 < |m| \leq R} |a_m| = o(R)$ as $R \rightarrow \infty$,

$f^*(x)$ and $f_*(x)$ are finite for x in $T_n - q$, (3) $f^*(x) = f_*(x)$ for x in $T_n - (W+q)$, and (4) $f_*(x)$ is in L^1 on T_n ; then (P) is the Fourier series of $f_*(x)$. T_n designates the

n -dimensional torus, $f^*(x) = \limsup_{t \rightarrow 0} \sum_m a_m e^{i(m,x) - |m|t}$

$= \limsup_{t \rightarrow 0} R(\Sigma) + i \limsup_{t \rightarrow 0} I(\Sigma)$, and $f_*(x)$ designates the corresponding $\lim_{t \rightarrow 0}$. Theorem I is a direct analog of Verblunsky's (A. Zygmund, Trigonometric series, Warsaw, 1935, p. 207) theorem in one dimension, and is a best possible result. Theorem II is false in one dimension. Condition 1 cannot be changed to $O(R)$ as $R \rightarrow \infty$. In 2 dimensions this is illustrated by the Fourier-Stieltjes series of the measure on T_2 which has unit mass at the origin and is zero elsewhere.

THE DIVERGENCE THEOREM WITHOUT DIFFERENTIABILITY CONDITIONS, by V. L. Shapiro. May 7, 1957, 3p. (AFOSR-TN-57-232) (AF 18(600)1595) AD 126529 Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 43: 411-412, May 1957.

The differentiability conditions stated previously (On Green's Theorem, Jour. London Math. Soc. 1957) are eliminated. The results are true in k -dimensional Euclidean space, $k \geq 2$ when proper consideration is given to the boundary of the domain of the theorem. Let D_1 be an open set in the plane. Let $X = (x, y)$ and let $C(x, t)$ equal the circumference of the circle with radius t and center X ; define the divergence of the continuous vector field $V(X) = [A(X), B(X)]$ at the point X_0 in D_1 as the limit of $(\pi t^2)^{-1} \int_{C(X_0, t)} A dy - B dx$ as $t \rightarrow 0$ if this limit exists and is finite. Under these conditions the limit is $\text{div } V(X_0)$. Theorem: Let D be a bounded domain in the (x, y) -plane and let C be its boundary. Let E be a closed set of logarithmic capacity zero contained in $D + C$. Suppose that (1) the boundary consists of one of several simple closed rectifiable curves, (2) the

RUT.01:005, 006; RUT.03:002

vector field $V(X) = [A(x), B(x)]$ is defined and continuous in the closure $D = D + C$, (3) at each point X_0 of $D - DE$, $\text{div } V(X_0)$ exists, and (4) $\text{div } V(X)$ is Lebesgue integrable on D ; then $\int_C [A(X)dy - B(X)dx] = \int_D \text{div } V(X)dX$. The theorem is proved by observing that the following lemma in double trigonometric series holds: Let $A(X)$ and $B(X)$ be continuous periodic function of period 2π in each variable with respective

double Fourier series $\sum a_M e^{i(M,X)}$ and $\sum b_M e^{i(M,X)}$.

Let the vector field $V(X) = [A(X), B(X)]$; suppose $\text{div } V(X_0)$ exists and is finite; then $\lim_{z \rightarrow 0^+} \sum i(ma_M +$

$nb_M) e^{i(M,X_0)} - |M|z = \text{div } V(X_0)$. $M = (m,n)$ represent the integral lattice points in the plane, $|M|^2 = m^2 + n^2$, and $(M,X) = mx + ny$.

Rutgers U. [Dept. of Mathematics] New Brunswick, N. J.

THE DIVERGENCE THEOREM FOR DISCONTINUOUS VECTOR FIELDS, by V. L. Shapiro. Sept. 11, 1957, 28p. incl. refs. (AFOSR-TN-57-569) (AF 18(600)-1595) AD 136554; PB 135089 Unclassified

Also published in Ann. Math., v. 68: 604-628, Nov. 1958.

The notation is as follows: $X = (x,y)$ and $C(X_0,t)$ is the circumference of the circle with center X_0 and radius t . $V(X) = [A(X), B(X)]$ is a continuous vector field in the neighborhood of X_0 , and

$$\text{div}^* V(X_0) = \limsup_{t \rightarrow 0} \frac{1}{\pi t^2} \int_{C(X_0,t)} A(X)dy - B(X)dx. A$$

similar definition is given for $\text{div}_* V(X_0)$. If $\text{div}_* = \text{div}^*$ is finite, this common value is $\text{div } V(X_0)$. D is a

bounded domain in the plane with a simple closed rectifiable curve C as its boundary, and Z is a closed set of measure zero contained in the interior of D . With respect to Z , the class of vector fields C_2 is

defined as follows: $V(X)$ is in C_2 if (1) $V(X)$ is continuous in $D + C - Z$, (2) $V(X)$ is in L^2 on D , (3) div_* and div^* are finite in $D - Z$, and (4) $\text{div } V(X)$ exists

almost everywhere in D and is in L^1 on D . Z is said to be a negligible set for the divergence theorem if V is in C_2 implies that the divergence theorem holds

for V with respect to D : $\int_C A(X)dy - B(X)dx =$

$\int_D \text{div } V(X)dX$. The principal result of the analysis is

the following theorem: A necessary and sufficient condition that Z be a negligible set for the divergence theorem is that Z be of logarithmic capacity zero.

HIGH NEGATIVE NUCLEAR POLARIZATIONS IN A LIQUID, by L. H. Bennett and H. C. Torrey. Aug. 8, 1957 [7]p. incl. diagrs. (AFOSR-TN-57-488) (Also bound with its Eleventh Annual Research Report, Jan. 1, 1958) (AF 18(603)6) AD 136550 Unclassified

Also published in Phys. Rev., v. 108: 499-500, Oct. 15, 1957.

Negative nuclear polarizations of the proton spins of up to 65 times the equilibrium value were observed in a simultaneous nuclear magnetic resonance experiment where the electron spin resonance (ESR) was partially saturated in a solution of Na and naphthalene in 1,2-dimethoxyethane. This was named an inverted Overhauser effect (Phys. Rev., v. 92: 411, 1953). The ESR of the ionic free radical formed from an electron in the naphthalene solution was detected by means of an amplitude bridge at 500 mc in a steady field of 17.8 oer. In the same field the proton resonance of the solvent ether was observed at 76.8 kc with a modified Pound-Watkins spectrometer. Small sine wave modulation of the field at 200 c/sec provided the derivative of the absorption curve which was monitored by a phase sensitive lock-in detector. Simultaneously the ESR was partially saturated by the application of a large 50-mc voltage across a 2-turn coil. The experimental values of nuclear polarization were plotted as a function of the degree of saturation of the ESR. A very small degree of

saturation of the ESR caused the depolarization of the nuclei. High saturation levels of ESR caused the proton polarization to increase in the negative direction. When negative polarization was achieved the detection of the NMR was by stimulated emission, indicating that the Overhauser effect could be used for a low-noise molecular amplifier. The observed saturation factor was plotted as a function of RMS. The computed value of s was 1.58×10^{-6} whereas the experimental value was 1.58×10^{-6} . These values are in good accord with the assumption that the protons can only relax to the lattice via their magnetic dipolar interaction with the free electron.

of states at or near the Fermi energy. It is believed that the second, positive part of the change in T_c is due to the increase in γ , and that the correlation between these quantities is in reasonable agreement with the recent theory of other investigators (Phys. Rev., v. 101: 939, 1956). During the course of the work a value of γ was obtained for pure tin which agrees well with a recent calorimetric result. Measurements of the residual resistance ratio of the samples show, as expected, that below the solubility limit this ratio increases linearly with impurity concentration with a slope which depends on the atomic radius of the impurity as well as on its valence.

THE SUPERCONDUCTIVE CRITICAL TEMPERATURE AND THE ELECTRONIC SPECIFIC HEAT OF IMPURE TIN, by E. A. Lynton, B. Serin, and M. Zucker. [1957] [10]p. incl. diagrs. tables, refs. (Also bound with its Eleventh Annual Research Report, Jan. 1, 1958) (AF 18(603)6) Unclassified

Published in Jour. Phys. Chem. Solids, v. 3: 165-174, 1957.

From measurements of the threshold magnetic field as a function of temperature for specimens of tin containing 0.04 to 2.0 at.-% of various impurities the superconductive critical temperature, T_c , of these samples has been obtained, as well as the temperature coefficient, γ , of the electronic specific heat of the normal phase. It was found that the change in T_c produced by the impurities consisted of two parts. There is a decrease which is linearly proportional to the increase in residual resistance ratio and hence to the decrease in electronic mean free path. Superimposed on this decrease there is an increase in T_c . The results also showed that the measurable changes in γ are positive for all solutes, indicating a minimum in the density

STEADY-STATE FREE PRECESSION IN NUCLEAR MAGNETIC RESONANCE, by H. Y. Carr. Sept. 1, 1958 [23]p. incl. diagrs. refs. (AFOSR-TN-58-1052) (AF 18(603)6) AD 206984 Unclassified

Also published in Phys. Rev., v. 112: 1693-1701, Dec. 1, 1958.

A steady-state free precession technique for observing nuclear magnetic resonance is described. A mathematical analysis is presented for certain special conditions, and initial experiments verifying the results of this analysis are reported. This technique provides two opportunities for improving the signal-to-noise ratio. First, it provides a mechanism, similar to that of the "spin echo," for eliminating the effect of the

RUT.03:007 - RUT.03:010

inhomogeneity of the magnetic field on signal strength. This permits the effective use of larger samples. In the second place it provides a steady-state signal which can be observed with a narrow-band detector. Under certain conditions the technique has a broad response as a function of frequency or field. The upper limit to the width of this response is determined by the electronic apparatus supplying the rf pulses rather than the magnet or the nuclear sample. (Contractor's abstract)

TEMPERATURE DEPENDENCE OF NUCLEAR SPIN RELAXATION IN WATER (Abstract), by J. H. Simpson and H. Y. Carr. [1958] [1]p. (AF 18(603)6) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in *Bull. Amer. Phys. Soc.*, Series II, v. 3: 22, Jan. 29, 1958.

The activation energies E_R and E_D of nuclear spin relaxation T_1 and translational self-diffusion D have been obtained for protons in water using nuclear magnetic resonance free precession techniques. These energies have been compared with E_V , the activation energy of T/η where T is the absolute temperature and η is the viscosity. E_R , E_D , and E_V are equal and approximately constant in the region 5-25°C. The three values decrease in the region 35-55°C. E_R decreases at a rate greater than that of E_D and E_V . In the region 65-100°C, E_D and E_V are constant and equal just within the ex-

perimental error; however E_R , although constant, has a value 16% less than that of E_V . This difference is well outside the experimental error. This information provides a basis for re-examination of the theories of liquid structure, the Bloembergen-Pound-Purcell theory of relaxation, the Stokes-Einstein relation, and various properties of water having anomalies near 40°C.

THE LATTICE CONDUCTIVITY OF TIN, by M. Garfinkel and P. Lindenfeld. [1958] [5]p. incl. diagrs. tables, refs. (AF 18(603)6) Unclassified

Published in *Phys. Rev.*, v. 110: 883-887, May 15, 1958.

The thermal conductivities of several impure tin specimens have been measured at liquid helium temperatures. Impurities of antimony, bismuth and indium between 0.1% and 6% were used to lower the electronic conductivity. The conductivities are found to be consistent with the equation $K = \alpha T + \beta T^2$, where the first term may be ascribed to the electronic conductivity and the second to the lattice conductivity. For impurities of 3% or less the values of α , combined with measurements of the residual electrical resistivity, agree to about one per cent with the prediction of the Wiedemann-Franz law. For the same samples β is approximately constant with a mean value of $3.5 \pm 0.4 \times 10^{-4}$ watts/cm deg³. The comparative constancy of this value of β indicates that it is characteristic of the intrinsic conductivity of the tin lattice. (Contractor's abstract)

MAGNETIZATION CURVES OF IMPURE TIN SPECIMENS, by E. A. Lynton and B. Serin. [1958] [3]p. incl. diags. table. (AF 18(603)6) Unclassified

Published in Phys. Rev., v. 112: 70-72, Oct. 1, 1958.

As amplification of the measurements of the flux trapping in large impure tin cylinders, magnetization curves have been obtained in a transverse field for composite specimens made up of about fifty small tin cylinders. The size of these samples made it possible to anneal them well in a short time. In all cases in which the impurity concentration did not exceed the limit of solubility, there was no flux trapped once the external magnetic field was entirely removed. However, the shape of the magnetization curves indicates that flux does migrate out of the specimens as the external field is reduced. In one specimen in which the impurity concentration did exceed the limit of solubility, there was appreciable flux trapping even in zero field. (Contractor's abstract)

CORRELATION OF ELECTRON WAVE FUNCTIONS IN METALS (Abstract), by P. R. Weiss and E. Abrahams. n.d. [1]p. (AF 18(603)6) Unclassified

The electron correlation function is defined as

$$g(r', r; E) = \sum_n \Psi_n^*(r') \Psi_n(r),$$

the sum being understood to be restricted to those values of n which belong to the particular energy E . The wave functions $\Psi_n(r)$ are proper functions of the Schrodinger equation. Particular interest in this function centers on how it is changed by the presence of impurities in metals. A free electron model of the metal is used to calculate the correlation averaged over all possible distributions of the locations of the impurities. The result is, when certain limiting conditions hold,

$$g(r', r, E) = p(E) \frac{\sin(2mE)^{\frac{1}{2}} |r' - r|}{|r' - r|} \exp(-|r' - r|/2\lambda),$$

where $p(E)$ is the density of states at E , and λ is a mean free path. This is just the result proposed by Bardeen; it is derived here from first principles. The essential limitation is that the density of the impurities be sufficiently small that certain multiple scatterings can be neglected. (Contractor's abstract)

SENSITIZATION OF MERCUROUS OXALATE BY DYES, by P. A. van der Meulen and R. H. Brill. Mar. 7, 1958 [7]p. incl. diags. tables. (Sponsored jointly by Squier Signal Lab., Fort Monmouth, N. J. under DA 36-039-sc-15560 and Air Force Office of Scientific Research under AF 18(600)1150) Unclassified

Published in Photographic Science and Engineering, v. 2: 121-127, Oct. 1958.

The adsorption of several sensitizing dyes by mercurous oxalate has been determined. The reflectance spectra of mercurous oxalate with adsorbed dye have been measured. Adsorption is often accompanied by a bathochromic shift of the absorption maxima. The best sensitizers found are Acriflavine, Acridine Orange, Acridine Yellow, and Proflavine; all are strongly adsorbed. Pyronin B and Acridine Red are weakly adsorbed and are feeble sensitizers. In the case of the phthalein dyes the order of sensitization is Erythrosin B > Eosin Y > Rose Bengal > Phloxin B. Erythrosin B, a better sensitizer than Eosin Y, is more strongly adsorbed; however, Rose Bengal does not sensitize as well as Eosin Y even though it is more strongly adsorbed. The cyanine dyes are not notably better sensitizers for mercurous oxalate than the other classes of dyes studied. In general, the spectral range of sensitization for mercurous oxalate by a given dye is virtually the same as the range for silver-halide emulsions. (Contractor's abstract)

ON NEGATIVE ENERGY STATES IN APPROXIMATELY RELATIVISTIC WAVE EQUATIONS, by Z. V. Chrapiviyv. Dec. 15, 1956, 1v. incl. tables, refs. (Technical rept. no. 4) (AFOSR- TN-57-29) (AF 18(600)789) AD 115064 Unclassified

Investigation is made to establish the role of negative energy states in nonrelativistic theory. The Foldy and Wouthuysen reduction method is used. A Dirac Hamiltonian is denoted by κ and the Foldy and Wouthuysen Hamiltonian by h_j . κ is a closed expression and h_j is an infinite series. The operator κ , mixes the components of the spinor ψ ; the 4-component wave equation formed with h_j falls apart into two 2-component equations, one for ψ_1, ψ_2 and one for ψ_3, ψ_4 , and one of the pairs is omitted. The operator h_j is obtained from κ by a succession of canonical transformations. While uncoupling the 2 pairs of the ψ components, the Foldy-Wouthuysen method separates the positive-energy states from the negative-energy states, and the solution of the reduced equation deals with positive-energy states only. This assertion holds for free particles in a weak field. The degree of weakness can be determined by comparing h_j with some other operator which, when used as the Hamiltonian in a 4-component wave equation, prevents mixture to any degree of approximation. The Schrödinger procedure for the one-particle 2-particle cases is summarized, and applications to other Hamiltonians are worked out. In the case of the Breit Hamiltonian, the negative-energy states are not separated by the transformations, and in the case of the Bethe-Salpeter equation the energy states are completely removed. Differences in the 2 equations are discussed.

CORRECTION TO THE LAMB SHIFT DUE TO PROTON CHARGE DISTRIBUTION (Abstract), by E. M. MacKinnon. [1957] [1]p. [AF 18(600)789] Unclassified

Presented at meeting of the Amer. Phys. Soc., Notre Dame U., South Bend, Ind., June 20-22, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 268, June 20, 1957.

Recent high-energy scattering experiments of electrons from protons in polyethylene indicate that the charge distribution of the proton can be represented by

$$4\pi\rho(r) = \frac{200}{3a_H^4} r \exp\left[-\frac{\sqrt{26}}{a_H} r\right], \quad a_H = (0.78 \pm 0.05)f.$$

The matrix element proper to the Lamb shift was re-

calculated using this charge distribution and suitably modified relativistic wave functions. This gives the result, $\Delta E_H = 1057.77 \pm 0.13$ mc, which is in agreement with experiment.

QUASI-RESONANCE AND VARIOUS APPROXIMATIONS IN THE ANDERSON THEORY OF PRESSURE BROADENING (Abstract), by L. J. Kieffer and A. V. Bushkovitch. [1957] [1]p. [AF 18(600)1590] Unclassified

Presented at meeting of the Amer. Phys. Soc., St. Louis, Mo., Nov. 29-30, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 358, Nov. 20, 1957.

Because of the difficulty of applying the P. W. Anderson theory of pressure broadening, simplifications have been proposed. In a recent article by Perkins, Bushkovitch, and Kieffer a simplified theory was outlined in detail and applied to three cases of foreign gas broadening of linear molecules. This paper presents an analysis of this simplified theory and shows that it is equivalent to assuming that all partial cross sections for linear molecules are quasi-resonant and equal to quasi-resonant partial cross section for large J_2 . With this general conclusion as a guide five common van der Waals interactions between linear molecules are examined, and a quantitative estimate of the errors involved in the use of the simplified theory is given.

FOREIGN GAS PRESSURE BROADENING OF OCS (Abstract), by L. J. Kieffer and A. V. Bushkovitch. [1957] [1]p. [AF 18(600)1590] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 44, Jan. 30, 1957.

Previous calculations, using the Anderson theory, of the collision diameters of OCS with He, O₂, and N₂O, using the $J = 1 - 2$ line of OCS, were in reasonable agreement with experiment, and indicated that the perturbing molecule could be treated classically in the case of foreign gas broadening. Two new calculations also using the Anderson theory, have been carried out which support that assumption. The collision-diameter of OCS with O₂ has been recomputed treating the O₂ molecule classically but including terms which were dropped in the previous

STL.02:004; SAU.01.001, 002;
SMI.01:001, 002

calculation due to the complexity and apparent smallness of the terms. The new value 5.48A, is only slightly larger than that previously reported, 5.41A. In the second calculation the perturbing molecule was treated quantum-mechanically. Closed expressions were derived by S_2 and the partial cross section. The value obtained for the collision diameter was 5.61A which is within three percent of the value obtained treating the perturbing molecule classically.

CRITICAL ANALYSIS AND APPLICATIONS OF A QUASI-RESONANT THEORY OF PRESSURE BROADENING OF LINEAR MOLECULES, by L. J. Kieffer and A. V. Bushkovitch. [1958] [8]p. incl. tables. (AF 18-(600)1590) (Also bound in its AFOSR-TR-59-29; final rept.) Unclassified

Published in Jour. Molecular Spectroscopy, v. 2: 558-565, Dec. 1958.

A simplified Anderson theory of the pressure broadening of linear molecules has been critically analyzed and applied to five common types of molecular interactions. It has been shown that the simplified theory is equivalent to assuming that all partial cross sections of the exact Anderson theory are of the same order of magnitude as the resonant partial cross sections. Quantitative estimates of the errors introduced in the partial cross sections of the exact theory by making this simplifying assumption are given. (Contractor's abstract)

THE EVALUATION OF LATTICE INTERACTIONS IN OR NEAR A CUBIC CRYSTAL, by G. S. Durham and B. A.

SIT.01:001 - SIT.01:004

Soderberg. Jan. 1958 [15]p. incl. table. (AFOSR-TN-58-55) (AF 18(600)775) AD 148096 Unclassified

Also published in Jour. Chem. Phys., v. 28: 1201-1206, June 1958.

Procedures, based on the methods of Madelung, have been developed for the evaluation of lattice sums of inverse-power particle-interactions, λa^{-n} , at any point in or near a cubic crystal. Although not as elegant mathematically as those of Hove and Krumhansl, they are more complete in including the important cases of a point near a plane or line of particles, and are sufficiently simple in principle to be understood and applied by anyone with a background in differential calculus. Applications to a face-centered cubic ionic crystal are discussed and, as an example, the dipole-dipole van der Waals energy of a chloride ion before a NaCl half-crystal is calculated. The Algoma meteorite, found in 1887 near Algoma, Wis., was cut and examined macroscopically and microscopically. The meteorite is an example of an ablated tabular discoid or shield shape meteorite. The discoid iron approaches an ellipse with major and minor axes of 22 and 14 cm, respectively; the average thickness is 2 cm. Macroscopic observations indicated a Widmanstätten pattern, swathing kamacite enclosing schreibersite inclusions, and zones of plessite. Microscopic examination revealed Neumann bands, oxide scale, taenite lamellae, and fields of plessite. The following cumulative observations were made after examining the meteorite macroscopically and microscopically: (1) the concave face shows effects of ablation to a lesser degree than the convex face, (2) a 0.1-mm-thick zone of thermal alteration on the convex face probably was a thin layer of flowing molten material in flight, (3) the convex face was the leading face in flight, (4) the curvature of the meteorite is due to ablation and not bending, and (5) a minimum value of 10% of the original mass was lost in ablation.

Also published in Geochimica et Cosmochimica Acta, v. 14: 287-290, 1958.

Data on the composition, form and distribution of tektites are examined in the light of knowledge of high speed impact phenomena to see how strong the evidence is for an impact origin. It is concluded that tektites could be of impact origin, but the arguments are inconclusive. A strong argument against such an origin is the lack of nickel-ferrous materials within the tektite. SIT.01:005 - SIT.01:007

Three classes of extraterrestrial material that reach the earth are discussed. These include (1) interplanetary dust, (2) debris from comets, and (3) meteorites or fragments of planets which once resided between Mars and Jupiter. Estimates of the quantity of material falling to the earth vary from 1 to 10,000 tons per day. The concepts of energy, momentum, and the quality of failure which are considered basic to terminal ballistics are defined. Some practical problems are outlined which concern (1) the possible penetration of the hulls of spaceships, satellites, and intercontinental ballistic missiles by meteoric particles, (2) the effects of surface erosions, and (3) possible damage to equipment. Suggestions for future experimentation include an increase in efforts to detect, identify, and describe meteoric material, an extension of impact studies to higher and higher velocities, and an investigation of the physical processes that operate during meteoric impact.

ORIGIN OF DEEP ELLIPSOIDAL PITS ON LARGE IRON METEORITES, by R. R. O'Neil and J. S. Rinehart. Dec. 12, 1957 [10]p. incl. diagrs. tables. (Technical rept. no. 5) (AFOSR-TN-57-752) (AF 18(600)1596) AD 136741 Unclassified

Large Fe meteorites frequently are morphologically marked by deep ellipsoidal pits, contrasting sharply with the broad shallow pits which are generally attributed to the ablation of the meteorite as it passes through the atmosphere. The Carbo meteorite is morphologically marked by 7 pits, all ellipsoids. On the Quinn Canyon meteorite there are 22 pits, excluding the base which was not presented on the plaster cast from which these observations were made. The major axes of each of the 2 groups of ellipsoidal pits were essentially parallel, and casual inspection of other large Fe meteorites, viz, Canyon Diablo and Grant, showed a similar parallelism of pits. Pit plots on a stereographic net indicated a preferred direction of orientation of the major axes of the ellipsoidal pits of both the Carbo and Quinn Canyon meteorites. It was considered doubtful whether severe local ablation could generate pits all similarly directed, for the axes of these pits are variously inclined to the meteorite surface. No casual relationship exists between direction of air flow and pit axis. Carbo is known to contain large ellipsoidal shaped inclusions of troilite, FeS, a compound whose melting point is below that of Fe. From observation on sections of the meteorite, these nodules are known to be aligned. Quinn Canyon also contains troilite, but reports have not discussed their alignment. There appeared to be little doubt but that the deep pits had their genesis in troilite nodules which were suddenly exposed as a consequence of ablation of material from

the meteorite. Whether the troilite melted out during the flight or eroded out after the meteorite came to rest could not be decided with certainty.

NEUMANN BANDS IN STONY-IRON METEORITES, by R. R. O'Neil and J. S. Rinehart. Dec. 12, 1957 [7]p. incl. illus. (Technical rept. no. 6) (AFOSR-TN-57-753) (AF 18(600)1596) AD 136742 Unclassified

The microstructure of the bits of Fe that occur within stony-Fe meteorites was investigated with a view toward interpreting their mechanical history. Polished and etched sections of stony-Fe meteorites were observed microscopically for mechanical twins (Neumann bands), deformed twins, and evidence of slip. These sections were cut from meteorites obtained from: (1) the Yatoor, India; (2) Tomhannock, N. Y.; (3) Weston, Conn.; (4) Udipi, India; and (5) Vaca Muerta, Chile. Lamellae that had the appearance of Neumann bands developed in the Fe grains of all except the Vaca Muerta meteorite. The 4 specimens with lamellae all revealed a mirror image relationship between the lamellae and the surrounding Fe when etch pits were developed. In addition to etch pits, etch facets and what appeared to be slip lines were further evidence of mechanical strain. In many of the Fe grains, the Neumann bands had a pronounced curvature. In their virgin state, Neumann bands are straight. It was therefore concluded that the grains had been subjected to severe mechanical stresses subsequent to the formation time.

ABLATION OF METEORITES (Abstract), by J. S. Rinehart. [1957] [1]p. [AF 18(600)1596] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 45, Jan. 30, 1957.

A meteorite enters the earth's atmosphere at high velocity (8 km/sec to 70 km/sec), suffers rapid loss of material through aerodynamic heating and abrading forces, but survives passage and finally comes to rest on the ground. The ablation of high-velocity missiles is a most complex fluid dynamics problem. Post mortem examination of meteorites can suggest salient aspects of the problem. Surface features of a large number of meteorites have been studied. Very little can be said about the total amount of material lost. Meteorite

SIT.01:008 - SIT.01:011

size and material are critical factors. Small (up to 3 in. in diam) meteorites are smoothly sculptured; large stones exhibit shallow elongated pits or depressions (2 cm by 1 cm by 5 mm deep); and large irons, very deep pits (5 cm in diam and 3 cm deep). The number, distribution, and size of the depressions on a particular surface or portion of surface depends upon how the surface element is oriented with respect to the direction of flight. Pronounced irregularities of shape increase ablation. Finally, heat from the surface penetrates at most only a few millimeters into the meteorite.

METEORITIC MATTER AT THE PLACE OF FALL OF THE TUNGUSKA METEORITE, by A. A. Yavnel, tr. by F. W. Wright and P. W. Hodge. Feb. 19, 1958 [9]p. incl. illus. (Technical rept. no. 7) (AFOSR-TN-58-244) (AF 18(600)1596) AD 154146 Unclassified

Also published in Soviet Astron., v. 1: 769-772, Sept.-Oct. 1957 (trans. of Astronomicheskii Zhur., v. 34: 794-796, July 20, 1957).

In an attempt to shed some light on the nature of the composition of the Tunguska meteorite, which fell in the Siberian taiga in 1908, investigations were made of surface and subsurface soil samples taken from the region of fall. Visual observation of the samples indicated that the material consisted basically of black crystals of magnetite amalgamated with rock. In addition, tiny particles of three types were found: (1) metallic particles of silvery-white color, resembling minute grooved petals and scrolls, reminiscent of chips of the size of tenths of mm in length; (2) oxidized metallic particles somewhat brick-shaped with maximal dimensions up to several mm; and (3) black shiny spherules, consisting apparently of magnetite, 30-60 μ in diam. Spectra analysis of all except the spherules revealed that the "chips" contained 7% nickel and 0.7% cobalt, and the oxides - 4% nickel and 0.3% cobalt. The data obtained indicated that the metal particles have a composition typical of an iron meteorite and are different from artificial iron alloys. Comparison of the data with results of the soil investigation at the place of fall of the Sikhote-Alin meteorite shows great similarity.

METEORITES AND BALLISTICS, by J. S. Rinehart. Apr. 21, 1958, 1v. incl. illus. diags. tables, refs. (Technical rept. no. 8) (AFOSR-TN-58-354) (AF 18(600)1596) AD 154259 Unclassified

Also published in Selected Topics on Ballistics, Cranz Centenary Colloquium, Freiburg U. (West Germany) (Apr. 21-25, 1958), London, Pergamon Press, 1959, p. 88-116.

A meteorite enters the earth's atmosphere at high velocity (11 km/sec to 72 km/sec), is subjected to powerful aerodynamic forces, suffers rapid loss of material through aerodynamic heating and abrasion, but occasionally survives passage and finally may strike the ground, producing an impact crater. The phenomena involved in these encounters of a meteorite with our atmosphere and our lithosphere are ones commonly met with in ballistic studies. For example, the surface features of a number of aerodynamically sculptured meteorites are germane to the complex ballistics problem of ablation of high velocity missiles. Meteorites striking the earth have produced the largest known impact craters and contribute significantly to the physics and chemistry of high speed impact. This paper discusses recent studies in the inter-related areas, meteoritics, ballistics, and astrobballistics, with specific reference to ablation fundamentals, the shapes and surface features of various meteorites, and the nature of impact craters. EVIDENCE ON THE NATURE OF AIRFLOW AROUND STONY METEORITES IN FLIGHT, by E. P. Henderson and D. T. Williams. Apr. 29, 1958, 1v. incl. illus. diags. (AFOSR-TN-58-436) (AF 18(600)1596) AD 158240 Unclassified

The flow markings on the surface of a series of stony meteorites were photographed and rationalized in the light of simple aerodynamic theory. Complete agreement between theory and experiment was demonstrated as relating to the orientation of the objects during flight, and separation of flow from bluff objects near the edges. The pits which are universally observed characteristics of meteorites showed flow lines inside. Some of the meteorites showing no flow lines were identified as being oriented in flight by other characteristics, leading to the conclusion that flow lines are not a unique indicator of non-tumbling flight. The petrography (particularly textures) and petrology of stony meteorites were studied as a key to the origin, evolution, and constitution at depth of the earth. Classifications, textures and mineralogy, and chemical compositions of numerous meteorites are given as well as 19 microphotographs. Discussions on the solar system evolution and the condensation of the chondrules included topics on (1) currently considered hypotheses for the formation of the solar system, (2) stellar temperatures and pressures, (3) effect of rotations, (4) phase equilibria, (5) adiabatic cooling, (6) condensation processes, (7) chondrule-dust fractionation, (8) optical measurements of Fe content of olivine in chondrites, and (9) accretion. The classification, mineralogy, textures, and chemical compositions of nonchondrites are presented and the relation of nonchondrites to chondrites is discussed. The topics covered in a discussion of parent meteorite planets encompassed: (1) a review of the central-melting model; (2) enstatite chondrites and aubrites, (3) the stony-irons, ureilites; (4) howardites and breccias, (5) shergottites, (6) mesosiderites, (7) occluded gases and the carbonaceous chondrites, and (8) amphoterites. A detailed study is presented of the theoretical and experimental aspects of the Coanda effect. The objectives of this research were (1) to define the physico-mathematical and experimental characteristics of the whole Coanda effect; (2) to verify experimentally its application to Coanda nozzles; and (3) to investigate the possible utilization of the "effect" in the design and construction of Lenticular aerodynes.

NEW PRODUCTS FROM THE REACTION OF BENZOYL PEROXIDE WITH BENZENE, by D. F. DeTar and R. A. J. Long. June 13, 1958, 3p. (AFOSR-TN-58-602) (AF 49(538)88) AD 162127; PB 138983 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 80: 4742-4743, Sept. 5, 1958.

The thermal decomposition of benzoyl peroxide in benzene in a nitrogen atmosphere has been found to produce two new products, which are tetrahydroquaterphenyl and dihydrobiphenyl. The phenylcyclohexadienyl radical is shown to be an intermediate in the biphenyl formation. The production of biaryl products in a solvent such as nitrobenzene is believed to depend on the conditions of: (a) the relative rates of formation of the isomeric substituted phenylcyclohexadienyl radicals, and (b) the subsequent possible differing rates of these radicals.

NON-WAVEGUIDE METHODS OF MILLIMETER WAVE TRANSMISSION, by R. G. Fellers. [1957] [15]p. incl. illus. diagrs. (AF 18(603)43) Unclassified

SCU.03:003; SCU.01:002, 003

Published in Proc. First Tri-Service Millimeter Wave Symposium, Army Signal Engineering Labs., Fort Monmouth, N. J., Sept. 10-11, 1957, p. 25-39.

One difficulty encountered in the use of millimeter wavelengths is the excessive attenuation of rectangular dominant-mode waveguide in this frequency range. Several possible solutions to the high attenuation problem have been proposed and are discussed. The use of a dielectric-rod waveguide in a hybrid dipole mode has been investigated by Chandier and Elsasser of the RCA Labs. By selection of a rod small in diam in terms of wavelength very low attenuation can be obtained. Such a small diam rod is characterized by fields which extend far beyond the rod and requires exciters of large dimensions. Under this low-loss condition radiation occurs from bends in the guide. It appears from these difficulties that one of the principal uses of dielectric rods is in a flexible waveguide of moderate attenuation where the field is virtually confined to the interior of the rod. The circular hollow pipe waveguide in the TE_{01} mode shows much promise as a low loss transmission medium. Experiments have indicated that extremely low loss can be obtained, i.e., several decibels per mile. Some problems have arisen due to the TM_{11} mode which is produced in bends and similar irregularities, but has been eliminated in part by using waveguides made of a helix or of annular rings imbedded in lossy material. Some difficulty has also been encountered in the design of a satisfactory broad-band compact launcher for this mode, but it still appears that this approach has much to recommend it. As an alternative to either of the above schemes, it is suggested that a free space system of transmission be utilized within radar or communications installations to replace a waveguide transmission system.

A CIRCULAR POLARIZATION DUPLEXER FOR MILLIMETER WAVES, by R. G. Fellers. Nov. 1, 1958, 12p. incl. illus. diags. (AFOSR-TN-58-771) (AF 18-603)43) AD 201774, PB 138740 Unclassified

Also published in Trans. Amer. Inst. Elec. Engineers, v. 78 (Part 1): 934-937, Jan. 1960.

A circular-polarization duplexer is described for use in the millimeter wavelength range. Such a duplexer finds its field of application in any system which utilizes the same antenna for simultaneous transmission and reception, as for example, a continuous-wave radar. The millimeter wavelengths are here defined as covering the range from 1 to 10 mm (frequency range 30,000 to 300,000 mc).

SYSTEMS OF LINEAR DIFFERENCE EQUATIONS AND SYSTEMS OF LINEAR DIFFERENTIAL EQUATIONS WHICH SATISFY CONDITIONS AT TWO POINTS, by T. Fort. Apr. 1957, 8p. (AFOSR-TN-57-174) (AF 18(603)-23) AD 126469 Unclassified

The difference equations:

$$y_k(i+1) = a_{k1}(i)y_1(i) + a_{k2}(i)y_2(i) + \dots + a_{kn}(i)y_n(i)$$

for $1 \leq k \leq n$, are defined to be representable in the following matrix form $\Gamma(i+1) = M(i)\Gamma(i)$. The i and k are limited to integral values and the $a_{kt}(i)$ are defined when $0 \leq i \leq b$. The solution of the set of equations is a set of functions, $y_1(i), y_2(i), \dots, y_n(i)$ which satisfy the equations at all points of $0 \leq i \leq b$. No gain in generality is found if $0 \leq i \leq b$ is replaced by $a \leq i \leq b$. It is shown that there exists one and only one solution of the set of difference equations taking on arbitrary prescribed values at 0. A set of analogous differential equations is studied by the use of a similar form of analysis.

LINEAR DIFFERENCE AND DIFFERENTIAL EQUATIONS SATISFYING CONDITIONS AT MORE THAN ONE POINT, by T. Fort. Technical rept. June 1957, 9p. (AFOSR-TN-57-307) (AF 18(603)23) AD 132378 Unclassified

Also published in Proc. Amer. Math. Soc., v. 9: 287-292, Apr. 1958.

Investigation is made of linear difference and differential equations which satisfy conditions at more than one point. Sufficient conditions on the coefficients are given so that a solution of a system of linear equations exists which consists of a set of functions, some of which take on prescribed values at one point, and others at other points. The approach to differential equations is through difference equations. The system of difference equations

$$\text{considered is } y_v(i+1) = \sum_{\mu=1}^n a_{v\mu}(i)y_\mu(i), \text{ where } v =$$

$1, \dots, n$; i is limited to integral values, and the coefficients $a_{v\mu}(i)$ are defined when $0 \leq i \leq b$. The set of differential

$$\text{equations considered is } \frac{dy_v}{dx} = \sum_{\mu=1}^n g_{v\mu}(x)y_\mu, \text{ where } v =$$

$1, \dots, n$, and the $g_{\mu\nu}(x)$ are continuous over the integral $0 \leq x \leq b$.

A PROBLEM OF RICHARD BELLMAN, by T. Fort. Technical rept. Aug. 1957, 5p. (AFOSR-TN-57-542) (AF 18(603)23) AD 136530 Unclassified

Also published in Proc. Amer. Math. Soc., v. 9: 282-286, April 1958.

Given the Sturm-Liouville problem (1) $u'' + \lambda [f(x) + \epsilon g(x)]u = 0$, (2) $u(0) = u(1) = 0$, where $f(x)$ and $g(x)$ are continuous functions over $[0, 1]$ with positive minima, and where λ_1 is regarded as the smallest characteristic value as a function of ϵ : determine whether λ_1 is an

analytic function of ϵ for $R(\epsilon) \geq 0$, and locate the singularity nearest the origin ($\epsilon=0$) (R. Bellman, Bull. Amer. Math. Soc., Jan. 1957). The method of differences is used. Regard $f(x)$ and $g(x)$ defined as continuous functions $-n \leq x \leq 1+n$ where $n > 0$ is arbitrarily small; assume $|f(x)| < N$, $|g(x)| < N$, where N is constant. Let $x_1 = 0, 1/n, 2/n, \dots, 1$ and consider

the difference equation (3) $n^2 \Delta^2 y(x_1) + \lambda [f(x_1) + \epsilon g(x_1)]y(x_{1+1}) = 0$ side by side with (1). The following theorems are proved: I. Let $u(x, \lambda, \epsilon)$ be a solution of (1) where $u(0, \lambda, \epsilon) = 0$ and $\frac{\partial}{\partial x} u(0, \lambda, \epsilon) = 1$; let $y(x, \lambda, \epsilon)$

be a solution of (3) such that $y(0, \lambda, \epsilon) = 0$ and $n \Delta xy(0, \lambda, \epsilon) = 1$; then when $n \rightarrow \infty$, $y(x, \lambda, \epsilon)$ approaches $u(x, \lambda, \epsilon)$ uniformly in x, λ, ϵ so long as $0 \leq x \leq 1, |\lambda| < M, |\epsilon| < M$, where M is a constant but otherwise arbitrary. Moreover, $u(x, \lambda, \epsilon)$ and $y(x, \lambda, \epsilon)$ are each expressible as power series in λ , where, when $n \rightarrow \infty$, the coefficients of the various powers of λ in the series for y approach uniformly the coefficients of like powers of λ in the power series for u . II. The function $\lambda_1 = X(\epsilon)$ obtained from

$u(1, \lambda_1, \epsilon) = 0$ for real ϵ can be analytically extended over any finite region not including the negative axis of reals; its singularity nearest the origin is $\min(-\frac{f(x)}{g(x)})$ when x is on $[0, 1]$.

LIMITS OF THE CHARACTERISTIC VALUES FOR CERTAIN BOUNDARY-VALUE PROBLEMS ASSOCIATED WITH DIFFERENCE EQUATIONS, by T. Fort. [1957] 11p. incl. table. (AF 18(603)23) Unclassified

Published in Jour. Math. and Phys., v. 35: 401-407, Jan. 1957.

The difference equation $\sum_{v=1}^{\mu} \Delta_{i_v} \{k_v(i_1, i_2, \dots, i_{v-1}, i_{v+1}, \dots, i_{\mu}) \cdot \Delta_{i_v} y(i_1, i_2, \dots, i_{v-1}, i_v, i_{v+1}, \dots, i_{\mu})\} + \left[\frac{\lambda}{n} - s(i_1, i_2, \dots, i_v, \dots, i_{\mu}) \right] y(i_1, i_2, \dots, i_v, \dots, i_{\mu}) = 0$.

It is assumed that i_1, i_2, \dots, i_{μ} are limited to integral values and that k and s are defined when $0 \leq i_q \leq m_q$, $q = 1, 2, \dots, \mu$ and that $k > 0, s > 0$. The point set for the fundamental domain is associated with an equation for each of the points. Boundary conditions for the y values on the boundary of the fundamental domain give m homogeneous linear equations in m variables. The characteristic equation, represented by the determinant of coefficients equated to zero so as to investigate the solutions, is solved as an equation in $\frac{\lambda}{n}$ and the roots are considered as characteristic values for the problem.

PARTIAL LINEAR DIFFERENCE EQUATIONS, by T. Fort. [1957] [7]p. (AF 18(603)23) Unclassified

Published in Amer. Math. Monthly, v. 64: 161-167, Mar. 1957.

In abbreviated notation, the equations studied are of the form

$$\sum \{k_{ab}(i, j)y(i+a, j+b): (a, b) \in P\} = R(i, j), (i, j) \in S,$$

where P is a given finite set of ordered pairs of integers, and $R(i, j)$, as well as $k_{ab}(i, j)$ for each $(a, b) \in P$,

is a given function of (i, j) whose domain S is the set of all integral points in a fixed rectangle. Particular attention is paid to the case where P is the "five-point pattern" $\{(-1, 0), (0, -1), (1, 0), (0, 1), (0, 0)\}$. The domain of a solution y is the set $\{(i+a, j+b): (i, j) \in S;$

$(a, b) \in P\}$. Auxiliary linear conditions, usually boundary conditions, are sometimes imposed. In this context, consideration is given to the concepts of fundamental domain, fundamental system of solutions, compatibility of a system, and Green's function.

A PROBLEM IN LINEAR DIFFERENTIAL EQUATIONS, by T. Fort. July 1958, 5p. (AFOSR-TN-58-619) (AF 18(603)23) AD 162148 Unclassified

Also published in Proc. Amer. Math. Soc., v. 10: 300-303, Apr. 1959.

Given the equation $u'' + (1 + \lambda g(x))u = 0$ with $\int_0^1 |g(x)| dx < \infty$ with $u_1(x)$ as the solution of this equation with the initial data $u_1(0) = 0$, and $u_1'(0) = 1$. It is known that $u_1(x) \sim r(\lambda) \sin(x + \theta(\lambda))$. Following a suggestion of Bellman, the dependence of the analytic properties of $r(\lambda)$ and $\theta(\lambda)$ on the complex parameter λ have been studied. It is shown that $r(\lambda)^2$ is an entire function

and that $\cos \theta(\lambda)$ is analytic and regular except at the points where $r(\lambda) = 0$. This is done by considering first an analogous problem for a difference equation and then passing to the limit.

STUDIES OF POSITRON LIFETIMES IN SOLIDS by A. P. French and A. R. Lowrey. Final rept. 1958, 55p. incl. illus. diagrs. tables, refs. (AFOSR-TR-58-63) (AF 49(638)74) AD 158241 Unclassified

The purpose of this work was to study the effect of an internal electric field on the mean lifetime of positrons in a ferroelectric material. The internal electric field can effectively be "turned on or off" by raising or lowering the samples' temperature above or below the Curie temperature. A fast coincidence circuit (resolving time approximately 3 msec) was assembled. The components not commercially available were constructed and the equipment was calibrated. Decay curves were run for several materials, some of which have been previously studied, (aluminum, teflon, polyethylene, and plexiglas). The results compare favorably with measurements obtained by others. The decay curve was run for Rochelle Salt, a ferroelectric crystal with an internal field of approximately 800 esu between the temperatures 255°K and 297°K. Several measurements were taken with the sample above the critical temperature of 297°K, and the lifetime was found to consist of one component, $\tau_1 = (5.25 \pm 0.25) \cdot 10^{-10}$ sec. DERIVATIVES OF SULFENIC ACIDS. XXIX [a]. THE CHARACTERIZATION OF CERTAIN STEROLS WITH 2,4-DINITROBENZENESULFENYL CHLORIDE, by R. B. Langford and N. Kharasch. [June 1957] [6]p. incl. table. (AFOSR-TN-57-295) [AF 18(600)844] AD 132366 Unclassified

Also published in Jour. Org. Chem., v. 22: 1673-1675, Dec. 1957. (Title varies)

The pyridine-catalyzed reactions of 2,4-dinitrobenzenesulfonyl chloride (I) with testosterone, 19-nortestosterone, 17-methyltestosterone and 11- α -hydroxyprogesterone are described. Evidence is presented for the conclusion that the products are sulfonate esters, formed by the reactions of I with the alcohol functions. It is suggested that these reactions, coupled with chromatographic separations of mixtures of the derivatives and regeneration of the sterols from the esters, which

SOC.02:008; SOC.03:003, 004; SOC.04:004, 005

has been achieved, may prove of value in isolation studies in this field of work. The synthesis of octadecyl 2,4-dinitrobenzenesulfonate is also reported. (Contractor's abstract)

NORBORNANE, by J. A. Berson and S. Suzuki. [Dec. 1958] [28]p. incl. diagrs. refs. (AFOSR-TN-58-1131) (AF 18(600)1544) AD 207976 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 81: 4088-4094, Aug. 5, 1959.

(-)-exo-Acetylnorbornane of known optical purity is prepared by the sequence (-)-exo-norbornanecarboxylic acid \rightarrow acid chloride \rightarrow (-)-exo-ketone. The optical rotation of enantiomerically pure exo-norbornyl acid phthalate is established by analysis of a partially resolved sample for enantiomer content by isotope dilution of exo-

norbornyl acid phthalate-C¹⁴. Combination of this result with data of Winstein and Trifan affords rotations of enantiomerically pure exo-norborneol and exo-norbornyl acetate. Perbenzoic acid of the active ketone gives exo-acetate with 94.2-100% retention of optical purity, indicating less than 2.9% attack at C.1. The implications of the results for an understanding of the type of hybridization in the transition state of 1,2-rearrangements is discussed. (Contractor's abstract)

Methods of computation of the sediment volume, which is to be utilized as a quantitative criterion of particle interaction, are presented along with some results for spherical particles and for simulated rod-like particles built of aggregates of spheres. The computational scheme was found adaptable for obtaining the sediment volume and sediment structure for a wide variety of particle shapes and assumed mechanics of particle interaction. The simplest type of interaction, rigid cohesion on first contact between particles, appeared to apply accurately to systems of glass spheres in nonpolar media containing small amounts of water. In addition to packing volume, the computational scheme leads to information about the structure of the sediment which may be useful in the estimation of interparticle forces. In the model investigated the number of multiparticle contacts diminished noticeably as the size distribution widened. (ASTIA abstract)

[COLLOID STATISTICS], by H. L. Frisch. Final rept. Aug. 1958, 3p. (AFOSR-TR-58-77) (AF 18(603)122) AD 158344 Unclassified

Work under the contract centered around 3 general aspects: (1) relaxation times in dilute systems, (2) phase transformations in colloidal systems, and (3) gelation theory. Experiments were performed to determine the time lag in the nucleation of second phase colloids. In the study of gels it was assumed that: (1) they are formed by growing networks of rigid ovaloids at a certain critical concentration strongly influenced by the ratio of radii of the ovaloids, and (2) that the density difference between the gel particles and the solvent is zero, eliminating the effect of gravity. The spontaneous growth of the network is then treated in first approximation as if it were a mathematical tree in analogy with the Flory gelatin theory of polyfunctional condensation polymers.

AN APPROACH TO EQUILIBRIUM, by H. L. Frisch. [1958] [8]p. incl. refs. (In cooperation with Bell Telephone Labs., Murray Hill, N. J.) [AF 18(603)122] Unclassified

Published in Phys. Rev., v. 109: 22-29, Jan. 1, 1958.

The concept of statistical equilibrium of an isolated mechanical system is modified to mean a state in which the observable local macroscopic properties such as the local density of particles, mean energy, temperature, entropy, etc., have attained their equilibrium values, i.e., the values which would be obtained

from the density in phase space which corresponds to the appropriate stationary solution of Liouville's equation. The approach to equilibrium in time in this sense (i.e., for the local properties which are suitable averages over the action variables of the system) of a wide class of multiply periodic systems is demonstrated under the condition that a local property exists initially. The question of extension of this ergodic result to less restricted mechanical systems has been discussed and the relationship to ergodic theory and coarse graining indicated. The general transport theory and the approach to spatial uniformity of a sufficiently ideal gas are investigated by using as a model a gas of elastic hard-sphere molecules with vanishing diameter. In particular it is shown that under suitable conditions the diffusion in density satisfies Fick's laws and the conduction of heat satisfies Fourier's law, albeit with time-dependent transport coefficients. A METHOD OF ALLEVIATING THE EFFECTS OF THE BOUNDARY LAYER SHOCK-WAVE INTERACTION AT COMPRESSION CORNER, by J. C. Williams, III. May 31, 1958, 46p. incl. illus. diags. (USCEC rept. no. 40-202) (AFOSR-TN-58-344) (AF 18(600)1145) AD 158248 Declassified

Experimental results are presented which indicate that the undesirable effects of boundary layer separation at a compression corner in supersonic flow can be reduced by a slight modification of the body geometry just ahead of the corner. This modification consists of introducing a rearward facing step of small depth and of moderate length just ahead of the corner. The experimental

results show that the pressure distribution after the compression corner (an inclined wedge in this case) is improved and that the length of forward influence of the separated region, due to the corner, is decreased by this simple change in geometry. Improvements such as these have direct application to the design of deflected control surfaces and ramp (or spike) type diffusers. The present investigation was carried out at a Mach number of 2.54 in the University of Southern California Supersonic Wind Tunnel Facility. (Contractor's abstract)

ON THE LAMINAR BOUNDARY LAYER WITH ARBITRARY PRESSURE GRADIENT AND WALL TEMPERATURE DISTRIBUTIONS, by J. C. Williams, III. July 31, 1958, 17p. incl. diagr. (USCEC rept. no. 40-204) (AFOSR-TN-58-583) (AF 18(600)1145) AD 162103 Unclassified

The laminar boundary layer equations for a compressible heat conducting gas are first transformed by the Stewartson transformation. The transformed equations are then attacked by the Blasius series procedure which is well known in incompressible boundary layer theory. This procedure yields a number of pairs of simultaneous ordinary differential equations which, when solved, define the boundary layer on a body with an arbitrary pressure distribution. The method also allows for an arbitrary wall temperature distribution or an arbitrary heat transfer rate distribution along the body. The resulting equations can probably best be solved on modern high speed computing machines. (Contractor's abstract)

AN INVESTIGATION OF SHOCK WAVE-BOUNDARY LAYER INTERACTION, by R. L. Chuan. Aug. 1958, 32p. incl. illus, diagrs. (USCEC rept. no. 40-101) (AFOSR-TR-58-145) (AF 18(600)1145) AD 302753 Declassified

An experimental study is made of the strong interaction between a boundary layer and a supersonic inviscid outer flow in the vicinity of a compression corner. Attempts are made to assess the validity of certain assumptions made in the Crocco-Lees theory of Interaction. A simple method is devised, on the basis of the experimental findings, for the control of a laminar boundary layer upstream of a compression corner. (Contractor's abstract)

INVESTIGATION OF SUPERSONIC DIFFUSER INSTABILITY, by A. C. Brown. Final rept. Nov. 30, 1956, 1v. incl. illus, diagrs. (USCEC rept. no. 41-101) (AFOSR-TR-57-1) (AF 18(600)1167) AD 115038 Unclassified

Investigation of the unstable flow through four different types of diffuser has been made. These were a pitot type intake, an axisymmetric model with a center body, a ramp and a scoop intake. The pitot was unique in that its only instability was at low and zero mass flow, and was of the acoustic organ pipe type. The other intakes were characterized by a high frequency oscillation at low mass flows, and a more complex phenomenon, known as buzz, at higher mass flows. It is believed that all diffusers which have a surface ahead of the inlet will have these two types of oscillation present to some degree, and that they will be of the form described in this report. The high frequency oscillation was caused by over-blowing of the fundamental organ pipe frequency due to higher energy content of the air flow past the lip for these three intakes. The buzz phenomenon can be broken down, for analysis purposes, into four phases, of which the second is the high frequency oscillation associated with low mass flows. The first is a statically divergent forward movement of the shock wave, whose origin has not yet been determined, the third is a rapid rearward movement of the normal shock from a position well forward of the lip to a supercritical position, and the final phase of the cycle is a slow relaxation of the shock wave to its original position. (Contractor's abstract)

An analysis was made of the theoretical investigation of the rate of deposition of solid nitrogen on a cooling surface in order to obtain design criteria for the condensing chamber of the two-phase wind tunnel. Results indicate that it is possible to solve the integral equation characterizing the process through the use of experimental data obtained from a study made at the A. D. Little Lab., and that the mass-flow requirements of the tunnel can be met with a condensing surface area of about 60 sq ft for runs lasting up to ten hr.

Presented at meeting of the Fluid Dynamics Div. of the Amer. Phys. Soc., Lehigh U., Bethlehem, Pa., Nov. 25-27, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 3: 288, June 19, 1958.

For the production of condensation-free hypersonic flow in a wind tunnel it is proposed to add energy to the electrons in the air downstream of the throat by high frequency electrodeless discharge, and allow electron energy to go into random kinetic energy of the molecules in the decay process. Previous work in this respect has dealt only with the discharge process, measuring the energy that can be added to the plasma by various types of discharges. The present work examines the decay processes in an attempt to channel as much of the electron energy as possible into raising the temperature of the gas, by preventing losses by ambipolar loss mechanism. Inhibition of ambipolar diffusion by means of an axial, constant magnetic field is examined, as well as the attendant possibility of having such an inhibiting effect nullified by drain diffusion resulting from hydromagnetic instability. An experimental investigation is being initiated. (Contractor's abstract)

A small experimental apparatus has been assembled to ascertain the feasibility of using the decay of a rf discharge-formed plasma to transfer energy to a supersonic air stream. The apparatus, shown schematically, consists of a glass Laval nozzle, rf electrodes surrounding it and a dc magnetic field coil producing a longitudinal field of 1000 gauss in the flow. The magnetic field is intended to reduce ambipolar diffusion of charge carriers to the nozzle wall, so as to allow a maximum of volume recombination within the gas flow to effect heating of the gas.

THE ABSORPTION SPECTRA OF HILL REACTION OXIDANTS, by R. J. Marcus, J. L. Hatchett, and K. M. Sancier. June 11, 1957, 15p. incl. diagrs. tables, refs. (Rept. no. 6; technical note no. 1) (AFOSR-TN-57-304) (AF 18(603)7) AD 132375 Unclassified

Presented at Symposium on Photochemical Storage of Energy, Dedham, Mass., Sept. 3-7, 1957.

Also published in Science, v. 127: 647-648, Mar. 21, 1958.

The absorption spectra of eight Hill reaction oxidants were examined, and compared to the absorption spectra of nine compounds which are inactive in the Hill reaction. These spectra showed that all compounds which are Hill reaction oxidants absorb light at wavelengths corresponding to the blue absorption peak of chlorophyll. Cobaltioxalate, whose Hill reaction activity was predicted on the basis of this correlation, has been shown to be a good electron acceptor. Further work on this problem has led to the conclusion that the oxidation-reduction potential is not the only factor influencing Hill reaction activity of various electron acceptors. An additional factor appears to be the matching of electronic levels of chlorophyll (electron donor) and of the oxidant (electron acceptor) which is required of electron transfer reactions by the Franck-Condon principle. This apparent additional restriction on the choice of Hill reaction oxidants should be useful in the search for additional compounds which will store energy in the course of their Hill reaction activity.

MASS SPECTROMETER STUDIES OF ALKALI METAL CHLORIDE VAPORS, by T. A. Milne, H. M. Klein, and D. Cubicciotti. Feb. 1958 [5]p. incl. table, refs. (Technical note no. 1) (AFOSR-TN-58-148) (AF 49(638)89) AD 152175 Unclassified

The importance of polymers in the ionized vapor phase of solid-vapor alkali metal systems has been studied to clarify conflicting results reported elsewhere. Five alkali-chloride salts were used and it was observed that dimer alkali complexes were present in each case while trimer complexes were observed for LiCl and NaCl. It has been found that the stabilities of the dimers increases uniformly with decreasing atomic number of the cation. A method has been proposed to study the relationship between measured ion intensities and molecular concentrations of the species in the vapor. A two-temperature Knudsen cell is employed to produce equilibrium polymer vapors. The intensities of the n types of polymer ion beams are measured at each of n temperatures for the top part of the Knudsen cell, and the n-1 partial pressure ratios are determined from equations involving ion beam intensities and cell temperatures. The ratio of constants of proportionality of ion beam intensity and partial pressure can be calculated, and from this the ratios for the ionization cross sections for the species can be determined if the relative response of the spectrometer to the different ion beams is determined.

A CALCULATION OF THE ENERGIES OF GASEOUS ALKALI HALIDE DIMER MOLECULES, by T. A. Milne and D. Cubicciotti. May 1958, 15p. incl. diagrs. tables, refs. (Technical note no. 2) (AFOSR-TN-58-475) (AF 49(638)89) AD 158286; PB 135405 Unclassified

Also published in Jour. Chem. Phys., v. 29: 846-851, Oct. 1958.

The energies of formation of gaseous alkali halide dimer molecules from the monomers have been calculated using a model suggested by Pauling. The dimers were found to be from 40 to 60 kcal more stable, energetically, than their separated monomers. These results are in agreement with the experimental data available. The free energies of dimerization were estimated and used to predict the trends observed in the ratio of monomer to dimer for several salts. It was found that the energies of dimers with different cations were slightly more negative than the average of the two pure dimers. Some experimental results supporting this conclusion are presented. (Contractor's abstract)

The application of the simple Pauling model to the calculation of the binding energies of the gaseous monomer and dimer alkali halide molecules has been extended to include the case of the trimer molecule. Consideration of the possible structures for a complete ionic trimer molecule has led to the decision that in the absence of directed bonds the six member planar ring will be the most stable. Thus the energies of such structures for the alkali halides were calculated with the Pauling model. The energy has been calculated by means of a numerical variational procedure. The energies of alkali halide M_2X^+ molecule ions were also calculated.

Let B be a Banach space and S a uniformly bounded semigroup of operators on B . S is called almost periodic (a.p.) [weakly almost periodic (w.a.p.)] if each orbit is conditionally compact in the norm topology [weak operator topology] of B . In both cases, the closure \bar{S} of S in the algebra of bounded operators on B supplied with the weak operator topology is a compact semigroup. Some results are announced, without proofs, in which such a "compactification" plays a role. (Math. Rev. abstract)

HOMOMORPHISMS OF CERTAIN ALGEBRAS OF MEASURES, by I. Glicksberg. Dec. 31, 1958, 25p. (Technical note no. 2) (AFOSR-TN-58-1042) (AF 49(638)294) AD 206572; PB 138743
Unclassified

Also published in Pacific Jour. Math., v. 10: 167-191, 1960.

Methods are discussed for determining all norm-decreasing homomorphisms of certain algebras of measures (similar to the Lie algebras) on G into the algebra of measures on H ; G and H are locally compact groups. Let $M(G)$ denote the Banach algebra of all finite, complex, regular Borel measures on G (with convolution as multiplication). $L_1(G)$ forms a subalgebra of $M(G)$, in fact an ideal. Because of this, knowledge of the norm-decreasing homomorphisms of L_1 algebras into algebras of measures on another group leads to the determination of all norm-decreasing isomorphisms between $M(G)$ and $M(H)$. When G and H are abelian, for each norm-decreasing isomorphism of a (not necessarily closed) subalgebra of $M(G)$ which contains $L_1(G)$ with a similar subalgebra of $M(H)$, there is an isomorphism γ of G onto H and a fixed character \hat{g} of G for which $T\mu$ is just the measure $\hat{g}\mu(\hat{g}u(dx) = \hat{g}(x)u(dx))$ transported to H via γ , where $TL_1(G) = L_1(H)$ and T is an isometry. In the noncommutative case, only the analogous result can be obtained for compact groups and T must be assumed to be an isometry.

A survey is presented of the theories of buckling of structural elements whose material is subject to creep deformations. Two fundamentally different approaches to the solution of the buckling problem are discussed. In one, the structural element is assumed to be perfect and perfectly centered under the loads, and buckling is initiated by a disturbance in the configuration. In the second, the creep deformations begin in consequence of the deviation of the unloaded centerline or median plane of the structural element from the line of load application. In both cases the element has a finite lifetime. A critical time of creep buckling is defined beyond which the element cannot be used to carry the prescribed loads. (Contractor's abstract)

A THEORY OF ELASTIC, PLASTIC, AND CREEP DEFORMATIONS OF AN INITIALLY ISOTROPIC MATERIAL SHOWING ANISOTROPIC STRAIN-HARDENING, CREEP RECOVERY, AND SECONDARY CREEP, by J. F. Besseling. [1958] [8]p. incl. diagrs. refs. (AF 49(838)223) Unclassified

Published in Jour. Appl. Mech., v. 25: 529-536, Dec. 1958.

Stress-strain relations are given for an initially isotropic material, which is macroscopically homogeneous, but inhomogeneous on a microscopic scale. An element of volume is considered to be composed of various portions, which can be represented by subelements showing secondary creep and isotropic work hardening in plastic deformation. If the condition is imposed that all sub-elements of an element of volume are subjected to the same total strain, it is demonstrated that the inelastic stress-strain relations of the material show anisotropic strain-hardening, creep recovery, and primary and secondary creep due to the nonuniform energy dissipation in deformation of the subelements. Only quasi-static deformations under isothermal conditions are considered. The theory is restricted to small total strains. (Contractor's abstract)

ON THE NATURE OF STALL, by S. J. Kline. June 1958, 72p. incl. illus. diags. refs. (Rept. no. MD-4) (AFOSR-TN-58-637) (AF 49(638)201 and AF 49(638)295) AD 162168 Unclassified

Also published in Jour. Basic Engineering, v. 81: 305-320, Sept. 1959.

The physical data available on the problem of stall are reviewed. The discussion is centered on the problem of flow in passages, but a few comparisons with external flow are given. The emphasis is placed on systematic visual data showing flow patterns as a function of geometrical parameters. These data lead to a view of stall as a spectrum including three or possibly four major types of flow patterns; these patterns involve both transient and steady elements. A qualitative parameter is formulated which provides a classification for the major types of stall. A few experiments performed specifically to check the concepts inherent in this parameter are described. Results show that these concepts are useful in rationalizing known but previously inexplicable results and in obtaining important qualitative predictions. (Contractor's abstract)

OPTIMUM DESIGN OF STRAIGHT-WALLED DIFFUSERS, by S. J. Kline, D. E. Abbott, and R. W. Fox. June 1958, 32p. incl. diags. table, refs. (Rept. no. PC-4) (AFOSR-TN-58-638) (AF 49(638)201 and AF 49(638)295) AD 162169 Unclassified

Also published in Jour. Basic Engineering, v. 81: 321-331, Sept. 1959.

Four common optimum problems in diffuser design are defined. These optima are located in relation to the overall flow regimes in terms of geometrical parameters for straight-walled units. Using an empirically derived transformation of variables between the conical and 2-dimensional geometries, all available data for optimum recovery at constant ratio of wall length to throat width are correlated by a single straight line. This line lies slightly above and parallel to the line of onset of large transitory stall on the chart of overall flow regimes. The correlated results are based on a literature survey. The range of conditions for each investigation is tabulated for convenient future reference. The emphasis is on design. Remarks concerning the possible extent and use of the correlations presented are included. (Contractor's abstract)

ELECTRON SCATTERING FROM ASPHERICAL NUCLEI, by B. W. Downs, D. G. Ravenhall, and D. R. Yennie. Feb. 1957 [18]p. incl. diags. (Technical rept. no. 22) (AFOSR-TN-57-36) (AF 18(600)545) AD 115074 Unclassified

Also published in Phys. Rev., v. 106: 1285-1289, June 15, 1957. (Title varies)

To explain the anomalously smooth cross sections observed in electron scattering from certain nuclei (Hf, Ta, W, U), the contributions to the cross section arising from the aspherical character of those nuclei have been examined. Approximations are developed for the calculation of these contributions, and for a sample case, Ta, numerical results are given; the value required for the nuclear distortion in order to obtain agreement with experiment in this case is in good agreement with the spectroscopic and Coulomb-excitation values. The results

suggest that in certain cases electron scattering will be a useful new method for measuring both the magnitude and the radial shape of nuclear deformations.

HARTREE-FOCK SOLUTION FOR THE HELIUM-4 NUCLEUS (Abstract), by C. L. Schwartz. [1957] [1]p. [AF 18(600)545]
Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 228, Apr. 25, 1957.

In a recent abstract Aviles and Jastrow have reported a Hartree-Fock calculation of the He⁴ nucleus using a Yukawa two-body force. They find a binding energy of only 10 mev, compared with 55 mev obtained by Irving who used the same force but a more complicated wave function. The purpose of this note is to point out that a large part of this discrepancy lies in the simple kinematical correlation associated with the free motion of the center of mass. If the total translational invariance of the trial function is assured by the unitary transformation previously described, the Hartree-Fock equation is modified only in that the kinetic energy term is multiplied by 3/4. A variational calculation with a simple one-parameter analytic function then yields a binding energy of 44 mev; the exact Hartree-Fock solution should give even more binding. Thus, at most, 20% of the binding in Irving's calculation is due to dynamical correlations. The smallness of such correlations is a measure of the validity of the independent particle model.

ELECTRON SCATTERING AND MODEL INDEPENDENCE, by D. G. Ravenhall and D. R. Yennie. [1957] [6]p. incl. diagrs. table, refs. [AF 18(600)545]
Unclassified

Published in Proc. Phys. Soc. (London), v. 70A: 857-862, Dec. 1, 1957.

A critical examination is made of the hypothesis of model independence in high-energy electron scattering from nuclei. Results are presented which indicate that, contrary to this hypothesis, any differences in nuclear charge distributions result in differences in the electron angular distributions which become more and more pronounced as the energy is increased. The fallacies of the arguments leading to this hypothesis are noted, and comments are made on the scattering process. (Contractor's abstract)

DETERMINANTAL APPROACH TO MESON-NUCLEON SCATTERING, by M. Baker. Feb. 1958 [57]p. incl. diagr. refs. (Technical rept. no. 26) (AFOSR-TN-58-136) (AF 18(600)545) AD 152163 Unclassified

Also published in Ann. Phys., v. 4: 271-305, July 1958.

A treatment of scattering is presented where the construction of the scattering phase-shifts is regarded as an energy-value problem. Using the relation between the phase-shift $\delta(E)$ and the energy-shift ΔE , the phases can be obtained directly from the infinite determinant
$$D(E) = \det \begin{pmatrix} E-H \\ E-H_0 \end{pmatrix} = \prod_k \left(\frac{E-E_k}{E-E_{0k}} \right) = \prod_k \left(1 - \frac{\Delta E_k}{E-E_{0k}} \right),$$

where the E_k are the energy eigenvalues of the interacting system and E_{0k} are the corresponding eigenvalues for the non-interacting system. For the problem of potential scattering this procedure is directly applicable and leads to results equivalent to the Fredholm solution of the scattering integral equation. However, for the interacting meson-nucleon system, $D(E)$ does not exist. In order to apply this method, $D(E)$ must be factored into convergent subdeterminants $O_i(E)$,

each of which refer to a particular class of states. From $D_1(E)$, the subdeterminant referring to a one-meson type state, the scattering phase-shifts can be calculated. A procedure for constructing $D_1(E)$ for the meson-nucleon system is developed by using the formal structure of $D(E)$. This method is then applied to calculate meson-nucleon scattering in the static model. The $D_1(E)$ is expanded in a power series, such that the first two terms of the expansion yield a solution for the phase-shifts similar to results given by the Chew-Low one-meson approximation. CONVERGENCE OF THE S-MATRIX, by D. R. Yennie and S. Gartenhaus. Feb. 1958, 29p. (Technical rept. no. 27) (AFOSR-TN-58-137) (AF 18(600)545) AD 152164 Unclassified

Also published in Nuovo Cimento, Series X, v. 9: 59-76, July 1, 1958.

An investigation is made of the convergence of the field-theoretic perturbation expansion of the elements of the S-matrix. A theory characterized by a coupling linear in the boson field is assumed, and a cutoff is introduced in momentum space. It is established that the transition amplitude for any given process over a finite time interval is bounded term by term by an exponential series. There is an extension of the method to interactions which are not linear in the boson field. The implications of the results for theories without a cutoff are discussed from a qualitative point of view. (Contractor's abstract, modified)

Also published in Phys. Rev., v. 111: 1684-1690, Sept. 15, 1958.

A qualitative discussion of the approximations implicit in the present theoretical treatment of the deuteron is presented. An improved sum rule which relates the total elastic and inelastic scattering of electrons from the deuteron to the free electron-nucleon cross sections is derived. It has the property of reducing to the correct relativistic result upon neglect of binding. It is proved that the use of folded nucleon and nuclear form factors is correct. It is shown that the finite-nucleon size does not affect any real photon process. (Contractor's abstract)

FORM FACTORS IN QUANTUM ELECTRODYNAMICS, by S. D. Drell and F. Zachariasen. June 1958, 37p. incl. diagra. refs. (Technical rept. no. 31) (AFOSR-TN-58-411) (AF 18(600)545) AD 158214
Unclassified

Also published in Phys. Rev., v. 111: 1727-1735, Sept. 15, 1958.

The electromagnetic form factors of an electron in pure quantum electrodynamics (QED) are analyzed with the techniques of dispersion relations. The viewpoint is adopted that no subtractions are required in the construction of dispersion relations for the electromagnetic vertex. This leads to coupled integral equations for the form factors in terms of other physical amplitudes, e.g., electron-positron scattering. The relation between this and the usual perturbation approach to QED, and the validity and consequences of the "no subtraction" philosophy, are discussed. (Contractor's abstract)

PC CONSERVATION IN STRONG INTERACTIONS, by S. D. Drell, S. C. Frautschi, and A. M. Lockett, III. May 1958, 7p. incl. refs. (Technical rept. no. 30) (In cooperation with Los Alamos Scientific Lab., N. Mex.) (AFOSR-TN-58-412) (AF 18(600)545) AD 158215
Unclassified

The combined PC symmetry operation has been suggested as valid both for weak and strong interactions. In the case of weak interactions PC conservation has been used as a tenable selection rule. Strong interactions are generally believed to have both P and C individually as symmetry operations. S. N. Gupta has pointed out: (1) that PC invariance plus gauge invariance insures both P and C invariance in electrodynamics, and (2) that PC invariance alone leads to parity conservation in neutral pseudoscalar-meson theory. The PC invariance parity conservation question has now been extended to include the charged mesons, hyperons, and K mesons. Consideration is given to experimental complications in the application of the PC selection rule to the strong interactions. It is observed that the combined PC invariance plus charge independence imply separate P and C invariance for the direct coupling of pseudoscalar-mesons with nucleons.

SUM RULES FOR INELASTIC ELECTRON SCATTERING, by S. D. Drell and C. L. Schwartz. June 1958 [40]p. incl. diagra. refs. (Technical rept. no. 32) (AFOSR-TN-58-476) (AF 18(600)545) AD 158287
Unclassified

Also published in Phys. Rev., v. 112: 568-579, Oct. 15, 1958.

Sum rules are constructed for the analysis of inelastic electron scattering at high energy (~150 mev) from light nuclei. Effects taken into account are: (1) nucleon charge, recoil, and magnetic-moment currents; (2) exchange currents; (3) finite nucleon size; (4) nuclear center-of-mass motion; and (5) the kinematical factors describing the correct relation between initial and final electron energies. It appears that a sensitive test of the role of exchange currents in the nuclear ground state is provided by a sum rule for the energy-weighted cross section for fixed-momentum transfer $q = \text{constant}$ $\sigma_E = \int \sigma(\epsilon, q) d\epsilon$. WIDE-ANGLE PAIR PRODUCTION AND QUANTUM ELECTRODYNAMICS AT SMALL DISTANCES, by J. D. Bjorken, S. D. Drell, and S. C. Frautschi. July 1958, 32p. incl. diagrs. table, refs. (Technical rept. no. 34) (AFOSR-TN-58-597) (AF 18(600)545) AD 162121
Unclassified

Also published in Phys. Rev., v. 112: 1409-1417, Nov. 15, 1958.

Wide angle photoproduction of high-energy electron-positron pairs in hydrogen is proposed and analyzed as a test of quantum electrodynamics at distances $\leq 10^{-13}$ cm. The effect of proton structure can be removed in terms of the two form factors measured in the elastic electron-proton scattering process. Cross sections are presented for pair production experiments in which: (1) one of the final particles is detected, and (2) coincidence is detected. In addition to kinematic, anomalous moment, and nucleon form-factor corrections to the Bethe-Heitler formula, dynamical corrections to the proton current and radiative corrections are calculated. The final theoretical formula is believed to be accurate to within 2 percent. A simple cutoff model suggests that 5 percent accuracy in a particle detection experiment tests the electron propagator at distances $\sim 0.7 \times 10^{-13}$ cm, while a 10 percent accuracy in a coincidence experiment probes the electron propagator at $\sim 0.3 \times 10^{-13}$ cm. NEW TECHNIQUES IN THE LAMB SHIFT CALCULATIONS, by H. M. Fried and D. R. Yennie. July 1958, 42p. incl. diagrs. table, refs. (Technical rept. no. 36) (AFOSR-TN-58-678) (AF 18(600)545) AD 162210
Unclassified

Also published in Phys. Rev., v. 112: 1391-1404, Nov. 15, 1958.

Based on the analogy between the calculations of radiative corrections to electron scattering and the Lamb shift, a new procedure applicable to bound state self-energy problems is developed, wherein the electron propagator is expanded in powers of the external potential. In the resulting sequence, a change in the gauge of the virtual photon field conveniently removes from

each term spurious lower order contributions and yields a new and considerably simpler sequence. The expectation value of the first two terms of the latter is shown to account for the major portion of the Bethe logarithm. A simple method is developed to sum all the $\alpha(Z\alpha)^4 \mu$ dependence, and the result is the lowest order Lamb shift formula. The straightforwardness in the above calculation, as well as in the calculation of the relativistic level shift correction of order $\alpha(Z\alpha)^5 \mu$ (not given in the present paper) indicates that the method may find application in the calculation of further higher order effects. SIGN OF THE GRAVITATIONAL MASS OF A POSITRON, by L. I. Schiff. Sept. 1958 [4]p. (Technical rept. no. 42) (AFOSR-TN-58-783) (AF 18(600)545) AD 202008
Unclassified

Also published in Phys. Rev. Letters, v. 1:254-255, Oct. 1, 1958.

It is suggested that an antiparticle may have the opposite sign of gravitational mass from its corresponding particles. Work is presented to point out that this sign can be determined experimentally in the case of a positron. In these experiments the ratio of gravitational to inertial mass was measured for several substances. An attempt was made to detect differences in this ratio between one substance and another but no definite evidence for such differences was found. In several cases, the uncertainties in the fractional differences of the ratios were less than one part in 10^8 . (Contractor's abstract, modified)

HIGH-ENERGY BREMSSTRAHLUNG IN ELECTRON-PROTON COLLISIONS, by R. A. Berg and C. N. Lindner. Sept. 1958 [20]p. incl. diagrs. refs. (Technical rept. no. 38) (AFOSR-TN-58-830) (AF 18(600)-545) AD 202915 Unclassified

Also published in Phys. Rev., v. 112: 2072-2076, Dec. 15, 1958.

The cross section for the bremsstrahlung resulting from high-energy collisions of electrons with protons is calculated, considering the electrons as extremely relativistic and taking into consideration the proton's recoil, anomalous magnetic moment, bremsstrahlung and form factors. The final cross section is integrated over the recoil proton and final photon to obtain a formula of interest for the Stanford accelerator experiments. The computation of the integrated cross section made without regard for radiative corrections and mesonic contributions is estimated to be accurate to 2% in the energy ranges of interest. This cross section is corrected for radiative effects, which produce an additional uncertainty of less than 5% and possibly as little as 1%. Resonance effects due to meson interactions in the virtual Compton effect diagrams, however, are significant in the range of interest. Their contribution to the cross section is discussed. A NEW CALCULATION OF THE NUMERICAL VALUE OF THE LAMB SHIFT, by C. [L.] Schwartz and J. J. Tiemann. Sept. 1958, 16p. incl. table (Technical rept. no. 41) (AFOSR-TN-58-833) (AF 18(600)545) AD 202918 Unclassified

Also published in Ann. Phys., v. 6: 178-187, Feb. 1959.

The calculation of the second-order perturbation in hydrogen which gives the low-energy part of the Lamb shift is attacked from a new extended approach. A formula is derived for $\ln(k_0)$ involving a double integral.

The final numerical evaluation using an electronic computer to sum the series expansion of this formula yields what appears to be the most accurate value of $\ln(k_0)$ yet given. Small discrepancies with the earlier results of Flannery are outside the realm of current physical significance. However, these discrepancies indicate the reliability of the earlier results to be badly overestimated. Approximate formulas for the radiative-perturbed wave functions are given, and may prove quite useful for further calculations. (Contractor's abstract)

ASYMPTOTIC EXPANSION FOR HIGH-ENERGY POTENTIAL SCATTERING, by J. J. Tie-nann. [1958] [6]p. incl. diags. (AF 18(600)545) Unclassified

Published in Phys. Rev., v. 109: 183-188, Jan. 15, 1958.

An asymptotic expansion of a previously derived approximate expression for high-energy potential scattering is obtained. This is used to compute numerical values for the large-angle differential scattering cross section of a Schrödinger particle scattered by a spherically symmetric parabolic potential well and of a relativistic electron scattered by a uniformly charged sphere. In both cases the parameters are such that the Born approximation cannot be used. These values are compared with the results of an exact partial wave calculation and (in the parabolic-well case) with the results of numerical integration of the full approximate expression, and of its asymptotic expansion. It is found that for both the Schrödinger equation and the Dirac equation the locations of the maxima and the minima of the scattering cross sections are reproduced with good accuracy. The magnitudes of the minima, however, are not given reliably and although the general shapes of the curves are correct, the magnitudes of the maxima differ from the correct values by 10 to 50%, depending on the value of kR . RADIATIVE CORRECTIONS TO THE HYPERFINE STRUCTURE IN THE 1S AND 2S STATES OF HYDROGEN (Abstract), by C. [L.] Schwartz. [1958] [1]p. [AF 18-(600)545] Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Los Angeles, Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 404, Dec. 29, 1958.

Mittleman has recently given an account, according to the relativistic quantum electrodynamics, of the ratio of the hyperfine-structure separations in the 1S and 2S states of hydrogen. His result, proportional to α^3 , appears to be in disagreement with the experimental value. Working in analogy with Bethe's first description of the Lamb shift in hydrogen, the non-relativistic third-order perturbation theory has been set up to describe the effect: emission and reabsorption of a transverse photon by a bound electron while interacting with the field of the nuclear magnetic moment. Divergences in this calculation are eliminated by keeping only the state-independent terms, and then cutting off the intermediate photons at $\hbar\omega = mc^2$. Comparing, where possible, with Mittleman's results, it is found that he lacks a term both in the nonrelativistic sum over states and in the $\ln\alpha$ terms. While the numerical value of this nonrelativistic calculation should not be compared with the experimental value until the entire calculation is redone relativistically, our correction for the leading $\ln\alpha$ term indicates a closer agreement between theory and experiment.

THE SOLUTION OF COMPRESSIBLE LAMINAR BOUNDARY LAYER PROBLEMS BY A FINITE DIFFERENCE METHOD. PART II. FURTHER DISCUSSION OF THE METHOD AND COMPUTATION OF EXAMPLES, by D. C. Baxter and I. Flügge-Lotz. Oct. 15, 1957, 220p. incl. diagrs. tables, refs. (Technical rept. no. 110) (AFOSR-TN-58-1) (AF 18(600)1488) AD 148040 Unclassified

The application of a finite difference solution of the corresponding differential equations to the investigation of the compressible boundary layer with variable pressure gradient and wall temperature is discussed. The Crocco form of the equations is used, and the method is programmed on an IBM 650 digital computer. For the purposes of the examples, the Prandtl number is assumed constant at 0.72, and the Sutherland viscosity law is used. With the exception of flows which involve overshoot, the method will allow determination of boundary-layer behavior under any combination of pressure gradient and wall temperature or heat flux variation. It is limited only in that (a) starting profiles must be provided at some distance downstream of the nose and (b) the time required to compute a particular example of interest may be long. The stability of the numerical solution of the boundary layer equations is investigated and consideration given to several examples involving flow over nonisothermal flat plates where the pressure gradient is zero. The heat transfer results are compared with the specializations and extensions of Lighthill's results.

THE SOLUTION OF COMPRESSIBLE LAMINAR BOUNDARY LAYER PROBLEMS BY A FINITE DIFFERENCE METHOD. PART III. THE INFLUENCE OF SUCTION OR BLOWING AT THE WALL, by I. Flügge-Lotz and J. T. Howe. Oct. 15, 1957, 44p. incl. diagrs. tables. (Technical rept. no. 111) (AFOSR-TN-58-2) (AF 18-(600)1488) AD 148041 Unclassified

The influence of a transverse velocity at a porous wall on skin friction, heat transfer, and laminar separation is treated on a finite difference basis. The finite difference-scheme employed in the solution of the boundary layer problem (item nos. STA.04:001-002) is modified to include the transverse velocity effects in the computation at the wall point. Series expansions involving the shear stress and the enthalpy derivative are employed at each wall point. Skin friction and heat transfer parameters can be influenced appreciably by a small transverse velocity at the wall. A number of examples are presented to illustrate the effects of the transverse velocity in subsonic and supersonic flow over both hot and cold walls; examples with and without pressure gradient are discussed. In the absence of pressure gradient it appears that both skin friction and heat transfer parameters decrease with increasing transverse velocity parameter and vice versa. In boundary layer flows with a pressure gradient, the wall point shear stress equation is of the third degree in terms of the wall shear stress, but is quadratic in terms of the transverse velocity at the wall. The transverse velocity necessary to obtain a specified behavior of the wall shear stress, or a desired shift of the point of laminar separation can be computed readily. (ASTIA abstract)

COMPRESSIBLE LAMINAR BOUNDARY LAYER BEHAVIOR STUDIED BY A FINITE DIFFERENCE METHOD, by D. C. Baxter and I. Flügge-Lotz. [1958] [16]p. incl. diagrs. refs. (AF 18(600)1488) Unclassified

Published in Zeitschr. Angew. Math. Phys., v. 9B: 81-96, Mar. 25, 1958.

The examples in this report show that in general the effects of pressure gradient are intensified at higher wall temperatures and higher Mach numbers. Raising the surface temperature has the effect of reducing skin friction, while lowering it tends to increase skin friction. However, surface temperature has much less effect on skin friction than it has on heat transfer. On the other hand pressure gradient does have an appreciable effect on heat transfer, although not as great as on skin friction. For flow over non-isothermal flat plates the

STA.07:025 - STA.07:027

specializations and extensions of Lighthill's result give very good agreement with the finite difference results for heat transfer. It follows that equally good agreement would be obtained with integral methods which assume unequal thicknesses for the velocity and thermal boundary layers. However, it is shown by the present examples that integral methods which make the assumption of equal thicknesses lead to inaccurate predictions of heat transfer performance when the wall temperature gradients are as high as those considered here (on the order of hundreds of degrees per foot). It appears that integral methods will give not unreasonable estimates for the skin friction even when that quantity is changing rapidly. This is not true of the correlation method, since the changes occurring in the present examples are too rapid to be related by the equilibrium conditions such a method assumes.

ELECTRON SCATTERING FROM THE DEUTERON AND THE NEUTRON-PROTON POTENTIAL, by J. A. McIntyre and S. Dnar. Feb. 28, 1957 [9]p. incl. diagrs. tables, refs. (Rept. no. HEPL-112) (AFOSR-TN-57-112) (Sponsored jointly by Office of Naval Research under N6onr-25116, Air Force Office of Scientific Research under AF 18(600)646, and Atomic Energy Commission) AD 120465 Unclassified

Also published in Phys. Rev., v. 106: 1074-1082, June 1, 1957.

Electron scattering from the deuteron has been investigated experimentally at higher energies and larger scattering angles than before. Calculations have been made also for the scattering expected from deuterons with repulsive-core and with Yukawa-type neutron-proton potentials. As before, it is found necessary to introduce a proton size into the deuteron (or to modify the Coulomb interaction) in order to obtain agreement between the experimental results and the scattering calculations. Using the proton size determined by electron-proton scattering experiments, a comparison is made between the various calculated curves and the experimental data. It is found to be impossible to rule out either the repulsive-core or the Yukawa potentials. (Contractor's abstract)

Consideration is given to the study of the inner features of nucleons and nuclei by the method of electron scattering. Results are presented which appear significant from the point of view of a present understanding of the structure of nucleons and the nature of the basic nuclear force. A finite proton size was observed, the core of which is larger than that indicated by field theory. The magnetic cloud in the neutron was probed. The neutron's size was within $\pm 15\%$ of that of the proton. The broad basis on which nuclei are built was determined. The rules are that (1) the skin thickness (90% to 10% distance) of the electric charge distribution is $2.4 \pm 0.3 \times 10^{-13}$ cm for nuclei between Mg and Pb; and (2) the distance to the half-density point scales is $1.07 \times 10^{-13} A^{1/3}$ cm. Inelastic electron scattering from excited levels provided a new method for investigating the excited states in nuclei.

Also published in Rev. Modern Phys., v. 28: 214-254, July 1956.

The influence of finite nuclear size on scattering formulae is described, and form-factors for the various models are derived. Phase-shift analysis for the heavy elements is discussed. The various scattering phenomena are explained, including nuclear excitation, electrodisintegration, the real and virtual radiative processes, magnetic scattering and effects due to "rotational levels". The spectrometer installations at the 190 mev and 550 mev points on the Stanford electron linear accelerator are described in detail, and a detailed review of the experimental work carried out at Stanford is given, in order of increasing target atomic number, viz. H, D, α , Li, Be, C, Mg, Si, S, A, Sr, heavier nuclei, and the neutron. The results include data on angular distribution, observed form-factors, cross-sections, etc. Comparisons are made with theory and conclusions drawn regarding the validity of the various models. For example, the data for protons indicate that the Gaussian, exponential and hollow-exponential models provide an equally good fit with experiment giving a mean proton radius for best fit of 0.77 ± 0.10 Fermi units. The Yukawa model does not satisfy the proton data. Finally, the validity of

STA.07:028 - STA.07:030

electrodynamics is discussed, and other methods of investigating nuclear structure are compared. It is concluded that the electron scattering method is promising, but still in an early stage of development. Future improvements are suggested.

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 14, Jan. 30, 1957.

Electrons with energies of 400 and 500 mev have been scattered from the deuteron. The scattering at the largest angles is a factor of five below that expected from scattering by a deuteron charge distribution. This discrepancy is removed by assuming that the proton in the deuteron has an rms radius of 0.78×10^{-13} cm. There is still some uncertainty in the expected deuteron scattering because of the various possible neutron-proton potentials in the deuteron. The scattering from three types of deuteron has been calculated using deuteron S- and D-state wave functions and the magnetic moment of the deuteron. One deuteron calculated has a repulsive core neutron-proton potential while the other two deuterons have Yukawa potentials. Comparison with the experimental data shows that agreement can be obtained for all deuteron models because of the uncertainty in the radius of the proton.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 392, Dec. 19, 1957.

Electromagnetic pair production in hydrogen with large

momentum transfer provides a test of the validity of quantum electrodynamics (QED) at distances $\leq 10^{-13}$ cm. Because of center-of-mass motion electron-electron (positron) scattering at present energies ($E_{\text{lab}} \approx 1$ bev) is insensitive to distances $< 10^{-12}$ cm, as are radiative corrections, such as the electron's anomalous magnetic moment. The electron-proton scattering experiments of Hofstadter show that QED is valid down to $\sim 10^{-13}$ cm at which distances effects of nucleon structure appear.

Assuming the validity of QED for distances $\leq 10^{-13}$ cm, one can completely summarize the results of the electron-proton scattering experiments in two invariant functions of the four-momentum transfer, the proton's charge and moment form factors. The cross section for electromagnetic pair production in hydrogen is then known in terms of these two form factors, and the proton can be used, with known electromagnetic interactions, to fix the center-of-mass relative to the laboratory system. A complete calculation has been carried out, including radiative corrections, of large-angle pair production for photons incident on "Hofstadter" protons.

NUCLEON CHARGE AND MOMENT DISTRIBUTIONS (Abstract), by L. I. Schiff. [1957] [1]p. [AF 18(600)646]
Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 389-390, Dec. 19, 1957.

The apparent failure of charge symmetry in the structure of the proton and the neutron is examined in the light of the possibility that the neutron charge density has zero volume integral and zero mean-square radius, but is not identically zero. Such a distribution must have at least two zeros as a function of radius. A simple analytic form is assumed that has a positive maximum at the origin, followed by a negative region and then a very small positive region. The proton charge density is then chosen so that when it is added to the neutron density, only the central positive maximum (the nucleon core distribution) remains. Proton and neutron magnetic moment densities are assumed to have the same form, and it makes little difference whether these have the simple shape used in earlier studies or the shape assumed here for the proton charge, which has one change of sign. It is then possible to fit the electron-proton and electron-deuteron elastic scattering data. The total electron-deuteron inelastic (break-up) scattering cross section is computed to be about 25 percent less than found experimentally. While these distributions can be regarded as meeting the requirements of charge

STA.07:031, 032; STA.08:002, 003

symmetry, they lead to a core distribution that has the same root-mean-square radius as that of the proton charge, although it has a more concentrated appearance.

SUM RULES FOR INELASTIC ELECTRON SCATTERING (Abstract), by S. D. Drell and C. L. Schwartz. [1957] [1]p. [AF 18(600)646] Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 390-391, Dec. 19, 1957.

Sum rules are constructed for the analysis of inelastic electron scattering at high energy (~150 mev) from light nuclei. Effects taken into account are: nucleon charge, recoil, and magnetic-moment currents; exchange currents; finite nucleon size; and nuclear center-of-mass motion. The form of the sum rule for fixed electron-scattering angle is complicated because of the kinematical connection between the momentum of the scattered electron and the energy of the final nuclear state. A more natural sum rule results for electron scattering with fixed momentum transfer. The energy region below meson threshold to which these considerations are restricted for reasons of ignorance of a relativistic nuclear description, precludes the possibility of learning about internucleon correlations (beyond the Pauli principle) from this work. However, it appears that a sensitive test of the role of exchange currents in the nucleus is provided by a sum rule for the energy-weighted cross section

$$\sigma_E = \int |q| = \text{const} \int \sigma(\epsilon, q) d\epsilon.$$

Published in Phys. Rev., v. 112: 2077-2086, Dec. 15, 1958.

Electron scattering by the deuteron has been studied experimentally at 400 and 500 mev. The results of the scattering are compared with the scattering expected by three different static deuteron models. All three models satisfy the usual deuteron requirements such as

binding energy, effective range, quadrupole moment, and percent D state. Two of the models have Yukawa neutron-proton potentials; the third has a repulsive-core potential. The experimental results agree with the repulsive-core model and disagree with the Yukawa models. This result applies only to the triplet-S neutron-proton potential.

OPTICAL MODEL ANALYSIS OF K^+ MESON SCATTERING (Abstract), by G. Igo, D. G. Ravenhall and others. [1957] [1]p. (Sponsored jointly by [Office of Naval Research], Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116; continuation of AF 18(600)646]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Boulder, Colo., Sept. 5-7, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 311, Sept. 5, 1957.

The scattering of K^+ mesons of energies near 150 mev and in the interval 40 to 100 mev has been analyzed in terms of a complex potential, $(V + iW)/(1 + \exp[(r - r_0)/d])$. The quantities r_0 and d were taken to be $1.07 A^{1/3}$ and 0.47 fermi, respectively. An exact phase shift analysis has been made for each element in the emulsion and at several energies in order to arrive at a suitable energy average for comparison with events detected in emulsions. Utilizing a repulsive potential, an adequate fit to the differential cross section for elastic scattering, the total cross section, and the inelastic cross section was obtained with V and W equal to 25 and -10.6 mev, respectively. At the lower energies, the best fit was obtained with V and W equal to 20 and -4.9 mev. When V is made attractive, the fits to the differential cross section for elastic scattering are less good particularly in the region of the interference minimum. The improvement over previous calculations of this process lies in its inclusion of W in the elastic cross section.

DETERMINATION OF THE FORM FACTOR OF THE DIFFERENCE BETWEEN THE PROTON AND THE NEUTRON MAGNETIC MOMENTS (Abstract), by W. K. H. Panofsky and E. A. Ailton. [1957] [1]p. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 391, Dec. 19, 1957.

Study has been made of inelastic electron scattering with the primary and secondary electron energies programed against each other to maintain the energy of the pion-nucleon system at the "resonance" energy. At this energy setting and a laboratory angle of 75° for the scattered electron, the momentum transfers can be varied from ~200 to 470 mev/c, thus exploring the form factor for the matrix element in question. This measurement can give independent evidence concerning the extent in space of the proton and neutron magnetic moment distributions, since the Chew-Low and dispersion theory matrix elements are proportional to the algebraic difference in the proton and neutron magnetic moments. Under the conditions mentioned the theoretical value for a point nucleon of the cross section for inelastic scattering of an electron leaving the proton-pion system at the energy corresponding to the 3/2, 3/2 resonance is $3.0 \times 10^{-34} \text{ cm}^2 \text{ sterad}^{-1} \text{ mev}^{-1}$. The experimental measurements deviate progressively from this value toward $(1.35 \pm 0.13) \times 10^{-34} \text{ cm}^2 \text{ sterad}^{-1} \text{ mev}^{-1}$ at a momentum transfer of 470 mev/c. The figure is in agreement if both the neutron and proton are given radii corresponding to the electromagnetic radius of the proton.

EFFECTS OF FINITE NUCLEAR SIZE IN ELECTRODISINTEGRATION EXPERIMENTS (Abstract), by W. C. Barber. [1957] [1]p. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116])
Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 389, Dec. 19, 1957.

The usual expressions giving the cross section for electrodisintegration reactions in terms of the photodisintegration cross sections are not valid when the nuclear size is comparable with the wavelength associated with the momentum transfer. Measurements of the ratio of the yields of C^{11} produced by the $C^{12}(e,e'n)$ and $C^{12}(\gamma,n)$ have been made using primary electrons of energy from 24 to 150 mev. At the higher energies a comparison of this ratio with theory requires consideration of the finite nuclear size. An approximate size correction has been included in the theory with the result that the comparison of experiment and theory is consistent, at all primary energies, with the interpretation that the transitions producing the reactions are predominantly electric dipole.

pole. A similar comparison of theory and the experimental yield ratios of the reactions $E^{19}(e,e'2p)N^{17}$ and $F^{19}(\gamma,2p)N^{17}$ measured by Reagon indicate these transitions are predominantly electric quadrupole.

ELECTRON DISINTEGRATION OF ELEMENTS FROM Z = 3 TO Z = 79 (Abstract), by H. W. Kendall and U. Meyer-Berkhout. [1957] [1]p. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116])
Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 378, Dec. 19, 1957.

Yields of protons and deuterons from electron disintegration of a series of elements from Li^6 to Ta^{181} have been studied. Targets were bombarded with 500-mev electrons and disintegration fragments of momentum $p < 550$ mev/c, after momentum analysis with a 36-in. magnetic spectrometer, were detected in plastic or NaI(Tl) scintillation counters. Angular distributions of protons and deuterons in the range of laboratory angles from 40° to 135° were determined absolutely by comparison with known elastic electron-scattering cross sections. Proton and deuteron yields are proportional to Z, and the ratio of deuteron to proton differential cross sections (taken either at equal particle energy or equal momentum) appears to be approximately constant with a value in the range 0.07-0.12. The results are interpreted in terms of a transverse electron-nucleus interaction, which is effectively a high-energy photodisintegration process. This process gives rise to high-energy protons and neutrons originating in the nuclear volume. The large deuteron yields are consistent with a pickup reaction at the nuclear surface in analogy with high-energy (p,d) and (n,d) reactions. No detailed theory explains the high deuteron yields, which are also observed in other processes.

STA.08:007 - STA.08:009

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 390, Dec. 19, 1957.

The nucleus Li^6 has been investigated with electrons of energy 426 mev scattered in the angular range 33° - 50° . Elastically scattered electrons are resolved from electrons which have been scattered with excitation of the first level, at 2.189 mev, and higher levels. To achieve this resolution in the presence of large inelastic cross sections, the elastic peaks were approximately 0.25% wide (full width) at half maximum. An analysis of the angular distribution has been carried out with the Born approximation and several possible nuclear models. An independent particle shell model, using an infinite harmonic well, fits the experimental data if the rms radius is chosen to be $2.2 \pm 0.2 \times 10^{-13}$ cm. A Gaussian will also fit moderately well with a similar radius, but this charge distribution is not significantly different from that of the shell model.

FORM FACTOR INVESTIGATION OF THE NEUTRON BY HIGH-ENERGY ELECTRON SCATTERING (Abstract), by M. R. Yearlan and R. Hofstadter. [1957] [1]p. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116])

Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 389, Dec. 19, 1957.

The magnetic form factor of the neutron can be investigated through a study of the inelastic continuum of electrons scattered from deuterons at high momentum transfers. The inelastic spectrum has been compared with elastic electron scattering from free protons at 500 mev (75° - 135°) and at 600 mev (135°). The inelastic spectra have been corrected for electron-pion production, for contamination by negative pions, and for shape distortion due to bremsstrahlung. The shapes of the spectra are roughly similar at all angles and agree well with predictions of a theory due to Jankus. The present results are: (1) irrespective of the details of applicable theories, the neutron's magnetic cloud is extended and is not a point; (2) the neutron's magnetic size and shape are approximately the same as those of the proton; and (3) the differences between the neutron and the proton can be determined from the present data upon development of an accurate theory of electro-disintegration of the deuteron.

FORM FACTOR STUDIES OF THE PROTON AT HIGH ENERGIES (Abstract), by F. Bumiller and R. Hofstadter. [1957] [1]p. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116])

Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 390, Dec. 19, 1957.

Elastic electron scattering experiments have been carried out against protons in CH_2 at energies of 500, 550, 575, 600, 650 mev between laboratory scattering angles of 75° and 135° , in order to investigate finite size effects in the proton. The new experiments attempt to distinguish between several different models of density distribution fitting the earlier data. Two methods of comparison with phenomenological models have been used. The first (I) employs a plot of F^2 versus q^2 where $F_1 = F_2 = F$. The second method (II) concentrates on the experimental ratio of $\sigma_{75^\circ}/\sigma_{135^\circ}$, which is sensitive index distinguishing between the various models and, furthermore, does not require a knowledge of absolute cross sections. The results of methods (I), (II) are as follows: (a) the present experiments are consistent with the earlier ones as far as the earlier ones go; (b) the newer data distinguish between the models previously proposed; (c) the most favorable case among the exponential, Gaussian, hollow exponential, and Yukawa I, II models is the exponential with rms size $r_e = r_m = 0.80 \times 10^{-13}$ cm; and (d) absolute cross sections are in good agreement with the exponential model.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 391, Dec. 19, 1957.

Inelastic scattering in hydrogen leading to pion production gives additional information as compared to

STA.08:010 - STA.08:012

photon production since: (a) Longitudinal matrix elements contribute to the process. (b) The relation between production by real and virtual photons is different depending on the multipole order of the meson-nucleon system. (c) Contrary to the situation in photo-production, the momentum transfer to the meson-nucleon system can exceed the energy transfer; "structure" effects in the matrix elements can thus be studied. All these effects are largest at large electron angles. For this reason, a procedure has been developed and tested to study the inelastic scattering process by observing the scattered electrons at a large angle. The contributions from secondary electrons due to large-angle bremsstrahlung can be calculated theoretically and are subtracted. Contributions due to converted γ rays from π^0 production, due to electron-positron pairs and due to high-energy π^- mesons produced by real and virtual photons, can be eliminated by studying the electron yield as a function of a radiator placed in the primary electron beam. This method has been tested and gives internally consistent results. Absolute cross sections are obtained by comparison with the elastic cross sections measured in the same apparatus.

INELASTIC SCATTERING OF 500-MEV ELECTRONS FROM Li^6 AND Li^7 (Abstract), by U. Meyer-Berkhout and R. Hofstadter. [1957] [1]p. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 390, Dec. 19, 1957.

An experiment was carried out in which 500-mev electrons have been scattered from enriched Li^6 and ordinary Li^7 between scattering angles of 60° and 135° in the laboratory system. The cross section integrated over the inelastic continuum at these large momentum transfers has been compared with the free proton cross section at the corresponding angles. The results are obtained by assuming that the scattering from the bound nucleons in first approximation can be considered as incoherent. The measured ratios, $\sigma_{\text{Li}}/\sigma_{\text{p}}$, seem to indicate that protons and neutrons in lithium make comparable contributions to the magnetic scattering at the larger angles. It is difficult at present to find the neutron's actual contribution to the cross section, since theoretical estimates of corrections, allowing for the momentum distribution of nucleons, final state interaction, meson production and exchange, are uncertain.

Therefore, only the quantity $R = 1/N[\sigma_{\text{Li}}/\sigma_{\text{p}} - 3]$, where $N = 3, 4$ for Li^6, Li^7 , respectively, has been derived from the data. R should be equal to $\sigma_{\text{N}}/\sigma_{\text{p}}$, if incoherency applies and if the corrections are negligible. If it is set tentatively that $\sigma_{\text{N}}/\sigma_{\text{p}} = R$, then $\sigma_{\text{N}}/\sigma_{\text{p}}$ is found to be (1.0 ± 0.4) at $135^\circ, 500 \text{ mev}$, and decreases to (0.5 ± 0.2) at $60^\circ, 500 \text{ mev}$.

MULTIPLE SCATTERING OF 600-MEV ELECTRONS BY A THIN ALUMINUM FOIL (Abstract), by R. C. Smith, R. E. Taylor and others. [1957] [1]p. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 389, Dec. 19, 1957.

A measurement has been made of the multiple scattering of a collimated beam of 600-mev electrons by a 3-mil ($0.0205 \text{ gm/cm}^2; 8.6 \times 10^{-4} \text{ rad length}$) aluminum foil. The scattered electrons pass through a glass plate at a distance of 40 ft and the location of the scattered electrons is determined by a densitometer measurement of the darkening of the plate. The linearity of darkening is established by making a series of similar measurements with different total numbers of incident electrons. The resulting multiple-scattering curve has a mean width of $0.70 \pm 0.05 \text{ mc}^2/E_0$. The accuracy of measurement does not allow it to be distinguished from a Gaussian. This number is in agreement with the $0.74 \text{ mc}^2/E_0$ value predicted by Moliere theory.

STA.08:013 - STA.08:015

Proton energy and angular distributions from the electro- and photodisintegration of C^{12} have been measured with an 18-in., 120° double-focusing magnetic spectrometer. Nine KI scintillation crystals mounted on the focal plane of the spectrometer provide simultaneous measurement of nine proton momentum groups. Preliminary measurements taken with a primary energy of 30 mev indicate a proton angular distribution peaked at nearly 90° slightly skewed in the forward direction for both electro- and photodisintegration and a sharp peak in the energy spectrum corresponding to photon absorption at the giant resonance with transitions to the ground state of B^{11} . There is also evidence for other proton levels.

SCATTERING OF 420 MEV ELECTRONS FROM SOME NUCLEI OF THE FIRST p-SHELL (Abstract), by H. Ehrenberg, U. Meyer-Berkhout and others. [1957] [1]p. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 390, Dec. 19, 1957.

Measurements of the elastic scattering cross sections of 420 mev electrons at various scattering angles have been performed for C^{12} and O^{16} and furnish new information on the shape and size of those nuclei. The experimental results were obtained as part of a program to study the charge distributions of the nuclei of the first p-shell and are compared with the predictions of a theoretical phase shift analysis derived for the harmonic well independent particle model of the nucleus. Pronounced diffraction minima in the angular distributions were observed for C^{12} and O^{16} . The new data on C^{12} are in excellent agreement with what one would expect from earlier measurements performed at 183 mev. Best fits of the experimental data with theoretical angular distributions make it possible to check the shell model predictions for the parameter α related to the number of protons in the first p-shell and furthermore give the value of the parameter a_0 , which is related to the curvature of the infinite harmonic well. a_0 varies within the p-shell. Values of α and the rms radius of the charge distribution used in the best fits are given. The freedom in choosing those parameters are discussed. Data on Li^6 and Be^9 are included in the discussion.

INVESTIGATION OF THE CHARGE FORM FACTOR OF THE PROTON (Abstract), by F. Bumiller and R. Hofstadter. [1958] [1]p. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116]) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 50, Jan. 29, 1958.

An examination of the proton's charge structure function (=Dirac form factor, F_1) has been carried out by scattering electrons from protons in CH_2 at electron energies 200 mev and 600 mev in the laboratory system. The method takes advantage of the fact that at small scattering angles the ratio of cross sections ($\sigma_{200}/\sigma_{600}$) is sensitive to F_1 and practically independent of the magnetic form factor F_2 . Thus very little knowledge of the magnetic form factor is required to determine precise features of the F_1 distribution. When the results are, for convenience, put in the form of a phenomenological charge-density distribution, the exponential model with rms radius 0.80×10^{-13} cm, gives a good fit. This result indicates that the electrical size of the proton is the same as the magnetic size, at the momentum-transfer values presently investigated. The data can also be presented equivalently, without referring to a model, in the form of phenomenological structure functions.

STUDY OF THE MAGNETIC FORM FACTOR OF THE NEUTRON AT 600 MEV (Abstract), by M. R. Yearian and R. Hofstadter. [1958] [1]p. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116]) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 50, Jan. 29, 1958.

Further experimental investigation of the neutron's magnetic form factor has been continued at 600 mev. The deuteron electrodisintegration data can be compared with theories of Jankus and Blankenbecler with inclusion of the proton and neutron form factors. When the form factors are included, the theoretical shape of the inelastic continuum changes with respect to the original theoretical shape calculated by Jankus for points. The present results at 600 mev are compared with a model which fits the 500-mev data. From these results, the neutron's magnetic cloud is definitely not a point and is of approximately the same size as the proton magnetic cloud. Possible differences between the neutron and proton will be discussed.

INCOHERENT ELECTRON SCATTERING FROM THE

NUCLEONS IN BERYLLIUM AND CARBON AND THE MAGNETIC SIZE OF THE NEUTRON, by H. F. Ehrenberg and R. Hofstadter. [1958] [7]p. incl. illus. diagrs. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116]) Unclassified

Published in Phys. Rev., v. 110: 544-550, Apr. 15, 1958.

The electron scattering at high momentum transfer has been measured from the nucleons in Be, in C, and from free proton. The data yield the cross section of the average nucleon and of the neutron in relation to that of the proton. $\sigma_n/\sigma_p(\theta)$ is found to be 1.16 ± 0.3 at 500 mev and 135° ; it decreases, as expected, for smaller angles and lower energies. If the assumption is made that meson-exchange effects and interactions in the final state are not important, the form factors obtained indicate an apparent root-mean-square radius of the neutron's magnetic-moment distribution of $(0.53 \pm 0.15) \times 10^{-13}$ cm. It is possible that the apparent small size of the neutron in Be and C is due to the neglect of meson-exchange effects and interactions in the final state. The present result is smaller than a neutron size, given by Yearian and Hofstadter, who compared the cross sections of deuteron and proton and found equal sizes for neutron and proton. If one accepts the latter result, the present experiment can be used to yield a measure of the above neglected effects. (Contractor's abstract)

MAGNETIC FORM FACTOR OF THE NEUTRON, by M. R. Yearian and R. Hofstadter. [1958] [13]p. incl. illus. diagrs. tables, refs. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116]) Unclassified

Published in Phys. Rev., v. 110: 552-564, Apr. 15, 1958.

Electron scattering from the bound neutron and proton in the deuteron has been studied at various scattering angles between 75° and 135° for 500-mev and 600-mev electrons. A comparison of these scattering cross sections with those of the free proton permits a determination of the density distribution of the magnetic cloud around the neutron. By using theories developed by Jankus and Blankenbecler, the root-mean-square radius of the neutron is shown to lie between the limits 0.80×10^{-13} cm and 0.90×10^{-13} cm. The choice between these radii depends on whether the deuteron total cross sections or differential (peak) cross sections are compared with the protonic scattering cross section. Since presently available theory has not yet developed sufficiently to decide definitely between these possibilities, the root-mean-square size may be taken to be

STA.08:020 - STA.08:022

$(0.85 \pm 0.10) \times 10^{-13}$ cm with small error. The neutron's magnetic cloud clearly does not have the small size obtained by measurement of its charge cloud from experiments on the neutron-electron interaction, and this anomaly challenges the present concepts of nucleon size. ELECTROMAGNETIC STRUCTURE OF THE PROTON AND NEUTRON, by R. Hofstadter, F. Bumiller, and M. R. Yearian. [1958] [16]p. Incl. diagrs. refs. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr 25116]) Unclassified

Published in Rev. Modern Phys., v. 30: 482-497, Apr. 1958.

A review is presented of the high energy scattering of electrons from protons and deuterium in order to establish the structure of the nucleons. It is found that the two form factors F_1 and F_2 introduced in the Rosenbluth point scattering curve are equal for the proton and that F_2 for the neutron is the same as that for the proton but that F_1 for the neutron is zero. The rms value for the charge distribution of the nucleons is found to be 0.80×10^{-13} cm. Scattering at high momentum transfer and at large angles measures the scattering due to the magnetic moment and yields a ratio for the neutron to proton scattering of .45 which indicates that the magnetic moment of the neutron is not point distribution but that the magnetic moment distribution of both nucleons is the same. An exponential model of the charge distribution is the best fit for the form factor distributions, however it is not possible to discount a model which has a negative charge singularity at the origin and a monotonic charge distribution such as the Yukawa potential elsewhere.

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 196, May 1, 1958.

Studies have been made of π^+ meson production at 90° cm angle and photon energies of 240, 335, and 375 mev, using polarized bremsstrahlung from the 600-mev electron beam of the Stanford linear accelerator. The polarized bremsstrahlung beam was obtained by selecting the bremsstrahlung produced in a 3-mil aluminum radiator at an angle of approximately $1/1000$ radian from the electron beam direction. To estimate the amount of polarization the aperture function and a measured value of the multiple scattering are folded into the polarization calculated by May using a relativistic small angle approximation. The ratio of meson production along and at right angles to the electric field vector is measured and compared with the values predicted by the relativistic dispersion relation.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 173, May 1, 1958.

The magnetic spectrometer previously described has been used to study the protons ejected from targets bombarded by the beam of the Stanford 40-mev linear electron accelerator. Either the electron beam alone or a combination of the electron beam plus the bremsstrahlung from a thin radiator can be incident on the target.

The protons from C^{12} have a narrow peak in the energy distribution at 6 mev corresponding with photon absorption at the giant resonance followed by transitions to the ground state of B^{11} . A high-energy tail of protons extends to the endpoint of the photon spectrum and shows evidence for subsidiary peaks near 8.5 and 13.5 mev. The angular distribution of those protons in the neighborhood of 6 mev fits the form $1 + 1.3 \sin^2 \theta (1 + 0.3 \cos \theta)^2$ for either the electron- or photon-induced processes. The protons from aluminum have a broad energy distribution with a peak near 4 mev. As with carbon, the high-energy tail shows evidence of structure. The angular distribution changes gradually from nearly isotropic at 4 mev to significantly forward at 13 mev.

The equivalent shunt impedance of a tightly coupled transmission cavity can be measured by inserting very small perturbing elements and using a simple bridge method to detect small shifts of transmission phase. A simple graphical procedure is developed for the interpretation of these measurements. It is shown that the procedure measures directly the shunt impedance R of the cavity, rather than the geometric quantity R/Q . Experimental results are presented for one such cavity, which show that phase information thus obtained is about 100 times as sensitive as amplitude information normally obtained from a transmission cavity. The inelastic scattering of electrons in hydrogen leading to pion formation has been examined. Measurements were carried out in which a hydrogen target was bombarded by electrons of energy E_1 with secondary electrons of energy E_2 being detected by a magnetic analyzer at a fixed angle of 75° . The energies of E_1 and E_2 were programmed together such that the pions were produced at a constant energy near the peak of the pion-nucleon resonance in the $(3/2, 3/2)$ state. At the same time the momentum transfer to the pion-nucleon system was varied. Special procedures were developed to eliminate contributions from competing processes. Approximately three fourths of the observed cross section corresponds to magnetic-dipole absorption of the incident virtual photon. The momentum transfer dependence can be interpreted in terms of a form factor of the difference between the magnetic moments of the neutron and proton. If the electron-scattering radii are

assumed for the proton, then the data appear to require an rms radius of the magnetic moment of the neutron of about 1.1×10^{-13} cm, based on an exponential model. Nucleon recoil corrections are still somewhat uncertain. (Contractor's abstract)

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 268, June 19, 1958.

Electrons at energies of 400 and 500 mev have been scattered by deuterons with accuracy higher than that attained in previous measurements. The results have been analyzed using Jankus' static calculation of electron-deuteron scattering. The sizes of the proton and the neutron in the deuteron have been introduced according to the analysis of Yennie, Levy, and Ravenhall. For direct comparison with experimental results, three deuteron wave functions satisfying the usual requirements have been substituted into Jankus' formula. Two of the wave functions are generated by Yukawa-type neutron-proton potentials while the other results from a repulsive-core (Gartenhaus) potential. The effect of the proton size has been eliminated experimentally by taking ratios between the electron-deuteron and electron-proton scattering. The neutron size has been assumed to be negligibly small. Using the analysis of the data outlined in the foregoing, the experiments agree with the repulsive-core deuteron scattering and do not agree with either of the Yukawa deuterons. This result tests only the S-state charge distribution of the deuteron.

STA.08:027 - STA.08:030

A magnetic spectrometer has been used in connection with the Stanford 40-mev linear electron accelerator to study the energy and angular distributions as well as the excitation functions of photoprotons from targets of C, Al, In, and Ta. In general the results indicate enough structure in the energy distribution that they cannot be explained by a single resonance modified by barrier effects. For C an analysis of the proton distributions leads to a cross section very similar to the $^{12}\text{C}(\gamma, n)$ cross section curve, as is expected from charge symmetry of nuclear forces. For In and Ta the Coulomb effects are very important, and the excitation functions prove that the protons are produced by photons of higher energy than those which produce photoneutrons. The high energy and large numbers of photoprotons from these elements indicate that they are produced in a "direct" process. (Contractor's abstract)

The study of electrons scattered inelastically from the deuteron has been extended to 600 mev. Data at 500 mev were reported in an earlier paper. Results are presented for seven scattering angles between 45° and 135°. A comparison of the deuteron's cross section at these angles with the corresponding free proton cross section permits a determination of the form factor associated with the magnetic moment distribution of the neutron. Two different methods of analyzing the data are described, and the rms radius of the neutron for an exponential density distribution of the magnetic cloud can be shown to lie between the limits of 0.75×10^{-13} cm and 0.95×10^{-13} cm. The rms radius of the neutron may be taken to be $(0.80 \pm 0.10) \times 10^{-13}$ cm and is very close to the value found for an exponential model of the magnetic cloud in the proton.

Yields from the reactions $\text{Be}^9(e, e'n)$ and $\text{Be}^9(\gamma, n)$, as well as the relative yields from $\text{C}^{12}(e, e'n)\text{C}^{11}$ and $\text{C}^{12}(\gamma, n)\text{C}^{11}$, were measured under conditions which permitted a comparison of the relative effects of electrons and bremsstrahlung from electrons in producing nuclear reactions. The primary electron energies were from 6 to 17 mev in the case of Be, and 24 to 145 mev in the case of C. Comparison of the experimental results with the theory of electrodisintegration gives information

about the multipole order of the electromagnetic transitions involved. The Be^9 results agree with theory if the reaction mechanism is predominantly electric-dipole. For C^{12} , a mixture of 92% electric-dipole with 8% electric-quadrupole intensities gives agreement with theory over the energy range 28-145 mev, provided that the finite size of the C nucleus is taken into account. The method of considering the finite nuclear size in the theory is presented, and the results previously obtained by Reagan for the reactions $\text{F}^{19}(\text{e},\text{e}'\text{p})\text{N}^{17}$ and $\text{F}^{19}(\gamma,2\text{p})\text{N}^{17}$ are shown to be in good agreement with the modified theory for an electric-quadrupole transition.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 421, Dec. 29, 1958.

A magnetic quadrupole lens has been designed and is being built which defines the desired field shape by a current distribution on the inside faces of a rectangular box; the current emerges on one set of opposite faces and returns along the other set. The motive for such a design is the need for a quadrupole lens in a strong-focusing system where the radial excursion in the focusing plane generally greatly exceeds the excursion in the defocusing plane. The particular design of 40-in. length employs an aperture of $23 > < 4$ in. at a gradient of 400 gauss/in. This quadrupole in combination with a conventional $6 > < 1$ in. quadrupole and a bending magnet constitutes a 1 bev/c magnetic spectrometer of 0.013-sterad aperture and a target-to-focus distance of 20 ft. It is intended to correct the aberration of the quadrupole by differential shunting of the windings.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 421, Dec. 29, 1958.

The spectrometer, which will focus singly charged particles of momentum $p < 425$ mev/c, has been constructed and tested using the Stanford Mark III linear accelerator beam as a physical ray-tracing device. The spectrometer consists of two identical magnets, $n \approx 0.27$, 110° deflecting, 30-in. radius of curvature, bending the particles in the same sense. It has been found that the double-focusing, zero-dispersion condition is obtained for particles of ~ 300 mev/c momentum with both source and image positions symmetrically located $47\frac{1}{2}$ in. from the magnets. This gives a useful solid angle of $\Omega_0 \sim 0.0055$ sterad for particles with central momentum p_0 originating from a point on the central axis. The solid angle does not change noticeably for particles originating from points as far as ± 1 in. from the central axis. It is believed that the addition of pole-tips will increase the effective solid angle of the system. The momentum acceptance $\Delta p/p_0$ is in excess of $\pm 4\%$ with a useful solid angle of ~ 0.0015 sterad at the 4% points. For a point source and the solid angles and momentum acceptances given above, second-order aberrations prevent all particles from coming to a point focus, but 90% fall within a 2-in. diam. circle at the first-order focus.

Presented at meeting of the Amer. Phys. Soc., California U., Los Angeles, Dec. 29-31, 1958.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 3: 421, Dec. 29, 1958.

Also published in Phys. Rev., v. 113: 1330-1338, Mar. 1, 1959.

Relative measurements of the cross sections for the production of positive pions by photons on protons have been carried out in the angular range $7^\circ < \theta$ center-of-mass $< 27^\circ$ for photon energies of 220, 300, 350, and 390 mev. Positive pions were detected via the decay positron from the $\pi^+ \rightarrow \mu^+ e$ chain which was observed in a series of gates following a pulse of photons and electrons from the Mark III linear accelerator. The relative cross sections at these energies are 202 ± 28 , 168 ± 23 , 246 ± 37 , and 395 ± 90 , in arbitrary units. The angular distribution in the range indicated above is uniform within $\pm 7\%$ statistics. The results have been compared with new dispersion theory calculations using a range of values of the coupling constant and resonance energy. The experimental data at these small angles are in good agreement with the calculations; however, the fit of the calculations with available data at larger angles is not satisfactory. It is shown that the fit in either case is substantially poorer if the so-called "retardation term," is omitted.

SCATTERING OF 200-MEV POSITRONS BY ELECTRONS (Abstract), by J. A. Poirier, D. M. Bernstein, and J. Pine. [1958] [1]p. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116]) Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Los Angeles, Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 421, Dec. 29, 1958.

A beryllium target 2 g/cm^2 thick was bombarded by 200-mev positrons. A diffusion cloud chamber with a magnetic field was located behind the target and was used to detect recoil electrons from positron-electron scattering. In addition, the positron flux was measured by counting positron tracks in the chamber. About 10,000 cloud-chamber pictures have been obtained, at a positron intensity of about 60 per picture. Analysis of the pictures is in progress and the results will be presented. Attention is being concentrated on events in which the recoil electron energy is greater than 100 mev. It is expected that about 300 such events will be seen. These events will permit a measurement of the absolute differential cross section $d\sigma/dE^-$ for positron scattering as a function of recoil electron energy E^- . The integrated cross section for E^- in the range 100-200 mev will have a statistical uncertainty of about 6%. Systematic errors are expected to increase this uncertainty by about a factor of 2.

MULTICHANNEL SPECTROMETER DETECTOR, by H. W. Kendall. [1958] [5]p. incl. illus. diags. (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, and Air Force Office of Scientific Research under [N6onr-25116]) Unclassified

Published in I.R.E. Trans. of Professional Group on Nuclear Science, v. NS-5: 190-194, Dec. 1958.

The use of a multichannel detector in the focal plane of a magnetic spectrometer effectively decouples the well-known reciprocal relation between spectrometer resolution and transmission applicable to single-channel detection. The Stanford 36-in. magnetic spectrometer is used in electron-scattering experiments in conjunction with the Mark III linear electron accelerator. In order to utilize the full momentum acceptance of the spectrometer ($\Delta p/p \approx 0.05$), we have constructed a 10-channel prototype of a 50-channel scintillation-Cerenkov detection system which will possess a resolution ($p/\Delta p \approx 1000$) close to the maximum obtainable from the spectrometer. The momentum channels are defined by small scintillation counters which detect ionizing particles, consisting primarily of high-energy pions and electrons. Electrons are distinguished from mesons by Cerenkov counters which back up blocks of 10 scintillators. A coincidence is required ($2\tau \approx 3 \times 10^{-8} \text{ } \mu\text{sec}$) between a scintillation detector and the associated Cerenkov counter. A 256-channel computer-type ferrite core memory (Radiation Counter Laboratories Mark 20), divided into four manually or electronically selected blocks of 64 channels, is used to store the information from the counter array.

A scintillation counter employing a 70-lb NaI(Tl) crystal and a Swiss (AfiF) multiplier phototube has been tested with electrons of energy up to 600 mev. The plot of pulse height vs energy of incident electrons is found to be linear up to the highest energy tested (600 mev). Energy resolution of 16% has been obtained at 350 mev. The crystal is 9 1/2 in. both in diameter and length. The incident radiation, which can be either electrons or gamma rays, induces a cascade electromagnetic shower within the mass of the crystal giving rise to light which enters the photomultiplier tube. Graphs showing linearity in energy response are presented as well as plots of line shape at constant energy of the incident particle. The procedure for obtaining line breadth semitheoretically is described, and the breadth so derived compared with the value obtained in actual practice. Details of the air-tight crystal enclosure and of the crystal-photomultiplier optical coupling system are shown. (Contractor's abstract)

FREE RADICALS IN BIOLOGICAL SYSTEMS, by M. S. Blois, Jr. and R. H. Sands. [Mar. 12, 1957] 7p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)1511] and Irvine Foundation)

Unclassified

This study is concerned with the manner in which free radicals may in principle be expected to originate in biological systems. The possibilities of intracellular free radical production by (1) ordinary univalent oxidation-reduction of endogenous compounds, (2) enzymatic oxidations, and (3) ionizing radiations are considered. It is concluded that bona fide free-radical reactions appear to be present in biological systems, however, their origins may only be inferred. The existence of reversible oxidation-reduction systems employing free-radical intermediates is supported by the in vitro study of biological quinones and quinoid compounds. There are excellent theoretical reasons and some experimental evidence that enzyme-substrate reactions may involve free radicals. The production of radiation of free radicals in a living system, or for that matter even in a simple solution, has not been observed under normal conditions. Nevertheless of the 3 mechanisms discussed, the last possesses the greatest weight of indirect experimental corroboration. It is pointed out that the eventual understanding of the kinetics of free radicals and associated antioxidants will probably emphasize further the speed and precision with which living systems manipulate electrons.

FREE-RADICALS, ANTIOXIDANTS, AND CANCER, by M. S. Blois, Jr. [1957] 9p. refs. [AF 18(600)1511]

Unclassified

It has been hypothesized that free radicals play a role in some forms of chemical carcinogenesis, in radiation carcinogenesis, and in the general biological response to radiation. It is known that when an organism or tissue is irradiated, a very short period ensues in which the original energy is converted into ionization and excited states of molecules. In the next phase, a fraction of this energy is found in the form of free radicals (in particular CH₂) which then either become paired off electronwise or undergo further reaction with molecules of the protoplasm. The resulting radicals have lifetimes that depend upon the resonance stability of the species,

STA.09:004 - STA.09:007; STA.10:003

being greater for the large polynuclear compounds. It is concluded that since insufficient data are available, the free-radical hypothesis cannot be vigorously evaluated.

EPR SPECTROMETER OF VERY HIGH SENSITIVITY, by H. Misra. [1958] [5]p. incl. diags. (Sponsored jointly by Varian Associates, Palo Alto, Calif., and Air Force Office of Scientific Research under AF 18-(600)1511) Unclassified

Published in Rev. Scient. Instruments, v. 29: 590-594, July 1958.

A recording electron paramagnetic resonance absorption spectrometer of very high sensitivity, operating at a wavelength of 3 cm, is described. It is of the reflection-cavity-in-magic-T-bridge type, using a superheterodyne receiver. Its special features are: (1) a two-cavity klystron oscillator with superior frequency stability and more available power; (2) a synchrodyne system to derive local oscillator power, thus avoiding the difficulty of tracking two independent oscillators; (3) a balanced magic-T mixer which considerably reduces the noise output; (4) a double-input low-noise intermediate frequency amplifier at 30 mc; and (5) a tunable high-Q sample-carrying cavity with an almost identical cavity to balance it in the magic-T bridge. Arrangements for an oscilloscopic display of the absorption vs magnetic field and a continuous recording of the derivative of absorption vs magnetic field have been incorporated. Sensitivity of the microwave bridge system and of the spectrometer have been tested. About 1.1×10^{-1} mol of diphenyl picryl hydrazyl dissolved in purified benzene, which corresponded to approximately 1.06×10^{-14} mol of crystalline sample, has been detected by the spectrometer. VELOCITY OF LIGHT MEASUREMENT, by E. L. Ginzton. Final rept. June 1957. 7p. incl. diag. (ML rept. no. 400) (AFOSR-TR-57-44) (AF 18(600)1593) AD 133388 Unclassified

The possibilities were examined of improving the

STA.11:011 - STA.11:013

microwave cavity method for measuring the velocity of light. In a carefully executed experiment, the largest uncertainty arose due to the surface conditions. If the cavity surface impedance could be estimated to an accuracy of 1%, the velocity of propagation could be determined to an uncertainty of less than one part in 10^6 . In general, the measurement of the cavity Q was not sufficient to predict surface conditions. As a result, the microwave cavity method could not be considered to produce a result more accurate than 2 or 3 parts in 10^6 . In view of other possible methods, both already tried and in proposal stages, this accuracy did not seem to be sufficiently high to justify pursuing a microwave cavity experiment further. An alternate method is proposed for measuring the velocity of light employing barium titanate crystals as fast light valves.

An investigation was conducted on a harmonic generator which utilizes traveling-wave circuits. An expression for the harmonic current and velocity in an electron beam modulated by a traveling electric field was derived which indicates that a high harmonic current content in the beam of a traveling-wave amplifier can be expected. A frequency multiplier employing 2 forward-wave single helices in cascade was selected as the most suitable for experimental study. A dispersive helix was chosen for the output section to permit selective amplification of a particular harmonic of the input frequency; a broadband helix was chosen for the input section. An experimental traveling-wave frequency multiplier, which has an output power level on the order of 10 mw, was built and tested. The input section utilizes a nondispersive helix normally operating from 0.5 to 1.0 kmc, while the output section uses a dispersive voltage-tunable helix covering a frequency range from 2.0 to 4.0 kmc. The input section had a useful frequency range from 0.1 to 1.0 kmc. Multiplication ratios up to 10 or 15 are feasible with substantial gain and with an output power corresponding to the normal operation of the second helix as an amplifier. By using an input frequency as low as 0.1 kmc, well below the design value, harmonic output on the order of tens of milliwatts was obtained at harmonics as high as the fortieth. For a beam power of 2 to 4 and input frequencies down to 0.25 kmc, the harmonic power varied between 20 and 100 mw, depending upon the input frequency and multiplication ratios.

A GENERAL THEORY OF KLYSTRONS WITH ARBITRARY, EXTENDED INTERACTION FIELDS, by T. Wessel-Berg. Mar. 1957, 286p. incl. illus. refs. (ML rept. no. 376) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25123) AD 134852

Unclassified

A general theory of the bunching of an electron beam in arbitrary longitudinal fields is established which can be applied to multicavity klystrons without restricting the number of cavities, the shape of the RF gap field, or the length of the interaction gaps. The theory is applied to klystrons with periodic (sinusoidal) gap fields. A kinematic approach (where the motion of each electron is followed along its path) and a space-charge wave theory (based on the concept of continuous space-charge flow) are used to analyze the bunching of the beam in arbitrary RF fields. The kinematic theory, a large signal approach, is valid only for zero space charge. The space-charge wave theory, a small signal approach, holds for arbitrary space charge. Both give identical results in the region of overlapping validity (where signals are small and space charge is negligible). The general interaction theories are used to analyze single-cavity oscillators or monotrons with arbitrary, extended interaction gaps. A general theory is given which permits a unified treatment of all monotron oscillators. An oscillator which uses a resonant slow-wave structure is analyzed.

HARMONIC GENERATION AT MICROWAVE FREQUENCIES USING FIELD-EMISSION CATHODES, by J. R. Fontana and H. J. Shaw. [1958] [2]p. incl. diagrs. (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under [N6onr-25123])

Unclassified

Published in Proc. Inst. Radio Engineers, v. 46: 1424-1425, July 1958.

An analysis is presented of harmonic amplitudes in terms of the emission properties of the cathodes and the operating conditions. It is shown that the analytical difficulties presented by the peculiar form of the current-voltage relationship and by the nature of the parameters controlling the operation can be solved by the use of approximations valid under practical operating conditions. The result is an equation for the harmonic amplitudes in the emission current from a field emitter subjected to rf modulation, from which the effects of the various parameters may be seen directly, and which may be used directly to calculate the performance of any field emitter for which the basic parameters are known. As a check, values calculated from this equation have been found to be consistent with values calculated by Dyke, obtained by numerical Fourier analysis of the known emission curve of a particular field emitter.

THE INFLUENCE OF ELECTRON BEAM BEHAVIOR ON KLYSTRON EFFICIENCY, by J. R. Senise. Oct. 1958, 91p. incl. illus. refs. (ML rept. no. 552) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25123) AD 208425. Unclassified

This investigation aims, through direct experiment, at a better understanding of the behavior or velocity-modulated electron beams, with emphasis on those factors which influence klystron efficiency. The conditions of operation are those which are usually not covered by any theory but which are typically encountered in high-power klystron amplifiers. The experiments were performed with an rf beam analyzer. The analyzer is essentially a pulse-operated, magnetically-focused, S-band two-cavity klystron amplifier, with shielded gun, designed on the basis of actual tube practice. The device differs from a conventional klystron in that it has a continuously variable drift length and a beam-scanning arrangement which permit complete cross sections of the beam to be obtained; these show both the dc and the rf radial current density distributions at any given drift distance. From the data presented it seems to be generally true that at high signal levels the best beam is not necessarily the one of highest rf content but rather is the beam that is best able to transfer its rf content to the output load.

CURRENT DISTRIBUTION IN MODULATED MAGNETICALLY FOCUSED ELECTRON BEAMS, by M. Chodorow, H. J. Shaw, and D. K. Winslow. [1958] [9]p. incl. illus. diagrs. (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under [N6onr-25123]) Unclassified

Published in Jour. Appl. Phys., v. 29: 1525-1533, Nov. 1958.

Detailed measurements have been made of the dc and rf current distribution in a modulated, magnetically focused electron beam having normalized parameters in the range of values appropriate for practical medium-power and high-power klystrons. The ratio of the total rf current to the total dc current in the beam as a function of drift distance was determined experimentally under Brillouin-flow conditions for selected values of α (the ratio of the rf voltage at the input gap to the dc beam voltage). These experimental values are compared with the results predicted theoretically. Similar experimental results are presented for higher focusing fields. Detailed radial distributions of the dc and rf current were experimentally determined by using an

iris (a plate with a small hole) to allow only a small portion of the beam to be selected at any radial position. These measurements were made at various values of α and drift distance. The results for small values of α show, as predicted by theoretical considerations for a modulated Brillouin-flow beam, that the radial rf current distribution in the beam is the same as that of a beam whose modulation is represented as sinusoidal scallops on a beam of constant (volume) charge density. As either α or the focusing field, or both, are increased, the rf current is no longer confined to the beam periphery but becomes more evenly distributed throughout the beam cross section. KINEMATICS OF GROWING WAVES, by P. A. Sturrock. [1958] [16]p. incl. diagrs. refs. (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under [N6onr-25123]) Unclassified

Published in Phys. Rev., v. 112: 1488-1503, Dec. 1, 1958.

This paper is concerned with the problem of distinguishing between amplifying and evanescent waves. These have, in the past, been distinguished by considerations of energy transfer or of the initial and boundary conditions with which a wave must be associated. Both procedures are open to criticism. The problem is here interpreted kinematically: we investigate the classes of wave functions which a given propagating system may support, without inquiring into the way these disturbances may be set up, and postponing inquiry into the boundary conditions necessary. In this way, we may distinguish between amplifying and evanescent waves by determining whether a wave function which may be analyzed into "real-frequency" waves may also be analyzed into "real-wave-number" waves. This question may be answered by means of a certain diagram, which may be constructed from knowledge of the dispersion relation. Interchange of the roles of time and space leads to the statement and solution of a further problem. If a propagating system is unstable, the instability may be such that a disturbance grows, but is propagated away from the point of origin: this is termed "convective instability." On the other hand, the instability may be such that the disturbance grows in amplitude and in extent, but always embraces the original point of origin: this is termed "nonconvective instability." The statement that the system supports amplifying waves is synonymous with the statement that the system exhibits convective instability. A system which exhibits nonconvective instability may not be used as an oscillator. It is possible to distinguish between convective and nonconvective instability by a further diagram which also may be constructed from knowledge of the dispersion relation. Our theory enables us to make the following assertions. If ω is real for all real k , then any complex k , for real ω , denotes an evanescent wave.

STA.19:001; STA.20:001, 002

Conversely, if k is real for all real ω , then any complex ω , for real k , denotes nonconvective instability. The theory is illustrated by certain simple examples and by discussion of the result of weak coupling between certain types of waves.

PLASMA RESEARCH AT STANFORD UNIVERSITY (Abstract), by M. Chodorow and G. S. Kino. [1958] [2]p. (Bound with its AFOSR-TR-58-125; AD 162274) (AF 49-838)415) Unclassified

Presented at Conf. on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

The study has as its aims (1) the investigation of the use of microwaves for diagnosing the properties of a plasma and (2) the investigation of the possibility of generating or amplifying microwave signals in devices which use a plasma column as the propagating circuit. An experiment to investigate the amplification of microwave signals along an electron beam passing through a plasma is being carried out. The plasma, in this case, is the positive column of a DC Hg vapor gas discharge at a pressure of the order of 10^{-3} mm. The electron beam passes along a straight section of the column parallel to its axis. The possible electromagnetic modes of the system have been investigated theoretically and it has been shown that RF fields growing exponentially in the direction of travel of the beam may be set up. There are 2 possible amplifying modes both of which give gain which is sharply peaked at the plasma frequency in the neighborhood of the beam. Consequently by making the electron gun movable it is possible to determine the charge density variation over the cross section of the plasma column. An experimental determination of microwave propagation along a plasma column is also being carried out. It has been shown theoretically and experimentally by Trivelpiece and Chorney that slow TM waves propagate along a uniform plasma column at frequencies below the plasma frequency. The theory has been extended by a variational method to be able to predict the propagation characteristics for a plasma which is not uniform over its cross section, making it possible to carry out an independent check of the charge density measurement made in the electron beam experiment.

RESTORATION IN THE PRESENCE OF ERRORS, by R. N. Bracewell. Oct. 3, 1957, 6p. incl. diagrs. table,

refs. (AFOSR-TN-57-533) (Bound with its AFOSR-TN-57-534; AD 136520) (AF 18(603)53) AD 136519 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 46: 106-111, Jan. 1958.

The observed antenna temperature due to a celestial source distribution differs from the true distribution in being smoother; various methods are known for operating on the observed distribution to gain better agreement with the true distribution. Current practice includes restoration by successive substitutions, by the chord construction, etc., but also shows a trend towards complete omission of any restoration, which is, no doubt, partly due to awareness that the true distribution is not fully determined by the observations. The isolation of a principal solution has, however, removed uncertainty as to the significance of nonuniqueness. The remaining question as to the degree of restoration which can be tolerated is solved here in terms of statistical properties of the errors. The solution shows that any proposed method of restoration must include mention of the character of the true distribution and of the errors; otherwise cases could be constructed where the proposed method led to deterioration. In the simplest case of independent random errors and a poorly resolved distribution, the rms level of the errors relative to the observed temperature is the relevant parameter; e.g., with a random error level as great as 15%, agreement with the true distribution improves up to the third stage of restoration by successive substitutions or on application of the chord construction. RADIO INTERFEROMETRY OF DISCRETE SOURCES, by R. N. Bracewell. Oct. 3, 1957, 9p. incl. diagrs. refs. (AFOSR-TN-57-534) (Bound with its AFOSR-TN-57-533; AD 136519) (AF 18(603)53) AD 136520 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 46: 97-105, Jan. 1958.

Salient features of the theory and practice of radio interferometry are presented with special attention to assumptions and to the specifically two-dimensional aspects of the subject. The measurable quantity on an interferometer record is defined as complex visibility by generalization from an analogous quantity in optical interferometry. Subject to conditions on antenna size and symmetry, the observed complex visibility is equal to the normalized two-dimensional Fourier transform of the source distribution, with respect to certain variables S_x and S_y which are defined. This transform is in turn identically equal to the complex degree of coherence Γ between the field phasors at the points occupied by the interferometer elements. The correlation between the

instantaneous fields, and that between the instantaneous intensities are less general parameters which are, however, deducible from T. A theorem is proved according to which only certain discrete stations on a rectangular lattice need be occupied for full determination of a discrete source distribution. Procedures in interferometry are discussed in the light of this result, and an optimum procedure is deduced. Current practice is considered over-conservative, e.g., independent data in the case of the sun are obtainable only at station spacings of about 100 wavelengths on the ground, a fact which has not hitherto been taken into account. Published in I.R.E. Trans. of Professional Group on Antennas and Propagation, v. AP-5: 154, Jan. 1957.

A new class of radio echoes from the ionosphere has recently been identified at Stanford U. These echoes originate within the E and F layers, under conditions where the line of sight from a radar meets a line of the earth's magnetic field at perpendicular incidence. This appears to be the first direct evidence of a potentially

useful ionospheric scatter occurring at F layer height. The echoes are seen primarily at night, and are readily detectable with low power radars operating in the 6 to 30 mc frequency range. They are observable for several hr at a time on a large percentage of the nights. Although their exact cause is unknown, it is reasonable to suppose that they are a manifestation of low-latitude, low-intensity auroral activity in view of their night-time occurrence, and their aspect-sensitivity with respect to the earth's magnetic field. On the other hand they have been seen regularly as far south as New Mexico and are not directly associated with geomagnetic disturbances. The field-aligned ionization may be used for communication purposes in much the same manner as auroral ionization, that is, by pointing the antennas at both locations wishing to communicate, generally towards the north. The geometry of reflection from the field aligned ionization is investigated, outlining the area of "useful" ionization and the "region of communication" for both the E and F layer heights of reflection. The probability of obtaining communication from a transmitter located at Stanford to a receiver at any location within the region of communication is determined.

Published in I.R.E. Trans. of Professional Group on Antennas and Propagation, v. AP-5: 157, Jan. 1957.

It has been found that radar echoes may be obtained from ionization lying within the E and F layers of the ionosphere, and behaving as if it consisted of scattering columns aligned with the earth's magnetic field. The echoes, while generally strongest in the hours around midnight, fluctuate considerably in intensity from time-to-time and from night-to-night. The strongest reflection is obtained when the line-of-sight from a transmitter meets a field line at perpendicular incidence at an altitude roughly corresponding to the ion density maxima of the E and F layers. Although this requirement restricts considerably the area from which echoes may be received at any given geographical location, it is nevertheless possible— in the case of the F-layer—to determine whether activity exists within a sector of roughly ± 30 degrees centered on geomagnetic north. This sector is considerably wider in the case of E-layer echoes. In an effort to determine whether a relationship exists between these echoes and fluctuations in

STA.06:015 - STA.06:017

the 5577A [OI] airglow, a scatter-sounder has been operated at the Upper Air Research Observatory, Sacramento Peak, New Mexico, in conjunction with the light measurements of E. A. Manring and H. B. Pettit. Several nights, during which simultaneous records were made, have been examined in detail. A reasonable agreement between F-layer radio echoes and light fluctuations was found, suggesting a strong connection between the two effects. Certain of the diurnal features of the green airglow emission and the F-region backscatter were found to be similar.

Radio echoes due to reflection from aspect sensitive ionization aligned with the earth's magnetic field lines are consistently observed at Stanford U. The echoes corresponding to oblique reflection from the E- and F-regions of the ionosphere, have many characteristics similar to auroral echoes, although their occurrence is not associated with magnetic disturbances. The appearance of the E-region aspect sensitive, oblique echoes, has been found to be correlated with the appearance of night time sporadic-E ionization at middle latitudes. The nature of the field aligned ionizations is such that it suggests a production mechanism of charged particle bombardment, thus offering a possible explanation for the production of night time sporadic-E ionization.

ON THE INTERPRETATION OF LONG-RANGE RADIO ECHOES FROM AURORAL IONIZATION (Abstract), by S. Stein, and O. G. Villard, Jr. [1957] [1]p. (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under [Nonr-22524]) Unclassified

Presented at IRE-URSI Symposium, Berkeley, Calif., Oct. 11-12, 1956.

Published in I.R.E. Trans. of Professional Group on Antennas and Propagation, v. AP-5: 166, Jan. 1957.

Ever since the inception of continuous scatter-sounder recordings at Stanford U., long-range radio echoes from the auroral zone have been detected. These long-range echoes are attributable to reflections from ionization associated with the aurora. Long-range propagation paths from Stanford into the auroral zone via the E layer and F layer were investigated to determine the loci of perpendicular intersection between the ray paths and the terrestrial magnetic field lines. Range histograms for auroral-zone echoes were obtained for the different radio frequencies of operation. Comparisons were made between the experimental histograms and the ranges predicted by the propagation modes that occur at each frequency, in order to determine the altitudes of reflection. Through analysis of scatter-sounder PPI recordings of individual long-range auroral-zone echoes, the propagation mode can frequently be deduced. The altitude of perpendicular intersection of the ray path with the magnetic field at the range of the auroral-zone echo was determined for many cases. A conclusion from this study is: long-range auroral-zone echoes result from long-range propagation into the auroral region with reflection from ionization situated at E-region heights. This result is in accord with the investigations of auroral echoes performed by other experimenters at high latitudes.

Presented at IRE-URSI Symposium, Berkeley, Calif., Oct. 11-12, 1956.

Published in I.R.E. Trans. of Professional Group on Antennas and Propagation, v. AP-5: 166, Jan. 1957.

A 17-mc scatter-sounder was operated aboard a military transport vessel during a voyage from California to the Marshall Islands (geomagnetic latitude approximately 3° north) and return, Mar. 5-30, 1956. The equipment had a peak power output of one kilowatt and a pulse length variable from 200 to 2000 μ sec. A beam antenna was used, consisting of a three-element Yagi rotatable in azimuth and capable of being tilted so as to direct its major lobe upwards as well as along the horizon. During the evening hr, at geomagnetic latitudes less than 15°, a strong echo was obtained from ionization believed to be the F-region scatter observed by Booker and Wells at Huancayo, Peru, and first reported in 1938. The echo was present at times when the f_oF_2 was as

low as 11 or 12-mc. The measurements suggest (1) that the ionization is not, in general, field-aligned; (2) that it is in the form of a horizontal layer; and (3) that its time of appearance is a function of the geomagnetic latitude of the observing station.

constant and radius is found to be self-consistent, and is related accurately to the metallic-rod measurements when the TE fields are accounted for.

INTERACTION-IMPEDANCE MEASUREMENTS BY PERTURBATION OF TRAVELING WAVES, by R. P. Lagerstrom. Feb. 11, 1957, 131p. Incl. diagrs. tables, refs. (Technical rept. no. 7) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-22524) AD 122989 Unclassified

Three methods of perturbing traveling waves on periodic slow-wave structures are analyzed as techniques for evaluating the interaction impedance of structures suitable for traveling-wave tube and backward-wave oscillator operation. A perturbational integral relating the fields at a material perturbation to a resulting change in the propagation constant of a single mode is derived. The integral is almost identical to Kino's normal-mode perturbation expression assuming a small change in propagation constant. A dielectric-rod perturbation placed in a non- θ -varying field is analyzed without the usual assumption that the field be uniform or that the radius or dielectric constant be small. Thus, correction factors for rods of finite size are obtained, and the effective dielectric constant is compared with conducting-rod perturbations which have been analyzed by Kino. The latter are found to give more perturbation for a given radius, but the dielectric rod can afford appreciably more selection of the TM fields over the TE portion of the wave. Curves and formulae are given for evaluating impedance from measured data of both perturbed standing waves (on a resonated structure) and traveling waves. A longitudinal string of conducting needles, spaced with the same period as the structure, is proposed for separating θ - and z -varying space harmonics by virtue of their essential orthogonality in these two coordinates. A perturbation formula is presented, with examples of the anticipated simple space pattern obtained by moving the needles in both the θ - and z -coordinates in the fields of a single traveling wave. A Fourier integration is not required to separate the dominant harmonics. The presence of more than one space harmonic should be easily detected as a sinusoidal departure from a constant perturbation. A small stretchable helix is also proposed, with a qualitative discussion of the nature of its effect, as a velocity sensitive perturbation resembling an electron beam. Experimental methods and sources of error are discussed. Experimental data obtained with dielectric- and metallic-rod perturbations of a tape helix are found to be in close agreement with the beam-measured data of Watkins and Siegman for essentially the same helix. The variation of the correction factors with dielectric

Published in I.R.E. National Convention Record, Pt. 1: 19-20, 1957.

Echoes of exceptionally long delay detected by a H. F. radar located in the West Indies are interpreted as ground backscatter propagated by two successive reflections from the F-region of the ionosphere, without intermediate ground reflection. Propagation of this sort between two points on the earth requires an initial ionospheric tilt followed by one of opposite sign. Tilts of the required sort take place regularly in equatorial regions as a consequence of two daily bulges in the ionosphere, one occurring at approximately 1900 local time over the geomagnetic equator, and the other occurring around noon in the vicinity of the sub-solar point. It is shown that tilt-supported propagation can take place at frequencies considerably in excess of the MUF predicted in the usual way. It is believed that these results may explain the reports by radio amateurs of anomalous propagation between North and South America.

A study was conducted on longitudinal and transverse capacitively loaded sheath helix circuits. The approach is primarily based on a matrix analysis of linear networks and is designed for application to the external circuit TWT interaction geometry. The results obtained may be used for approximations of other types of lumped-distributed circuits. The interaction structure assumed is uniformly periodic. From the viewpoint of dispersion, the transversely loaded helix appeared to be the better circuit for forward-wave amplifier operation. The impedance in the forward mode was smaller than that for the longitudinal mode. This deficiency could be overcome by combining the advantages of the 2 types of loading: the circuit could be loaded both transversely and longitudinally with the gaps in the longitudinal arms. The transversely loaded helix with high impedance properties was recommended for backward wave oscillator operations.

SPACE CHARGE WAVES IN HARRIS-FLOW BEAMS, by H. C. Hsieh. June 6, 1957, 55p. incl. diagrs. table, refs. (Technical rept. no. 16) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 134943

Unclassified

The investigation of space-charge waves in Harris-flow beams was made under the usual assumptions of small signals and non-relativistic velocities. Emphasis was on slow TM waves propagating on an axially symmetric hollow cylindrical beam focused by a radial d-c electric field. Starting with Maxwell's equations and with aid of the equation of motion, the continuity equation, and the definition of current density, the field equations for the regions both inside and outside of the beam were found. A perturbation technique was applied to the steady-state-flow beam in obtaining the wave equation for the beam region; due to the radial component of electron motion, the beam surface is rippled. The rippled beam was replaced by a uniform cylindrical beam with an a-c surface current density. Upon applying appropriate boundary conditions, the determinantal equation was obtained. From this determinantal equation the plasma-frequency reduction factor was derived. To obtain the impedance reduction factor, an ideally thin beam was established and the thin-beam theory was employed. Thus the expressions both for the plasma-frequency reduction factor and for the impedance reduction factor have been derived and the curves showing these factors as a function of the product of beam thickness and wave propagation constant were plotted. Matched filters are defined. Their properties as optimum signal detectors are discussed, and conditions are enumerated under which matched filters are realizable. The synthesis procedure employing tapped delay lines allows the greatest adaptability. Matched filters are advantageously used in systems in which the transmitted signal may be specified by the system designer. The quality of input and output signal shapes is measured quantitatively by the effective bandwidth W_e and the effective time duration T_e . Binary matched signals offer good W_e and T_e . Two novel methods of synthesizing

matched filters, namely multiple band-pass and all-pass inverse-matched filters, are investigated. Both appear to be inferior to tapped-delay-line matched filters. (Contractor's abstract, modified)

EFFECTS OF IONOSPHERIC LAYER TILTS ON HIGH-FREQUENCY RADIO PROPAGATION (Abstract), by S. Stein. [1957] [1]p. (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under [Nonr-22524]) Unclassified

Presented at IRE-URSI Symposium, Washington, D. C., May 22-25, 1957.

Published in I.R.E. Trans. of Professional Group on Antennas and Propagation, v. AP-5: 330-331, July 1957.

The F layer, as is well known, has a complex global distribution of ion density. In addition to the conventional ionospheric parameters, the F layer may be further characterized by an equivalent layer tilt, a function of frequency and takeoff angle. Low angle rays reflected from a tilted F layer may propagate beyond the bulge of the earth, without striking the ground, and illuminate the ionosphere again. When sufficient ion density exists at the second illuminated region, the rays will propagate on around the earth. A ray may be reflected several times before striking a properly oriented tilt so that the surface of the earth is illuminated. These modes are called n^{F} modes, where n is the number of layer reflections. The theory of tilt supported modes has been successfully applied to the anomalous propagation across the equator. Theoretical Chapman layers and other models are investigated to find the ray trajectories and determine equivalent layer tilts. These results form the nucleus of a prediction scheme for tilt supported modes. The characteristics of multiple-hop ground backscatter were investigated in order to assist in recognition of n^{F} mode ground scatter. Detection of n^{F} mode ground scatter occurs as a consequence of geometrical time-delay focusing and to a lateral beam effect. Under some conditions Peterson's "minimum-time-delay" focusing is also considered. Comparisons are made between calculations and experimental backscatter records obtained at the location of Stanford U. Tilt supported rays may propagate long distances without the necessity of ground reflections and without reentering the absorbing D region except on the last leg where the earth's surface is illuminated. The radio frequency of n^{F} mode propagation is examined in comparison with the conventional muf.

POTENTIAL-MINIMUM NOISE IN THE MICROWAVE DIODE, by A. E. Siegman and D. A. Watkins. July 2, 1957 [5]p. incl. diagrs. refs. (Technical rept. no. 19) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 136032 Unclassified

Also published in I.R.E. Trans. of the Professional Group on Electron Devices, v. ED-4: 82-86, Jan. 1957.

An analysis of the potential-minimum region in the microwave diode is presented which predicts the amount of noise convection current at the potential minimum under conditions present in guns of low-noise traveling-wave tubes and klystrons. Contrary to previous work by one of the authors, this analysis partially includes the effects of finite transit angle between the cathode and potential minimum. The results indicate that under certain conditions of space-charge limitation, the noise convection current may be larger than full shot noise, whereas under other conditions reduction by as much as a factor of four may be obtained. When the results of this work are applied to the noise-figure theory of traveling-wave tubes and klystrons, it is found that their minimum obtainable noise figure may be in the vicinity of 4 db rather than the previously predicted 6 db with reasonable cathode current densities. For very large current densities or low operating frequencies, the present theory indicates that there is no theoretical limit to the minimum noise figure of such devices, in agreement with the previous work. ON THE USE OF DELAY LINES AS NETWORK ELEMENTS, by L. E. Franks. July 29, 1957, 126p. incl. diagrs. refs. (Technical rept. no. 18) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 138790 Unclassified

This study concerns the development of analysis and synthesis techniques for networks containing idealized distributed-constant elements in addition to the usual set of lumped-constant elements having parameters R , L , and C . The idealized distributed element is taken to be a lossless delay line represented by the parameters R_0 and T_0 . R_0 is the characteristic resistance and T_0 is the electrical length in terms of the time delay between terminal pairs of the delay-line element. Networks consisting of delay lines and lumped elements are called line-lumped networks. Analysis procedures are directed toward finding transfer functions for a network containing an arbitrary interconnection of delay lines and lumped

STA.06:028 - STA.06:031

elements. Some matrix methods for finding these transfer functions are presented. The transfer functions are not rational in the complex frequency variable and the usual procedures for transient analysis are not applicable. A method for transient analysis based on the time-series representation is presented. A particularly useful form of the time-series representation is the z-transform, a familiar mathematical tool for the analysis of sampled-data systems. An examination of the time-domain and frequency-domain response properties of line-lumped networks reveals some characteristics remarkably different from the responses of lumped-element networks. These characteristics are used to advantage in the development of synthesis procedures for approximating a prescribed impulse response by z-transform methods. The z-transform methods are particularly applicable to numerically prescribed data. Special emphasis is given to synthesis of networks having impulse responses of limited time duration. THE INITIAL RADIUS OF METEORIC IONIZATION TRAILS, by L. A. Manning. Aug. 20, 1957, 27p. incl. diags. tables. (Technical rept. no. 22) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 143608 Unclassified

Also published in Jour. Geophys. Research, v. 63: 181, Mar. 1958.

The formation about the path of a meteor of regions of ionized and neutral atoms of meteoric material is investigated from the viewpoint of kinetic theory. It is found that the high initial velocity of the diffusing particles causes the trail to quickly reach an "initial radius" from which normal diffusion then proceeds. It is shown that the reflected signal may for most purposes be computed on the assumption that the trail reaches this initial radius instantaneously. The value of the initial radius is approximately 14 mean-free-paths; it is thus greater for the neutral than for the ionized trail. It is shown that at very high frequencies the initial radius may reduce the amplitude of the returned signal from under-dense trails by as much as 50 db. If heating is neglected, it is shown that the effect of initial radius on over-dense trails is marked at the same heights and frequencies as for under-dense trails. (Contractor's abstract)

THE ROLE OF IONOSPHERIC-LAYER TILTS IN LONG RANGE HIGH-FREQUENCY RADIO PROPAGATION, by

S. Stein. Aug. 20, 1957, 91p. incl. illus. diags. tables, refs. (Technical rept. no. 21) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 139831 Unclassified

Long range propagation of HF and VHF radio wave propagation due to horizontal density variations in the F-layer has been studied for various multiple reflection modes. The build-up of the modes has been explained in terms of geometrical time-delay focusing. The times of occurrence, length of individual occurrence, and direction of occurrence are related to the structure of the F-layer and scattering from the top of the E-layer. Auroral reflections and radar surveillance of the auroral ionization are discussed.

TRANSISTOR MEASUREMENTS USING THE INDEFINITE ADMITTANCE MATRIX, by J. P. Paddock. Aug. 20, 1957, 27p. incl. illus. diags. tables. (Technical rept. no. 20) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 142978 Unclassified

A method is shown whereby four measurements made directly on commercial bridges may be used to find the admittance parameters of a transistor in any orientation common-base, common-emitter, or common-collector merely by taking appropriate sums of the measured quantities. Although apparently twelve short-circuit admittances are necessary to describe a transistor in all three orientations, only nine of these are unique. As shown by Shekel, the nine quantities may be arranged in a three-by-three matrix, the indefinite admittance matrix. This matrix may be completely determined if only four elements are known, since the sum of the elements in any row or column is zero. Some sets of four elements offer advantages in convenience, accuracy in measurement, and accuracy in determining the indefinite admittance matrix. The set of four elements which is superior in most circumstances is specified for junction transistors. Instruments and circuit arrangements for measuring the admittance parameters at r-f are described. (Contractor's abstract)

STA.06:032 - STA.06:034

The results are presented from a study to observe average behavior of Sporadic-E, E_s , derived from a continuous 3-yr back-scatter record. The lifetime of the 2700 E_s patches observed varied from a few minutes to 10.5 hr with a mean value of 3 hr. Every patch was examined for motion, and plots of 251 cases were made. Speed and direction distributions are presented with geographic, diurnal, and seasonal occurrence information. The speed distribution is peaked at 250 km/hr with a range from less than 100 to 1000 km/hr. Motion is predominantly west. Speeds are found to agree generally with measurements of meteor trail drift and apparent ionospheric motion measured by radio fading methods. Supporting evidence of the reality of the observed motion was obtained from vertical-incidence sounding equipment. Speed and directional variation of moving patches showed small systematic annual and diurnal variations with maximum speeds occurring in summer and winter. A larger fraction of the patches moved at night and in winter. A measure of speed change with height of occurrence of the E_s patch is obtained with an average value of 19 km/hr speed increase per km increase in height. The E_s appears more patchy when viewed looking south and west from Stanford. Evidence against E_s formation and motion by thunderstorms or electromagnetic radiation is presented. E_s formation and motion is related to turbulence and winds. (Contractor's abstract)

A STATISTICAL STUDY OF TRANSISTOR HIGH-FREQUENCY EQUIVALENT CIRCUITS, by R. L. Walker. Sept. 20, 1957, 83p. incl. diagrs. tables, refs. (Technical rept. no. 23) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 145430 Unclassified

An experiment performed upon statistically significant numbers of transistors is described. Its purpose was to evaluate the efficacies of a number of high-frequency equivalent circuits by comparing directly for each individual transistor the numerical values of selected quadripole parameters obtained by measurement and by means of the equivalent circuits under scrutiny. For a group of 93 alloy junction Ge transistors and a group of 47 surface-barrier Ge units, the percentage of error was obtained for high-frequency values of common base G_{11} , $|Y_{12}|$, $|Y_{21}|$ and G_{22} derived from the equivalent circuit and compared with values determined by direct bridge measurement. The means, standard deviations, and form of distribution of these error percentages were studied. A simple equivalent circuit coupled with a moderately complex rational

approximation for the frequency dependence of alpha produced about 10% errors in the prediction of the 4 high-frequency factors. A simpler alpha expression resulted in 25% errors, but more sophisticated expressions offered no improvement in results. The simple equivalent circuit was established as a valuable link between transistor device parameters and the quadripole parameters. New methods were developed for the determination of the base spreading resistance, the collector depletion layer capacitance, and the alpha generator cut-off frequency.

ELECTRON TRAJECTORIES IN THE BACKWARD-WAVE OSCILLATOR, by J. W. Gewartowski. Oct. 29, 1957, 55p. incl. illus. diagrs. refs. (Technical rept. no. 25) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 144456 Unclassified

Results are presented of an experimental study of the spent beam of a backward-wave oscillator. The instantaneous velocity and current of the spent beam are measured using a velocity analyzer built onto the collector of a scaled 80-mc backward-wave oscillator. The tube employs a sheet beam and interdigital line, twelve ft long. It is designed to be representative of large-space-charge tubes. The measured trajectories of the spent beam are examined to deduce the mechanism of interaction between the beam and the circuit along the whole length of the tube. It is found that the level of oscillation is determined by nonlinear effects in the convection current. Finally, the mechanism of r-f output efficiency saturation at high beam currents is found to be caused by electrons which fall back in phase from a retarding to an accelerating circuit field. THEORY OF C-W SOLID STATE MASERS, by P. N. Butcher. Dec. 15, 1957, 125p. incl. illus. refs. (Technical rept. no. 155-1) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under [Nonr-22524] and DA 33-039-sc-73178) AD 150860 Unclassified

Attention was directed toward several aspects of the theory of CW solid state masers which use crystals containing paramagnetic ions as the active material. There are 6 relaxation parameters which are of prime significance. The required pump power is determined by the product of the spin-spin and spin-lattice relaxation times for the pump transition. Contribution to the cavity Q (at the signal frequency) from the paramagnetic ions is inversely proportional to the spin-spin relaxation time

STA.06:035 - STA.06:037

for the signal transition. The value is negative if a relaxation parameter called the pump relaxation time ratio is sufficiently great, and consequently the cavity Q is negative if the ohmic losses are sufficiently small. The large-signal characteristics of a maser are controlled by the product of the spin-spin and spin-lattice relaxation times for the signal transition and the product of the pump relaxation time ratio and a sixth relaxation parameter called the signal relaxation time ratio. Cavity maser amplifiers have a constant root-gain-fractional-bandwidth product. An analysis was made of the noise in a maser, in which the ions are treated quantum-mechanically and the electromagnetic field is treated classically. The noise parameter of a 1-port cavity maser is equal to the ratio of the modulus of the cavity Q in the presence of the paramagnetic ions to the cavity Q in the absence of the paramagnetic ions. Noise parameter of a 2-port cavity maser is always greater than that of a 1-port cavity maser with the same cavity Q in the presence of the paramagnetic ions. Energy-level diagrams for the chromium ions in cobalt-diluted potassium chromite, for various directions of the magnetic field, are given in an appendix.

SIMULTANEOUS ASYNCHRONOUS OSCILLATIONS IN CLASS-C OSCILLATORS, by M. I. Disman and W. A. Edson. Oct. 7, 1957, rev. Jan. 2, 1958 [9]p. incl. diags. (Technical rept. no. 42) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22510 and [Nonr-22524]) AD 203097 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 46: 895-903, May 1958.

Consideration is given to simultaneous asynchronous oscillations in systems having a moving reference point. The system chosen for study is a Class-C pentode oscillator. It is shown, both analytically and experimentally, that self-starting asynchronous oscillations are attainable in such a system. Transient and steady-state solutions are obtained for the Class-C oscillator containing one and two degrees of freedom. The method of analysis employed is that of equivalent linearization as described by Kryloff and Bogoluboff. The existence of asynchronous oscillations is also explained by the phenomenon of negative discrimination. (Contractor's abstract)

THE GEOMETRY OF AURORAL COMMUNICATIONS, by R. L. Leadabrand and I. [W.] Yabroff. [1958] [8]p. incl. diags. refs. (Sponsored jointly by Office of Naval

Research, Signal Corps, and Air Force [Office of Scientific Research] under [Nonr-22524]) Unclassified

Presented at IRE-URSI Symposium, Washington, D. C., Apr. 30-May 3, 1956.

Abstract published in I.R.E. Trans. of Professional Group on Antennas and Propagation, v. AP-5: 154, Jan. 1957.

Published in I.R.E. Trans. of Professional Group on Antennas and Propagation, v. AP-6: 80-87, Jan. 1958.

As early as 1939, radio amateurs found auroral ionization useful for communication purposes. Such ionization makes hf and vhf propagation possible over paths as great as several hundred kilometers when other more normal ionospheric propagation modes do not exist. The geometry of reflection is investigated for a variety of transmitter locations based upon the assumption of specular reflection from columnar ionization aligned with the earth's magnetic field lines. The results of the investigations outline the region of useful auroral ionization and the regions on the earth within which the auroral propagation is possible. The probability has been determined of obtaining propagation from a particular transmitter location to any receiver location within the region of propagation. These geometrical studies allow the communicator to predict the most useful transmitter and receiver locations in utilizing auroral ionization for communication purposes. The studies also may suggest methods of minimizing the effects of auroral propagation when it is considered a detrimental propagating mode, for example, when it results in undesirable multipath effects. FERRITE ATTENUATORS FOR TRAVELING-WAVE TUBES, by L. C. Bacon. Feb. 11, 1958, 175p. incl. diags. refs. (Technical rept. no. 26) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 153715 Unclassified

Several ways of employing ferrites in traveling-wave-amplifier attenuator systems are evaluated. The properties of conventional attenuators are reviewed with special attention given to the interrupted-circuited type. The phenomenon of nonreciprocal absorption in the region of resonance for a gyromagnetic material is considered. In a discussion of the experiments with the use of ferrites in conjunction with TWT's, several difficulties are pointed out, including dielectric loading, beam defocusing, and alteration of circuit phase velocity. Suggestions for ameliorating the conditions are given. A modified version of S. E. Miller's coupled-mode theory is employed to study 2 methods of utilizing nonreciprocal coupled helices with ferrites based above resonance. A description is

given of the design and operation of a high power circuit or a traveling-wave amplifier circuit that uses a ferrite attenuator. Comparison is made with the performance of a severed circuit attenuator. The general characteristics of the ferrite attenuators are briefly discussed.

An investigation was undertaken to formulate a method for the design of multi-stage, narrow-band, transistor amplifiers. Toward this objective, a complete analysis was undertaken of the transducer gain of a multi-stage, narrow-band, iterative amplifier employing 2-terminal interstages with ideal coupling transformers, and the transducer gain of the amplifier subsequently optimized with respect to the input and output terminations and the interstage networks of the amplifier. The optimum transducer gain of the amplifier was expressed in terms of an amplifier design parameter γ . It is shown that γ is directly related to the conductance level of the amplifier. A general design method for multi-stage narrow-band amplifiers employing general 2-port active devices was formulated, with the general design criteria that, for an amplifier employing inherently stable, active devices, the amplifier so designed should develop maximum transducer power gain; for an amplifier employing potentially unstable active devices, the amplifier so designed should develop optimum transducer power gain with a certain prescribed margin of stability. The stability margin for the amplifier is related to γ , or the conductance level of the amplifier. The control of the stability of the amplifier is effected through appropriate choice of γ . Experimental evidence obtained from actual amplifier performance indicates favorably the validity of the theoretical formulations.

Because of the growing importance of two-dimensional sheet or strip beams and hollow beams in microwave

devices, a need has arisen for design data applicable to these cases. Data are presented on space-charge-limited flow, applicable to the design of convergent Pierce guns for strip beams. The nonthermal case is treated first, in order to lay the foundation for the thermal case which follows. This treatment allows calculation of the trajectory of a strip beam with zero emission velocity and includes a provision for taking into account the effect of the anode lens. A first-order analysis of the effects of initial transverse velocities is presented, following the method of Cutler and Hines. The results indicate that the beam trajectory can be calculated, including the effects of both space charge and thermal velocities. The general nature of the results is the same as in the pencil-beam case, i.e., the beam becomes thicker at points of high convergence, and the point of minimum thickness is shifted toward the cathode. The theoretical results are applied to an example taken from an experimental tube. The nonthermal strip-beam analysis can be applied under certain conditions to the case of a convergent hollow beam, and design data for this case are presented. (Contractor's abstract)

GAIN, BANDWIDTH, AND NOISE CHARACTERISTICS OF THE VARIABLE-PARAMETER AMPLIFIER, by H. Heffner and G. Wade. Feb. 26, 1958, 32p. incl. diagrs. (Technical rept. no. 28) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under Nonr-22524) AD 153170

Unclassified

Also published in Jour. Appl. Phys., v. 29: 1321-1331, Sept. 1958.

The variable parameter (or parametric) principle of amplification is characterized by a typical arrangement in which a variable energy-storage element, such as an inductor or a capacitor, is suitably coupled to two resonant circuits. If the value of the energy-storage element is made to vary in the proper way, energy is fed from the source which drives the element (that is, the pump) to the fields of both the resonant circuits. This paper describes the behavior relative to gain, bandwidth and noise of this type of amplifier. Specifically, it is shown that to increase gain, the Q of one of the resonant circuits, the one commonly called the idling circuit, must be increased or the variation in the variable reactance must be increased. The bandwidth is inversely proportional to this Q and to the voltage gain. Hence, for high gain, the amplifier is normally a narrow-band device. One of the most important sources of noise is the thermal noise originating in the idling circuit. However, in principle this source can be reduced indefinitely by making the idling frequency approach the pumping frequency or by artificially cooling the idling circuit. In this fashion very low noise figures should be possible. The parametric principle can also be applied

STA.06:041 - STA.06:043

to producing frequency conversion with large conversion gain. The appendix presents the expressions for gain, bandwidth and noise figure for this application. The behavior of the converter relative to gain, bandwidth and noise is quite similar to that of the amplifier. (Contractor's abstract)

OBLIQUE ECHOES FROM OVER-DENSE METEOR TRAILS, by L. A. Manning. Feb. 28, 1958, 20p. incl. diags. (Technical rept. no. 29) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 157095 Unclassified

Ray paths are computed for waves refracted by meteor trails having a Gaussian radial distribution of ionization density. From the spreading of initially parallel rays as they pass through the trail, a measure of reflected signal intensity versus scattering angle is obtained; the results are presented in polar scattering diagrams, valid in the limit of large trail size. Equivalence theorems are derived relating both intensity and scattering angle for rays incident upon the trail at an arbitrary angle to the intensity, and scattering angle for rays incident in the plane normal to the trail. Curves are presented showing the dependence of echo duration of forward-scatter angle with trail orientation as parameter; it is found that the $\sec^2 \theta$ law developed for underdense trails applies to over-dense trails only if the plane of propagation contains the trail axis. If not, the effective secant exponent may be as small as 0.3. The theory is compared with McKinley and McNamara's duration measurements. It is found that although the general agreement is satisfactory, the details of their experimental results depend on the way that winds change the trail orientation. The ray theory is also compared with Keitel's wave theory solution. Unfortunately, he could not get wave solutions for dense trails of age greater than 0.357% of the minimum echo duration. Even so the ray solutions agree with Keitel's results for scatter angles up to 155° , thus including all angles available to ground based stations. (Contractor's abstract)

INVESTIGATION OF THE TRANSVERSE-FIELD KLYSTRON, by B. Fank. Mar. 10, 1958, 79p. incl. illus. (Technical rept. no. 305-1) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under [Nonr-22524]) AD 159571 Unclassified

A theoretical and experimental investigation was made of the noise characteristics of a transverse-field tube. The transverse-field klystron was chosen as the simplest type of such tube for the investigation. A theory of operation was developed which includes expressions for tube transconductance, beam loading, and noise figure. Three low-frequency experimental klystrons were built to test the theory. The fundamental beam noise in a transverse-field tube is due to two independent sources: (1) the transverse velocity fluctuations, and (2) the transverse displacement fluctuations. Theoretical calculations using these two noise sources give relatively good agreement with experimental results. Although the experimental tubes were not low noise tubes, their agreement with the theory indicates the possibility that transverse-field klystrons can be designed to have low noise figures. MICROWAVE INTERACTION OF ELECTRON BEAMS AND NON-PROPAGATING PERIODIC STRUCTURES, by J. A. Ruetz. Mar. 27, 1958, 145p. incl. diags. refs. (Technical rept. no. 30) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 156783 Unclassified

The possibility of obtaining gain in periodic nonpropagating structures is investigated. The analysis uses an equivalent circuit representation of the microwave structure. The electron beam is assumed to flow through constant-field gaps followed by field-free drift regions. The gap voltage is associated with 2 different voltages of the equivalent circuit. One case assumes that the gap-voltage is the voltage appearing across a part of the shunt branch of the equivalent circuit while the other case assumes that the gap-voltage is the voltage across part of the series branch of the equivalent circuit. By making TWT approximations, one case reduces to a Bernier type analysis while the other case uses a pierce type analysis. Various approximations to the characteristic equations are discussed, and regions of validity of these approximations are investigated. The equations expressing the excitation conditions are derived in terms of the characteristic roots for the 2 types of representations. Expressions are derived relating the microwave structure to the equivalent circuit. Measurements or calculations are performed on the microwave structure to determine the circuit parameters. A calculation for a folded rectangular waveguide structure including initial modulation conditions is presented. The gain is found to be very dependent upon the terminating impedance of the structure.

Presented at IRE National Convention, New York, Mar. 23-26, 1959.

Also published in I.R.E. National Convention Record, Pt. 4: 130-140, 1959.

An investigation revealed that radar reception in the presence of jamming noise contains the elements of a conflict situation and is therefore a problem in the theory of games. The radar operators are constrained to a certain average power and a matched filter is the radar receiver. The design variable for the radar operators is the shape of the power spectral density function. The jammers, also, may choose a power spectral density function subject to an average power limitation. These spectral shapes comprise the strategies for both teams in a game. Various criteria of performance of the radar are determined by the spectral shapes chosen by each team. These criteria—the output signal-to-noise ratio, the mean square range error, and the mean square velocity error—are each, in turn, made the payoff function of the game. An analysis of each of these games reveals optimum spectral shapes from the point of view of both the jammers and the radar operators. When signal-to-noise ratio is the payoff function, constant-density, band-limited spectra are optimum for both teams. The optimum spectra associated with the other two payoff functions are discovered after finding a method to simplify the resulting games. (Contractor's abstract)

BAYES ESTIMATION OF RADAR SIGNAL PARAMETERS, by J. E. Keigler. Apr. 21, 1958, 67p. incl. diagrs. refs. (Technical rept. no. 35) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 160470

Unclassified

The concepts of statistical decision theory are applied to the problem of evaluating the parameters of a returned radar signal immersed in noise, these parameters being related to the properties of the target. It is shown that the Bayes estimation procedure is the logical procedure to use in a practical radar system and that the bounded absolute error loss function is more

appropriate to many radar situations than the customary squared error. On these premises, receivers are designed for several types of targets. The principal part of these receivers is the posteriori probability density computer which utilizes delay lines and relatively short duration impulse-response matched filters to obtain correlation between the transmitted and received signals over a much longer period. A bonus feature of some of the derived receivers is the simultaneous solution of both the detection and estimation problems. Finally, the performance of the Bayes receiver in terms of average risk, which is measured by the Monte Carlo method, is discussed. (Contractor's abstract)

Research is concerned with the study of external-circuit traveling-wave amplifiers. The inspection of the propagation and interaction characteristics of various lumped and distributed filter circuits points to 3 potential slow-wave structures for wide-band amplifier operation: (1) lumped filter networks of the bandpass type using negative-mutual inductive coupling between sections, (2) simultaneously loaded and grounded helices, and (3) single-ended loaded helices. The theory, design, construction, and operation of each of these structures is investigated. Considerable experimental evidence is given to demonstrate the possibilities as well as the limitations of these circuits with regard to size, interaction impedance, matching, bandwidth, attenuation, and gain. The results are examined in the light of existing traveling-wave tube theory. Amplifier operation is obtained in the region between 150 and 500 mc with relative bandwidths up to 50% and average gains up to 25 db. A method is presented to design attenuation in the form of resistance paper applied onto the circuits. Experimental verification of this method is included.

AIR FORCE SCIENTIFIC RESEARCH

STA.06:048 - STA.06:051

The theoretical and experimental behavior of the heli-tron oscillator was investigated. Basically the tube utilizes Harris-flow focusing; the beam travels in a helical path in which the centrifugal force on the electron is balanced by an inward electric-field force. The principal feature of this device, as distinguished from the Russian spiratron, is that interaction between the beam and circuit is such that gain in circuit field is obtained at the expense of change in potential energy of the beam. Experimental data on the 3 tubes indicated continuous voltage tuning from 1.2 to 2.4 kmc with an accompanying change in tuning voltage of from 650 to 1700 v. Power output was in the vicinity of 1 to 10 mw; and start-oscillation current was approximately 0.4 ma for a structure 4 in. long.

This study presents a method of designing interstages for transistor video amplifiers. The transistors are represented by the hybrid- π equivalent circuit. The problem of designing interstages is shown equivalent to the problem of synthesizing a transfer impedance function proportional to the stage gain where the resulting interstage network must have certain specified terminating impedances. These terminating impedances represent the effects of the transistors. The interstage synthesis technique developed emphasizes the importance of the interstage using a limited number of elements and providing a satisfactory gain-bandwidth product. Actual synthesis need never be completed until it is certain a satisfactory gain-bandwidth-product can be obtained with a given method of realization. Interstages synthesized using this interstage synthesis technique compare favorably with previously developed interstages. A set of general theoretical limitations on gain-bandwidth product have been derived. Specific limitations have been developed for two and three-terminal interstages, and it has been found quite important to specify whether or not transformers are allowed. The use of these limitations has required the derivation of a new more general resistance integral theorem. (Contractor's abstract)

The utilization of a multifilar helix as a slow wave circuit in a traveling-wave amplifier is discussed with special emphasis on the bifilar helix. A method of strapping the bifilar helix with rods directly through the center was developed. Slow-wave circuits with mode-selective loss and mode-selective stop bands were designed and constructed with the objective of eliminating the backward-wave oscillation in the anti-symmetric mode while affecting only slightly the desirable forward-wave properties of the symmetric mode. A typical circuit has a stop band in the anti-symmetric mode 50% wide in frequency, a forward-wave bandwidth of almost two to one and impedance about two-thirds that of a simple bifilar helix operated in the same mode. In addition to extensive theoretical calculations and cold-circuit measurements, two models of an experimental traveling-wave tube were constructed and operated in good agreement with the theoretical expectations.

A LUMPED MODEL ANALYSIS OF NOISE IN SEMI-CONDUCTOR DEVICES, by R. N. Beatie. May 1958 [8]p.

incl. illus. (Technical rept. no. 1505-1) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 227142
Unclassified

Also published in I.R.E. Trans. of Professional Group on Electron Devices, v. ED-6: 133-140, Apr. 1959.

A clear picture of the noise properties of semiconductor devices may be gained through a study of lumped models. When a semiconductor device is represented by a lumped model, it is found that all the noise may be accounted for by associating a noise-current generator with each of the conductances appearing in the lumped model. The expressions describing these noise-current generators are easily found, and the determination of the device noise properties involves only lumped model analysis. Such analysis to a diode model and a transistor model yields results which are in agreement with the results of other authors, and with experimental measurements cited by them. The mechanisms considered in this paper do not, however, account for the so-called $1/f$ noise. (Contractor's abstract)

A method is advanced for expanding a class of gaussian stochastic processes in terms of a complete set of orthonormal functions such that the coefficients of the terms of the series expansion will be statistically independent. The class of processes considered are those whose correlation functions are the solutions of systems of linear, homogeneous differential equations with constant coefficients. (Contractor's abstract)

A study was conducted on a linear sweep generator composed of a triggered gate generator and a bootstrap circuit, with particular attention paid to the linearity of the sweep generator output voltage and to the effects of temperature on the gate generator. For this applica-

tion germanium junction transistors can be satisfactorily used, provided care is taken in the design of the circuit. The heart of the sweep generator lies in a bootstrap type of circuit, which requires an amplifier with high input impedance and close to unity amplification. A novel way of combining 2 transistors to meet these requirements is introduced. The constant-current pair, as it will be called, is compared to the Darlington pair, and it is shown that the former presents definite advantages in this application. A solution is presented for the recovery-time problem common to bootstrap circuits. It is shown that 3 transistors are sufficient to construct a triggered sweep generator, although four may be used if only very small amounts of non-linearity can be tolerated in the sweep voltage. In the study of avalanche transistors, the simultaneous occurrence of avalanche multiplication and voltage punch-through was discovered to produce either large current pulses or pulses with a very fast rise time. An analysis of this mode of operation is given which includes some quantitative results and a description of the regenerative mechanism. The avalanche transistor was approximated by a model in order to analyze quantitatively circuits which utilize avalanche multiplication. The distributed system of the transistor can be approximated by a lumped model. The lumped model represents the flow of holes and electrons by drift and diffusion, the p-n junction relationships, the displacement currents, and avalanche multiplication within the transistor. The form of the resulting finite-difference equations does not permit their numerical solution to be usable unless the time interval in each step-by-step calculation is small. In the multiplication phenomenon, a consideration of the space charge of the conducting carriers in the depleted region is shown to account qualitatively for the dependence of avalanche multiplication upon voltage and current. Useful circuits are given for measuring the voltage at which punch-through occurs, the breakdown voltage, and the voltage at which the current gain of the transistor is unity.

Kotzebue. [1958] [1]p. [Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under Nonr-22524] Unclassified

Published in Proc. Inst. Radio Engineers, v. 46: 1301, June 1958.

The amplifier employs a back-biased germanium junction diode placed between central parts inside a rectangular cavity. With proper adjustments of the tuning screws, the cavity with diode in place can be made simultaneously resonant at 3500 mc, 2300 mc, and 1200 mc. Net gain up to 40 db has been obtained, although at such high gains the amplifier is extremely sensitive to load variations since no isolator or circulator is employed.

SOLID-STATE MICROWAVE AMPLIFIERS, by H. Heffner. July 25, 1958 [9]p. incl. illus. diagrs. tables, refs. (Technical rept. no. 56) [Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under Nonr-22524] AD 218021 Unclassified

Published in I.R.E. Trans. of Professional Group on Microwave Theory and Techniques, v. MTT-7: 83-91, Jan. 1959.

The maser and the parametric amplifier form a new class of microwave amplifiers which can exploit the properties of bound electrons in a solid. These amplifiers have several common characteristics, among them being their very low-noise performance. This paper reviews the method of operation of these amplifiers, discusses the performance achieved and achievable by the various versions, and points up some of the difficulties involved in effectively utilizing the extremely low-noise figures obtainable. A bibliography is included in which an attempt has been made to include all published papers on masers and parametric amplifiers.

Presented at I.R.E. National Convention, New York, Mar. 24-27, 1958.

Also published in I.R.E. National Convention Record, Pt. 4: 22-26, 1958.

"Comparison of Experiments" is the name given to a recently developed topic in statistical decision theory. It deals not with the making of decisions but with the data (or experiment) upon which the decision is based. After a brief discussion of statistical decision theory and comparison of experiments in general, some practical methods are developed for comparing experiments with an infinite as well as a finite number of outcomes. Examples are then given of the application of these methods to radar detection and elementary binary coding. In the radar case comparison of experiments amounts to comparison of the signals used to detect a target. This application may therefore be coded comparison of radar signals. In the coding case the problem of signal repetition to provide reliability of data transmission is considered. The relationship between the number of repetitions and the probability of correct transmission of a single digit is investigated. (Contractor's abstract)

THE LINEAR LEAST SQUARES SYNTHESIS OF CONTINUOUS AND SAMPLED DATA MULTIVARIABLE SYSTEMS, by R. C. Amara. July 28, 1958, 130p. incl. diagrs. refs. (Technical rept. no. 40) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 201443 Unclassified

The class of systems treated in this report is that characterized by a multiplicity of inputs and outputs. For such linear multivariable systems subject to continuous and sampled stochastic inputs with arbitrary self- and cross-correlations, a derivation is made of the minimization equations to be satisfied by the optimum transfer-function matrix. The criterion of performance which is used is the minimization of the sum of the mean-square errors between the set of actual outputs and a set of desired outputs. In each case the errors are evaluated at all instants of time. The analysis divides the multivariable problem into two principal parts. In the first, designated the filter case, are included those systems in which the only restriction on the linear transfer-function matrix to be realized is that of physical realizability. Included in the second, the control case, are those systems in which a controlled matrix is specified which imposes additional restrictions on the overall performance of the system. The results of the analysis are presented compactly in matrix form. (Contractor's abstract)

Specific regenerative comparator circuits employing semiconductor diodes are studied and analyzed. Linear analysis reveals certain criteria useful in minimizing comparison errors due to temperature variations. Also linear analysis is found useful in the study of the limits imposed upon comparator accuracy by circuit noise. Nonlinear analysis is a necessary method for studying the transition region between stability and instability in regenerative circuits. Experimental studies substantiate the usefulness of temperature compensation techniques and the limit to which they may be carried. Measurements made at a constant temperature clearly indicate that noise within the comparator circuit limits the precision with which comparison can be effected.

SLALOM INJECTION FOR THE HELITRON OSCILLATOR, by J. L. Jones. July 28, 1958, 71p. incl. illus. diagrs. (Technical rept. no. 46) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 202509
Unclassified

The study is concerned with a new type of electron beam injection for the helitron oscillator. The helitron is a voltage-tuned backward-wave oscillator in which the focusing of the electron beam depends upon a balance between centrifugal force of helical motion and a radial electrostatic field. The injection mechanism is called slalom injection since the beam is first launched into a path like that of Slalom-Focusing and then injected from the slalom path into the concentric-cylinder geometry of the helitron. A physical description of the slalom injection scheme is followed by a discussion of electron-trajectory computations which were made using data measured on a 2-dimensional model painted on Teledeltos paper. A new electron gun was designed which produces a convergent strip beam. Test results indicated a 95% beam transmission out of the gun, although the shape of the beam and the minimum thickness were not entirely satisfactory. Test results with an experimental beam tester tube indicated a beam transmission of 40% of cathode current to the collector. A variation of 20 to 40% transmission was measured over a simulated tuning range of 2 to 1 in frequency. (Contractor's abstract)

A study was conducted to introduce and demonstrate some properties of the iterative method of zero-pole network synthesis in the frequency domain, as well as to extend its applications. Maximally flat or equal ripple frequency response approximation is used in illustrations and applications. The philosophy of the iterative method consists of the choice of reasonable starting poles or zeros of a network function corresponding to a designated circuit configuration, and the repeated computation of zeros from poles and vice versa through the use of the realization and frequency response constraints, alternately, until it converges within the desired accuracy. Some special outcomes of the iterative process are identified and illustrated. A degeneration phenomenon makes some element values of the original circuit zeros or infinity ultimately as the iteration progresses. An oscillation phenomenon does not yield convergent solutions (even if a solution exists) but poles and zeros of the network function oscillate between two different sets of points. A quasi-divergence phenomenon behaves like a random process and does not converge practically. The last two phenomena justify a statement that the iterative method may not work even though a solution exists. A description of limitations of the iterative method, comparison of the equating-coefficient and Darlington's methods in the iterative computation, and a modified equation of iteration are given. Linear-phase networks with equal ripple approximation utilizing allpass transfer function are synthesized. Design charts for these allpass transfer functions of lower orders are computed. Applications to the synthesis of two-channel amplifier circuits and three-terminal pair networks are illustrated.

Also published in Proc. Inst. Radio Engineers, v. 46: 1141-1152, June 1958.

Lumped models are shown which can be used to approximate the properties of transistors and diodes over a wide

STA.06:063 - STA.06:066

range of conditions and applications. Two analytical procedures lead to a lumped model approximating a distributed system. In the familiar one, a differential analysis of the distributed system is made, subsequently a rational approximation is made to the transcendental functions resulting from the differential analysis. In the other, one makes a lumped model at the outset to approximate the distributed system and analyzes it. The lumping approximation at the outset generally amplifies the analysis and permits consideration of phenomena which would be prohibitive to analyze on a differential basis. Throughout, it provides a close tie of analysis to the physical phenomena involved. A lumped model for diffusion transistors is shown which is analogous in end result to the Ebers-Moll model. The simple model is subsequently amended to account for the drift phenomenon, photo effects and avalanche multiplication. (Contractor's abstract)

SENSITIVITY OF ACTIVE NETWORKS TO VARIATIONS IN INTERNAL PARAMETER, by E. M. Davis, Jr. Aug. 29, 1958, 159p. incl. diagrs. refs. (Technical rept. no. 47) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 203049 Unclassified

An important consideration in the design of an amplifier is the extent to which the amplifier's performance can be desensitized to changes in its active elements. The three possible methods of achieving gain constancy despite changes in the parameters of a linear network are described. The sensitivity of the amplifier's gain to parameter variations is mathematically defined both for the case of differential changes in elements and for the case of large changes. The over-all gain of a linear circuit is shown to be a bilinear transformation of any internal element. The conditions necessary for amplification to be independent of changes in the active elements are presented in terms of the coefficients of the bilinear transformation and also in terms of circuit (or system) parameters. The sensitivity of the amplification of a linear network to changes in an internal two-terminal element is proportional to the impedance mismatch existing between that element and the remainder of the circuit. A measure, related to mismatch in the two-terminal case, is given which is proportional to the sensitivity to variations of transfer parameters.

GAIN, BANDWIDTH AND NOISE IN A CAVITY-TYPE PARAMETRIC AMPLIFIER USING AN ELECTRON BEAM, by G. Wade and H. Heffner. Oct. 2, 1958 [13]p. incl. diagrs. refs. (Technical rept. no. 54) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 212293 Unclassified

Also published in Jour. Electronics and Control, v. 5: 497-509, Dec. 1958.

A modulated electron beam flowing across the gap of a resonant cavity can change the gap capacitance at the modulating frequency, thus producing the variable capacitance needed for a parametric amplifier. Such a beam-type parametric amplifier has been proposed independently by the authors and by T. J. Bridges and has been constructed by Bridges. This paper presents an investigation of the gain, bandwidth, and noise figure which can be expected. It shows that complete cancellation simultaneously of the two uncorrelated noise sources in the electron beam, while feasible in principle, is virtually impossible in practice. The conflicting requirements of large beam current for acceptable capacitance variation and large plasma wavelength for optimum noise cancellation lead to practical minimum noise figures in the vicinity of 3 db. A design example is worked out for an amplifier with pump frequency at 2000 mc amplifying at 500 mc/s with a gain of about 15 db. The resulting bandwidth is 43 kc. A noise figure of 3.4 db could be achieved with some difficulty. (Contractor's abstract)

COUPLING NETWORK DESIGN USING DISCRETE-FREQUENCY DATA, by P. A. Ligonides. Oct. 22, 1958, 179p. incl. illustrations. (Technical rept. no. 45) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 206210 Unclassified

A method for the design of practical lossless ladder networks, based on a point-by-point matching in the frequency domain, is described. The load-terminating

STA.06:067 - STA.06:069;
STA.21:001

Impedance and the desired input impedance to the coupling network when so terminated, are described in the data by values at a number of discrete frequencies (as might result from source and load measurements). The values of the electrical elements in the coupling structure are related by convenient means to its matching properties. A simple design procedure is developed, for two- and three-element ladders, by minimizing the mean-square error in the desired input admittance or impedance at the frequencies considered in the data. The minimization procedure is simple enough when three variables (electrical elements) are involved--and for most practical cases two- and three-element networks are satisfactory on account of their simplicity. (Contractor's abstract)

A SEMICONDUCTOR-DIODE PARAMETRIC AMPLIFIER AT MICROWAVE FREQUENCIES, by K. L. Kotzebue. Nov. 4, 1958, 66p. incl. illus. (Technical rept. no. 49) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-22524) AD 206202 Unclassified

A microwave parametric amplifier is examined both theoretically and experimentally. The usual small-signal theory of "three-frequency" parametric amplifiers is presented and extended, yielding information regarding the large-signal behavior as well as the small-signal performance. Expressions are developed for the small-signal gain, bandwidth, and noise figure; and approximate large-signal expressions are developed for the saturated power output, the required pump power to start oscillation, the power output as an oscillator, and the efficiency as an amplifier and oscillator. Assuming that the variable-reactance element used in the parametric amplifier is a back-biased semiconductor diode, minimum diode characteristics are obtained in terms of the diode "Q" and fractional capacitance swing. AIR MOTIONS AND THE FADING, DIVERSITY, AND ASPECT SENSITIVITY OF METEORIC ECHOES, by L. A. Manning. Dec. 10, 1958, 29p. incl. illus. refs. (Technical rept. no. 50) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research] under Nonr-22524) AD 211624 Unclassified

A theory is presented that discusses those properties of meteoric echoes that depend on distortion of the trail by winds. The existing results concerning the delay in the start of echo fading (Greenhow), the delay in echo

appearance with aspect (McKinley and Millman), the spectral composition of the received signal (Manning, Villard, and Peterson), and the regularity of the fading pattern, are quantitatively explicable. In addition, the theory predicts that the ensemble average rate of echo fading should rise characteristically with time and should then drop precipitously at the end of the ensemble echo. Moreover, it predicts that the correlation of fading patterns at two ground receivers should be a Gaussian function of the product of receiver spacing and echo fading cycle-number. Experimental results are given confirming these predictions and making possible the determination of the principal properties of the wind profile. It is concluded that at the times of observation the small-scale cut-off wavelength of the turbulence spectrum was about a kilometer, that lack of correlation of wind velocities existed in a vertical range of about a scale height, that the rms variable component of N-S wind velocity was about 50 m/s, and that the rms value of the relative maxima of the vertical gradient of a component of the wind velocity was about 100 m/s. These figures agree with photographic studies of meteor trails made by Whipple. (Contractor's abstract)

REFLECTION AND TRANSMISSION AT A SHARPLY-BOUNDED IONOSPHERE, by I. W. Yabroff. July 29, 1957, 70p. incl. diagrs. refs. (Technical rept. no. 1) (AFOSR-TN-57-466) (AF 18(603)126) AD 136457 Unclassified

Experimental evidence indicates the ionosphere can be treated as sharply-bounded for radio waves incident from below at frequencies less than 200 kc. Equations are derived for the calculation of reflection coefficients and characteristics of the waves excited within the ionosphere such as the direction of phase and energy

STA.21:002 - STA.21:004; STT.01:001

propagation, phase velocity and attenuation rate. These equations are valid at all frequencies and any arbitrary angle of incidence. A complete set of curves is shown for an isotropic medium and some curves are shown for an ionosphere with the earth's magnetic field included. At very low frequencies, it is shown that the reflection coefficients are independent of azimuthal angle of incidence, to a first approximation. The "quasi-longitudinal" approximation, which is often used at very low frequencies, is shown to give reflection coefficients which are accurate to within ten percent when the plasma frequency is larger than twenty times the wave frequency. However, the calculated wave normal and ray directions within the ionosphere are very much in error when this approximation is used. The case of incidence from within the ionosphere is treated and a sample calculation is shown.

COMPARISON OF WHISTLERS WITH MAGNETO-IONIC DUCT SIGNALS FROM STATION NSS (Abstract), by R. A. Helliwell and E. Gehreis. [1958] [1]p. (Sponsored jointly by [Air Force Office of Scientific Research] under AF 18(603)126 and [Office of Naval Research] under Nonr-22527) Unclassified

Presented at IRE-URSI Symposium, Washington, D. C., Apr. 23-26, 1958.

Published in I.R.E. Trans. of Professional Group on Antennas and Propagation, v. AP-6: 312, July 1958.

The time delays of one-hop whistlers and echoes from NSS (near Washington, D. C.), were measured at Cape Horn on 15.5 kc. They correlated closely, even though their day-to-day variations were large. The whistler variations could not, therefore, be attributed to changes in the location of the causative lightning flashes. At Washington, D. C., there were eighteen two-hop whistlers which were coincident at Cape Horn. Their dispersions were thirty per cent greater, on the average, than twice those at Cape Horn. If the propagation path had been the same for the Cape Horn and Washington whistlers, the dispersion ratio should have been exactly two. These results are compared with NSS split-echo data and recent whistler data from the IGY program. The study provides new evidence that magneto-ionic duct signals are often restricted to discrete paths. Two possible models for such paths are compared. They are based on (1) columns of field-aligned ionization extending into the outer ionosphere and (2) irregularities in the E or F2 layer. Tape recordings of whistlers at Washington, D. C., were kindly supplied by H. E. Dinger of the Naval Research Laboratory.

SELECTED SCALING PROCEDURES FOR LIQUID-FUEL ROCKET ENGINES, by S. S. Penner. Mar. 31, 1958, 14p. (Rept. no. S/TD 1241; technical note no. 6) (AFOSR-TN-58-416) (AF 18(603)107) AD 158219; PB 144656
Unclassified

The scaling rules of intermediate scope were considered and included studies of (1) scaling with maintenance of stability for high- and low-frequency motor oscillations, and (2) scaling with maintenance of similarity for selected Reynolds numbers and for high-frequency stability. The approaches investigated in the latter study included (1) Crocco's procedure of using a fixed injector configuration and constant chamber Reynolds number, and (2) constant Reynolds number based on the spacing of fuel and oxidizer injector orifices. The interplay of spray formation, evaporation and chemical reactions, superimposed on the complex flow patterns in real engines, presented interpretive and analytical problems. The studies on similarity analysis and engine scaling indicated that the requirements for similarity of some important aspects of engine combustion were mutually contradictory. The studies suggested a need for an experimental program which may lead to logical procedures for optimizing the required violation of the similarity rules. (Contractor's abstract)

An investigation is made of Markov chains to point out that the properties of Markov processes satisfying certain conditions are true even for generalized processes. A matrix function $P(t) = (p_{jk}(t))$ is a generalized Markov process if (1) $0 \leq p_{jk}(t) \leq 1$, (2) $p_{jk}(s+t) = \sum_m p_{jm}(s) p_{mk}(t)$, and (3) $\lim_{t \rightarrow 0} p_{jk}(t) = \delta_{jk} = p_{jk}(0)$, where the indices j, k, m range over all non-negative integers, the parameters s, t range over all positive real numbers, and δ_{jk} is the Kronecker symbol. An ordinary Markov process is supposed to be substochastic

This report is a survey of the literature in the field of liquid spray behavior. Part I is a discussion of the known means for atomizing liquids and the mechanisms for jet and sheet breakup under the various environments of non-burning media. The subsequent distributions and behavior of liquid drops in sprays are then examined. Application to rocket motors of sprays formed by impinging jets is considered in some detail. Part II deals with those aspects of sprays associated with the combustion process. Mixing of propellants is considered first. Then the empirical laws of evaporation are reviewed, both for single droplets and for sprays. Finally spray combustion is examined. It is concluded that the combustion process is quite complex in that it involves the interaction of many physical and chemical rate processes, the details of which still pose a formidable challenge. Nevertheless, our understanding of the essential features of spray combustion has progressed sufficiently to permit reasonable semi-empirical correlations in terms of measurable quantities. (a) $\sum_k p_{jk}(t) \leq 1, j = 0, 1, \dots; t > 0$. Of probabilistic interest are regular Markov processes which are supposed to be strictly stochastic, (b) $\sum_k p_{jk}(t) = 1, j = 0, 1, \dots; t > 0$. Consideration is given the processes satisfying conditions a and b. The analytic theory developed attains a symmetric status since rows are not preferred and the transposed matrix $P^*(t)$ also satisfies condition 1, 2, and 3. The known results are completed for ordinary Markov processes, and some new results are obtained. Discussions are presented of semigroups of positive matrices, semigroups of Toeplitz matrices, and semigroups of symmetric matrices. (ASTIA abstract)

THE LIMIT DISTRIBUTIONS FOR SUMS OF MARKOV CHAIN VARIABLES WITHOUT SECOND MOMENTS, by L. J. Cote. Sept. 1957 [7]p. (Research rept. no. 15) (AFOSR-TN-57-647) (AF 18(600)760) AD 136633
Unclassified

Proof is completed for the limit distributions of sums of Markov chain variables without second moments. With notation taken from a previous study, let $\{X_n\}$ be a stationary Markov chain whose states, the non-negative integers, form a positive recurrent class; let the recurrence time distribution for some state i have a $(1 + \delta)^{\text{th}}$ moment; if $f(\cdot)$ is any real-valued function of integers such that for all constants, A ,

$$Z_1 = \sum_{\alpha = v_1}^{v_2-1} [f(X_\alpha) - A]$$

has a distribution in some stable domain with characteristic exponent $\neq 1$, then $S_n = \sum_1^n f(X_\alpha)$, when properly

normed has a stable distribution. The following assumptions are made: (1) for every A the distribution of the Z_v is in some stable domain with characteristic expo-

nent different from unity; and (2) the recurrence time distribution for state i has a $(1 + \epsilon)^{\text{th}}$ moment. The norming constants, B_{ρ_i} , are similar to those of Doeblin which are the sums of the norming constants for the Y_v and those for the recurrence times. Condition 2 may be lightened since it is imposed to avoid difficulty in choosing the B_{ρ_i} .

Five aspects of Markov chains were investigated during the contract period: (1) continuous parameter Markov chains, (2) discrete parameter Markov chains, (3) general Markov processes, (4) application to random walks, and (5) application to stochastic approximation. Important results include the first proof of the existence of a continuous derivative of the transition probability function $p_{ij}(t)$ when i is a stable state; the first nontrivial instance of the strong Markovian property; and the

SYR.01:023-025; SYR.09:001, 002

discovery that analytical results can be obtained without any assumption regarding the row sums of the matrix, thus rendering the roles of the rows and columns symmetrical.

if i is stable), then for each j , $p_{ij}'(t) \in C(0, +\infty)$ and $p_{ij}(t_1 + t_2) = \sum_k p_{ik}'(t_1)p_{kj}(t_2)$. He now proves that if j is stable, then for each i , $p_{ij}'(t) \in C(0, +\infty)$ and $p_{ij}'(t_1 + t_2) = \sum_k p_{ik}(t_1)p_{kj}'(t_2)$. He also notes (at the suggestion of K. L. Chung) that $p_{ij}(+\infty) = 0$ if either i or j is stable. (Math. Rev. abstract)

TWO-COMPONENT SPINORS IN GENERAL RELATIVITY (Abstract), by P. G. Bergman. [1957] [1]p. (AF 18(600)1124) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 240, Apr. 25, 1957.

Originally, H. Weyl related two-component spinors to a general Riemannian metric through quadrupoles, thus introducing local Lorentz transformations. As an alternative procedure, formulation is undertaken of the basic algebraic relationships in a direct covariant manner without reference to quadrupoles. In this formalism the groups of coordinate transformations in four-space and of unimodular transformations in the 2×2 spin space are unrelated to each other. It is possible to introduce spin-affine connections and, with their help, to construct a spin-curvature tensor. The latter is simply related to the usual Riemann-Christoffel tensor of Riemannian geometry.

TRAPPING LIFETIME AND SPIN-LATTICE RELAXATION OF PHOTOEXCITED CONDUCTION ELECTRONS IN SILICON (Abstract), by A. Honig. [1958] [1]p. (AF 18(603)50) Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago U., Ill., Nov. 28-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 377, Nov. 28, 1958.

The spins of electrons bound to the impurity atoms in nondegenerate n-silicon can relax to the Boltzmann distribution by means of electron exchange with the conduction electrons. At liquid helium temperatures, electrons can be excited into the conduction band with infrared radiation. By measuring the time for the bound spins to relax to the Boltzmann distribution as a function of the number of photons absorbed per sec per cm^3 , one can obtain the electron's lifetime against trapping, provided the conduction electron spin-lattice relaxation time, τ_{s-L}^C , is known. Such a determination of trapping lifetime was made, using for τ_{s-L}^C the value obtained from the line width in a degenerate phosphorus doped silicon sample. Recent experiments on nondegenerate phosphorus doped silicon samples of varying donor concentration and degree of compensation indicate that τ_{s-L}^C of the photoexcited electrons depends on the number of impurities and is considerably shorter than τ_{s-L}^C of electrons in low concentration degenerate samples. Using τ_{s-L}^C obtained from these experiments,

SYR.10:003; SYR.11:001;

The effect of yielding of variables in the stimulus characteristics, the group characteristics, learning characteristics, and individual characteristics, was studied. Conformity, normative influence, or yielding were defined as the tendency of an individual to express judgments publicly which are in agreement with the expressed consensus of the group. An 80-item test was developed. Perceptual, attitudinal, and informational items were included. The test was shown to be reliable. Age was inversely related to susceptibility to normative influence. Females were more conforming than males. The persistency of the influence effect was inversely related to the length of time the subjects were exposed to group consensus without reinforcement. Among the group factors, the larger the group majority, the more influence it had on the modification of the individual's judgments. The presence of the stimulus and its influence on conformity were compared with that of responding from memory. No differential effects were found. The more ambiguous the situation, the more was the individual influenced by the decision of others. The individual's own habit hierarchy and his own perceptions were shown to affect the degree to which the individual was influenced by others. The degree to which individuals yield may be reduced under motivations where their personal needs may be threatened if performance is not satisfactory.

MEASUREMENT OF SPIN-SPIN RELAXATION TIME IN PHOSPHORUS-DOPED SILICON (Abstract), by A. Honig and E. Stupp. [1958] [1]p. [AF 18(603)50]
Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 9, Jan. 29, 1958.

The electronic spin-lattice relaxation times are of the order of minutes for sufficiently dilute concentrations of phosphorus in silicon. Because of this isolation of the spin system from the lattice, it has been possible to investigate directly the kinetics of the spin-spin relaxation by a simple procedure. Abragam and Combrisson have shown that a partial spin temperature is established at a value of the magnetic field such that the Zeeman and hyperfine energies are equal. At this field value, a redistribution of the populations of the three lowest lying states can occur via the spin-spin interaction without any energy exchange with the lattice. By sweeping the magnetic field through this region at varying rates, and subsequently measuring the populations of the different hyperfine levels by microwave resonances, we obtained a measure of the spin-spin relaxation time. For a phosphorus concentration of $1.4 \times 10^{16}/\text{cm}^3$, about 1 second must be spent in passing over the line width to obtain half of the relaxation. In interpreting this result, it must be kept in mind that for a particular value of the external magnetic field, the spin packets that can interact to produce a spin temperature are restricted to those which do not require energy from the lattice.

TWO-COMPONENT SPINORS IN GENERAL RELATIVITY, by P. G. Bergmann. May 1957, 19p. (Technical note no. P-9) (AFOSR-TN-57-259) (AF 18(600)459) AD 126557 Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 240, Apr. 25, 1957.

Also published in Phys. Rev., v. 107: 624-629, July 15, 1957.

A general-relativistic theory is developed of two-component spinors somewhat along the lines pioneered more than twenty years ago by H. Weyl and by L. Infeld and B. L. van der Waerden. This formalism is in some respects more natural than the theory of four-component spinors. To begin a set of four 2×2 Hermitian matrices, σ^μ , are introduced into a four-dimensional manifold (the basic geometric structure used). It is shown that these matrices by themselves define uniquely a Riemannian metric with the usual signature of a space time manifold. It turns out that one can describe the gravitational field and its laws very conveniently in this matrix formalism; at the same time the σ^μ enable one to construct invariant two-component and four-component spinor wave equations. These formal possibilities are then used to define local Lorentz transformations and, in particular, the transformations corresponding to time reversal and to parity. QUANTUM MECHANICAL IRREVERSIBLE GIBBSIAN ENSEMBLES, by C. R. Willis and P. G. Bergmann. Oct. 1957, 37p. (Technical note no. P-11) (AFOSR-TN-57-623) (AF 18(600)459) AD 136611 Unclassified

A model of irreversible processes of Lebowitz and Bergmann is extended from the classical to the quantum mechanical domain. This model permits the construction of Gibbs-type ensemble for open systems not in equilibrium. The internal dynamics of the system that is engaged in a non-equilibrium process is assumed to be described fully by its Hamiltonian. Its interaction with its surroundings, i.e., the driving reservoirs, is described in terms of the weak, but sustained, interactions of perturbation theory. The reservoir consists of either free fermions or free bosons linearly or quadratically coupled to the system. The ensemble obeys an integral equation in configuration space, containing both the terms of the Liouville equation and a stochastic integral term that describes the interaction with the reservoir. It is shown for a restricted but important class of interactions that equilibrium is approached monotonically. (Contractor's abstract)

Also published in Phys. Rev., v. 111: 1182-1187, Aug. 15, 1958.

The construction of a complete set of quantities in general relativity, whose functional form is invariant under coordinate transformations, is indicated. The set obtained is highly redundant. The Cauchy problem for obtaining an independent complete set of observables is discussed. It is also pointed out, that the observables obtained may alternatively be viewed as the metric tensor in a special gauge, i.e., with a special coordinate condition. This latter viewpoint may readily facilitate the quantization of general relativity. (Contractor's abstract)

SUMMARY OF THE CHAPEL HILL CONFERENCE, by P. G. Bergmann. [1957] [3]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)-459] and National Science Foundation) Unclassified

Published in Rev. Modern Phys., v. 29: 352-354, July 1957.

A summary of the relativity conference on the role of gravitation in physics which was held at the University of North Carolina in Jan. 1957 and a commentary on the three central headings of the conference papers are presented in terms of the accomplishments described in the several papers and the expectations of progress in each of these areas. The discussion is presented under two main headings: (1) the nonquantum theory of gravitation, and (2) the quantum theory of gravitation. A third topic, the theory of measurement, serves as a link between the other two.

MODEL OF A NONEQUILIBRIUM ENSEMBLE: THE KNUDSEN GAS, by J. L. Lebowitz and H. L. Frisch. [1958] 27p. (AFOSR-TN-58-266) (AF 18(600)459) AD 134845
Unclassified

Also published in Phys. Rev., v. 107: 917-923, Aug. 15, 1957.

An example of a nonequilibrium ensemble is constructed: a Knudsen gas in a container whose walls are maintained at different temperatures. The approach to a stationary state is investigated, and an iteration procedure for finding the stationary velocity distribution is derived. An explicit stationary solution is found for the case where a Knudsen thermal accommodation coefficient completely characterizes the effect of gas collisions with the walls. An expression for the rate of heat transfer from the wall is calculated. A stochastic mathemati-

A THEORY OF PARTICLES OF SPIN ONE-HALF, by A. O. Barut. [1958] [11]p. [Technical note no. P-15] (AFOSR-TN-58-820) [AF 18(600)459] AD 222413
Unclassified

Also published in *Ann. Phys.*, v. 5: 95-105, Oct. 1958.

From the two-component second order fermion theory of Feynman and Gell-Mann a four component theory of spin- $\frac{1}{2}$ particles in Hamiltonian form is derived. When a suitable indefinite metric is introduced in the spin space by means of charge density, the spin as well as the charge degrees of freedom may be separated. Spin and angular momentum are separately constants of the motion which is not the case for the Dirac equation. If states with positive norm describe particles, the states of the corresponding charge conjugate particles have negative norm. The Hamiltonian is quadratic in the momenta which allows a straightforward transition to the nonrelativistic Pauli equation. The law of transformation of the wave function under the Lorentz transformations is given, and the relation and equivalence of the theory to Dirac and Foldy-Wouthuysen equations is established. CONSTRUCTION OF OBSERVABLES IN GENERAL RELATIVITY (Abstract), by A. Komar. [1958] [1]p. [AF 18(600)459]
Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in *Bull. Amer. Phys. Soc.*, Series II, v. 3: 68, Jan. 29, 1958.

If the field equations of general relativity are satisfied, then one can construct at each world point exactly four A^i as the roots of eigenvalue problems involving the curvature tensor. If these four scalars are algebraically independent of each other, they can serve as a uniquely defined (local) "canonical" coordinate system. The components of the corresponding canonical metric tensor are individually invariants; if they are given as functions of the four A^i , the Riemannian manifold is thereby uniquely characterized. Hence, these ten functions of four arguments represent a complete system of observables. This system is still highly redundant. In addition to the usual ten field equations, the components of the canonical metric tensor satisfy four additional differential equations, "coordinate conditions" that assure the canonical character of the coordinate system A^i . The Cauchy problem for these fourteen differential equations will be discussed. Its solution will yield a complete set of independent observables.

SUBSIDIARY CONDITIONS IN COVARIANT THEORIES, by P. G. Bergmann and A. I. Janis. [1958] [10]p. Incl. refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)459], Office of Naval Research, and National Science Foundation) Unclassified

Published in *Phys. Rev.*, v. 111: 1191-1200, Aug. 15, 1958.

We have investigated the effect that coordinate conditions and similar conditions will have on the formal properties of covariant theories. Two distinct types of coordinate conditions were included, those involving first derivatives of the field variables (such as the gauge condition of Lorentz and the coordinate conditions of De Donder) and those algebraic in the field variables (of which the

Coulomb gauge is an example). We have found that with either type of coordinate condition we can construct a variational principle, or a Hamiltonian formalism, which leads to physically meaningful field equations if associated with appropriate initial conditions on a space-like hypersurface. Thus the existence of a properly set Cauchy problem is always assured. It had been found previously that the infinitesimal invariant transformations of covariant theories form a group and the coordinate (and similar) transformations represent a normal subgroup. The members of the resulting factor group are in one-to-one correspondence with the true observables of the theory, those dynamical variables which alone possess intrinsic significance without reference to a particular frame of description and whose commutator algebra is presumably reflected in the commutators of the corresponding Hilbert operators of the quantized theory. In this paper we have established the appropriate transformation groups (and their subgroups and factor groups) of a theory with either type of coordinate conditions. We have found that in any of these versions the theory will yield the same observables with the same commutator algebra. One may therefore hope that a quantization scheme based on a theory with subsidiary conditions will be free of the arbitrariness involved in the choice of particular conditions. WAVE PROPAGATION IN NON-RECIPROCAL MEDIA, by R. F. Harrington. Final rept. Oct. 1958, 19p. incl. diagrs. table. (Rept. no. EE 368-5610F) (AFOSR-TR-58-151) (AF 18(600)1529) AD 222529 Unclassified

The problem of a non-reciprocal waveguide consisting of a thin axially-magnetized ferrite cylinder coaxially placed in a circular guide has received considerable attention because it is considered to be a useful geometry. Kales derived a characteristic equation for the determination of the propagation constants, but obtained no explicit solution or numerical values because of the complexity of the solution. Suhl and Walker have attacked the problem from a perturbation approach. It is proposed here that the exact characteristic equation be used to obtain approximate solutions. Compared to the perturbation approach, this has the inherent advantages of (a) allowing mathematical evaluation of the accuracy of solution, and (b) yielding exact answers if successive approximations are used.

FERROMAGNETIC RESONANCE IN MAGNETITE BELOW TRANSITION TEMPERATURE, by G. Herz, R. A. Johnson, and D. W. Healy, Jr. Final rept. June 1958, 38p. incl. diagrs. tables, refs. (Rept. no. EE472-587F) (AFOSR-TR-58-118) (AF 49(638)77) AD 201883; PB 137552 Unclassified

The conditions for electronic resonance in an orthorhombic magnetic crystal are examined and the relationship between ω and H required for resonance is predicted.

In addition a calculation is made of the critical fields, H_c , above which the magnetization is aligned with applied field. Experimental verification of the relationship predicted between ω and H was attempted (for magnetite below its transition temperature) but is restricted to a narrow part of the total frequency and magnetic field spectrum needed for complete verification. The effect of pressure and a biasing magnetic field on the selection of the easy axis of magnetization are also examined as well as the role which magnetic dipolar forces may play in the observed anisotropy. (Contractor's abstract)

CONSERVATION LAWS IN GENERAL RELATIVITY AS THE GENERATORS OF COORDINATE TRANSFORMATIONS, by P. G. Bergmann. [1958] [3p. incl. refs. [AF 18(600)459] Unclassified

Published in Phys. Rev., v. 112: 287-289, Oct. 1, 1958.

The components of the so-called canonical energy-stress pseudotensor in general relativity may be thought of as the generators of infinitesimal coordinate transformations corresponding to a rigid parallel displacement of the coordinate origin, just as in Lorentz-covariant theories. In this paper it is shown that the canonical expressions, as well as the expressions proposed by Landau and Lifshitz and the expressions for the angular momentum density, are all special cases of an infinity of conservation laws whose pseudovectors generate arbitrary curvilinear coordinate transformations. This approach enables us to construct the transform of every one of these conservation laws under an arbitrary (finite) coordinate transformation. Finally it is shown that every one of these conservation laws may be used to obtain a surface integral relationship that describes the motion of singularities in a general-relativistic theory. It is concluded that there is an infinite number of parameters that describes a singularity of the field, a fact that had previously been in doubt. (Contractor's abstract)

APPLICATION OF DONNELL-TYPE DYNAMIC EQUATIONS INCLUDING AND EXCLUDING THE EFFECTS OF TRANSVERSE SHEAR AND ROTATIONAL INERTIA TO VIBRATIONS OF INFINITELY LONG CYLINDRICAL SHELLS, by Y.-Y. Yu. July 1957, 1v. incl. diagrs. tables. (Rept. no. ME390-577TN2) (AFOSR-TN-57-390) (AF 18(603)5) AD 132465
Unclassified

Donnell-type dynamic equations of cylindrical shells have been obtained from Flügge's equations and from equations including the effects of transverse shear deformation and rotational inertia. In the present paper the latter equations are further given in such a form that the transverse shear and rotation effects may easily be suppressed; thus, two sets of equations which include and exclude these effects, respectively, and which are exact counterparts of each other were obtained. Equations excluding the transverse shear and rotation effects are found to be slightly different from the Donnell-type Flügge equations obtained previously. By means of the two sets of Donnell-type equations, including and excluding, respectively, the transverse shear and rotation effects, the free flexural vibration of infinitely long cylindrical shells and thus the propagation of flexural waves in such shells are then discussed. Expressions in compact form are derived for the frequency, modes, phase and group velocities, and numerical calculations have been carried out accordingly. (Contractor's abstract, modified)

ON THE DONNELL EQUATIONS AND DONNELL-TYPE EQUATIONS OF THIN CYLINDRICAL SHELLS, by Y.-Y. Yu. Aug. 1957, 21p. refs. (Rept. no. ME390-578TN3) (AFOSR-TN-57-464) (AF 18(603)5) AD 136455
Unclassified

Also published in Proc. Third U. S. Nat'l. Congress of Appl. Mech., Brown U., Providence, R. I. (June 11-14, 1958), N. Y., Amer. Soc. Mech. Engineers, 1958, p. 479-487.

The Donnell equations of thin cylindrical shells are characterized by being in a completely uncoupled form, but they also involve simplifying assumptions concerning the strain expressions. Equations of thin cylindrical shells in such uncoupled form are called Donnell-type equations when no simplification of the strain expressions is involved in the derivation. A review of the previous results is first given on these equations, both static and dynamic, and either including or excluding the effects of transverse shear deformation and rotational inertia, together with their applications. A most

complete set of Donnell-type dynamic equations including the shear and rotation effects is then derived, which is shown to be reducible to the previous results. In particular, from this set of Donnell-type dynamic equations is deduced a set of Donnell dynamic equations, also including the shear and rotation effects. (Contractor's abstract)

Presented at Structures Session, Twenty-sixth annual meeting, Inst. Aeronaut. Sciences, New York, Jan. 27-30, 1958.

Published in Jour. Aero/Space Sciences, v. 25: 699-715, Nov. 1958.

The Donnell-type equations of thin cylindrical shells are characterized by being in a completely uncoupled form such that one equation of the set involves the radial displacement component w as the only dependent variable, and each of the remaining equations relates one of the other displacement components to w . Derivation is first given for Donnell-type dynamic equations including and excluding, respectively, the effects of transverse shear deformation and rotational inertia. The equations are then applied in a convenient and straightforward manner to the analysis of free vibrations of infinitely long cylindrical shells, with comprehensive results given for the frequency, modes, and phase and group velocities. Results on the frequency and modes are also immediately applicable to finite shells with simply supported edges. The cases of finite shells with clamped and flexibly supported edges are finally discussed by further making use of the Galerkin method in conjunction with the Donnell-type equations. Also published in Jour. Phys. Chem., v. 61: 1216-1222, Sept. 1957.

Also published in Science et Industries Photographiques, v. 29: 60, 1958.

The zeta potentials of silver bromide sols have been determined in the presence of some compounds commonly found in photographic processing solutions. It has been shown that conclusions regarding the zeta potential at the silver bromide surface are open to considerable question when gelatin, sensitizing dyes, quaternary salts, etc., are simultaneously present. The data clearly indicate the importance of adsorption processes in photographic development. The zeta potential-concentration curves (for different substances) are fitted

by a Langmuir adsorption isotherm $\theta = \frac{kc}{1+kc}$

where $k = 3 \times 10^8 \text{ cm}^{-3}/\text{mole}$ and $\theta = \frac{\zeta_1 - \zeta_m}{\zeta_0 - \zeta_m}$

where ζ_0 , ζ_1 and ζ_m are the zeta potentials in the absence of the adsorbed compound, the zeta potential at concentration c_1 of the adsorbed compound and the zeta potential when the surface is completely covered by adsorbed compound, respectively. (Contractor's abstract)

A concept of molecular affinity, α , a measure of chemical reactivity based on the molecular ionization potential, I , and the molecular electron affinity, A , has been developed. $\alpha = I + A$. Molecular reactivity, ρ , has been defined as $\rho = \alpha \pm \lambda$ where $\lambda = \alpha \frac{A}{I}$ has been designated

the localization affinity. The negative sign is used when the molecule acts as an electron donor and the positive sign when the molecule acts as an electron acceptor. The molecular reactivity is the effective molecular affinity at the point of attack of the participating molecules. Hypotheses for the application of the concept

have been postulated and a few examples treated. A table of atomic affinities for the entire periodic system has been computed from atomic electronegativities for use in computing molecular affinities. The theoretical basis for this concept has been briefly discussed. (Contractor's abstract)

The molecular affinity concept has been applied to the correlation of some physical properties. Molecular electron affinities have been computed from ionization potential data. Molecular electron affinities and energies of solution (solvent affinities) have been computed from ionization potential and polarographic half-wave potential data. Heats of hydration (water affinities) have been correlated with the differential molecular affinity, $\Delta\alpha$. Proton affinities have been correlated with differential molecular affinities, $\Delta\alpha$, and polarization (or localization affinities) energies deduced. Nucleophilic affinities have been correlated with molecular affinities. Radical affinities have been correlated with $\Delta\alpha$ and with differential molecular reactivities, $\Delta\rho$. It has been demonstrated that the localization affinity is inversely and linearly related to the quantum mechanical localization energy. The concept of resonance energy per atom constituting the molecule has been developed, and it has been shown that the molecular affinity of related compounds was linearly related to the resonance energy per atom, and that within any linear relationship, the molecular affinity minus the resonance energy per atom was a constant. MOLECULAR AFFINITY. IV. CORRELATION WITH CHEMICAL KINETIC DATA, by J. E. LuValle. July 1957, 1v. incl. diagrs. tables, refs. (Rept. no. TO1 57-21) (AFOSR-TN-57-556) (AF 18(600)371) AD 136540

Unclassified

The application of the molecular affinity concept to kinetic data has demonstrated that when the proper transition state has been chosen, the differential molecular affinity, $\Delta\alpha$, tends to be linearly related to the $\log k$ where k is the specific rate constant. The concept that $\Delta\omega = \Delta\alpha + \Delta F^*$ tends to be a constant for a given

TOI.01:011 - TOI.01:013

reaction, i.e., the reaction tends to be isoenergetic where $\Delta\omega$ is the total energy required for reaction, and ΔF^* is the free energy of reaction, has proven very useful in selecting the proper transition state. The hypothesis that the total energy of reaction, $\Delta\omega$, tends to be a minimum has supplemented the isoenergetic hypothesis in the choice of transition state. The correlation of kinetic data was best when reliable free energy of activation data were available. In some cases sufficient data were available so that steric effects could be computed. The data for some SN_2 reactions led to the conclusion that reaction proceeds by concerted attack of the entering group and at least two molecules of solvent. It also appeared probable that the molecule undergoing attack was solvated prior to reaction with the entering group and the two molecules of solvent. (Contractor's abstract)

MOLECULAR AFFINITY. V. CORRELATION WITH CHEMICAL EQUILIBRIA DATA, by J. E. LuValle. July 1957, 1v. incl. diagrs. tables, refs. (Rept. no. TOI 57-22) (AFOSR-TN-57-557) (AF 18(600)371) AD 136541 Unclassified

Considerable data on equilibrium systems have been correlated by application of the molecular affinity concept. Data on the pK_a acids and bases showed that isoenergetic groupings were present. These data also led to the conclusion that the transition state for acid ionization must include the water equilibrium,

$H_3O^+ + OH^- \rightleftharpoons 2H_2O$. The data on keto-enol tautomerism of acetoacetic ester suggested that the extent of enolization increased as the molecular affinity of the solvent became different from that of the solute; i.e., as the acidity or basicity of the solvent increased relative to acetoacetic ester, the extent of enolization increased. Equilibrium data on charge transfer complexes and on the trimethylboron-amine complexes showed that the stability of the complexes were a function of $\Delta\omega$, where $\Delta\omega = \Delta F_{eq} + \Delta\alpha$. Polarographic half-wave data for some 4-amino-N-diethylanilines were used to establish isoenergetic groupings and to compute the steric strain for some 2-substituted N-alkyl anilines. The photographic and allergenic activities of these compounds were correlated with $\Delta\alpha$ and $\Delta\omega$. (Contractor's abstract)

MOLECULAR AFFINITY. VI. CORRELATION WITH ORIENTING POWER OF SUBSTITUENTS AND WITH

THE HAMMETT SUBSTITUENT SIGMAS, by J. E. LuValle. July 1957, 1v. incl. diagrs. tables, refs. (Rept. no. TOI 57-23) (AFOSR-TN-57-558) (AF 18(600)371) AD 136542 Unclassified

It has been demonstrated that the orienting power of a substituent in monosubstituted benzenes for both electrophilic attack and phenyl radical attack may be correlated with the molecular affinity of the substituted molecule. It has also been shown that Hammett's σ , Taft's σ^* , σ_I , σ_R and E_S , Roberts and Moreland's σ' and Brown's σ_p^+ may be correlated with the molecular affinity of the substituted molecule or the substituent. It has been concluded that none of the sigmas represent just one effect. Hammett's σ , Taft's σ^* , and σ_I , Roberts and Moreland's σ' and Brown's σ_p^+ all contain resonance and steric effects as well as polar effects; Taft's σ_R contains polar and steric effects as well as resonance effects and Taft's steric substituent constant, E_S , contains polar and resonance effects as well as steric effects. Taft's σ^* , σ_I and σ_R do represent a considerable improvement over Hammett's σ and do show better correlation with molecular affinity computations than do Hammett's substituent sigmas. MOLECULAR AFFINITY. III. CORRELATION WITH DATA OBTAINED FROM THE INTERACTION OF ELECTROMAGNETIC RADIATION WITH MOLECULES, by J. E. LuValle. July 1957, 1v. incl. diagrs. tables, refs. (Rept. no. TOI 57-20) (AFOSR-TN-57-566) (AF 18(600)371) AD 136549 Unclassified

The correlation of molecular affinity computations with quadrupole coupling data and chemical shift data indicated that both sets of data are functions of the size, shape, steric relationships and intramolecular resonance energies. Furthermore, the data are also perturbed by media effects. Similar conclusions were reached in regard to diamagnetic susceptibility, molecular refraction and dipole moment data. Infra-red absorption spectra were correlated quite well with molecular affinity computations. However here again, the stereochemistry of the molecule and media effects were shown to perturb the absorption spectra. In the visible and uv spectra of condensed ring hydrocarbons, the assumption that the compounds donate electrons in the absorption process permitted computation of molecular reactivities which exhibited excellent linear correlation with the energy of the first absorption band. Molecular affinities and molecular reactivities were also correlated with reported charge transfer spectra. Where it was possible to compute molecular reactivities, the correlation was better than for molecular

TOI.01:014 - TOI.01:017

affinities. The data for the spectra of biacetyl appear to indicate an error in the ionization potential. (Contractor's abstract)

A linear correlation exists between $\Delta\alpha$, the difference in molecular affinities of the quinone and the solvent, and E_λ , the energy of the absorption band. In general, the frequency of the absorption band decreases as the value of $\Delta\alpha$ increases. The ionization potentials of the donor molecules are almost identical with donor molecule reactivity. This will be true whenever the electron affinity is small. The data show that chloranil forms 1:1 molecular complexes with both triethyl- and triphenylamine. The hexamethylbenzene chloranil complex was isolated and the infrared absorption spectrum obtained. The data lend strong support to the hypothesis that quinones in general tend to form complexes with Lewis bases. The linear relationships between molecular affinity and E_λ and the molecular reactivity and E_λ support the idea that the differential molecular affinity and the differential molecular reactivity are related to the interaction energy of acceptor and base. The techniques of analysis of kinetic data are discussed. Practical limitations of these techniques as well as mathematical limitations on the handling of the differential equations involved are pointed out. The application of an analog computer to the analysis of some model reaction systems is illustrated. It is concluded that the widespread usage of concentration-extent of reaction and rate-extent of reaction curves would be of considerable benefit to investigations in chemical kinetics. These phase plots are much more sensitive to reaction complexity than are the usual concentration-time or integrated plots.

THE PHOTOGRAPHIC IMPLICATIONS OF THE CHEMISTRY OF QUINONE. FOG, ACCELERATED, CONTAGIOUS, INFECTIOUS AND SUPERADDITIVE DEVELOPMENT, LATENSIFICATION AND DESENSITIZATION, by J. E. LuValle and G. M. Goldberg. July 31, 1958, 21p. incl. tables, refs. (Rept. no. TOI 58-28) (AFOSR-TN-58-723) (AF 18(600)371) AD 162258

Unclassified

Also published in Jour. Photographic Science, v. 6: 176-184, Nov./Dec. 1958. (Title varies)

Data obtained in an investigation of the chemistry of quinone were used in conjunction with sensitometric data to relate fog with accelerated, contagious, infectious, and superadditive developments. Latensification and desensitization were studied. Experiments indicated that either hydroxyhydroquinone (I) or its precursors was the prime cause of fog in hydroquinone developing agents. The superadditive components of the developers Phenidone and Elon were found to be the best antifogging agents against I. Benzotriazole also appeared to react with I to form a nonfogging compound. Tests of the latensifying action of several free radicals indicated that Frey's salt could be used to give reproducible latensification without aerial drying. Inhibition by the products of development in paraphenylenediamine developers was due to the destruction of latent image and small development centers by the semiquinone and the dimine of the paraphenylenediamine. Wurster's Blue and methylpyridinium iodine could desensitize exposed film. A dilute solution of Wurster's Blue could desensitize unexposed film.

The chemistry of p-benzoquinone has been examined in detail. Of particular interest were the transitory colored intermediates observed in the early stages of some of the known reactions of quinone and the monomeric products thought to be formed on alkaline decomposition of quinone. Hydroxyhydroquinone, hydroxyquinone and 2,5-dihydroxyquinone were synthesized and their reactions were extensively investigated. It appears likely that a path of decomposition of quinone proceeds through the intermediates hydroxyhydroquinone, hydroxyquinone and dihydroxyhydroquinone to dihydroxyquinone. No evidence for the dismutation of quinone or hydroxyquinone was found. Observations on the behavior of

quinone in acid and alkaline solutions led to the formulation of two general mechanisms useful for the explanation of the reactions of quinone in solution. A series of ionic and free radical intermediates formed from quinone are capable of adding ions from solution to form the monomeric reaction products or of adding to other quinone molecules to form the polymeric humic acids. The extreme reactivity of quinone appears to arise as a result of the facile opening of its carbonyl bonds by either acidic or basic reagents. (Contractor's abstract)

The fluorescence intensities of anthracene and naphthalene vapors, and a mixture of these, excited by the β -radiation from tritium gas, were measured by a photomultiplier, through filters. An analysis of the results shows them to be consistent with absorption by anthracene of the naphthalene 3500A fluorescence. There is no evidence for photon emission from the third naphthalene band (2500A). The tritium-activated fluorescence spectrum of anthracene vapor has been observed, extending from 3900A to 4500A. There is no evidence of emission from the second anthracene band at 3500A.

tion of the synthetic procedures used is included in this report as well as all data obtained in the photographic testing program. Several heterocyclic compounds containing or capable of reacting to form the structure thought to be responsible for good developing action were found to be photographically active. The only heterocyclic compound showing practical developing activity was 2, 3, 6-triaminopyridine. Extensive testing of this compound indicated it was at least as active as hydroquinone. A patent application covering this compound will be filed. A short summary of the sensitometric data concerning 2, 3, 6-triaminopyridine (TAP) is included in this report. (Contractor's abstract)

QUALITATIVE CONVERSION BY PHOSPHORS OF THE ENERGY OF BETA PARTICLES INTO FLUORESCENT QUANTA, by A. Shepp. Final rept. Apr. 1958, 67p. incl. diags. tables, refs. (Rept. no. TOI 58-12) (AFOSR-TR-58-56) (AF 18(600)1134) AD 154270 Unclassified

This final report is divided into three sections. Section I is an extensively detailed report on the method and results for the absolute fluorescence energy efficiency and the practical fluorescence energy efficiency of a crystal of anthracene, at room temperature, under excitation of Sr^{90} β -ray. The results are 33% for the absolute energy efficiency, and 2.2% for the practical efficiency. Section II is a moderately detailed report concerning work on the vapor phase fluorescence of anthracene and naphthalene under tritium (T^3) β -ray excitation, in which it is shown that fluorescence directly from upper excited states does not occur. Section III briefly reviews work on inorganic phosphors, purification techniques, and plastic scintillators.

A TRAVELING WAVE GAS CELL MASER, by M. Newstein and R. T. Daly. Feb. 27, 1957 [27]p. incl. diags. table, refs. (AFOSR-TN-57-111) (AF 18(600)-1313) AD 120464 Unclassified

An apparatus is described which will amplify an incident RF wave by causing the signal to pass through a substance in a nonequilibrium thermodynamic state and stimulate it into radiating coherently at the same frequency. The name, Maser, an acronym for microwave amplification by stimulated emission of radiation is applied to the device. The operation of the apparatus is based on increasing the population of an excited state over the ground state in a particular transition in a certain volume of the maser cell. The RF signal to be amplified is localized to that region of the cell containing an excess of the excited state. In motivating the design of the apparatus, the transition between the inversion levels of the 3-3 level of NH_3 is considered. Calculations show the possibility of constructing a traveling-wave gas-cell maser. The question of the feasibility of its operation with a particular gain is reduced to the question of whether sufficiently strong electric fields can be produced without

SPURIOUS SIGNAL GENERATED BY "SHIMMING" PULSES, by M. Newstein. Apr. 1958, 27p. incl. illus. diags. (AFOSR-TN-57-612) (AF 18(600)1313) AD 136602 Unclassified

Further investigation was conducted on the spurious signal generated by shimming pulses. In previous discussions of the recluster experiment, each one of the shimming pulses was represented by a matrix which rotated each element of the spin spectrum by precisely 180° about the direction of the applied magnetic field. The pulses that are actually applied to the spin system differ from the idealized pulses in several respects. The effect of two of these differences is discussed. Expressions are derived for spurious signal amplitude and the transverse magnetization after a string of pulses. (ASTIA abstract)

FURTHER RESEARCH ON THE PHYSICS OF AIR VISCOSITY, by M. Reiner. Research progress summary rept. Feb. 15-Sept. 30, 1957, 1v. incl. illus. diags. tables. (AFOSR-TN-58-454) (AF 61(514)964) AD 158261 Unclassified

A history is given of the first centripetal air-pressure pump. The problem was to enable the rotor to rotate

at high speeds with the smallest amplitude of longitudinal vibrations when the rotor-stator gap was extremely small and the speed was high. An instrument is described which consists of 2 circular metal plates, one stationary, and the other rotating opposite it, with a very narrow adjustable gap between them. In the center of the stationary plate a manometer is attached at an opening. The manometer registers pressures increasing with the speed of rotation and decreasing with increasing width of gap. At 15μ the pressure disappears, and at larger gaps it becomes a suction. Another instrument that works as a centripetal vacuum pump is described which consists of 2 circular plates similar to the ones mentioned. Observations were made with speeds of rotation of 1000 to 13,000 rpm and 2 different loads from rotor. Second-order effects in infinitesimal elasticity were examined theoretically for different measures of strain and 2 cases of torsion of a right circular cylinder with free and prevented extension.

THE CENTRIPETAL-PUMP EFFECT IN A VACUUM PUMP, by M. Reiner. [1958] [16]p. incl. diags. tables, refs. (AF 61(052)10) Unclassified

Published in Proc. Royal Soc. (London), v. 247A: 152-167, Sept. 16, 1958.

An instrument is described which works as a centripetal vacuum pump. It consists of two circular metal plates, one stationary, the other rotating opposite it. The stator has an opening in the center. The rotor can be freely displaced along the axis of rotation. By centripetal pumping action it is kept floating on an air cushion of thickness D. The relation between D and the speed of rotation was determined for different weights of the rotor to be supported. The results are interpreted on the basis of Maxwell's theory of the elasto-viscosity of air. (Contractor's abstract)

This report deals with the measurements of the thickness of the boundary layer with a capacity probe. This probe flush inserted into the wall of the shock tube and

THB.01:002; THB.04:005;
THB.06:001, 002

thus avoiding any disturbances in the flow is sensitive to the thickness of the boundary layer, when the gas in the undisturbed flow is ionized. The experimental results for argon at Mach numbers between 5 and 10 show the usefulness of the probe for measuring the thickness of the boundary layer, the relaxation time of ionization and the coefficient of diffusion. The experiments were carried out in argon because high Mach numbers could be achieved in argon even with a small shock tube. (Contractor's abstract)

SYSTEMATIC INVESTIGATIONS ON SECONDARY FLOW LOSSES IN CASCADES, by N. Scholz. Mar. 27, 1957, 62p. incl. illus. diags. tables. refs. (Rept. no. 56/18a) (AFOSR-TR-57-39) (AF 61(514)650-C) AD 132400
Unclassified

An extensive program on experimental investigations of secondary flow losses in cascades have been carried out. These investigations are an extension of previous measurements on two-dimensional cascades. The scope and kind of the present measurements is outlined and the evaluation is discussed. The program includes secondary flow effects at blade tip and blade foot for turbine and compressor cascades. The blade section is NACA 8410. There are no fillets at the blade foot, and the blade tip is cut off bluntly. The solidity ratio, the blade angle, and the angle inflow of the cascade have been varied. The losses of the cascades have been obtained from wake surveys in a plane behind the cascade. The distribution of local values of the losses over the blade length and the blade distance is given. From these averaged values have been obtained by integration. The

very comprehensive results have a good insight about the magnitude of the secondary flow losses, and how they depend on the cascade geometry.

PRESSURE DISTRIBUTION MEASUREMENTS ON TWO-DIMENSIONAL CASCADES AT HIGH SUBSONIC MACH NUMBERS. PART I, by K. H. Grewe. Mar. 12, 1957, 47p. incl. diags. tables. (Rept. no. 57/6a) (AFOSR-TN-57-289) (AF 61(514)934) AD 132360
Unclassified

A selection of the first measurements in the new High Speed Cascade Wind Tunnel of the Deutsche Forschungsanstalt für Luftfahrt (DFL) is presented. They concern pressure distribution measurements on two-dimensional cascades with blade sections NACA 0010 and NACA 8410, with variation of solidity ratio, blade angle, and angle of inflow. Extending previous measurements in incompressible flow the influence of the Mach number on the pressure distribution of the cascade blades has been investigated. The measurements cover the subsonic Mach number range up to the choking number. The Reynolds number was constant, throughout, $Re_1 = 3 \times 10^5$. The results show that up

to those Mach numbers, where the velocity of sound is reached locally at the blade surface (critical Mach number), the pressure distribution over the blade surface is determined by the nonviscous subsonic flow through the cascade. At higher Mach numbers, however, up to the choking Mach number, the pressure distribution is influenced very much by shock waves.

Some preliminary results of measurements of loss coefficients for cascades with profiles NACA 0010 and NACA 8410 at high subsonic Mach numbers are given. These measurements were done by wake-surveys varying independently the Reynolds number and the Mach number. Fully turbulent flow was obtained in all cases by turbulence wires on the blades. At low Mach numbers the loss coefficients vary with the Reynolds number according to the $Re^{-1/5}$ -law of incompressible flow. The loss coefficients increase considerably, when approaching the choking Mach number. (ASTIA abstract)

INVESTIGATIONS ON THE STALLING CHARACTER-
ISTICS OF DELTA WINGS IN INCOMPRESSIBLE FLOW,
by E. Truckenbrodt and E. G. Feindt. Final rept. June
4, 1957, 46p. incl. diagrs. tables. (Rept. no. 57/11a)
(AFOSR-TN-57-538) (AF 61(514)935) AD 136524;
PB 132349 Unclassified

Also published in Zeitschr. Flugwissensch., v. 6: 97-
102, Apr. 1958.

The stalling characteristics of Delta wing plan-forms in symmetrical flow have been investigated for Reynolds numbers up to $Re = 1,7 \times 10^6$ in incompressible flow. Four of these Delta wings with different aspect ratios have wing section NACA 0012 and one has NACA 0005. The critical angle of incidence at which separation begins has been determined from wake measurements according to a method due to X. Hafer. Thus the spanwise distribution of the critical angle of incidence was obtained, and also the vertical position of the maximum loss in total head in the wake. For the Delta wings with small aspect ratio separation begins for higher angles of incidence than for Delta wings with large aspect ratio. The wing plan forms with the 12% thick profile have a smaller tendency for separation than the wing plan-form with a 5% thick profile. For all wing plan-forms investigated separation starts at the wing tip and with increasing angle of incidence proceeds to the root. In all cases the separation phenomena are symmetrical on the two halves of the wing plan-form. The results of the measurements of the critical angle of incidence are compared with pressure distribution measurements. (Contractor's abstract, modified)

THE RING AIRFOIL WITH DEFLECTED CONTROL
SURFACE IN STEADY INCOMPRESSIBLE FLOW, by
J. Weissinger. Jan. 1957, 19p. diagrs. tables.
(AFOSR-TR-57-8, Pt. I) (AF 61(514)904) AD 115097
Unclassified

A brief review of an earlier report by this author (Zeitschr. Flugwissensch., v. 4: 141-150, 1956) is given and numerical material was added. The general reciprocity theorem of wing theory in the special form for ring airfoils in steady incompressible flow is used in deriving formulas for the distribution of radial force and pitching moment along the circumference and for the total lift and pitching moment caused by the deflection of a control surface. The numerical results show

a strong influence of ring shape (characterized by the length-diameter ratio $\lambda = L/D$) on the effectiveness of the control surface. (Contractor's abstract, modified)

THE INFLUENCE OF PROFILE THICKNESS ON RING
AIRFOILS IN STEADY INCOMPRESSIBLE FLOW, by
J. Weissinger. Jan. 1957, 43p. diagrs. tables. (AFOSR-
TR-57-8, Pt. II) (AF 61(514)904) AD 120424
Unclassified

In order to produce profile thickness for ring airfoils - contrary to two-dimensional theory - not only a source distribution is needed, but also a vortex distribution. This vortex distribution is determined by an integral equation the kernel of which has been tabulated. The axial velocity at a cylinder covered with sources and vortices in such a way as to produce ring airfoils is given in a form suitable for practical computation; these formulas have an explicit term and a second term, which must be calculated by numerical quadrature using tabulated kernel functions, in most cases however, this second term can be neglected because of its smallness. The values of these integrals have been tabulated for the most interesting cases so that for actual computations only a superposition of explicit and tabulated terms is necessary. Finally it is shown how from these velocities at the circular cylinder the velocity at the profile may be calculated.

MAGNETIC PROPERTIES OF RARE EARTH METALS

THM.01:002; THM.02:001; THM.03:001

AT VERY LOW TEMPERATURES. MAGNETIC SUSCEPTIBILITY OF METALLIC NEODYMIUM IN THE TEMPERATURE RANGE BETWEEN 1.5 AND 300°K, by H. Leipfinger. May 1-Oct. 31, 1956 [14]p. incl. illus. diagrs. table, refs. (AFOSR-TN-57-4) (AF 61-514)94;) AD 115034 Unclassified

The magnetic susceptibility of metallic neodymium was measured in the intervals 1.74°K - 4.17°K, 14.2°K - 20.2°K, 66.0°K - 76.9°K and at 90°K, 199°K, 293°K. It was established, that over 14.2°K the metal obeys the Curie-Weiss-law with a Curie-temperature of -0.16°K and an effective moment of 3.58 magnetons. (Theoretical value of the free Nd^{+++} ion at low temperatures 3.62). At liquid helium temperatures the susceptibility decreases with decreasing temperatures. Therefore neodymium metal is antiferromagnetic at these temperatures. The Neel-point lies in the range between 4.17°K and 14.2°K, which cannot be covered with the usual cryostatic methods. Its value is about 6.5°K. (Contractor's abstract)

Technische Hochschule. Physikalisches Inst., Munich (Germany).

MAGNETIC PROPERTIES OF RARE EARTH METALS AT VERY LOW TEMPERATURES, by H. Leipfinger. May 1, 1956-July 31, 1957, 40p. incl. diagrs. tables, refs. (AFOSR-TN-57-561) (AF 61(514)941) AD 136546 Unclassified

The magnetic susceptibilities of the rare earth metals Ce, Pr, Nd, Sm, Dy, Yb were measured from 293°K down to 1.5°K. With the exception of Yb and possibly Eu (not yet measured) the ions, which constitute the lattice of the metal, are the same as the salts or oxides. Yb is built up foremost by divalent ions. The small magnetism allows not more than 2% Yb^{3+} ions and even this magnetism can be caused by impurities. In the salts the deviations from the Curie-law are caused by crystal field splitting of the electronic terms, in metals this splitting is, if it exists at all, weak, whilst exchange coupling brings in most cases either antiferromagnetism or ferromagnetism. Together with the measurements of other metals not yet finished, one can guess the rule, that at very low temperatures the metals of the first half, Ce-Eu, are antiferromagnetic, and the metals of the second half, ferromagnetic. No coupling effects were observed in Pr and Yb, the latter being built up by divalent ions. (Contractor's abstract)

CONNECTION BETWEEN SILVER BROMIDE GRAINS

AND THE SENSITIVITY OF THE EMULSIONS, by W. Waidelich. Technical rept. May 1, 1956-Sept. 30, 1957. Oct. 1, 1957, 33p. incl. diagrs. tables, refs. (AFOSR-TR-57-75) (AF 61(514)942) AD 136637 Unclassified

By precision-measurements of the half-breadth of the Debye fringes of photographic grains the sizes of the coherent lattice domains were determined. There is a connection between domain size and sensitivity; the higher the speed, the smaller the domain. Since there are other influences, e.g., the size of the grains, the connection is merely a stochastic one, if one compares all emulsions together, but by comparing similar emulsions one gets nearly smooth curves with a small scattering of the points. It is concluded from the results, that the internal image is formed mainly at "inner surfaces", i.e., the boundaries of the coherent domains. This can be interpreted in this way, that in the inner part of an undisturbed AgBr lattice there is no place for a growing center. By separated development of the internal and the surface image it could be shown that the number of internal development centers is higher the more internal surfaces are present.

SUPERSONIC FLOW PAST SLENDER BODIES OF ARBITRARY SHAPE (PRACTICAL NUMERICAL METHODS FOR ELECTRONIC COMPUTERS), by R. Sauer. [1957] 15p. incl. diagrs. (Technical note no. 1) (AFOSR-TN-57-162) (AF 61(514)1080) AD 126454 Unclassified

The linearized supersonic steady flow around slender bodies of arbitrary shape is discussed. The velocity potential is developed into a Fourier series. The coefficients of the Fourier series are finite or infinite sums of Legendre functions of the second kind. The terms of the Fourier series correspond to singularities distributed along the axis of the body. The two first terms give the well known solution of von Kármán, Moore, and Tsien for bodies of revolution with zero or small angle of attack. The following terms characterize deformations of the body of revolution and in this way one obtains a flow past "slender bodies of arbitrary shape". Considering only the first terms of the sums of Legendre functions, one gets conical flow fields. As an example, the flow past a delta wing with elliptic cross section is discussed. Next, the flow past a slender body of arbitrary shape is approximated by superposition of conical flow fields along the axis. In this way a practical numerical method results for the calculation of the flow around arbitrary slender bodies by solving a system of algebraic linear equations. The most important application of this method is the wing body interference since a wing body combination is a "slender body of arbitrary shape".

THM.03:002 - THM.03:006

The practical numerical work that is to be done will be performed by use of the Electronic Computer "PERM" of the Technische Hochschule, Munich (Germany). (Contractor's abstract)

CALCULATION OF SUPERSONIC FLOW PAST SLOWLY OSCILLATING BODIES OF REVOLUTION BY USE OF ELECTRONIC COMPUTERS, by J. Muench. [1957] 21p. incl. diagrs. (Technical note no. 2) (AFOSR-TN-57-673) (AF 61(514)1080) AD 136662 Unclassified

The linearized supersonic flow around slowly oscillating bodies of revolution as determined by means of electronic computers is discussed. The calculation of surface pressure and of the quasisteady and unsteady aerodynamic coefficients is reduced to matrix operations. The procedure deals with triangular matrices, the elements of which are hyperbolic cosines or square roots, or their linear combinations.

Technische Hochschule. [Physikalisches Inst.] Munich (Germany).

SUPERSONIC FLOW AROUND QUASI-CONICAL BODIES, WITH APPLICATION TO WING-BODY INTERFERENCE, by H. J. Stetter. [1958] 24p. incl. diagrs. (Technical note no. 3) (AFOSR-TN-58-167) (AF 61(514)1080) AD 152194 Unclassified

A theory was developed for the computation of the linearized supersonic flow field around a quasi-conical body. The disturbance potential and its derivatives are gained from the boundary condition either by the use of characteristic functions or by reduction to the quasi-cylindrical problem (involving the solution of an integral equation). The theory permits not only the computation of the flow field around a slightly bumped or indented circular cone, but also the solution of the wing-body interference problem for a circular conical body with wings with supersonic leading edges. No practical numerical work was performed, but use of the Munich electronic computer is proposed.

ON THE VALIDITY OF THE "THEOREM OF EQUIVALENCE" AND THE AREA-RULE IN SUPERSONIC FLOW,

by W. Werner. Mar. 28, 1958 [26]p. incl. diagrs. tables. (Technical note no. 4) (AFOSR-TN-58-361) (AF 61-514)1080) AD 154266; PB 142539 Unclassified

An analysis is presented of the deviations in equivalence rules to show that they can be explained by influences obtained from the linearized equation of motion of a perfect fluid. The flow potential of a body with source-sink distribution in a plane of symmetry is discussed. Assumptions pertaining to the source-sink distribution allow a decomposition of the potential with certain postulated properties to be given. The result will be a modified theorem of equivalence, the Keune-Oswattsch formulation being a special case that holds only if the source-sink distribution is subject to a stronger condition of equivalence. A modified area-rule is formulated showing that bodies not equivalent in the restricted sense generally do not satisfy the modified area-rule. Comparison of theoretical results is made with the results of a numerical computation carried out on a computer.

SPECTRAL REFLECTIVITY AS A FUNCTION OF TEMPERATURE OF β -BRASS TYPE ALLOYS, by L. Muldawer. Oct. 15, 1957, 20p. diags. tables, refs. (AFOSR-TN-57-667) (AF 49(638)73)
AD 136656

Unclassified

A number of β -brass type alloys undergo reversible color changes as a function of temperature. β -Brass turns copper-red at about 250°C, the color change taking place gradually. β -AgZn is pink at room temperature, it is silver gray at 250°C. Similar changes have been observed in β -AgCd, β -AuZn, and β -AuCd. Color changes consistent with the above observations have been noted on cooling to liquid nitrogen temperatures. Although disordering takes place in some of these alloys it is not thought that these color change phenomena are primarily due to disordering or to surface films. Quantitative measurements of reflectivity as a function of wavelength at several temperatures have been made on β -CuZn, β -AgZn, β -AuZn, β -AgCd, and α -brass. The reflectivity edge for β -brass shifts from 5000Å at 27°C to 5300Å at 275°C. This is a shift of about 5.6×10^{-4} ev/°C. No such edge shift was observed with α -brass or with copper, gold, or Cu_3Au as judged visually. It is believed that these color shifts are due to changes in the energy spacings of electron bands. EFFECT OF COLD WORK ON THE SPECTRAL REFLECTIVITY OF CsCl TYPE ALLOYS (Abstract), by L. Muldawer. [1957] [1]p. [AF 49(638)73]

Unclassified

Presented at meeting of the Amer. Phys. Soc., Philadelphia, Pa., Mar. 21-23, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 144, Mar. 21, 1957.

Many CsCl structure alloys are normally strongly colored but tend toward silver-gray upon cold working. The normal color is regained as a function of time even when the specimen is not in contact with air. This color recovery is presumably associated with the mechanical recovery of such alloys which occurs at room temperature. Spectral reflectivity curves show that cold working is similar to increased temperature in some respects. In β -brass, the reflectivity minimum disappears, the steepness of the reflectivity edge lessens, and the difference in reflectivity on either side of the edge decreases. Similar effects are seen with β -AgZn, β -AgCd, and β -AuZn. Inasmuch as the strain produced by cold work is extremely inhomogeneous, it should be expected that the reflectivity edge would be smeared out. The possible nature of this effect is considered.

Alloys similar in character to β -brass have been studied with respect to spectral reflectivity and color as a function of temperature and surface treatment. Large changes in reflectivity edge position and color were

TEM.01:007 - TEM.01:010

observed for changes in temperature; a tendency toward edge disappearance was observed upon cold working. Alloys which are basically face-centered cubic do not show those properties. Electron and x-ray diffraction studies indicate stress induced phase transformations in many of the alloys of the β -brass type. The discussion presents a correlation of the observed results with known simple theory. (Contractor's abstract)

Studies of the behavior of pure ozone with various fuel gases and of the decomposition of O_3 to O_2 are presented. A stable ozone-oxygen flame was found to exist and a maximum flame temperature of 2877°K was recorded with 100 mol-% O_3 in O_2 . Burning velocities for the O_3 - O_2 reaction were determined by the standard schlieren method and compared with the theoretical data of von Kármán. Pure ozone when mixed with cyanogen produces a flame temperature of 5200°K.

In this study, it is pointed out that pure O_3 can be mixed with pure H_2 at -78° and even at 20° and 1 atm without explosion, and with no, or practically no, reaction for several hr. Pure O_3 - H_2 mixtures of any desired composition were prepared by mixing known volumes of the 2 gases. The mixtures were burned at -78° initial temperature. The experimental burning velocities at 195°K initial temperature and 1 atm were for 6.0, 12.0, 18.2, 18.5, 25.0, and 100 mol-% O_3 , respectively, 207 ± 5 , 644 ± 57 , 1290 ± 20 , 1330 ± 30 , 1680 ± 80 , and 270 ± 7 cm/sec. Mixtures of 94.0 to 75% H_2 (the rest being pure O_3) were readily burned. The resulting O_3 - H_2 flames are brighter than the corresponding O_2 flames, but their luminosity is also low. The stoichiometric mixture burns very rapidly at 1680 ± 80 cm/sec. In mixtures on the O_3 -rich side of the stoichiometric point, the flame front degenerates rapidly to a detonation front. Such mixtures cannot be burned successfully.

Also published in Jour. Amer. Chem. Soc., v. 79: 5583, Oct. 20, 1957.

Static experiments showed that $(CN)_2$ and pure O_3 can be mixed and stored for a considerable time without reaction. The mixture $3(CN)_2 + 4O_3$ was kept in a 100 cc pyrex vessel, at 1000 mm Hg at 0°C for two hr with no noticeable change in pressure; identical results were obtained with the mixture, $3(CN)_2 + 2O_3$. Burning velocities of $(CN)_2$ - O_3 mixtures containing 25.0, 33.3, 40.0 and 100.0 mol-% O_3 were, respectively, 60 ± 3 , 242 ± 12 , 285 ± 6 , and 420 ± 6 cm/sec. A mixture beyond the stoichiometric point, on the O_3 -rich side, containing 50.0 at-% O detonated immediately upon ignition. All flames on the $(CN)_2$ -rich side up to and including the mixture burning to $2CO + N_2$ burn uniformly, noiselessly, as brightly as an electric arc and with a pink-violet color. The $2(CN)_2 + O_3$ flame is particularly bright and has a

TEM.01:011 - TEM.01:015

different characteristic blue-green color. The temperatures of the flames ($^{\circ}\text{K} \pm 2^{\circ}$) for $(\text{CN})_2 + \text{O}_2$ and $3(\text{CN})_2 + 2\text{O}_3$ at 1.0 and 10.0 atm are 4856 and 5025, and 5208 and 5506 $^{\circ}$, respectively.

PURE OZONE FLAMES, ALONE AND WITH VARIOUS FUEL GASES, by A. V. Grosse and A. G. Streng. Aug. 1, 1957, 1v. incl. illus. diags. tables, refs. (Technical note no. 4) (AFOSR-TN-57-511) (AF 18(600)1475) AD 136497 Unclassified

This report covers the experiments conducted at Temple, first, to combust pure ozone to oxygen, and, second, pure ozone with various fuel gases, such as hydrogen, cyanogen, methane, carbon monoxide, and ethylene. Static experiments have shown that all of the above gases, with the exception of carbon monoxide and ethylene, can be premixed with pure ozone. After this had been established premixed flames with pure ozone were burned successfully and the burning velocities determined and compared with the corresponding oxygen flames. As was to be expected, the ozone flames are substantially faster than the corresponding oxygen flames. This is particularly true in the cases of flames containing the element hydrogen. An Appendix covering a critical review of the physical properties of ozone, as well as of ozone-oxygen mixtures, has been prepared. (Contractor's abstract)

Also published in *Jour. Molecular Spectroscopy*, v. 1: 81-94, Sept. 1957.

A critical list of 143 vibronic bands of the 2700-4800A absorption system of ClO_2 vapor is compiled. Vibrational quantum number assignments are given to 117 of these bands. Five progressions (a), (b), (c), (m), (d) including the four strongest are given the assignments (a) $(v_1'00) \cdot (000)$, (b) $(v_1'10) \cdot (000)$, (c) $(v_1'02) \cdot (000)$, (m) $(v_1'12) \cdot (000)$, (d) $(v_1'04) \cdot (000)$. The fact that three of the anharmonicity constants are calculated in several independent ways with consistent results is regarded as support for this analysis. The three zero order frequencies and the six anharmonicity constants are determined for the excited electronic state. Furthermore, by combining information obtained from electronic spectra with that obtained from known infrared data, the nine vibrational constants of the ground electronic state are determined. An explanation of anomalous intensities is suggested.

INEQUALITY OF BOND DISTANCES IN ClO_2 (Abstract), by J. B. Coon, J. K. Ward, and C. M. Lloyd. [1957] [1]p. [AF 18(600)439] Unclassified

Presented at meeting of the Amer. Phys. Soc., Oklahoma U., Norman, Mar. 1-2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 100, Mar. 1, 1957.

Four v_1' progressions (a), (b), (c), and (d) dominate the appearance of the 3000-5000A absorption system of ClO_2 vapor. If it is assumed that $r_1'' = r_2''$ and $r_1' = r_2'$, where r designates a Cl-O bond distance, the four progressions must be given the excited state assignments (a), ($v_1'00$); (b), ($v_1'10$); (c), ($v_1'02$); and (d), ($v_1'04$). All four progressions are assigned to the (000) level of the ground state. However, a calculation of Condon overlap integrals leads to an intensity ratio $I(c)/I(a) = 0.02$ which compares poorly with the observed ratio 0.5. Similarly, the calculated value of $I(d)/I(a) = 0.0006$ compares poorly with the observed value of about 0.15 for this ratio. The large value of the observed intensities of progressions (c) and (d) may be explained by assuming a slight difference in bond distances for the excited state. This alters the selection rules, and the assignments (c), ($v_1'01$) and (d), ($v_1'02$) may be made. On the basis of this interpretation, large intensity ratios are possible. Calculations are being made to test whether each of the foregoing observed intensity ratios is explained by the same inequality of bond distances for the excited state.

Presented at meeting of the Texas Academy of Science, Southern Methodist U., Dallas, Dec. 12-14, 1957.

Partially resolved rotational structure of two bands of the 3400 - 3900A absorption system of SO_2 have been investigated. The results $\Delta(A-B) = 0.282$ and $\Delta B = -0.0364$. These results confirm the values of these rotational constants obtained by a quantitative application of the Franck-Condon principle. The bands are shown to have perpendicular polarization. NUCLEAR MAGNETIC RESONANCE RELAXATION IN BINARY SOLUTIONS (Abstract), by R. W. Mitchell and M. Eisner. [1958] [1]p. [AF 18(600)1300]

Unclassified

Presented at meeting of the Amer. Phys. Soc., Ithaca, N. Y., June 19-21, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 262, June 19, 1958.

Spin-lattice relaxation times for hydrogen nuclei were measured as a function of concentration for the following binary solutions: $C_6H_6 - CCl_4$, $C_6H_6 - CS_2$, $C_6H_{12} - CCl_4$ and $C_6H_{12} - CS_2$. Both the rotational and translational correlation times are found to be proportional to the macroscopic solution viscosity. The rotational and translational contributions to T_1 have been calculated for C_6H_6 and C_6H_{12} from this data. The rotational correlation times are found to be 4.3×10^{12} for C_6H_6 and 4.6×10^{12} for C_6H_{12} , both values referring to the pure solutions. T_1 measurements were also made for both resonance lines in $C_6H_6 - C_6H_{12}$ solutions. The contribution of the $C_6H_6 - C_6H_{12}$ collisions to the relaxation of both lines has been calculated by subtracting off the rotational and like translational contributions obtained from the previously measured correlation times.

CONCENTRATION DEPENDENCE OF CHEMICAL SHIFTS AND T_1 's FOR PROTONS IN AQUEOUS SOLUTIONS OF ACETIC ANHYDRIDE (Abstract), by M. Eisner. [1957] [1]p. [AF 18(600)1300] Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 384, Dec. 19, 1957.

T_1 and chemical shifts have been measured, at 5000 gauss, for protons in both OH and CH_3 groups in aqueous solutions of acetic anhydride. No shift is observed between the OH and CH_3 until acetic acid proportions are reached; the subsequent shifts are in substantial agreement with those reported by Bhar and Linstrom. Both T_1 's exhibit minima, however, they display different dependence on the macroscopic viscosity. An analysis of the T_1 variations, in the region of the anomalous behavior of the chemical shifts, seems to lend support to the explanation of this anomaly in terms of the effect of an active solvent on the dimer-monomer equilibrium.

DEVELOPMENT OF SUBSONIC AND SUPERSONIC TOTAL TEMPERATURE PROBES FOR A BLOW-DOWN TYPE WIND TUNNEL, by G. L. Alexander. June 1957, 45p. Incl. illus. diags. tables, refs. (Rept. no. DRL-399) (AFOSR-TN-57-164) (AF 18(600)589) AD 126456 Unclassified

This study is an experimental approach to the development of supersonic and subsonic total temperature probes for a blow-down type wind tunnel. Probes of small mass and relatively low conductive heat loss were developed for subsonic testing. Heated shields were used to determine the magnitude of radiation errors, and a supersonic, heated shield probe was developed. In both the subsonic and supersonic cases the probes performed with less than 1/2 percent error. This accuracy could be maintained over wide ranges of temperature variations and transient conditions.

A HIGH STAGNATION TEMPERATURE INTERMITTENT

FLOW SUPERSONIC WIND TUNNEL, by J. L. Harkness. Mar. 11, 1957, 48p. incl. illus. diags. refs. (Rept. no. DRL-406) (AFOSR-TN-57-222) (AF 18(600)589) AD 126520 Unclassified

A high stagnation temperature intermittent-flow supersonic wind tunnel is described. Preliminary design considerations are briefly outlined, while the bulk of the report concerns the detailed description of the resulting test facility. Each basic component of the wind tunnel circuit is described along with the currently available instrumentation for model testing. The design and development work for the major components of the circuit have been described in other reports, with the exception of the working section of the tunnel, and these reports are referenced herein to avoid duplication. One section is included covering the design and fabrication of the supersonic nozzles in detail. This was considered consistent with a following section that presents the flow calibration data using the Mach number 5.0 nozzle. Mach number distributions in the supersonic test region as well as stagnation temperature distributions in the stilling chamber and supersonic test region are included.

THEORETICAL AND EXPERIMENTAL STUDIES OF BOUNDARY LAYER CHARACTERISTICS AT SUPERSONIC SPEEDS IN AIR, INCLUDING INVESTIGATIONS OF SKIN FRICTION, VELOCITY DISTRIBUTION AND HEAT TRANSFER, by J. L. Harkness. Annual rept. Jan. 5, 1957, 27p. illus. diags. tables. (AF 18(600)589) Unclassified

The major portion of this report concerns the experimental phase of the program. A first section under this phase presents the final development work on the wind-tunnel circuit including special equipment additions and general instrumentation revisions and additions. A second section presents a summary of the complete calibration testing in the wind tunnel. The special instrumentation developed for this purpose is described, and the final results of the testing are presented. A special heated-shield, thermocouple-probe was developed for the measurement of stagnation temperatures in the stilling chamber and test section region, and a complete description of this investigation is included. The calibration work represents the largest portion of the effort during the subject report period. A third section reports the present status of the flat-plate heat transfer models and includes a brief description of this unit. The theoretical effort has concerned only the analytical investigations necessary under the experimental phase, and a brief discussion of this work is presented. A final section reports the coordination efforts on the project. (Contractor's abstract)

USE OF VARIABLE FEEDBACK TO COMPENSATE FOR NON-LINEARITIES AND DESIGN UNCERTAINTIES IN A CLOSED-LOOP SYSTEM, by W. H. Hartwig. [1957] 18p. illus. tables, refs. (AF 18(600)589)

Unclassified

Presented at Ninth annual Southwestern Inst. of Radio Engineers Conf., Houston, Tex., Apr. 11-13, 1957.

Design of a heat exchanger of 420 kw capacity to maintain stagnation temperature constant in a supersonic blow-down wind tunnel was the basic problem. The transfer functions for the individual elements of the system contained significant amounts of non-linearities of several types. In addition, determination of the essential constants of the system was inadequate due to inability to predict the system interactions. This paper describes the theoretical design of the system. Equipped with feedback adjustments the system was built and stabilized on the first trial. The theoretical transfer function is shown to predict the performance actually measured. Van Driest's boundary layer temperature equation is modified in an attempt to account for the Prandtl number not being unity. The modified theory is applied to existing data at Mach numbers of 2.00, 2.50, and 5.00. A study is made of the effect of temperature recovery coefficient, Mach number and Reynolds number upon an introduced parameter that represents the modified theory. It is determined that the theory accounts for a variable Prandtl number for turbulent flow and can be used to predict the temperature distribution in a compressible turbulent boundary layer for the case of zero heat transfer with reasonable accuracy. INTERFERENCE EFFECTS BETWEEN TOTAL-PRESSURE PROBES IN THE BOUNDARY LAYER OF

A SUPERSONIC WIND TUNNEL, by J. R. Lacy. Jan. 1958, 1v. incl. illus. diagrs. (Rept. no. DRL-420) (AFOSR-TN-58-6) (AF 18(600)589) AD 148045

Unclassified

An experimental investigation was undertaken in a 6 x 6 in. Mach number 5 wind tunnel to determine the extent of any mutual interference effects between total-pressure probes in supersonic flow. Blunt-nosed total-pressure probes of 0.035 in. outside diam were tested at several different positions in the wall boundary layer of the wind tunnel. The results of these tests indicated the definite presence of mutual interference between total-pressure probes at a spacing between probes of approximately 0.025 to 0.030 in. An approximate method of determining shock wave shape and location ahead of plane and axially symmetric bodies was utilized to provide an indication of minimum probe spacing to prevent mutual interference between probes of other sizes. HEAT TRANSFER MEASUREMENTS ON A FLAT PLATE MODEL AT MACH NUMBER 5.0, by J. L. Harkness. Jan. 8, 1958, 1v. incl. illus. diagrs. tables, refs. (Rept. no. DRL-423) (AFOSR-TN-58-74) (AF 18(600)589) AD 148118

Unclassified

The results of heat transfer measurements made on a flat plate model in a 6x7-in. wind tunnel at a free-stream Mach number of 5.05 are presented. The internal surface of the model was cooled, and the heat transfer rate was determined by measuring the temperature drop across the model once temperature stabilization was achieved. A general description of the wind tunnel facility used is presented and a description of the design and construction details of the heat transfer model is given. The results of the tests are discussed and the data are presented both in tabular form and graphically for comparison with existing theories. Some laminar data were obtained but in most cases the flow over the model was largely turbulent. It is concluded that the turbulent theory of Van Driest (item no. NAA.01:003) predicts values at least 15% below the measured values. (Contractor's abstract)

EFFECTS OF HIGH PRESSURE ON THE NEAR ULTRAVIOLET ABSORPTION SPECTRA OF BENZENE AND MONOSUBSTITUTED BENZENES, by W. W. Robertson, S. E. Babb, Jr., and F. A. Matsen. [1957] [4]p. incl. diags. tables, refs. (AF 18(600)430)

Unclassified

Published in Jour. Chem. Phys., v. 26: 367-370, Feb. 1957.

The near ultraviolet absorption spectra of benzene and several monosubstituted benzenes have been obtained in the vapor phase with partial pressures of nitrogen to 550 atm and in hydrocarbon solution with pressures up to 5500 atm. The spectra broaden asymmetrically and shift to longer wavelengths under pressure. The wavelength varies linearly with dielectric constant, both in the vapor phase and in solution, $\Delta\lambda/\Delta K$ lying between 20 and 29 Å. A rough correlation is found between $\Delta\lambda/\Delta K$ and the oscillator strength of the transition. (Contractor's abstract)

An initial series of measurements of the rate of decomposition of butane made in a special flow reactor gave an order of reaction and rate constants in essential

TEX.06:002-005; TEX.05:015

agreement with results of others, but the energy of activation found was quite low. Further experiments, using direct calibrations of the analytical apparatus and improved flow control made by two different investigators confirmed the previous results. The decomposition is essentially first order and the rate constant for the initial stages of reaction is $k = 3.5 \cdot 10^9 \exp - 46,000/RT \text{ sec}^{-1}$. The value of the energy of activation found is about 12,000 cal/mol less than that established by others. However, their data also indicate a trend toward a lower value for the initial decomposition reaction itself, without the complications of later steps; and the approach to calculations used here represents an improved method for extrapolating to zero conversion. DECOMPOSITION OF BUTANE IN A LINEAR FLOW REACTOR (Abstract), by J. A. Cunningham, F. A. Matsen, and R. C. Anderson. [1958] [1]p. [AF 18(603)-142] Unclassified

Presented at meeting of the Phys. Chem. Div. of the Amer. Chem. Soc., Chicago, Ill., Sept. 7-12, 1958.

Published in 134th meeting of the Amer. Chem. Soc. Abstracts of Papers, 1958, p. 51-S.

The pyrolysis of butane has been studied in a linear flow reactor, using vapor-liquid partition chromatography for analysis of the products. The resulting data have been used to find the order of reaction, specific reaction velocity constants, and the apparent activation energy by a mathematical treatment for flow systems developed by Matsen, Streetman, and Cunningham. Temperatures in the range of 560° to 600° were used at atmospheric pressure. Residence times were of the order of 10 to 80 sec. The products of reaction are primarily propene and methane or ethene and ethane, and the reaction is essentially homogeneous and first order. These results, and the specific reaction constant in the region of 580°, are in good agreement with the results of other workers. Analysis of the temperature effect, however, gives energy of activation factors of 40 to 46 kcal/mol (depending upon the extent of reaction involved). These values are markedly lower than those of earlier investigators.

EXPLORATORY EXPERIMENTS ON SURFACE DEPOSITS ON METALS FROM PYROLYSIS OF HYDROCARBONS, by J. H. Dent and R. C. Anderson. Dec. 1957, 5p. (Technical note no. 2) (AFOSR-TN-58-50) (AF 18(603)142) AD 148090 Unclassified

Exploratory experiments have been made on surface reactions of acetylene and hexane with various metals over ranges of 250-900°. These results show that specific interactions occur between the gases and certain metals, under conditions where physical condensation is highly unlikely. Tests with octatriyne indicate that such compounds may be chemisorbed, and that they can activate a surface for further reaction and deposit formation. Quantitative study of such systems is now being undertaken. (Contractor's abstract)

TEX.06:003

Texas U. [Dept. of Chemistry] Austin.

THERMAL DECOMPOSITION OF BUTANE II, by J. [A.] Cunningham and R. C. Anderson. Aug. 1958 [28]p. incl. diags. tables. (Technical note no. 3) (AFOSR-TN-58-761) (AF 18(603)142) AD 201860 Unclassified

Experimental studies of the thermal decomposition of butane have been extended to additional temperatures and to a wider range of flow velocities. The effects of increased surface, and of added oxygen and ethylene oxide were also investigated. The overall rate equation, extrapolated to the earliest stages of reaction was found to be $k = 8.0 \times 10^7 e^{-39,300/RT}$. This differs markedly from results of earlier work in the low apparent energy of activation. Possibilities of surface effects or trace catalytic or inhibitory effects, which might cause such a variation, have been carefully checked, but no evidence of such an effect has yet been found. (Contractor's abstract)

TEX.05:016 - TEX.05:018

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 37-38, Jan. 30, 1957.

Also published in Phys. Rev., v. 108: 257-262, Oct. 25, 1957.

A new type of instrument has been used for measurements on Mg metal and single crystals of LiF, NaCl, KCl, KBr, and KI. The data, after correction for instrument resolution, yield the momentum distribution of either the photons or the center of mass of the positron and electron just prior to annihilation. The momentum distribution obtained for NaCl is accounted for by assuming (a) that the positron is bound to the chloride ion in an s state, (b) that annihilation takes place with one of the electrons of the closed shell, and (c) that the overlap wave function is of the form $(r-b)^2 e^{-mr}$. Best agreement with experiment was obtained for 30% of the annihilations taking place with s electrons for which $b = 0.75 \text{ \AA}$, and $m = 3.64 \text{ \AA}^{-1}$ and the other 70% with p electrons for which $b = 0.70 \text{ \AA}$ and $m = 4.00 \text{ \AA}^{-1}$.

NEW TYPE OF APPARATUS FOR MEASUREMENT OF THE ANGULAR CORRELATION OF ANNIHILATION RADIATION (Abstract), by R. Castillo-Bahena and W. E. Millett. [1957] [1p. [AF 33(038)20681]

Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Series II, v. 2: 37, Jan. 30, 1957.

The apparatus described in previous investigations of this type makes use of two rectangular collimators. The angular acceptance in one plane is made narrow but that in the other plane is broad. The new type of apparatus makes use of a circular slit in one collimator and a circular hole in the other. The advantages obtained by this arrangement may be understood by considering the following fact. If one of two annihilation gamma rays correlated at an angle θ passes along a line, then its partner must pass along a cone of angle θ which is symmetric about the line of the first. The new arrangement therefore has an increased solid angle without deterioration of the resolution. In fact, both the solid angle and the resolution are increased by going from rectangular slits to circular slits. The method of determining the resolution curves of the apparatus and of correcting the data according to these resolution curves is discussed.

MEAN LIFE OF POSITRONS IN ALKALI HALIDE CRYSTALS (Abstract), by L. Brown, C. [R.] Hatcher, and W. E. Millett. [1957] [1p. [AF 33(038)20681] Unclassified

Presented at meeting of the Amer. Phys. Soc., Boulder, Colo., Sept. 5-7, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 314, Sept. 5, 1957.

The mean life of positrons in LiF, NaCl, KCl, and KI has been measured by using Gerholm's technique. Only a fast component has been observed and the capabilities of the equipment are such as to reveal any long component accounting for more than 1% of the annihilations. The values obtained in units of 10^{-10} sec are LiF 2.3, NaCl 3.2, KCl 3.2, and KI 3.1; the probable error associated with each measurement is 0.3. Measurements were made of the mean lives in Al and Teflon for comparison with the work of other investigators. Good agreement with the values reported by Gerholm was found except that no long component was observed in Al; the effect on which the report of the long component had been based was observed but the same effect was noticed in the four crystals and, to a lesser extent, in the ^{60}Co resolution curve.

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 377, Dec. 19, 1957.

Also published in Phys. Rev., v. 111: 12-15, July 1, 1958.

Positrons emitted from Na^{22} have been used to study the lifetimes and the ratio of decays in long and short modes. The mode with a lifetime 10 fold larger has been found to occur from 35% to 4% of the times and have been lifetime from 1.6 to 2.5×10^{-9} sec for a series of organic compounds, most of which are derived from benzene. A correlation between the lifetime of the long mode and the molecular structure has been found. The observed lifetimes in benzene and its halogen derivatives decrease as the size of the halogen increases. As the bond strength of the weakest bond increases and as the asymmetry of the molecule increases, the lifetime is found to decrease.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 4: 100, Mar. 6, 1959.

Also published in Phys. Rev., v. 112: 1924-1926, Dec. 15, 1958.

The mean life of the τ_2 component of the decay of iodine in normal heptane solutions has been measured and used to find a cross section of 10^{-17} cm^2 for the collision annihilation of triplet positronium by molecular iodine. A decrease is observed in the τ_2 mean life as the iodine concentration in solution increases and this quenching has been attributed to an enhancement of pickoff annihilation resulting either from formation of positronium iodide or from high polarizability of the iodine molecule. The intensity of the τ_2 component seems to decrease as the iodine concentration increases, but large errors in the data render this point inconclusive.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 165, May 1, 1958.

The energy distributions of the neutrons emitted at 90° from a beam of 14.9 mev neutrons incident upon iron and lead scatterers have been obtained using a simplified associated-particle time-of-flight technique. This technique was originated by O'Neill and has been modified in the present experiment. The apparatus will be described and the energy distributions from iron and lead will be presented.

ANNIHILATION OF POSITRONS IN S, C, Cu, AND BI (Abstract), by F. Castillo-Jimenez, J. B. Ashe, and W. E. Millett. [1958] [1]p. [AF 33(038)20681] Unclassified

Presented at meeting of the Amer. Phys. Soc., British Columbia U., Vancouver (Canada), Aug. 26-28, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 326-327, Aug. 26, 1958.

The angular correlation of two-photon annihilation radiation has been studied by means of an apparatus having conical geometry. The data have been analyzed to give $N(p)$, the number of pairs which annihilate with momentum p , as a function of p . There is a noticeable difference between the momentum distributions for monoclinic and rhombic sulfur and for diamond and graphite. The curves for Cu and Bi are in agreement with previous results which indicate that for decay in metals annihilation occurs primarily with Fermi electrons. A new apparatus, using the same type of geometry but having better resolution, has been used to study oriented graphite in two positions. A slightly different $N(p)$ curve was obtained when the sample was rotated 90° about an axis perpendicular to the axis of the apparatus.

PRESSURE EFFECTS ON THE ULTRAVIOLET ABSORPTION SPECTRA OF SOME AROMATIC COMPOUNDS, by W. W. Robertson, O. E. Weigang, Jr.,

and F. A. Matsen. Apr. 1957 [31]p. Incl. diagrs. tables, refs. (Technical note no. 1) (AFOSR-TN-57-61) (AF 49(638)35; continuation of AF 18(600)430) AD 120401 Unclassified

Also published in Jour. Molecular Spectroscopy, v. 1: 1-10, July 1957.

A study is presented of the change in frequency of an electronic absorption band of a chromophore on change in the surrounding medium. Changes in the medium have been affected not by choosing different solvents, but by varying the density of one solvent, n-pentane, through the application of pressures up to 5,500 bars. Aromatic hydrocarbons were chosen as chromophores for which several transitions could be observed, thereby maintaining constant several important factors. The observations are discussed in terms of the London formula for dispersion forces. (Contractor's abstract)

INTERMOLECULAR FORCES AND PRESSURE SHIFTS OF THE SPECTRA OF AROMATIC HYDROCARBONS, by W. W. Robertson, S. E. Babb, Jr., and O. E. Weigang, Jr. [1957] 1v. Incl. illus. diagrs. refs. (AFOSR-TN-57-601) (AF 49(638)35) AJ 36586 Unclassified

Also published in Internat'l. Colloquium on the Optical and Acoustical Properties of Compressed Fluids and Molecular Interactions. Bellvue (France) (July 1-6, 1957), Paris, Centre National de la Recherche Scientifique, 1959, p. 293-310.

The absorption spectra of liquid benzene and of benzene, several monosubstituted benzenes, and a number of condensed ring aromatics in solution in n-pentane have been recorded at hydrostatic pressures up to 6000 bars. The vapor spectrum of benzene in various diluent gases has been taken over a wide density range and in carbon dioxide at temperatures above and below the critical temperature. A red shift in the absorption spectrum of the chromophore results from an increase in density of solvent or diluent gas in every case with the exception of helium, which produces a blue shift. The rate of shift of frequency with density is found to be a linear function of the oscillator strength of the transition for the stronger transitions and essentially constant for the very weak transitions. Various theoretical interpretations are considered. (Contractor's abstract)

May 1958.

The absorption spectrum of benzene has been obtained in the diluents carbon dioxide, ethylene and ethane over a wide range of densities both above and below the critical temperatures. The red spectral shifts are linear functions of the density throughout the density range for ethylene and ethane and are independent of the state of the diluent. A break in the linear wave-length-density curve occurs at high densities of carbon dioxide. These results support the view that gases and liquids are essentially the same thing in those cases where specific interactions are not involved and suggest further that the radial distribution remains constant from low to high densities of gas and into the liquid state. ENHANCEMENT OF INFRARED ABSORPTION BANDS OF CHARGE TRANSFER COMPLEXES, by E. E. Ferguson and F. A. Matsen. [1958] 9p. incl. refs.
(AFOSR-TN-57-771) (AF 49(638)35) AD 148001
Unclassified

Also published in Jour. Chem. Phys., v. 29: 105-107,
July 1958.

An enhancement of infrared absorption bands is shown to be inherent in charge-transfer theory due to change in vertical ionization energy or change in vertical electron affinity during the course of molecular vibration. A semiquantitative calculation of the intensity enhancement of the symmetric ring stretching vibrational mode of benzene in the benzene-iodine complex agrees well with the experimentally observed value. This result shows that previous investigators' assumptions of charge-transfer complex asymmetry, based on observed infrared absorption bands may not be valid. (Contractor's abstract)

EFFECTS OF HIGH PRESSURE ON THE NEAR ULTRAVIOLET VAPOR ABSORPTION SPECTRUM OF BENZENE IN VARIOUS DILUENT GASES (Abstract), by W. W. Robertson and S. E. Babb, Jr. [1957] [1]p.
(AF 49(638)35) Unclassified

Presented at Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 10-14, 1957.

Published in Symposium on Molecular Structure and Spectroscopy. Abstracts, 1957, p. 48.

The near ultraviolet vapor absorption spectrum of benzene has been recorded in various diluent gases covering a density range that extends from the vapor density of benzene through the density region of liquid hydrocarbons. The wavelength of absorption shifts to the red smoothly with an increasing slope with increasing density of diluent gas, but is linear with dielectric constant. The frequency of absorption then decreases with increasing dielectric constant and has an increasing slope. The smoothness of the curves suggests that there is no essential difference in mechanism between that described by the collision theory generally used to interpret wavelength shifts resulting from intermolecular interactions at low densities and the mechanism described by the statistical theory that would be applied in the region of liquid densities. Data is presented on carbon dioxide as a diluent, both above and below the critical temperature. Behavior in liquid and gaseous phases at equal densities is presented.

EFFECTS OF HYDROSTATIC PRESSURE ON THE INTENSITY OF THE SINGLET-TRIPLET TRANSITION OF α -CHLORONAPHTHALENE IN ETHYL IODIDE, by W. W. Robertson and R. E. Reynolds. [1958] 11p. diags. (AFOSR-TN-58-297) (AF 49(638)35)
AD 154206; PB 133955 Unclassified

Also published in Jour. Chem. Phys., v. 29: 138-141,
July 1958.

The extinction coefficient of the singlet-triplet transition of α -chloronaphthalene in ethyl iodide was found to increase almost linearly with the density of the compressed mixture. Study of a 1:2 vol ratio of these components over a pressure range from 1 to 3644 atm resulted in about a two-fold increase in light absorption, with little other changes in band envelope. No increase in absorption coefficient was obtained for pure liquid α -chloronaphthalene subjected to comparable increase in hydrostatic pressure. The increase in extinction coefficient was attributed to the increase in collisional frequency resulting from the increase in concentration of the constituents and the corresponding decrease in the liquid "cage" dimensions with increased density.

Also published in Jour. Chem. Phys., v. 23: 243-244, July 1958.

The wave length shift with pressure of the near UV absorption spectrum of benzene in ethane with benzene in ethylene, and of benzene in pentane with liquid benzene have been compared. Within the range of experimental error, the wave length shift of benzene with density of ethylene and of ethane was found to be linear from low through high diluent densities and from the gas into a liquid phase. The benzene-ethylene and benzene-ethane $\pi - \pi$ and $\pi - \sigma$ electron interactions have been calculated by using the methods developed by Haugh and Hirschfelder. The $\pi - \pi$ energies are found to be roughly twice as large as the $\pi - \sigma$ energies, so that little difference is to be expected in the ground state interaction energy between benzene in an unsaturated solvent and benzene in a saturated solvent since each double bond is replaced by two single bonds. Excited state interaction energies have not been calculated, but it is assumed that these energies are larger than, but proportional to, the ground state interaction energies.

THE GENETIC EFFECTS OF COSMIC RAYS, by W. S. Stone. Final rept. July 29, 1958, 4p. incl. table. (AFOSR-TR-58-104) (AF 49(638)51) AD 162246; PB 136887 Unclassified

Cosmic radiation is interesting as one of the features

of the universe, as a physical tool, and as a source of biological danger and damage. As humans investigate and move into space, the biological damage, including possible damage to humans, will increase. It is necessary to measure the amount of damage encountered in space to be prepared to protect organisms. This hazard includes genetic damage and these experiments are intended to measure this factor. Microorganisms were prepared and sent to Minnesota for balloon flights as called for between December 1, 1956 through May 31, 1958. Control tests were run in the laboratory to test spontaneous mutation rates with these materials. The one successful short flight, 780, in which our material was flown carried Neurospora spores, which were tested for the presence of mutations by direct mutation test.

JET MIXING AS A COMBUSTION TOOL, by J. J. Lovingham. [1957] [24]p. incl. illus. diagrs. tables. [ARS publication no. 514-57] (AF 18(600)1184) Unclassified

Presented at Twelfth annual meeting of the Amer. Rocket Soc., New York, Dec. 2-5, 1957.

The interdependencies of the preparatory processes affecting the precombustion treatment of propellants in a liquid rocket engine are not fully understood. As an aid in obtaining an insight into this problem area an analytical and experimental investigation was undertaken. This study had as its goal the establishment of the relationships between the parameters controlling these processes. The analytical approach taken was a dimensional analysis which served to establish parameters. These parameters were later experimentally evaluated in a specially built 5000-lb thrust rocket engine. STUDY OF IONIZATION IN ROCKET FLAMES (Abstract), by R. Ellison. [1958] [1]p. (Bound with its AFOSR-TR-58-125; AD 126674) (AF 49(638)305)
Unclassified

Presented at Conf. on Ion and Plasma Research,
Maryland U., College Park, Sept. 30-Oct. 2, 1958.

The theory of a pressure probe is presented in the form of an orifice in the side of a tube which may be orientated in any direction relevant to that of the mass motion and which is so small compared with the local mean free path, that free-molecule flow occurs. The theory shows that such a tube will measure the local speed ratio in isentropic and nonisentropic flows and suggests that in strong shock waves it may be possible to determine the viscosity and heat conduction, that is, the deviation from Maxwellian molecular motion. (Contractor's abstract)

The development of an ionization probe for use with rocket flames has been attacked as part of a project to measure and to manipulate the ionization in rocket engines. Data taken in open flames indicates that: (1) refractory coatings on water cooled probes interfere with the desired measurement; (2) water cooling of a given probe design results in a lower probe current than measured with the same probe and no cooling; and (3) uncooled probe measurements are comparable to measurements reported in the literature. The design assembly and testing of a laboratory micromotor has been completed using hydrogen and oxygen gases. Initial measurements of ionization in the chamber are reported to the extent data are obtained.

PERFORMANCE OF A MACH 4 AXIALLY SYMMETRIC NOZZLE DESIGNED TO OPERATE AT 40 MICRONS HG IN THE UTIA LOW DENSITY WIND TUNNEL, by A. V. Sreekanth. Sept. 1956 [68]p. incl. illus. diagrs. tables. (UTIA Technical note no. 10) (AFOSR-TN-57-94) (AF 18(600)1185) AD 120443
Unclassified

The performance of a Mach 4 axisymmetric nozzle designed to operate at a test chamber pressure of 40μ of Hg was investigated in the UTIA low density wind tunnel both at the design condition and for other values. The anticipated Mach number distribution was obtained at the design operating conditions. The results of a series of runs at pressures from 29 to 46μ of Hg indicated that the boundary layer displacement thickness varied inversely as the square root of the operating static pressure. The boundary layer thickness at the nozzle throat, as determined from mass flow measurements, agreed well with the calculated value based on the assumption of zero rate of boundary layer growth at the throat. Additional investigations were made on the effect of the stagnation temperature and the pressure in the open jet test chamber on the flow.

Experimental tests of conventional impact probes and

TOR.01:009 - TOR.01:011

of a new type of probe (orifice probe) were made in the transition-flow regime and in free-molecule flow. The data may be applied to relate pressure readings to the free-stream Mach number when calibrating rarefied gas streams. The readings of conventional impact probes having 10° internally and externally chamfered mouths and a length/radius ratio of 50 are compared with the Rayleigh supersonic pitot-tube formula over the range $1.2 < M_1 < 2.0$, $0.36 < R_e < 41$, and with

continuum and free-molecule flow theory in subsonic flows over the range $0.13 < M_1 < 0.95$, $0.011 < R_e <$

0.11. At a Reynolds number of 1, the measured impact pressure at $M = 2$ was twice that given by the Rayleigh formula, and even larger departures from continuum theory were obtained in subsonic flows. The orifice probe, which consisted of a cylinder transverse to the stream with an orifice for taking pressure readings pierced in a piece of tinfoil cemented over an opening in the side, gave results which agreed with free-molecule flow theory in tests made in a subsonic nozzle at $M = 0.13$ to 0.86 and Knudsen numbers from 6.6 to 8.6 . From extensive tests in the transition flow region at Mach numbers up to 2 , an empirical formula was devised expressing orifice probe pressure readings as a function of Mach and Knudsen number from continuum to free-molecule flow. The pressure distribution around a cylinder in free-molecule flow was determined by rotating an orifice probe on its axis at several subsonic Mach numbers; the results agreed well with theory.

MOLECULAR APPROACH TO PROBLEMS OF HIGH-ALTITUDE, HIGH-SPEED FLIGHT, by G. N. Patterson. May 1957 [65]p. incl. illus. diagrs. tables, refs. (UTIA Review no. 10; NATO AGARD rept. no. 134) (AFOSR-TN-57-311) (AF 18(600)1185) AD 132382

Unclassified

Presented at Eleventh meeting of the Wind Tunnel and Model Testing Panel, Scheveningen (Netherlands), July 8-12, 1957.

In order to obtain a better understanding of the aerodynamics of high performance aircraft it is necessary to investigate the effects of rarefaction and high temperatures on the flow of gases. Both effects show the increasingly important role played by the molecular structure of a gas in its macroscopic motion. In the introductory sections of this review it is pointed out that flight at very high speed can only occur at extreme altitudes. The zones of the upper atmosphere, the regimes of fluid mechanics based on considerations of rarefaction and temperature, and the modern experimental methods for investigations in some of these regimes are discussed. Rarefaction effects are then discussed in terms of gas

surface interactions, free molecule flow and slip flow, and Newtonian flow is considered as an extension of free molecule motion. The effects of high temperature are indicated for undissociated air and air in dissociation equilibrium, and the important effects of relaxation are outlined. (Contractor's abstract)

The UTIA low density wind tunnel is a continuous, open circuit tunnel with vacuum pump drive designed to operate at Mach numbers up to 5 over a range of low pressures suitable for the study of rarefied gas flows. Booster-type oil diffusion pumps are used to provide a range of operating pressures from 0.001 to 0.070 mm Hg for Reynolds numbers of 0.1 to 4×10^3 per inch. The design, construction, operation, and instrumentation of the tunnel are presented. A theoretical study of conventional nozzles and slotted wall nozzles with boundary-layer suction and the calibration of axisymmetric nozzles for Mach 4 , Mach 2 and subsonic flow are given. These nozzles have solid walls and were operated at pressures of 0.040 , 0.020 , and 0.008 mm Hg, respectively. The flow in the supersonic nozzles is essentially a continuum flow at low Reynolds number with the boundary layer filling most of the jet, while in the subsonic nozzle the density was low enough to produce slip on the walls. New studies of outgassing effects on pressure probes in free molecule flow are given in an appendix. A bibliography of low density references is included in the report. An expression has been derived for the mass flow through a circular tube in free molecule flow when the tube and gas are in relative motion. The gas entering the tube is assumed to have a Maxwellian distribution function and the molecular reflection process at the wall is assumed to be diffuse. The theory has been used to

TOR.01:012, 013; TOR.02:001, 002

determine the pressure read by an impact probe in free molecule flow. Although the general expressions derived apply to any value of gas velocity and tube size, the detailed calculations for the pressure probe are difficult except for the case of low speeds and long tubes. An experimental check of the theory has been carried out using impact probes in a whirling arm apparatus and in the UTIA low density wind tunnel. Agreement between theory and experiment is quite satisfactory. (Contractor's abstract)

AN EXPERIMENTAL INVESTIGATION OF THE OSCILLATING PRESSURES ON A CIRCULAR CYLINDER IN A FLUID STREAM, by D. M. McGregor. June 1957 [35]p. incl. illus. diagrs. table. (UTIA Technical note no. 14) (AFOSR-TN-58-339) ([Sponsored jointly by Air Force Office of Scientific Research under AF 49(638)249] and Canadian Defence Research Board) AD 154243

Unclassified

Results of experimental investigations of the fluctuating pressures on a circular cylinder are presented. The cylinder was mounted in a wind tunnel at right angles to the flow and contained within it the microphone used as the pressure transducer. By making assumptions about the correlation of the pressure around the circumference of the cylinder, estimations were made - by integration of the surface pressure coefficients - of the oscillating lift and drag coefficients of the cylinder. The lift coefficient remained essentially constant at approximately 0.6, while the drag coefficient decreased with increasing speed from approximately 0.075 to 0.044. It was found that the pressure level of the fundamental frequency was very low at the front of the cylinder, but rose sharply to a large maximum at the sides. After remaining constant over an appreciable arc ($\approx 60^\circ$), it decreased to the background level at the rear. The level of the second harmonic was masked by the background except in the rear 1/3 of the cylinder where it increased steadily to a maximum in the downstream direction. An attempt was made to develop a simple mathematical model of the flow by considering an alternating vortex standing at the rear of the cylinder. This endeavor met with moderate success. INVESTIGATION OF FREE-MOLECULE AND TRANSITION FLOWS NEAR THE LEADING EDGE OF A FLAT PLATE, by E. L. Harris. Nov. 1958 [88]p. incl. illus. diagrs. table, refs. (UTIA rept. no. 53) (AFOSR-TN-58-1043) (AF 18(600)1185) AD 206757; PB 144754

Unclassified

Pressure measurements using orifice probes were made in the flow over a thin flat plate set parallel to the stream in the UTIA low-density wind tunnel. The length of the plate was approximately 7 mean free paths and speed ratios of 0.55 and 0.78 were used. Reasonably good agreement between theoretical and experimental pressures in a region less than one mean free path downstream from the leading edge demonstrated the existence of free molecule flow in this region. Velocity gradients made the results concerning the nature of the flow over the complete plate qualitative. In an appendix theoretical and experimental results are given on the pressure indicated by an impact probe in free molecule flow when the length of the probe is not small with respect to its diameter. Unclassified

An acoustically quieted air-duct facility has been constructed for the purpose of investigating the boundary layer noise generated by turbulent flow past a flexible panel. The facility is basically an open-circuit wind-tunnel with interchangeable 33 ft rectangular duct sections 12 in. wide and 1 in., 2 in., 4 in., or 8 in., deep. The downstream end of the duct, where fully developed channel flow is obtained, contains the test panel, fitted flush in one wall. Maximum speed in the 4 in. duct using

TOR.02:003 - TOR.02:006

a 10 hp blower is 200 fps. Details of the design and the aerodynamic performance such as the velocity profiles and pressure gradients are given.

ON THE STRENGTH DISTRIBUTION OF NOISE SOURCES ALONG A JET, by H. S. Ribner. Apr. 1958 [26]p. incl. diags. refs. (UTIA rept. no. 51) (AFOSR-TN-58-359) (Sponsored jointly by Air Force Office of Scientific Research under AF 49(638)249 and Canadian Defence Research Board) AD 154264; PB 132745
Unclassified

Also published in Jour. Acoust. Soc. Amer., v. 30: 876, Sept. 1958.

The spatial distribution of noise sources along a jet is investigated by application of Lighthill's theory to regions of so-called similar profiles. The analysis refers to the noise power emitted by a section of the jet between two adjacent planes normal to the axis, as a function of distance x of the section from the nozzle. It is found that this power is essentially constant with x in the initial mixing region and falls off as x^{-7} in the region about 10 diameters downstream from the nozzle in the fully developed jet. Because of this striking attenuation of strength with distance, it is concluded that the mixing region produces the bulk of the noise and must dominate in muffler behavior; conversely, the 'fat' part of the jet must contribute much less to the total noise power than is commonly supposed. A qualitative interpretation is given of Powell's experiments on the effects of nozzle velocity profile on total noise power, as is the behavior of multiple-nozzle or corrugated mufflers, both as to the overall quieting and frequency-shifting. The possibility emerges that such mufflers may be improved without serious thrust loss by the addition of a sound-attenuating shroud. (Contractor's abstract, modified)

NOTE ON ACOUSTIC ENERGY FLOW IN A MOVING MEDIUM, by H. S. Ribner. Apr. 1958 [8]p. incl. diags. (UTIA Technical note no. 21) (AFOSR-TN-58-360) (Sponsored jointly by Air Force Office of Scientific Research under AF 49(638)249 and Canadian Defence Research Board) AD 154265; PB 134663
Unclassified

Both acoustic energy density and energy flow are known to be modified by motion of the medium, as in a jet. Comparison is made of similarities and discrepancies in the formulas of three investigators in order to infer a correct formulation. Example applications show how variations in the velocity of a stream carrying plane

sound waves can change the 'linear theory' acoustic energy density from positive through zero to negative, with corresponding changes in the energy flow. (Contractor's abstract)

MEASUREMENT OF TWO POINT CORRELATIONS OF THE SURFACE PRESSURE ON A CIRCULAR CYLINDER, by V. Prendergast. July 1958 [28]p. incl. diags. (UTIA Technical note no. 23) (AFOSR-TN-58-861) (Sponsored jointly by Air Force Office of Scientific Research under AF 49(638)249 and Canadian Defence Research Board) AD 203674; PB 144739
Unclassified

Results of an experimental investigation of the two-point correlations of the surface pressure on a circular cylinder are presented. The cylinder was mounted in a wind tunnel at right angles to the flow and contained within it the two microphones which were used as pressure transducers. The curves of correlation coefficient vs hole spacing obtained did not follow the expected form, in that the correlation curves approached a constant value (approximately 0.2) rather than zero, as the hole spacing was increased to very large values. Three possible explanations are: (1) The measured results represent a true correlation. No theoretical explanation for such behavior is offered, beyond the suggestion that it may be a tunnel wall effect. (2) There is some fault in the experimental set-up or instrumentation. No such

TRL01:003, 004; TUF01:001, 002

fault could be discovered. (3) Vibration of the cylinder provides a coupling mechanism between the flow at points remote from one another. No evidence of such vibration was found. A correction involving a simple scale expansion has been employed to alter the form of the curves so that they approach zero at large hole spacings, which it is felt gives at least a good first approximation to the ideal free-field, rigid-cylinder correlation. Finally, employing the above assumption, a plot of correlation length vs Reynolds's number has been presented. (Contractor's abstract)

THE CONVERGENCE OF SERIES OF CHARACTERISTIC FUNCTIONS OF THE DIFFERENTIAL OPERATOR $-d^2/dz^2 + z^N$, by W. J. Klimczak. Sept. 30, 1957, 13p. (AFOSR-TN-57-605) (AF 18(600)1397) AD 1365. Unclassified

The domain of absolute convergence $R(n)$ of power series $W = \sum_{n=0}^{\infty} a_n w_n(z)$ in terms of the functions $w_n(z)$ which satisfy the differential operator $(-d^2/dz^2 + z^N)$ is investigated. The cases $n = 1, 2$ have been previously studied: when $n = 1$, the Airy series is absolutely convergent in the entire complex plane; and when $n = 2$, the resulting Hermite series converges absolutely for the values of z in the strip $-\infty < \text{Im}(z) < \infty$. The eigenvalue equation is solved to find the relationship between the power n and $R(n)$. It is found that there exists an infinite sequence of real eigenvalues such that $\lim_{n \rightarrow \infty} \lambda_n = \infty$.

The set of corresponding eigenfunctions is complete and orthogonal in $L^2(0, \infty)$. $R(n)$ is found to consist of the strip $-\tau < \text{Im}(z) < \tau$, such that $\tau = \lim_{n \rightarrow \infty} \sup$

$$(1/\sqrt{\lambda_n}) \cdot \log |f_n|.$$

REGULARITY PRESERVING FACTOR SEQUENCE TRANSFORMATIONS OF SERIES OF CHARACTERISTIC FUNCTIONS OF THE DIFFERENTIAL OPERATOR $z^N - d^2/dz^2$, by W. J. Klimczak. Nov. 30, 1958, 24p. (AFOSR-TN-58-1059) (AF 18(600)1597) AD 206990; PB 139083 Unclassified

Special types of regularity preserving factor sequence transformations are studied for series of the form

$$f(z) = \sum_{n=0}^{\infty} a_n w_n(z), \text{ where } w_n(z) \text{ are the characteristic}$$

functions of the second-order differential operator

$\delta_z = z^N - d^2/dz^2$, N being a positive integer. Let $A = \{a_n\}$ denote a factor sequence and consider the series $F(z) = \sum_{n=0}^{\infty} a_n w_n(z)$. If the ordinate of conver-

gence of $F(z)$ is not less than that of $f(z)$, assumed to be positive, and if it is possible to continue $F(z)$ analytically along any finite path along which $f(z)$ can be continued, then the transformation $A[f(z)] = F(z)$ is a regularity preserving factor sequence transformation of $f(z)$. The conditions under which A is a regularity preserving transformation of $f(z)$ are studied. The theory of differential operators $G(\delta_z)$ are investigated, and the re-

sults are utilized for the study of some classes of regularity preserving factor sequence transformations of $f(z)$. (ASTIA abstract)

HUMAN ENGINEERING BIBLIOGRAPHY 1956-1957, by E. V. Saul, M. W. Raben and others. Washington, Office of Naval Research, Oct. 1958 [360]p. (ONR rept. no. ACR-32) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under Nonr-49413) AD 205931; PB 131507S Unclassified

Personnel responsible for the human factors considerations in the design and development of equipment have a major need for rapid and easy access to the literature pertinent to their work. The fact that the literature associated with human engineering derives from some 490 different journals and periodicals as well as a host of publications from governmental, industrial, and academic laboratories presents a compelling requirement for the development of useful bibliographic aids. This bibliography is one of a planned series of annual

TUS.01:003 - TUS.01:005

bibliographies of literature pertinent to human engineering which has been designed to meet this requirement. Two major considerations—ease of use and appropriate selection of material—strongly influenced this bibliography. As a result, five main parts exist: (1) a topical outline which defines over 300 topic headings established for this bibliography, (2) an index which associates the approximately 1400 bibliographic entries with the topic headings, (3) an alphabetic index of the common search terms which would aid those using this bibliography but who are unfamiliar with the topic headings, (4) an annotated bibliography of some 1400 citations, and (5) an index of the authors of these citations.

PREPARATION AND PROPERTIES OF ALPHA-FLUOROMETHYL ESTERS, by C. T. Mason. Oct. 1957, 14p. incl. tables. (AFOSR-TN-57-653) (AF 18(600)779) AD 136639 Unclassified

Various metal fluorides were tried as fluorine-for-chlorine exchange agents chloromethyl acetate. HgF_2 was found to be the most efficient of those tried. Petroleum ether (bp 40-45°) and Nujol were found to be the most useful solvents in the exchange reaction. No halogen exchange was observed when the fluorides of the following metals were refluxed with chloromethyl esters: aluminum, chromium, antimony, tin, and K. On the other hand, AgF and TlF were effective as exchange agents, but the temperature necessary for the reaction was so high that rapid decomposition and lower yields resulted. Some of the properties of the fluoromethyl esters are cited.

REACTIONS OF METALS WITH 1-ALKOXY-1-CHLOROETHANES AND CHLOROMETHYL ACETATES, by C. T. Mason. Oct. 1957, 8p. incl. tables. (AFOSR-TR-57-66) (AF 18(600)779) AD 136590 Unclassified

Metallic K reacted with alkoxychloromethanes and $CH_2ClCHClOMe$ uncontrollably to give tars from which no identifiable product could be isolated. With 1-butoxy-1-chloroethane, the reaction was easily controlled and BuOH, butyl acetal, and a small amount of high-boiling liquid were isolated. Acetal and the high-boiling component were obtained in the reaction of K with 1-

chloro-1-propoxyethane. Acetal, alkyl halide, and alcohol were the products of decomposition of 1-alkoxy-1-chloro-ethanes. Theories on the decomposition were postulated which agree with the experimental results and can be used for explaining the reactions of other metals with $CH_3CHClOR$. With heavier and less active

metals than Na and K, the reaction of the metal with the decomposition products from the 1-alkoxy-1-chloroethane were not vigorous enough to indicate that the metal was involved in the reaction. With alkoxychloromethanes, Na reacted to form the Wurtz product through an organosodium intermediate. Chloromethyl acetate reacted uncontrollably with Na in the absence of a solvent. With PhMe or benzene as a solvent, the reaction, if any, was very slow and most of the Na and chloromethyl acetate was recovered even after long refluxing. No apparent reaction resulted with Li, Zn, K, and Cu dust. Chloromethyl acetate reacted with a slight excess of BuMgCl to give a 55% yield of pentanol-1 and a higher-boiling compound.

PREPARATION AND PROPERTIES OF SOME CYCLIC ALPHA-FLUOROETHERS, by C. T. Mason. Nov. 1957, 15p. incl. tables, refs. (AFOSR-TR-57-91) (AF 18(600)779) AD 136726 Unclassified

Various chlorine derivatives of 1,4-dioxane, tetrahydrofuran, and thiophene were treated with metal fluorides, and attempts were made to isolate the fluoro derivative. For the most part, the observations made on previous preparations of alpha-fluoroalkyl ethers and esters seem to be true with the presently investigated cyclic compounds. An exchange reaction took place when HgF_2 was used as an exchange agent for the alpha-chlorine in dioxane and in tetrahydrofuran. The preparation of the fluoro derivative of thiophene is a complex reaction not simply one involving the exchange of fluorine for chlorine. The yields in the preparations of the alpha-fluoroethers are limited by the stability of the ethers. Multiple halogen on the same carbon or on adjacent carbon atoms lend stability to the compound. Fluorine atoms on adjacent carbon atoms give more stability than chlorine atoms in the same positions. Instability, particularly with the fluoroethers, is greatest when dehydrohalogenation is possible. It is extremely difficult to isolate an alpha-fluoroether when the fluorine is on a carbon attached to a carbon containing two hydrogen atoms. In general, the chemical properties of the fluorodioxanes seem to be similar to those of their chlorine analogues. The fluoro derivatives, on the basis of only a few reactions, are more reactive and less stable than their chlorine counterparts.

RESEARCH ON "LOCALIZED RADIO-LESIONS."

PART I. THE EFFECT OF HIGH ENERGY PROTONS ON THE SPINAL CORD, by B. Larsson, L. Leksell and others. May 1, 1958, 11p. incl. refs. (AFOSR-TN-58-677) (AF 61(514)1247) AD 226788

Unclassified

Also published in Acta Radiologica, v. 51: 53-64, Jan. 1959.

The spinal cord in the rabbit has been irradiated with a 185 mev proton beam from a 230 cm synchrocyclotron. Using a 1.5 mm broad beam it has been possible to effect sharply delimited lesions of the spinal cord with only minimal hemorrhages and without any general reactions. With a 10 mm beam the tissue reactions are much more severe. The histopathology of the acute radiation necrosis is described and the factors responsible for its appearance are discussed, especially the width of the proton beam and the size of the single radiation dose. THE DECAY OF THE ISOTOPES Au¹⁹¹⁻¹⁹⁶, by G. Bäckström, O. Bergman and others. [1957] [4]p. incl. tables. (Bound with its AFOSR-TR-58-26; AD 152201) [AF 61(514)1015, phase B] Unclassified

The decay of Au¹⁹¹⁻¹⁹³ has been comparatively little studied, probably because of the short half-lives and the high bombarding energy necessary to produce these isotopes. The samples used in this investigation have been produced by irradiating a Pt foil with 60 mev protons at the synchro-cyclotron, Uppsala. After chemical separation the carrier-free Au was collected on a thin silver layer, constituting an almost ideal source. The data found concerning these isotopes, of half-lives 30^h, 5^h and 15^h respectively, are very preliminary, and no attempt to establish decay schemes has yet been done. The 30^h and 15^h activities show a very rich low energy spectrum, whereas the levels of Pt¹⁹² seem to be more widely spaced. Efforts have been concentrated

on the extremely complicated decay Au¹⁹⁴ - Pt¹⁹⁴. The decay is being studied by means of three instruments: the iron free double focusing spectrometer up to about 100 kev, its iron pole equivalent up to 3 mev and the double lens spectrometer for e - e coincidences. There is evidence for about 100 γ -conversion lines belonging to Pt¹⁹⁴, but this number is expected to increase.

The decay of Au¹⁹⁶ - Pt¹⁹⁶ is very simple, proceeding through two excited states. The energies for the cascade γ -transitions are 0.33285 mev and 0.35580 mev. The E 2 cross-over has been found to be about an order of magnitude more forbidden than in other even-even nuclei in this region.

GAMMA TRANSITIONS IN As⁷⁶ - Se⁷⁶, by G. Bäckström. [1957] [2]p. incl. diagrs. table. (Bound with its AFOSR-TR-58-26; AD 152201) [AF 61(514)-1015, phase B] Unclassified

In order to check the consistency of the present decay scheme of As⁷⁶, an investigation was made of the γ -lines using a double focusing spectrometer. The following energies and intensities were found: 0.5591 \pm 2 (1), 0.6571 \pm 2 (0.20), 1.2159 \pm 4 (0.17) and 1.2290 \pm 6 (0.04). A new feature of the decay was a splitting of the 1.20 mev line, which was fully established as a line belonging to the decay of As. The investigation showed that the strongest component of the doublet was the one

that paralleled the 0.66 - 0.56 mev cascade. Work is in progress to establish the place of the new transition, and at present it may be regarded as an indication for a level between 1.22 and 2.59 mev.

ANTIPROTONS IN NUCLEAR EMULSIONS, by A. G. Ekspong, S. Johansson, and B. E. Ronne. [1958] 1v. incl. diagrs. tables. (AFOSR-TR-58-25) (Sponsored jointly by Air Force Office of Scientific Research under AF 61(514)1015, phase A and Swedish [Atomic Committee] AD 152200; PB 138491 Unclassified

Investigations were made of the properties and behavior in matter of antiprotons and negative K-mesons. By using the bevatron as the particle source, one large stack of nuclear research plates were exposed to antiprotons, while two stacks were exposed to K-mesons. The antiproton stack, consisting of 120 pellicles 4 x 7 in. in size, was scanned twice, yielding a total of 10 antiprotons. Two associated problems investigated were (1) the decay products of the negative K-mesons, in which the existence of the τ ' mode of decay among the negative K-particles is established; and (2) the nature and energy of the interaction products. (ASTIA abstract)

THE INTERNAL COMPTON EFFECT. A DETERMINATION OF CROSS SECTION AND ANGULAR CORRELATION, by T. Lindqvist, B.-G. Pettersson, and K. Siegbahn. [1958] [11]p. incl. diags. table, refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 61(514)1015, phase B] and Swedish Atomic Committee) Unclassified

Published in Nuclear Phys., v. 5: 47-57, Jan. 1958.

The internal Compton effect, a nuclear transition in which there is a simultaneous ejection of a bound electron and emission of a gamma ray, has been unambiguously demonstrated. The experiment concerned the 662 kev transition in Ba^{137m} and was carried out with a gamma scintillation spectrometer and a beta-ray spectrometer in coincidence. The presence of other effects was carefully considered. The experimental cross section was found to be 1.86×10^{-5} photons in the energy region 97 kev - 120 kev per conversion electron at 90° between the electron and photon directions. Angular correlation experiments were carried out. Comparison with various theories shows that the theory by Spruch and Goertzel does fit the experimental results excellently both regarding absolute cross section and angular correlation. K⁻ INTERACTIONS IN FLIGHT, by A. Frisk and S. Nilsson. [1958] 6p. incl. diag. tables, refs. (Technical note no. 2) (AFOSR-TN-58-879) (Sponsored jointly by Air Force Office of Scientific Research under AF 61(052)13, phase A and Swedish [Atomic Committee]) AD 203909; PB 136865 Unclassified

Also published in Ark. Fys., v. 14: 277-292, 1958. (Title varies)

A total track length of 41 m of K⁻ mesons has been measured in the energy interval 0-140 mev and 208 interactions in flight have been analyzed to yield the total cross section per nucleus in emulsion $\sigma = 780 \pm 60$ mb. The corresponding average total nucleon cross section in nuclear matter is calculated to be $\bar{\sigma} = 80 \pm 15$ mg. The mean free path $\lambda = 0.95 \times 10^{-13}$ cm implies a large absorptive potential ~ 60 mev. The derived limits on the free neutron cross sections do not contradict the assumption that charge independence holds in the absorption and scattering processes. The differential cross section for elastic scattering between 5°-30° is given. An attractive K⁻ nuclear potential is inferred from the percentage of reemerging K⁻ mesons. (Contractor's abstract)

POINT FOCUSING APPARATUS FOR STUDYING SMALL-ANGLE SCATTERING OF X-RAYS, by K. Siegbahn. [1958] [9]p. incl. illus. diagrs. (Bound with its AFOSR-TN-58-1078; AD 207457) [AF 61(052)13, phases B and C] Unclassified

Published in Ann. Acad. Regiae Scientiarum Upsaliensis, v. 2: 102-110, 1958.

An x-ray spectrometer which is used to study the small angle diffraction has been developed by the use of a pair of spherically bent crystals. The spectrometer is used at large Bragg angles so that the spherical surface approximates a toroidal surface which would produce a true point focus. Large dispersion and low anastigmatic aberration are possible for the monochromatic beam. Preliminary diffraction studies have been carried out on polystyrene latex particles.

U.P.P.04:017

[Uppsala U. Inst. of Physics (Sweden).]

SMALL-ANGLE SCATTERING OF X-RAYS, by G. Wassberg and K. Siegbahn. [1958] 15p. incl. illus. diagrs. tables, refs. (Bound with its AFOSR-TN-58-1078; AD 207457) [AF 61(052)13, phases B and C] Unclassified

Published in Ark. Fys., v. 14: 1-15, 1958.

The construction and use of an x-ray spectrometer which employs two spherically bent crystals is described. The spectrometer has achieved anastigmatic two-dimensional focusing of the monochromatic beam and has reduced the exposure time as compared with previous spectrometers thus making possible the study of scattering at small angles. The theory of scattering at small angles of x-rays from single spherical particles and agglomerates of spherical particles is presented. Experimental results of scattering from polystyrene latex particles of size 3400 Å are found to deviate from expected results in the positioning of the first few diffraction maxima.

A VECTOR ANALYSIS OF A SOLENOID-TYPE ELECTROMAGNETIC ACCELERATOR, by B. E. Bona and L. D. Harris. May 1957, 37p. Incl. illus. diagrs. tables, refs. (Technical rept. no. 8) (AFOSR-TN-57-292) (AF 18(600)1217) AD 132363 Unclassified

An analysis is presented of a one-stage or single-solenoid accelerator. The solenoid-type accelerator consists of a hollow coil in which a conducting projectile is placed. Energy is supplied to the solenoid by discharging a capacitor bank through it. The voltages induced in, and the forces acting on the projectile are analyzed from a vector approach. To simplify the analysis, the projectile is thought of as being a single loop conductor. The current in the projectile is eliminated from a set of parametric equations, and a second-order differential equation in velocity results. An approximate solution to this equation is obtained for 2 values of projectile resistance. A picture of an accelerated projectile is shown for establishing the validity of the differential equation. The maximum obtainable velocity from the solenoid-type accelerator is a function of the circuit frequency and of the projectile length. The inductance of the solenoid and the capacitance of the energy source are more important parameters than the projectile length. The temperature rise which occurs in the projectile seriously limits the possibility of constructing such a high-velocity accelerator.

AN INVESTIGATION OF CRATERS FORMED BY HIGH-VELOCITY PELLETS, by W. S. Partridge, H. B. VanFleet, and C. R. Whited. May 1957, 45p. Incl. illus. refs. (Technical rept. no. 9) (AFOSR-TN-57-293) (AF 18(600)1217) AD 132364 Unclassified

High-velocity-impact studies were conducted in which Zn, Sn, Cu, Pb, Al, and Fe spheres were accelerated to velocities of 0.75 to 2.25 km/sec and then impacted normally upon targets of the same material. Conditions were maintained so that the pellet lost no mass before striking the target. The target mass was large in comparison with that of the pellet so that they could

be considered semi-infinite. A correlation between crater volume, depth, and cross-sectional area to the energy and momentum of the pellet and parameters of the different metals is presented. The volume of a crater produced by a high-velocity pellet of the same material was found to be directly proportional to the kinetic energy of the pellet. The penetration varied linearly with the velocity over the velocity range and materials investigated. This relationship is compared with the one suggested by Huth (Jour. Appl. Mechanics, v. 64: 65, Mar. 1957). Results showed that the area of the crater is directly proportional to the kinetic energy of the pellet for the metals listed over the energy range under consideration.

PROJECTILE DECELERATION BY ELECTROMAGNETIC FIELDS, by L. D. Harris and L. E. Jenkins. May 1957, 43p. incl. diagrs. tables. (Technical rept. no. 10) (AFOSR-TN-57-294) (AF 18(600)1217) AD 132365 Unclassified

A comprehensive statement of the general theory of decelerating projectiles with electromagnetic fields is followed by a detailed analysis of the individual components that contribute to the retarding force. An experimental verification was made of calculations of the retarding forces on a 50-cal machine gun bullet fired through a 0.073-m-long solenoid, with a 0.009-m radius; the solenoid consisted of 90 turns wound in 2 layers. Almost a 5000-amp current was flowing through the solenoid when the projectile was passing through. The calculations indicate a deceleration of 28 m/sec, while the tests resulted in a deceleration of an average of 43 m/sec. This represents a 3.2% deceleration according to calculations and a 4.2% deceleration according to test results.

UTA.01:011

LADDER AND SIMILAR NETWORKS USED FOR PROJECTILE ACCELERATION BY ELECTROMAGNETIC METHODS, by L. D. Harris and D. S. Humphreys. May 1957, 77p. incl. illus. diagrs. tables. (Technical rept. no. 11) (AFOSR-TN-57-301) (AF 18(600)1217) AD 132372 Unclassified

The efficiency of the electromagnetic acceleration of projectiles can be increased by using 2 stages of acceleration. The first accelerator consists of a large capacity, high-voltage condenser which discharges through a very low inductance coil. The charging currents in the coil produce eddy currents in the pellet which react with the radial component of the flux to produce the accelerating force. With a 2-stage accelerator the current

in the second coil must be zero (or very small) until the pellet reaches its center, at which point the current must build up rapidly to provide another stage of acceleration. The period of zero current in the second coil is called the time delay; its magnitude depends upon the speed of the pellet and the distance it must travel. A simple 2-mesh RC circuit and a multiple-mesh ladder network are theoretically and experimentally investigated for the current configurations and possible delays produced. Results indicate that (1) a basic 2-mesh circuit is practical for velocities about twice those presently available, (2) a modification of the basic circuit (a coil is tightly coupled to the first accelerating coil after being added to the shunt leg in series with the second capacitor) would provide a time delay more compatible with present velocities, and (3) the ladder can be used when extremely high velocities are obtained although at slow speeds it is very expensive and inefficient.

UTA.01:012

Utah U. Dept. of Electrical Engineering, Salt Lake City.

A MULTI-STAGE ELECTROMAGNETIC ACCELERATOR MODEL, by A. S. Jones and L. D. Harris. Sept. 1957, 30p. incl. illus. diags. refs. (Technical rept. no. 12) (AFOSR-TN-57-551) (AF 18(600)1217) AD 136535 Unclassified

A multi-stage electromagnetic accelerator was made from a number of short solenoid coils spaced axially along a plastic tube running through their centers. The projectile used was a hollow aluminum cylinder whose length was slightly less than one half the length of the coil. An electronic system discharged a capacitor into each coil at the appropriate time. The frequency of the current in each coil was varied while the energy supplied to the coil was held constant. It was found that each stage had an optimum frequency for maximum transfer of energy to the projectile. If each stage operated at its own optimum frequency, the efficiency of conversion of stored electrical energy to kinetic energy in the projectile was the same for each stage. This efficiency was found to be slightly less than five per cent. (Contractor's abstract)

SOME NEW DATA ON HIGH-SPEED IMPACT PHENOMENA, by J. H. Huth, J. S. Thompson, and M. E. Valkenburg. [1957] [4]p. incl. diags. [AF 18(600)-1217] Unclassified

Presented at annual meeting of the Amer. Soc. Mech. Engineers, New York, Nov. 25-30, 1956.

Published in Jour. Appl. Mech., v. 24: 65-68, Mar. 1957.

A summary is presented of some recent experimental work aimed at evaluating the role of various physical parameters in high-speed impact phenomena. It is shown that penetration into thick targets by projectiles of the same material, for certain common metals, can be expressed approximately through a single relationship of the form $(p/d) = 2.5(V/c)^{1.4}$ in a range of about $0.1 \leq (V/c) \leq 1.0$. Here p represents penetration (crater depth) measured from the initial target surface, d , a characteristic dimension of the projectile, and V , the impact velocity. c is the "sonic" velocity in the projectile and target material as expressed by the formula $c = \sqrt{E/\rho}$, where E is Young's modulus and ρ the density. Experimental results are given for steel, aluminum, brass, lead, magnesium, and a magnesium-lithium alloy. (Contractor's abstract)

THE COIL TYPE OF ELECTROMAGNETIC ACCELERATOR, by L. D. Harris. [1957] [5]p. incl. illus. diag. table. [AF 18(600)1217] Unclassified

Published in Proc. Second Hypervelocity and Impact Effects Symposium, Washington, D. C. (May 22-24, 1957), Washington, Naval Research Lab., v. 1: 163-167, Dec. 1957.

An analysis is presented of the quantity of energy transferred from the accelerating coil of gun to the pellet projectile in terms of the coil current, pellet inductance and the mutual inductance of the system. An experimental single-stage electromagnetic gun has been constructed which is capable of accelerating a 4.5 gm aluminum pellet to a final velocity of 200 m/sec. A projection of system changes required to build a gun which would produce 10 km/sec particles is given.

HIGH-VELOCITY IMPACT STUDIES AT THE UNIVERSITY OF UTAH, by W. S. Partridge. [1957] [16]p. incl. illus. diags. table, refs. [AF 18(600)1217] Unclassified

Published in Proc. Second Hypervelocity and Impact Effects Symposium, Washington, D. C. (May 22-24, 1957), Washington, Naval Research Lab., v. 1: 93-108, Dec. 1957.

A survey is presented of (1) the interaction of hypervelocity pellets and the atmosphere; and (2) the factors affecting the crater formation in targets which have the

UTA.01:016 - UTA.01:019

same composition as the pellets. The ionization intensity and the time delay in the occurrence of the ionization have been studied as a function of the pellet velocity. The ablation of material from the pellet has been studied as a function of distance. The impact studies include: measurements of the ratio of crater area to pellet area as a function of impact velocity, in the case of wax particles which have velocities above the velocity of sound propagation in the wax; the study of the relationship between crater volume and particle energy; the relationship between crater volume per unit particle energy and a strength parameter of the material; the penetration of the pellet as a function of the velocity; and the variation of the crater volume per unit energy as a function of tin-lead composition.

SIMILARITIES BETWEEN LUNAR AND HIGH VELOCITY IMPACT CRATERS, by H. B. Van Fleet and W. S. Partridge. [1958] 5p. illus. diagr. (AFOSR-TN-58-27) (AF 18(600)1217) AD 148066 Unclassified

Also published in *Astrophys. Jour.*, v. 128: 416-419, Sept. 1958.

Craters formed by firing small spherical pellets of metal and wax into targets of the same material at velocities up to 5 km/sec exhibit many of the characteristics observed in lunar craters. The following similarities between lunar and high-velocity craters have been noted: (1) the material in the crater lip and in the raised portion of the surface around the crater itself is approximately equal to the volume of material removed in forming the crater; (2) a system of rays resembling lace-work and extending outward from the crater has been observed and postulated to be made up of fragments thrown from the crater at the time of impact; (3) a wrinkled appearance observed around metal targets and attributed to slippage of crystal planes in the solid material resembles very closely the surface surrounding some lunar craters. Other phenomena characteristic of lunar craters and reproducible by high-speed pellets are craters occurring in pairs and others with central peaks. By varying the pellet shape, the target material, and the impact velocity, it is possible to duplicate almost any crater shape observed on the moon.

HIGH VELOCITY IMPACT CRATERS IN LEAD-TIN ALLOYS, by H. B. Van Fleet, C. R. Whited, and W. S. Partridge. Jan. 1958 [46]p. incl. illus. diagrs. tables. (Technical rept. no. 13) (AFOSR-TN-58-28) (AF 18(600)1217) AD 148067 Unclassified

Impact phenomena have been investigated for the lead-tin alloys by firing 3/16 in. spherical pellets from an experimental gun at velocities up to 2.2 km/sec into targets which were large compared to the resultant craters. The pellets and targets were of the same-lead-tin composition in all cases. Quantitative data for the volume, diameter, and depth, along with the mass and velocity of the impinging pellet were obtained for each crater. Correlation has been made between the crater parameters and various functions of the pellet mass and velocity for the following samples: 100% Pb; 90% Pb, 10% Sn; ...; 10% Pb, 90% Sn; 100% Sn. WAX MODELLING STUDIES OF HIGH-VELOCITY IMPACT IN WAX, by W. S. Partridge and W. G. Clay. [1958] [16]p. incl. illus. diagrs. (AFOSR-TN-58-121) (AF 18(600)1217) AD 152029 Unclassified

Also published in *Jour. Appl. Phys.*, v. 29: 939-942, June 1958. (Title varies)

Penetration of wax pellets into wax targets was found to vary linearly with the cube root of the pellet mass and the pellet velocity up to velocities in excess of twice the sonic velocity in the wax target. The crater area varies directly as the impact velocity, but there is a marked increase in the constant of proportionality above the target sonic velocity. The volume of the crater per unit energy of the pellet was found to be $2.23 \times 10^{-8} \text{ m}^3/\text{joule}$ for the lower velocity range and above the target sonic velocity the value was found to be $2.75 \times 10^{-8} \text{ m}^3/\text{joule}$. It was observed that a large part of the crater volume is created by deformation of the target material and that only a small part is due to ejection of the target material. (Contractor's abstract)

Spheres of copper, lead, tin, iron, aluminum, zinc, silver, and lead-tin alloys were accelerated to velocities of 0.75 to 2.25 km/sec and impacted normally upon targets of the same material as the pellets. Conditions were maintained so that the pellets lost no mass before striking the target. The target mass was large compared to the mass of the pellet, so the targets could be considered semi-infinite. The volume of the crater produced was found to be directly proportional to the kinetic energy of the pellet in the energy range investigated. The penetration varied linearly with the momentum of the pellet. (Contractor's abstract)

A solenoid-type accelerator was considered in a study

of the feasibility of an electromagnetic device to accelerate small projectiles to velocities of 10 km/sec. The solenoid-type accelerator consists of a hollow coil in which a conducting projectile is placed. A heavy current is passed through the coil, and the resulting magnetic field induces currents in the projectile which react with the magnetic field to accelerate the projectile. Speculation is made on the feasibility of an electromagnetic accelerator that will give a terminal velocity of 10 km/sec to a 5-g projectile. Calculations are appended which predict the length of a multistage accelerator that will produce the desired velocity. The kinetic energy in a 5-g projectile at 10 km/sec is 2.5×10^5 J. With a 10% energy conversion, the energy source must deliver 2.5×10^6 J to the accelerating system. For an accelerator with a 50-m length, the average power requirement from the source is 2.5×10^8 W. The following assumptions were made: (1) the projectile resistance was independent of temperature rise and was that of dc, (2) all energy converted to heat within the projectile is stored, and (3) the slip velocity was constant.

An initial investigation of the fundamental principles of cratering by multi-particle and single-particle projectiles was carried out to describe actions that occur under one type of loading - that which may develop when an explosive charge is detonated in intimate contact with a body or when one body of high impulse impacts against another. The primary objectives were to investigate jet formation, jet structure, and the initial stages of target penetration by lined cavity charges in regard to impulsive loading. The jet formation and structure studies

UTA.03:002 - UTA.03:005

were carried out to provide some needed information for interpreting ultra-high speed photographs of the penetration of targets by multi-particle projectiles. (Contractor's abstract, modified)

MEASUREMENTS OF IONIZATION AND ELECTRON DENSITIES IN THE DETONATION WAVE OF SOLID EXPLOSIVES, by R. T. Keyes and L. D. Lee. Sept. 15, 1956 [37]p. incl. diagrs. tables, refs. (Technical note no. 1) (AFOSR-TN-57-85) (AF 18(603)100) AD 120433 Unclassified

The hydrodynamic theory of penetration of targets by shaped charge jets is summarized and extended to account for crater volumes produced by shaped charge jets. It is then applied in discussing cratering by single-particle projectiles in high velocity and in ultra-high velocity impact, and cratering by multi-particle streams of independently penetrating particles. The conditions for impact explosions of targets and/or projectiles are discussed and theoretical results presented. Finally, impact and explosion cratering are compared.

Electrical conduction measurements were made in the detonation wave of loose explosives TNT (coarse and fine), RDX, PETN, tetryl, EDNA, 80/20 AN (ammonium nitrate) - TNT, and in the cast explosives TNT and Composition B. The measured conductivities were found to be of the same order of magnitude as those found in good semi-conductors. The electrical conductivities were used to calculate electron densities within the detonation wave, and these were found to be of the order of 10^{17} $1/cm^3$ in the ionization region for the explosives tested. Known methods of producing ionization were considered and the conclusion was reached that apparently the only mechanism which can produce ionization of the magnitudes observed is chemical reaction within the detonation wave. In the light of this conclusion, electron-ion recombination times were considered and were concluded to be in the vicinity of 10^{-8} sec, the limitations being imposed by electronic transition probabilities rather than kinetic theory. Since such a recombination time is small compared to explosive reaction times, the results of reaction zone length determinations by means of the current theories were compared with the ionization zone length measurements. Rather good agreement was obtained with one of the published theories of reaction zone length (the "geometrical model"). This result adds credence to the conclusion that chemical reactions are the source of the ionization. Furthermore, since the recombination times were believed to be short and the electron densities high, it appears that there may be approximately one electron liberated for every explosive molecule that reacts in the detonation reaction zone. These free electrons no doubt contribute to various electrical, magnetic and electromagnetic phenomena found recently and presently being studied under this contract. (Contractor's abstract)

THE GENERATION OF HIGH VELOCITY PROJECTILES WITH HIGH EXPLOSIVES, by R. T. Keyes and M. A. Cook. Oct. 1, 1957, 21p. incl. diagrs. (AFOSR-TN-57-696) (AF 18(603)100) AD 136698; PB 136441 Unclassified

Also published in Jour. Appl. Phys., v. 29: 1651-1657, Dec. 1958.

A technique of controlling the shape of detonation wave fronts in high explosives by inert wave control inserts was applied to generate discrete ultra-high velocity pellets. Tests to determine the most suitable pellet shape as well as the optimum charge configuration are described, and velocities up to 7600 m/sec were realized for 0.95 g aluminum pellets. The mechanism whereby pellets are accelerated by "shaped" waves is discussed, and the conclusion was reached that a simple model based upon the transmission of shock from the detonation wave to the pellet was not applicable.

Utah U. [Dept. of Metallurgy] Salt Lake City.

MECHANISM OF CRATERING IN ULTRA-HIGH VE-

UTA.03:006; UTA.02:025, 026

accompanying shock wave. The mechanism of conduction was considered, and it was shown that electron flow through the plasma accounted for practically all of the current. With this in mind, it was concluded that the current flow through the plasma region was of the same nature as current flow in a metal. Conduction measurements in atmospheres of Cl_2 , O_2 , N_2 , He, and air showed that the rate of decay of the plasma was dependent upon the gaseous medium and can be explained on the basis of negative ion formation. The plasma exhibited pulsations, and it was concluded that an adhesive attraction exists in the plasma through a quasi-lattice structure. Electron densities of 10^{16} electrons/cc were calculated from conduction measurements of the plasma after it had spread from the 1 in. diameter charge to a 2 in. diameter constraining tube. Presented at meeting of the Phys. and Inorg. Chem. Div. of the Amer. Chem. Soc., Atlantic City, N. J., Sept. 16-21, 1956.

Abstract published in 130th meeting of the Amer. Chem. Soc. Abstracts of Papers. 1955. p. 24-R.

The classical theories concerning the inhibitor action for chain processes attribute the inhibitory action to the reaction, $\beta(\text{or } \mu) + 1 \rightarrow \text{product}$, where β is the radical which reacts bimolecularly in the chain propagation steps in the Rice-Herzfeld mechanism, μ is the radical acting monomolecularly, 1 is inhibitor, and the term product indicates the substances which are indifferent from the chain reaction system. A mechanism is proposed by which 1 destroys the chain carriers and is regenerated from the bound states, (βI) and (μI) . Here, (βI) and (μI) are the complexes which are formed by reactions of 1 with β and μ . Introducing these mechanisms into the Rice-Herzfeld scheme of uninhibited reactions, and applying the steady-state treatment for 12 possible inhibited reaction systems, 2 equations for r/r_0 are obtained in agreement with experiment. Here r and r_0 are the rates of the inhibited and uninhibited reactions, respectively. Results showed that r/r_0 is smaller if the attraction between chain carriers and 1 is larger, the consumption of 1 is smaller, the chain length of the uninhibited reactions is larger, and the reactivities of (βI) and (μI) are smaller. The theory is successfully applied for the inhibited decompositions of normal hydrocarbons and diethyl ether by NO and propylene, for the inhibited pyrolyses of aldehydes, ethers, and ketones by propylene, and for the inhibition of benzaldehyde decomposition by NO. Electrical conduction measurements were made in the detonation waves of the loose, granular explosives TNT (coarse and fine), RDX, PETN, tetryl, EDNA, 80/20 ammonium nitrate-TNT, and in the cast explosives, TNT and Composition B. The electrical conductivities were used to compute electron densities within the detonation wave, and these were found to be greater than $10^{17}/\text{cm}^3$ in the front of the detonation wave for the explosives considered. Known methods of producing ionization were considered, and it was concluded that only chemionization can produce such high concentrations of electrons. Electron-ion recombination times appeared to be no longer than 10^{-8} sec, the limitation imposed by electronic transition probabilities. Therefore, it was concluded that the conductivity-time curve should be approximately proportional to the chemical reaction rate. On this basis, rather good agreement was obtained with one of the three published theories of the reaction zone length (the geometrical model). Furthermore, it appears that there may be approximately one electron liberated for every explosive molecule formed in the detonation reaction zone, and that a plasma is therefore the transition state (or "activated complex") in the chemical reactions of high explosives. KINETICS AND MECHANISM OF DIBORANE PYROLYSIS, by J. R. Morrey and G. R. Hill. Jan. 8, 1958, 137p. incl. illus. diagrs. tables, refs. (Technical rept. no. 1) (AFOSR-TN-58-220) (AF 49(638)28) AD 154121; PB 134751
Unclassified

A comprehensive literature survey of reactions pertaining to the pyrolysis of boranes has been made in an effort to correlate the pertinent findings so far established. To facilitate further investigation, a heatable infrared cell was constructed. Its description along with the electronic circuit of the temperature controller and pressure measuring devices has been included. Two sets of equations are presented for the analytical determination of mixtures of diborane, tetraborane, pentaborane-9 and pentaborane-11 from infrared spectra for high pressures and for low pressures. A study of the kinetics of pyrolysis of diborane in the infrared cell as well as pyrex cells is herein reported. Evidence is given for second order disappearance at low temperatures and a transition from second order to 3/2 order at about 150°C. First order disappearance data are also discussed. Data are provided to substantiate induction periods in diborane pyrolysis. The catalytic effects of sodium chloride, silicone rubber, teflon, Apieson lubricant and mercury are discussed. Total-pressure-curve characterization has been attempted in order to correlate the various types of curves obtained by different investigators. Unstable, unidentified intermediates in the pyrolysis of diborane have been detected using a "differential method." Preliminary investigations on pentaborane-11 and tetraborane pyrolysis are also presented. In conclusion a mechanism has been postulated which accounts for the activation entropies and enthalpies of the first and three-halves order diborane disappearance. As yet no suitable second-order mechanism has been postulated. (Contractor's abstract)

UNSTABLE INTERMEDIATES IN THE PYROLYSIS OF DIBORANE, by J. R. Morrey, A. E. Johnson and others. [1958] [17]p. incl. illus. diagrs. tables. (AF 49(638)28)
Unclassified

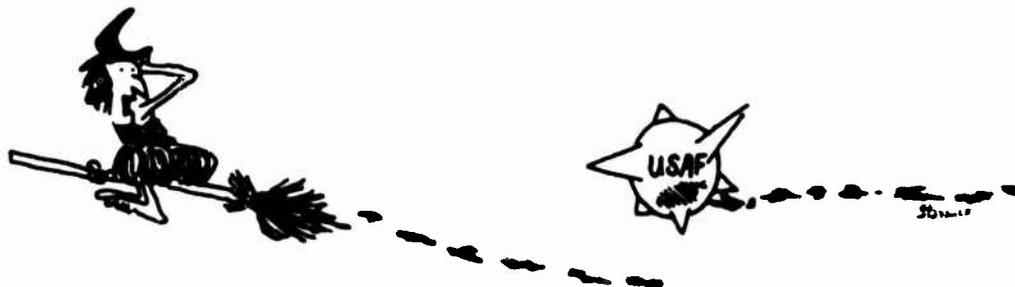

Presented at meeting of the Inorg. Div. of the Amer. Chem. Soc., San Francisco, Calif., Apr. 15, 1958.

Also published in 133rd meeting of the Amer. Chem. Soc. Abstracts of Papers, 1958, p. 14-L.

Pyrolysis of diborane was carried out in a borosilicate glass cell so designed as to freeze out any products that would condense at dry ice-acetone temperature. Between 100° and 130°C, pentaborane-11 was the main condensable product. The stoichiometry of such a reaction caused a decrease in total pressure, since pentaborane-11 exhibits little vapor pressure:

However, without exception, an initial increase in pressure was observed. Data are presented to show that such a pressure rise was not due to fast initial decomposition of pentaborane-11 to polymer or pentaborane-9. Neither could it be attributed to slow attainment of temperature equilibrium in the cell. An alternative explanation appeared to be a high initial concentration of unstable intermediates in the formation of pentaborane-11. To test this hypothesis, a differential infrared technique was used. Two gas cells filled with diborane were placed in the reference and sample beams of a dual-beam infrared spectrometer and adjusted to compensate each other at room temperature. Rapid heating of the cell in the sample beam produced intermediates which were detected by differential infrared spectra. These intermediates could not be attributed to any of the common volatile hydrides nor to polymer. Assuming the spectrum of the intermediate is due to BH_3 , theoretical calculations have been made of the in-plane bending and stretching and out-of-plane bending force constants, assuming D_{3h} symmetry. On the basis of these constants, the infrared inactive frequency of BH_3 and the normal modes of BD_3 have been predicted. (Contractor's abstract)

THE CORROSION OF SINGLE CRYSTALS AND RE-CRYSTALLIZED SINGLE CRYSTALS OF IRON AND STEEL IN CITRIC ACID, by W. R. Buck, III and H. Leidheiser, Jr. [1957] [8]p. incl. illus. diags. table, refs. [AF 18(600)1319] Unclassified

Published in Jour. Electrochem. Soc., v. 104: 474-481, Aug. 1957.

Corrosion studies, largely in 0.2M citric acid at 20°C and the boiling point, were made on polycrystalline disks and monocrystalline spheres and disks of Armco iron and type L steel. Preliminary experiments indicated that the (100) face corroded at the slowest rate and the minor faces, of which the (321) is an example, corroded at the most rapid rate. Quantitative measurements were confined to these two crystal faces. The (100) face was cathodic to the (321) face as shown by potential measurements in 0.2M citric acid in the presence and absence of air. The rate of corrosion of the (321) face was approximately twice that of the (100) face on specimens which were chemically polished, electrolytically polished, machined with a sharp lathe tool, or polished with emery paper. The rates of corrosion of the polycrystalline starting material from which the single crystals were prepared were several times greater

than those of the single crystals. Conversion of the single crystals to polycrystalline material by heating through the transformation temperature resulted in a considerably increased corrosion rate. In the presence of 40-45 ppm of Sn(II) the rates of corrosion of the single crystals in 0.2M citric acid at the boiling point were reduced greatly and no significant difference between the (100) and (321) faces was observed. CORROSION OF TEN METALS IN BOILING HYDROCHLORIC ACID WHEN IN CONTACT WITH RHODIUM, PALLADIUM, IRIIDIUM, AND PLATINUM, by W. R. Buck, III, and H. Leidheiser, Jr. [1958] [2]p. [AF 18(600)1319] Unclassified

Published in Nature, v. 181: 1691-1682, June 14, 1958.

The rates of corrosion of aluminum, cadmium, cobalt, iron, lead, manganese, nickel, tin, titanium, and zinc were studied in boiling 2M HCl, with and without contact with platinum, iridium, rhodium and palladium. With the exception of titanium, the rates of corrosion were increased when coupled to the platinum metals. The relative effectiveness of the platinum metals in increasing the corrosion varied with the metal undergoing corrosion. The discrimination between the platinum metals was least for those farther away from platinum in the emf series and greatest for the more noble metals. For eight of the ten metals studied, the average rate of corrosion when coupled to the four platinum metals was related to the standard electrode potential.

THE ACTIVATION AND INHIBITION OF CORROSION OF METALS BY METALLIC CATIONS, by W. R. Buck, III, and H. Leidheiser, Jr. [1958] [5]p. [AF 18(600)1319] Unclassified

Published in Corrosion, v. 14: 22-26, July 1958.

A broad survey was made of the corrosion of Al, Cd, Cu, Au, Fe, Mg, Mn, Mo, Ni, Ag, Sn, Ti, W, Zn, and Zr by fruit and mineral acids at the boiling point in the presence of low concentrations of foreign metallic ions. As a general rule, cations of the elements in Groups II through V in the periodic table showed the highest tendency to decrease the rate of corrosion, and the transition elements in Group VIII showed the highest tendency to increase the rate of corrosion. The relative effectiveness of the ions was a function of the metal undergoing corrosion and the acid used.

ANAEROBIC CORROSION OF METALS IN SOLUTIONS CONTAINING VARIOUS METALLIC CATIONS-INACTIVATION AND ACTIVATION, by W. R. Buck, III, and H. Leidheiser, Jr. [1958] [6]p. Incl. diagrs. tables, refs. [AF 18(600)1319] Unclassified

Published in Zeitschr. Elektrochemie, v. 62: 690-695, 1958.

Three cases of the inactivation of a metal by small amounts of a foreign metal originally present as a cation in solution are cited: the inactivation of iron by Sn(II) and Pb(II) ions in boiling 0.2M citric acid; the inactivation of Ni by Cu(II) ions in boiling 2M HCl; and the inactivation of titanium in boiling 2M HCl by the Group VIII metals, rhodium, ruthenium, palladium, iridium, osmium, and platinum. Experiments on the activation of aluminum, copper, iron, nickel, silver, tin, and zinc in boiling acids by the Group VIII metals are also described. The foreign metal is considered to exert its influence on the activity of the corroding metal only after it is reduced to the metallic state at the surface. It is suggested that the corrosion rate which results is controlled by the type of electron transfer which occurs between the two kinds of metal atoms at the solution-metal interface. FLOW IN THE FORWARD STAGNATION REGION OF BLUNT BODIES, by R. W. Truitt. [1957] [2]p. Incl. diagrs. (AF 18(600)641) Unclassified

Published in Jour. Aeronaut. Sciences, v. 24: 380-381, May 1957.

The shock detachment parameter b/a has been calculated for a sphere and cylinder at $M_\infty = 5.8$. It is seen that the calculated value of b agrees with the "average" radius of the experimental shock; similar results were found for the cylinder. It is important to note that a comparison of the theoretical ratio $(b/a)_{\text{sphere}} / (b/a)_{\text{cylinder}}$ for $M_\infty = 5.8$, shows excellent agreement with the experimental ratio measured at the nose. The calculated values of the dimensionless stagnation velocity gradient $\beta D/U$ are plotted versus M_∞ ; the experimental values are given for a hemispherical nose. Although the values of b/a for a cylinder and sphere are different for the same Mach number, the values of $\beta D/U$ are the same in the hypersonic range. Pressure distributions have been calculated for a sphere at $M_\infty = 1.97$ and 3.8 and compared with experimental

values. Although the present analysis is valid only in the stagnation region, the calculated pressure distributions agree with experiment over practically the entire hemisphere.

APPROXIMATE SOLUTION FOR SLIGHTLY YAWED n-POWER BODIES AT HYPERSONIC SPEEDS, by R. W. Truitt. [1958] [2]p. Incl. tables. (AF 18(600)641) Unclassified

Published in Jour. Aeronaut. Sciences, v. 25: 206-207, Mar. 1958.

Neglecting centrifugal forces, a reasonable approximation for the pressure distribution over a general slender body at finite hypersonic speeds and small angle of attack may be written as $C_p = 2\{1 + \lambda[(1+N)/4]\}(\cos \alpha \sin \theta - \sin \alpha \cos \theta \sin \beta)$. Perhaps the most suitable type body of revolution at hypersonic speeds is the n-power body, of fineness ratio $f = L/d$, with meridian section shape given by $y/(d/2) = (x/L)^n$ where $L =$ length and $d =$ diameter of the body. Cole, taking into account centrifugal forces, derived an expression for the drag coefficient of n-power bodies for the special case of zero angle of attack and $N = 0$. A comparison of Cole's results with those presented in this paper suggests the use of an approximate centrifugal-force correction.

QUASI-OPEN MAPPINGS, by G. T. Whyburn. July 1957, 11p. (Technical note no. 1) (AFOSR-TN-57-395) (AF 49(638)71) AD 132470 Unclassified

Also published in Rev. Math. Pures Appl., v. 2: 47-52, 1957.

A characterization is given of quasi-open mappings from one plane to another in terms of the minimum modulus property which is based on the characterization of such mappings in terms of their action on elementary plane regions. A general mapping result is obtained, and one of its consequences is the result that in a very general setting the quasi-open mappings form a closed class under uniform convergence. The principal theorem states: Let X and Y be locally connected generalized continua and let the sequence of quasi-open mappings $f_n: X \rightarrow Y$ converge almost uniformly to the mapping $f: X \rightarrow Y$. For any $y \in Y$ and any open set V in X containing a nonempty compact component: K of $f^{-1}(y)$, there exists

VRU.01:002 - VRU.01:004

a conditionally compact open set U in X with $K \subset \bar{U} \subset V$, a region R in Y about y and an integer N such that for each $n > N$, U contains a component Q_n of $f_n^{-1}(R)$ so that $f_n(Q_n) = R$. The following results are derived from the theorem: (1) the limit mapping f is quasi-open; (2) if each f_n is weakly monotone and $f^{-1}(y)$ has a nonempty compact component for each $y \in Y$, then f is compact and monotone; (3) if f_n is a $\frac{1}{n}$ -mapping for each n and $f^{-1}(y)$ has a nonempty compact component for each $y \in Y$, then f is compact and monotone; and (4) if f is light, the sequence is uniformly approximately open on every compact set A in X . The designation of light means that $f^{-1}(y)$ is totally disconnected for every $y \in Y$.

UNIFORM CONVERGENCE FOR MONOTONE MAPPINGS, by G. T. Whyburn. Sept. 1957, 12p. (Technical note no. 3) (AFOSR-TN-57-589) (AF 49(638)71) AD 136645 Unclassified

Also published in *Proc. Nat'l. Acad. Sciences*, v. 43: 992-998, Nov. 1957.

Outlines are presented for some results and methods which lead to existence conclusions for uniform convergence of sequences of mappings in a topological setting of interest; their relation and applicability to sequences of real functions is indicated. A sequence of square mappings of a circle onto itself exists which converges everywhere to the identity mapping but the convergence is not uniform. A general theorem is proved from which it follows that if X and Y are circles and the sequence $h_n(x)$ of homeomorphisms of X onto Y converges everywhere on X to a mapping $f(x)$, then either f is a constant or the convergence is uniform and f is monotone; both cases are realizable. The form of the theorem is con-

finer to the case where the domain space X of the mappings is a continuum and where Y is cyclic and the mappings in the sequences are monotone and onto. Corresponding results in less restricted cases are discussed and applied to real functions and to other simplified situations. A statement without proof is given for a result concerned with sequences of quasi-open rather than monotone mappings.

ON CONVERGENCE OF MAPPINGS, by G. T. Whyburn. Oct. 1957, 16p. (Technical note no. 4) (AFOSR-TN-57-709) (AF 49(638)71) AD 136703; PB 133320

Unclassified

Also published in *Colloquium Mathematicum* (Poland), v. 6: 311-318, 1958.

In this paper the author develops conditions sufficient that sequences of compact mappings and that sequences of quasi-open mappings converge almost uniformly. An example of a sequence of homeomorphisms of the plane onto itself which converges to the identity but for which the convergence fails to be almost uniform is first given. This illustrates that even the strongest conditions on the individual mappings are not sufficient for almost uniform convergence. The first theorem is concerned with a sequence of compact monotone mappings $f_n(X) = Y_n$ and a limit mapping $f(X) = Y'$ where X , Y and Y' are closed generalized continua in a locally compact separable metric space with $Y' \subset Y$ and for each $y \in Y$, Y' intersects each component of $Y - y$. Under the conditions that: (a) the sets Y_n converge 0-regularly to Y (i.e., for any $\epsilon > 0$ there is an N and a $\delta > 0$ such that for all $n > N$ any pair of points $y, y' \in Y_n$, of distance $< \delta$, are in a connected set in Y_n of diameter $< \epsilon$); and (b) for each $x \in X$ and $\epsilon > 0$ there exists an ϵ -neighborhood U of x with boundary C such that $\limsup f_n(C)$ is strictly contained in $f(C)$ (i.e., for every $\epsilon > 0$ almost all of the $f_n(C)$ are in the ϵ -neighborhood of $f(C)$); it is shown that the sequence $\{f_n(x)\}$ converges almost uniformly to $f(x)$ on X and also, if each $f^{-1}(y)$, $y \in Y'$, has a non-empty compact component, that f is compact and monotone. The second theorem is concerned with a sequence of quasi-open mappings $f_n: X \rightarrow Y$, with X and Y locally connected generalized continua such that, for each $y \in Y$, each component of $Y - y$ is non-compact. Under the condition that there exists a mapping $f: X \rightarrow Y$ such that for each $x \in X$ and $\epsilon > 0$ there is a conditionally compact region R , boundary C , $x \in R$ and R in the ϵ -neighborhood of $f^{-1}(f(x))$ with $\limsup f_n(C)$ strictly contained in $f(C)$, it is shown that the sequence $\{f_n(x)\}$ converges almost uniformly to $f(x)$ on X .

Further study of spaces in which the open property is a topological invariant for subsets of that space is undertaken. Euclidean spaces and manifolds have this Brouwer property. An invariance theorem concerning the Brouwer property under certain types of mappings is established. This yields not only the existence of spaces other than Euclidean manifolds having this property but also a method of generating such spaces in various ways.

ON THE HILBERT MATRIX, II, by M. Rosenblum. July 1957, 6p. refs. (Technical note no. 1) (AFOSR-TN-57-394) (AF 49(638)72) AD 132469 Unclassified

Also published in Proc. Amer. Math. Soc., v. 9: 561-565, Aug. 1958.

A study is presented of the Hilbert matrix, $H_k = ((n+m+1-k)^{-1})_{n,m}$, $n, m = 0, 1, 2, \dots$, where k is a real number that is not a positive integer. When considered as a linear operator on the complex sequential Hilbert space l_2 , H_k is a bounded symmetric operator.

For each real k , a monotone function $\rho_k(\lambda)$ and an isometric map V_k of $L^2(0, \infty)$ onto $L^2(d\rho_k)$ is exhibited

such that $V_k H_k V_k^{-1}$ is a multiplication operator. From this the spectral nature of H_k is determined.

A THEOREM ON QUASI-COMPACT MAPPING, by P. McDougale. Aug. 1957, 6p. (Technical note no. 2) (AFOSR-TN-57-514) (AF 49(638)72) AD 156884

Unclassified

Also published in Proc. Amer. Math. Soc., v. 9: 474-477, June 1958.

The ascertainment of conditions for topological invariances under various types of mappings, especially where the domain space is metric and the mappings are closed or quasi-compact, has received a considerable amount of recent attention. Results indicate that if f is a quasi-compact mapping of a locally compact, separable metric space X onto the topological space Y ; then Y is a locally compact, separable metric space if, and only if, f is a semi-closed, P_2 mapping.

ON A THEOREM OF FUGLEDE AND PUTNAM, by M. Rosenblum. Nov. 1957, 3p. (Technical rept. no. 3) (AFOSR-TN-57-703) (AF 49(638)72) AD 136696

Unclassified

Also published in Jour. London Math. Soc., v. 33: 376-377, July 1958.

A concise proof of Putnam's theorem is given. The case of bounded operators is treated first. An application of Liouville's theorem on the constancy of bounded entire functions is considered. The unbounded case is deduced from the bounded case by employing spectral projections of the operators. The proof presented here is non-spatial, i.e., avoids invoking the Gelfand-Neumark representation theorem.

ON THE EQUIVALENCE OF TWO COHOMOLOGY DIMENSIONS, by E. E. Floyd. July 1958, 11p. (Technical note no. 7) (AFOSR-TN-58-705) (AF 49-638)72 AD 162239; PB 137349 Unclassified

Alexandroff's classical dimension as stated in cohomology form for locally compact Hausdorff spaces X is defined by $\dim_K X \leq n$ if the cohomology groups $H^i(U, K)$ vanish for all $i > n$ and all open $U \subset X$. This Alexander-Spanier cohomology with compact supports is studied so as to show the equivalence with Cartan's cohomology dimension defined in terms of sheaves of coefficients. The $\dim_{\phi, K} X \leq n$ (ϕ is the family of compact subsets of X) if the cohomology groups $H_{\phi}^i(X, F)$ vanish for all $i > n$ and all K-sheaves F on X.

SEMI-COMPACT MAPPINGS, by P. McDougle. July 1958, 9p. (Technical note no. 5) (AFOSR-TN-58-768) (AF 49(638)72) AD 201923; PB 138175 Unclassified

The semi-compact mapping property is introduced to relate certain important properties in the study of decomposition spaces. Since certain equivalences have been established among space property invariants, mapping properties, and decomposition properties, it seemed feasible to introduce a system of spaces and mappings which characterize many decomposition space problems while obviating the decomposition construction. Particular emphasis is given to the case where point inverses are connected and have bicomact boundaries. (ASTIA abstract)

STATIONARY POINTS FOR FINITE TRANSFORMATION GROUPS, by J. Greever. Aug. 1958, 15p. (Technical note no. 6) (AFOSR-TN-58-797) (AF 49(638)72) AD 202230; PB 138171 Unclassified

Also published in Duke Math. Jour., v. 27: 163-170, June 1960.

Let (G, X) be a transformation group in which G is finite and X is a finite-dimensional compact Hausdorff space. Various sets of sufficient conditions are given for the existence of at least one fixed point i.e., point fixed under all the transformations of the group. Each set contains (1) the assumption that X is homologically or cohomologically trivial over specified coefficients; (2) the condition that G admits a normal chain of specified type; (3) the hypothesis that the integral cohomology groups of the set F_H of fixed points of the subgroup H

be finitely generated for each H appearing in the normal chain in (2). The quotient groups which appear in (2) are of prime power orders, and at most three distinct primes occur. Suppose, in particular, that the integral cohomology groups of F_H are finitely generated for every subgroup H of G and that those of X are trivial. The theorems above then show that F_G is non-empty when G is abelian and $[G: 1] \leq 210$, also when G is non-abelian and $[G: 1]$ is less than 60 and unequal to 36.

VAPOR PHASE CARBOTHERMIC REDUCTIONS OF MAGNESIUM OXIDE IN THE HIGH INTENSITY ARC, by S. Korman, A. [W.] Diniak, and C. Sheer. Aug. 22, 1958, 18p. incl. illus. diagrs. tables. (Technical note no. 6) (AFOSR-TN-58-498) (AF 18(803)3) AD 158308; PB 143656 Unclassified

A laboratory investigation of the vapor-phase reduction of magnesium oxide has been carried out in the tail flame of a d-c high intensity arc. Thermodynamic considerations were used to predict an approximate temperature-dependence for the homogeneous reaction, $\text{MgO} + \text{C} \rightarrow \text{Mg} + \text{CO}$, indicating this reaction goes to completion above 1800°C. Since the lowest recorded temperature in the flame was ~2000°C, it was assumed that the flame consisted predominantly of reaction products. This was verified by spectrographic observation. The positioning of a water-cooled, copper quench plate for product sampling was fixed by considerations of heat flux and flame temperature as determined spectrographically. For 5/8-in. diameter anodes, containing slightly greater than a stoichiometric fraction of carbon, a 7 kw arc operating in 0.1 atm of nitrogen yielded a product representing 64% reduction of the oxide with an equivalent power consumption of 8.2 kwh/lb of metal. It was concluded that the reaction was a homogeneous one and that the high intensity arc technique offers interesting possibilities in the carbothermic reduction of stable metal oxides. THE HIGH INTENSITY ARC AS A PLASMA PROPULSION SOURCE (Abstract), by C. Sheer, L. Mead, and C. D. Fitz. [1958] [1]p. (Bound with its AFOSR-TN-58-125; AD 162274) (Sponsored jointly by Wright Air Development Center under AF 33(616)3669 and Air Force Office of Scientific Research under AF 18(803)3) Unclassified

Presented at Conf. on Ion and Plasma Research, Maryland U. College Park, Sept 30-Oct. 2, 1958.

The use of a plasma jet as the working fluid of a propulsion device provides a system intermediate in properties between the high mass flow - low exhaust velocity, characteristic of the chemical rocket engine, and the low mass flow - high exhaust velocity of the ion propulsion engine. Propulsion by means of a plasma jet is distinguished from ion propulsion in that the latter involves the acceleration of a pair of separated, homogeneous, oppositely-charged particle streams. On the other hand, the plasma medium consists of a partially ionized stream of gas consisting predominantly of neutral particles but containing a sufficient concentration of oppositely charged particles to provide the necessary plasma characteristics. Thus instead of

separate beams of charged particles, there is a single beam characterized by a statistical distribution of electrical dipole moment within the beam. The advantages of a plasma beam over the two ion beams are shown to be (1) that a much higher particle flux can be obtained in a practical generator for the plasma jet and (2) that the energy required to produce the charged particles within the plasma (i.e. establish the electric dipole distribution) is considerably less than that required for the production and separation of pure charged particle beams. As a result of these and other advantages the plasma jet offers promise of superior performance provided an efficient method for plasma acceleration is developed.

A proof is given that $\|\Gamma_\lambda \alpha(n)\|_p < B(p) \|\alpha\|_p$, ($1 < p < \infty$), where $\Gamma_\lambda \alpha(n) =$

$$\int_{m=0}^{\infty} \alpha(m) \int_{-1}^{\lambda} (n+\frac{1}{2})^{\frac{1}{2}} (m+\frac{1}{2})^{\frac{1}{2}} P_m(x) P_n(x) dx$$

and $B(p)$ depends only upon p and not upon λ . This result is an analog of Pollard's theorem (Trans. Amer. Math. Soc., v. 62: 387-403, 1947; v. 83: 355-387, 1948; and Duke Math. Jour., v. 18: 189-191, 1949).

WEIGHTED QUADRATIC NORMS AND ULTRASPHERICAL POLYNOMIALS, I, by R. Askey and I. I. Hirschman, Jr. [1957] 24p. refs. (AFOSR-TN-57-349) (AF 18(600)588) AD 132422 Unclassified

Also published in Trans. Amer. Math. Soc., v. 91: 294-313, May 1959.

The functions $f(x)$ on $[-1, 1]$ which satisfy the condition

$$R_{\beta, \alpha} [f] = \left[\int_{-1}^1 f(x)^2 (1+x)^\beta (1-x)^\alpha (1-x^2)^{\nu-\frac{1}{2}} dx \right]^{\frac{1}{2}} < \infty$$

a linear metric space $R_{\beta, \alpha}$ with $R_{\beta, \alpha} [f]$ as metric.

The sufficient conditions are sought to ensure the boundedness of a linear transformation T of $R_{\beta, \alpha}$ into itself when T is defined by $(Tf)^\wedge(n) = f^\wedge(n)t(n)$ and so commutes with the convolution operator in the sense that $(Tf_1)^\wedge * f_2^\wedge = f_1^\wedge * (Tf_2)^\wedge$, where the $f^\wedge(n)$ are the coefficients in an expansion of $f(x)$ in terms of the ultraspherical polynomials $W(n, x)$, i.e. $f^\wedge(n) =$

$$\int_{-1}^1 f(x) W(n, x) (1-x^2)^{\nu-\frac{1}{2}} dx \text{ for } n = 0, 1, 2, \dots$$

The main conclusion is that T has a bound $C \cdot A(\alpha, \beta, \nu)$

provided that $-\frac{1}{2} < \alpha, \beta < \frac{1}{2}$ and $|t(n)| \leq C, \sum |t(k) - t(k-1)| \leq$

C for sums over $2^n \leq k < 2^{n+1}$. Various relationships between weighted quadratic norms of $f(x)$ and series involving its coefficients $f^\wedge(x)$ are given.

WEIGHTED QUADRATIC NORMS AND ULTRASPHERICAL POLYNOMIALS, II, by I. I. Hirschman, Jr. [1957] 24p. (AFOSR-TN-57-350) (AF 18(600)568) AD 132423 Unclassified

Also published in Trans. Amer. Math. Soc., v. 91: 314-326, May 1959.

The results of this investigation are the dual of those found in (item no. WAS.02:028). A transformation t of sequences $F(n)$ which commutes with the convolution operator in the sense that $tF_1 * F_2 = F_1 * tF_2$ determines a measurable function $t(x)$ on $[-1, 1]$ so that $[tF]^\wedge(x) = F^\wedge(x)t(x)$. The sequences which $R_\alpha [F] =$

$$\left[\sum F(n)^2 \omega(n) (n+1)^{2\alpha} \right]^{\frac{1}{2}} < \infty, \quad (-\frac{1}{2} < \alpha < \frac{1}{2})$$

form a linear metric space R_α with $R_\alpha [F]$ as metric. A transformation t of R_α into itself has a bound $C \cdot A(\alpha, \nu)$ provided that

$$|t(\cos \theta)| \leq C \text{ for } 0 \leq \theta \leq \pi \text{ and } \int |dt(\cos \theta)| \leq C$$

if the integral is taken over intervals with end points $\frac{1}{2}\pi(1+2^{-k})$ and $\frac{1}{2}\pi(1+2^{-k+1})$ for all $k = 1, 2, 3, \dots$. Various relationships between weighted quadratic norms of expansion coefficients $F^\wedge(x)$ and series of the function $F(n)$ are given.

ON RINGS OF (γ, δ) -TYPE, by L. A. Kokoris. [1957] [8]p. (AFOSR-TN-57-363) (AF 18(600)568) AD 132458
Unclassified

Also published in Proc. Amer. Math. Soc., v. 9: 897-904, Dec. 1958. (Title varies)

Among the algebras of type (γ, δ) [Albert, Portugal Math., v. 8: 23-26, 1949; Kokoris, Canad. Jour. Math., v. 8: 250-255, 1956] those of type $(-1,0)$ and $(1,1)$ are residual cases in the classification of almost alternative algebras relative to quasi-equivalence. In this paper the following results concerning rings are proved. (a) Any ring of type $(-1,0)$ is anti-isomorphic to a ring of type $(1,1)$. (b) Let A be a simple ring of type $(1,1)$ whose characteristic is not 2 and which contains an idempotent e ; then either A is associative, or e is the unity element of A . In an appendix is given the extension by Kleinfeld, to rings, of the author's earlier results on algebras of type (γ, δ) . (Math. Rev. abstract)

MULTIPLIER TRANSFORMATIONS ON $L^{2,\sigma}$, by A. Devinatz and I. I. Hirschman, Jr. [1958] [21]p. (AFOSR-TN-58-177) (AF 18(600)568) AD 152210; PB 134648
Unclassified

Also published in Ann. Math., v. 69: 575-587, May 1959.

A study is made of the Banach algebra M_σ of those bounded linear transformations of $L^{2,\sigma}$ into itself which commute with convolution. The symbolism is as follows: $L^{2,\sigma}$ is the Banach space of those complex functions $F(n)$ for which $\|F\|_{2,\sigma} < \infty$, and $\|F(n)\|_{2,\sigma} =$

$\sum_{n=-\infty}^{\infty} |F(n)|^2 (|n| + 1)^{2\sigma}$, $-\frac{1}{2} < \sigma < \frac{1}{2}$, and the operation of convolution, $*$, is defined by $(F*G)(n) = \sum_{k=-\infty}^{\infty} F(n-k)G(k)$. Particular emphasis is given to questions of spectral structure.

THE SPECTRA OF MULTIPLIER TRANSFORMS ON L^p , by A. Devinatz and I. I. Hirschman, Jr. [1958] 20p. incl. refs. (AFOSR-TN-58-178) (AF 18(600)568) AD 152211; PB 134647
Unclassified

Also published in Amer. Jour. Math., v. 80: 829-842, Oct. 1958.

Basic, elementary facts about multiplier transforms defined on sequence spaces l^p , $1 < p < \infty$, are summarized, and every such operator T on l^p is shown to correspond to a unique (almost everywhere), bounded, measurable function $T^\wedge(\theta)$ defined on the interval $[0,1]$. A wide class of functions $T^\wedge(\theta)$ is characterized for which the spectrum of the corresponding multiplier transform T is the essential range of the function. Theorems are given which lead to a characterization of the point spectrum of certain classes of operators in terms of sets of multiplicity for l^p . A method is developed which results in asymptotic formulas for the probabilities

$$P\left(\frac{m-Np}{\sqrt{Npq}} \geq \gamma(N)\right), \text{ where } \gamma(N) = O(N^{-\frac{1}{2}}).$$

WAS.07:001; WAS.03:006, 007

G a compact topological group with elements x, x_0 , etc. is considered in which a dx is taken which denotes the Haar measure of G normalized by the condition that the measure of G is 1. The matrices $[g(\alpha, i, j, x)]_{i, j=1}^{r(\alpha)}$ $\alpha \in A$ are taken as a complete set of inequivalent unitary representations of G which implies:

$$\int_G g(\alpha, i, j, x) g(\beta, k, l, x) dx = \frac{\delta(\alpha, i, j; \beta, k, l)}{r(\alpha)}$$

$\delta(\alpha, i, j; \beta, k, l)$ is 1 if $\alpha = \beta, i = k$ and $j = l$, otherwise it is zero. Further if $f(x) \in L^2(G)$ and if $c(\alpha, i, j, \eta) = \int_G f(x) g(\alpha, i, j, x) dx$ then

$$\left\{ \sum_{\alpha} r(\alpha) \sum_{i, j=1}^{r(\alpha)} |c(\alpha, i, j, \eta)|^2 \right\}^{1/2} = \|f\|_2$$

Let $1 < p \leq 2, 1/p + 1/q = 1$. The inequalities

$$\left\{ \sum_{\alpha} r(\alpha)^2 - q/2 \left[\sum_{i, j=1}^{r(\alpha)} |c(\alpha, i, j, \eta)|^2 \right]^{q/2} \right\}^{1/q} \leq \|f\|_p$$

and $\left\{ \sum_{\alpha} r(\alpha)^2 - p/2 \left[\sum_{i, j=1}^{r(\alpha)} |c(\alpha, i, j, \eta)|^2 \right]^{p/2} \right\}^{1/p} \geq \|f\|_q$

are shown and determined for $p \neq 2$ for all cases on which equality occurs. (See also item nos. WAS.02:007 and WAS.02:013, Vol. D).

ON A LEMMA OF U. V. LINNİK, by A. Devinatz. July 17, 1958, 3p. (AFOSR-TN-58-552) (AF 49(638)-218; continuation of AF 18(600)568) AD 158370
Unclassified

The following theorem is a stronger result of a lemma from the theory of positive functions proposed by U. V. Linnik. If (1) $f(x)$ and $g(x)$ are continuous positive definite functions, (2) and if $g(x)$ is infinitely differentiable, (3) then the Hamburger moment sequence $\{(-i)^n g^{(n)}(0)\}_{n=0}^{\infty}$ is determined, and (4) the origin is a limit point of the zeroes of $f(x) - g(x)$, then $f(x) = g(x)$ on the whole axis.

ISOTOPIC SPIN AND ANTINUCLEON-NUCLEON SCATTERING, by B. I. Malenka and H. Primakoff. [1957] [6]p. incl. diag. table. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18-(60J).77], Office of Naval Research, and Atomic Energy Commission)
Unclassified

Published in Phys. Rev., v. 105: 338-343, Jan. 1, 1957.

The total isotopic spin operator and its square are determined for the quantized nucleon-antinucleon field. In the customary configuration space representation, it is found that in the formula for the total isotopic spin of a system of nucleons and antinucleons, the antinucleons contribute terms with the transposed negatives of the τ operators replacing the corresponding τ 's. The form that has been usually anticipated is found only after a suitable canonical transformation. The results are specifically applied to a 2-particle system consisting of a nucleon and an antinucleon. Expressions are also obtained for the isotopic spin dependence of the ratio of elastic charge exchange to elastic noncharge exchange scattering of an antiproton by a neutron and by a proton. These are discussed and evaluated under certain simplifying assumptions. (Contractor's abstract)

FURTHER REFINEMENTS ON THE BRILLOUIN-WIGNER PERTURBATION PROCEDURE, by E. Feenberg and P. Goldhammer. [1957] [6]p. incl. tables. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)777], Office of Naval Research, and Atomic Energy Commission)
Unclassified

Published in Phys. Rev., v. 105: 750-755, Jan. 15, 1957.

The first-order correction to the wave function in the Brillouin-Wigner perturbation procedure is generalized by associating independent amplitude coefficients G_x with each physically distinct type of interaction $W^{(x)}$ occurring in the interaction operator. The modified formulas for wave function and energy can be evaluated by using only quantities which occur in the original formulation of the perturbation procedure (characterized by $G_x = 1$). The energy formula is invariant under a transformation which changes the scale of all energy denominators by a constant factor. A uniform displacement of the zeroth-order energy spectrum provides an additional variational parameter. A simple example is worked out to show how the computed energy improves as the amplitude parameters are displaced from $G_x = 1$ to optimum values. An incidental result is the observation that the statistical weight of the first order correction to the wave function depends strongly on the amplitude parameters. Finally, results for degenerate and nondegenerate zeroth order states are embodied in an effective interaction operator which determines the energy and the correct zeroth-order linear combination. Research under the contract concentrated on various aspects of "stripping" reactions. Proton angular distributions were measured by a nuclear emulsion technique. To obtain better results faster a nickel-delay Hutchinson-Scarrott type multichannel pulse-height analyzer was constructed with a proportional counter telescope followed by a scintillation detector. Experimental results are summarized for the following:

Na²³ (d,p)Na²⁴; Ti⁴⁷ (d,p)Ti⁴⁸; Ti⁴⁸ (d,p)Ti⁴⁹;
Fe⁵⁸ (d,p)Fe⁵⁷; Fe⁵⁷ (d,p)Fe⁵⁸; Ni⁶⁰ (d,p)Ni⁶¹;
Ni⁸¹ (d,p)Ni⁶²; Zn⁶⁴ (d,p)Zn⁶⁵; Zn⁶⁶ (d,p)Zn⁶⁷;
Zn⁶⁷ (d,p)Zn⁶⁸; and Zn⁶⁸ (d,p)Zn⁶⁹. Contrary to the Butler theory, the Zn isotope reactions yielded a relatively high intensity for proton groups whose angular distributions indicate capture in f or g states, with correspondingly high values of l_n .

TRANSIENT ELECTRON INDUCTION SIGNALS FROM SODIUM-AMMONIA SOLUTIONS (Abstract), by V. L. Poilak and R. E. Norberg. [1956] [1]p. (AF 18(600)-1133) Unclassified

Presented at meeting of the Amer. Phys. Soc., Monterey, Calif., Dec. 27-29, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 397, Dec. 27, 1956.

Observations are reported of electron induction decay signals from solutions of sodium in liquid NH₃. The signals appear following the application of fractional microsecond 30 mc radio-frequency pulses to samples in a 10.7 oe static magnetic field. The initial tuning of the oscillator, radio-frequency bridge, and signal amplifier is accomplished by observation of transient piezoelectric signals from an NH₄H₂PO₄ powder sample inserted into one of the high impedance coils of the bridge. Measurements of electron relaxation times in the metal-ammonia solutions have been made with both photographic and electronic integrating techniques. The dependence of the transient induction signals upon the spacing of the pulses has yielded an electron T₁ of 2.0 microseconds in a sample of about 0.2

SEARCH FOR PARAMAGNETIC RESONANCE ABSORPTION IN PHOTOREduced CHLOROPHYLL, by H. Linschitz and S. I. Weissman. [1957] [2]p. (Technical rept. no. 16) (AFOSR-TN-57-185) (In cooperation with Syracuse U., N. Y.) THE ELECTRONIC SPECTRA OF AROMATIC CARBOXYL CARBON ANIONS, by E. de Boer and S. I. Weissman. [1957] [3]p. incl. table. [Technical rept. no. 19] (AFOSR-TN-58-812) (AF 18(600)1133; continued by AF 49(638)464) AD 162140

Unclassified

Also published in Recueil Trav. Chim. Pays-Bas, 824-826, Sept./Oct. 1957.

The electronic spectra of several mono- and divalent negative aromatic ions were measured by the use of a Cary spectrophotometer. Comparison is made with the spectra obtained from the same set of ions which were however prepared with the use of sodium as a reducing agent rather than with the use of potassium as in the present case. It is found that the absorption bands are shifted to lower wavelengths by an amount of 0.2 kilo-Kayser in the case in which potassium has been used. In the present case tetrahydrofuran has been used as solvent instead of quaterphenyl.

Presented at meeting of the Amer. Phys. Soc., Oklahoma U., Norman, Mar. 1-2, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II v. 2: 106, Mar. 1, 1957.

Also published in Phys. Rev., v. 107: 1490-1492, Sept. 15, 1957.

Drift velocities of nitrogen ions in nitrogen gas as a function of field over pressure have been studied by a pulsed Townsend discharge method at temperatures of 77°K, 300°K, and 450°K. Results support the theory that N_2^+ ions are responsible for drift velocities at high E/p_0 values, N_4^+ ions are responsible for drift velocities at low E/p_0 values, while the drift velocity at intermediate E/p_0 values is an average velocity determined by the relative lifetimes in transit of the N_4^+ and N_2^+ ions. Present results further substantiate the existence of N_4^+ at low E/p_0 and N_2^+ at high E/p_0 by showing opposite temperature effects on the mobility of the two ions. The binding energy of the N_4^+ ion has been estimated at 0.14 ev. (Contractor's abstract)

N^+ , N_2^+ , N_3^+ , and N_4^+ ions have been identified in nitrogen gas by use of a mass spectrometer operated with the ion source in the pressure range from 10^{-3} mm Hg to 0.6 mm Hg. Appearance potentials occur at 15.5 ± 0.2 ev for N_2^+ , at 15.8 ± 0.3 ev for N_4^+ , at 22.1 ± 0.5 ev for N_3^+ , and at 24.2 ± 0.4 ev for N^+ ; N_3^+ ions thus are formed only at much higher electron energies than N_2^+ but still at 2 ev less energy than N^+ . It is believed that the N_4^+ is formed by the process $N_2^+ + N_2 - N_4^{++}$ (excited vibrationally) and the N_3^+ is formed by the process $N_2^{++} + N_2 - N_3^+ + N$, where N_2^{++} is an excited ion. N_4^+ and N_3^+ currents decrease with increasing E/p in the source, suggesting that they may be dissociated by molecular impacts. The N_4^+ ions are considerably more readily lost than the N_3^+ ions. Since the formation of N_3^+ must necessarily release a nitrogen atom, this process constitutes a form of dissociation of N_2 which may account for the value of the dissociation energy of 7.38 ev found by some methods.

Electron spin resonance has been used to investigate the role of free radicals in biochemical processes. Studies of simple enzyme systems, chloroplast systems, and living cells of *Chlorella* have shown the presence of free radicals and have confirmed the prediction of Michaelis that biochemical oxidation-reduction occurs in successive univalent steps which gives rise to free radical intermediates. The chloroplast system studied exhibits both a long and short lifetime persistent radiation after illumination. These emissions can be associated with an electron-transport free radical and an activated chlorophyll complex, respectively.

ELECTRON-SPIN RESONANCE STUDIES OF FREE-RADICAL INTERMEDIATES IN OXIDATION-REDUCTION ENZYME SYSTEMS, by B. Commoner, B. B. Lippincott, and J. V. Passonneau. [1958] [12]p. incl. diagrs. table, refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)1592] and Office of Naval Research) Unclassified

Published in Proc. Nat'l. Acad. Sciences, v. 44: 1099-1110, Nov. 1958.

The oxidation-reduction processes that occur in living cells and in systems composed of isolated enzymes involve a succession of reactions in which electron transfer is the common characteristic. This conclusion has been inferred from chemical evidence about the structure and reactivity of the system components, but relatively little is known about the physical processes which govern electron transfer among them. This paper is concerned with one of the unresolved problems: the valence of electron transfer. Direct chemical evidence indicates that the net effect of many biochemical oxidation-reduction reactions is the transfer of two electrons. In other cases, notably the cytochrome-cytochrome oxidase system, the same type of evidence indicates that the transfer is univalent. The thermodynamic barriers to the necessary coupling of 2-electron and 1-electron processes are formidable, and this problem has been under active consideration for some time. On the basis of work with model systems, Michaelis proposed a solution which is best summarized in his own statement that "all oxidations of organic molecules, although they are bivalent, proceed in two successive univalent steps, the intermediate state being a free radical." The operative conclusion which emerges from Michaelis' work is that free radicals must occur as intermediates in all biochemical oxidation-reduction processes. The present paper reports detailed experiments on a flavoprotein oxidation-reduction enzyme and less detailed studies of a series of common oxidation-reduction enzyme systems. The

results confirm Michaelis' proposal that free-radical intermediates are characteristic features of enzymatic electron transport. (Contractor's abstract)

LIGHT-INDUCED FREE RADICALS IN FMN AND FLAVOPROTEIN ENZYMES, by B. Commoner and B. B. Lippincott. [1958] [7]p. incl. diagrs. refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)1592] and Office of Naval Research) Unclassified

Published in Proc. Nat'l. Acad. Sciences, v. 44: 1110-1116, Nov. 1958.

There is some evidence that visible light may influence the rate of cellular respiration and of isolated oxidation-reduction enzyme systems. The evidence is not sufficiently extensive to indicate whether the effect is a general one, nor is it sufficiently detailed to suggest a possible mechanism. The experiments reported provide evidence on these questions. They show that flavin prosthetic groups and flavoprotein oxidation-reduction enzymes readily form free radicals when exposed to ordinary intensities of visible light. The light-induced free radicals appear to be identical with those ordinarily formed as intermediates in the oxidation-reduction process carried out by these components. This effect provides a mechanism which can mediate the influence of light on cellular oxidation-reduction. Since flavoprotein enzymes participate in a wide range of metabolic systems, the evidence also indicates that the observed effect of light on cellular processes is probably of quite general significance.

Also published in *Phys. Rev.*, v. 107: 46-61, July 1, 1957.

A beat structure has been found on free induction decays associated with the pulsed nuclear magnetic resonance of nuclei in rigid lattices. A general quantum mechanical theory is developed for the shapes of induction decays. The theory is specialized to the case of rigid solids and applied to the magnetic dipolar interactions among the F^{19} nuclei in a fluorite (CaF_2) crystal. It is also shown rigorously that, except at very low temperatures, a free induction decay is the Fourier transform of the corresponding steady state resonance line shape. The calculation of the shape of an induction decay in CaF_2 thus corresponds to the calculation of the shape of the F^{19} resonance line for the crystal. It is demonstrated that the resonance line shape for an ordered rigid lattice is not Gaussian. (Contractor's abstract)

An expression is derived in first Born approximation for the correction to high-energy elastic electron-nucleus scattering arising from the existence of non-radiative inelastic processes. The magnitude of this correction is estimated for electron-proton and electron-deuteron scattering and is shown to be a very small but rapidly increasing function of energy over the range of incident electron energies from 150 to 450 mev. The correction to electron-deuteron scattering also shows a marked angular dependence increasing with increasing scattering angle. (Contractor's abstract)

Unclassified

Also published in *Philosophical Magazine*, v. 3: 328-333, Apr. 1958.

The process $\pi^+ - \pi^0 + e^+ + \nu$ has not yet been observed. Estimates of its branching ratio relative to $\pi^+ - \mu^+ + \nu$ can be derived (1): from a phase space volume argument in conjunction with the available experimental information on π^+ and (assumed analogous) K^+ processes, and (2): from a calculation of the rate of the beta decay transition between the π^+ and π^0 states of a bound

nucleon-antinucleon structure. A possible experimental scheme for detection of $\pi^+ - \pi^0 + e^+ + \nu$ in the presence of the overwhelmingly more frequent $\pi^+ - \mu^+ + \nu$ is outlined.

ANALYSIS OF THE SCHRÖDINGER ENERGY SERIES, by E. Feenberg. Mar. 1958 [12]p. incl. refs. (Technical rept. no. 6) (AFOSR-TN-57-687) (AF 18(603)108) AD 136682 Unclassified

Also published in Ann. Phys., v. 3: 292-303, Mar. 1958.

The rate of convergence of the Brillouin-Wigner and Schrödinger energy series can be modified by using elements of freedom present in the formulation of the perturbation problem. Two such elements of freedom are (a) a uniform displacement of the zeroth order energy spectrum and (b) a uniform change of scale in the spacing of the zeroth order energy levels. Transformation a is used to generate the Schrödinger energy series from the corresponding Brillouin-Wigner series. The effect of transformation b on the former series is worked out and exhibited explicitly. The problem of defining a criterion for determining the scale factor is bypassed by the observation that continued fraction approximants to the Schrödinger energy series are invariant under transformation b. Explicit formulas are given for the first three invariant forms. (Contractor's abstract)

ANGULAR DISTRIBUTION OF D(d,n)He³ NEUTRONS (Abstract), by J. M. Fowler and W. [W.] Daehnick. [1957] [1]p. [AF 18(603)108] Unclassified

Presented at meeting of the Amer. Phys. Soc., St. Louis, Mo., Nov. 29-30, 1957.

Published in Bull. Amer. Phys. Soc., Series-II, v. 2: 350, Nov. 29, 1957.

The angular distribution of neutrons from the reaction D(d,n)He³ has been obtained over the angular range of 0-90° center-of-mass at a deuteron energy of 9.0 mev. The neutrons were detected with a 1 in. x 1 in. x 5 mm plastic scintillator and the photomultiplier pulses were displayed on a multichannel Hutchinson-Scarrott, pulse-height analyzer. The target was deuterium gas at 200 lb per sq in. and the background was measured by comparing "gas in" and "gas out" bombardments. The ex-

perimental angular distributions are compared with the Legendre coefficients found by Brolley, Putnam, and Rosen, and with the predictions of the "exchange stripping" theory.

ANGULAR DISTRIBUTIONS OF NEUTRONS FROM THE (d,n) REACTION ON B¹¹ (Abstract), by B. Zeidman and J. M. Fowler. [1957] [1]p. [AF 18(603)108] Unclassified

Presented at meeting of the Amer. Phys. Soc., St. Louis, Mo., Nov. 29-30, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 351, Nov. 29, 1957.

The complete angular distributions, from 10° to 160°, of neutrons from the (d,n) reactions on B¹¹ leading to the ground and first excited state of C¹² have been obtained at an incident deuteron energy of 10 mev. The neutrons were detected by a recoil proton telescope consisting of a hydrogenous radiator and two proportional counters operated in coincidence with a scintillation counter. The angular distributions at forward angles have peaks as predicted by the Butler stripping theory with $l_p = 1$. At

large angles the distributions for both groups exhibit a nonisotropic structure. Analysis of the distributions in terms of the Owen-Madansky "exchange" stripping theory is discussed. A preliminary analysis indicates that a value of $l_d = 0$, for the angular momentum with which the deuteron is captured and equal probabilities for the forward and backward stripping components gives an adequate fit for the ground-state data.

DOUBLE PULSE NUCLEAR RESONANCE IN SOLIDS (Abstract), by I. J. Lowe. [1957] [1]p. [AF 18(603)108] Unclassified

Presented at meeting of the Amer. Phys. Soc., St. Louis, Mo., Nov. 29-30, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 344, Nov. 29, 1957.

The general formula describing a free induction decay following one rf pulse has been extended by the insertion of the proper rotation operators to the description of the shape of the free induction signal following two rf pulses separated by time τ . For the case of a rigid

WAS.08:010 - WAS.08:013

solid made up of one magnetically active nuclear species, the formula predicts that a 90° , 180° pulse sequence should produce a free induction signal identical to that for a single 90° pulse and that a 90° , 90° pulse sequence should produce a free induction signal different from that for a single 90° pulse. Experimentally, a "solid echo" is observed to follow the 90° , 90° pulse sequence in all rigid solids examined. For a rigid solid made up of two magnetically active nuclear species A and B, the formula predicts that the free induction signal following a 90°_A , 180°_A pulse sequence should be different from the free induction signal following a 90°_A pulse, and should be identical to the free induction signal following a 90°_A , 180°_B pulse sequence. A "solid echo" has been observed to follow a 90°_F , 180°_F pulse sequence in LiF and NH_4F .

LONGITUDINAL POLARIZATION OF BETA PARTICLES FROM P^{32} (Abstract), by C. R. Dulgeroff, E. D. Lambe, and T. A. Pond. [1957] [1]p. [AF 18(603)108] Unclassified

Presented at meeting of the Amer. Phys. Soc., St. Louis, Mo., Nov. 29-30, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 348, Nov. 29, 1957.

A horizontal beam of P^{32} electrons is incident on an aluminum foil (typically 0.008 in.) alternately from the east and the west. Electrons multiply scattered downward through 90° are analyzed for transverse polarization by comparison of Mott scattering rates through angles of 75° from vertical in north and south azimuth.

For gold thickness below 0.5 mg/cm^2 (thinnest used: 0.18 mg/cm^2) a constant asymmetry is observed: ratio of north to south scattering rates with source in east, divided by the same ratio with source in the west is 0.840 ± 0.015 . The asymmetry decreases with thicker gold scatterers, indicating the onset of plural scattering. An initial longitudinal polarization of v/c integrated over the measured spectrum analyzed in the Mott scattering leads to a value of the above ratio 0.746 ± 0.050 , the uncertainties lying in the absorption and energy loss corrections to the spectrum. This value includes a correction for the precession of the spins coupled to the multiple scattering process, but does not allow for any further depolarizations.

DOUBLE BETA DECAY, by H. Primakoff and S. P. Rosen. [1958] [46]p. incl. diags. tables, refs. (Technical rept. no. 23) (AFOSR-TN-58-333) (AF 18(603)108) AD 229973

Also published in Repts. on Prog. in Phys., v. 22: 121-166, 1959.

The phenomenon of double beta decay is discussed rather fully both from the experimental and from the theoretical point of view, the relation between double beta decay and the possible kinds of inverse beta decay being also briefly treated. A summary of the available experimental data is given, all methods of detection of the various double beta decay processes being

considered. The theory of double beta decay, both in the no-neutrino and in the two-neutrino cases, is worked out, ab initio, on the basis of a nucleon-lepton interaction without conservation of parity. It is particularly emphasized that, with a "two-component neutrino" type nucleon-lepton interaction without conservation of parity, absence of no-neutrino $\beta\beta$ decay does not by itself uniquely imply that neutrino and anti-neutrino are distinguishable and that the total lepton charge is conserved. Comparison of the experimental limits on the double beta decay half-lives with the corresponding theoretical values indicates that two neutrinos are emitted together with two electrons in each double beta decay process—this conclusion is, however, not yet certain and must be confirmed by further experimental work. A treatment is given of the implications of the actual occurrence of two-neutrino rather than no-neutrino double beta decay cations for the problems of neutrino-anti-neutrino identity and conservation of total lepton charge. It is concluded, on the basis of (i) the available double beta decay, inverse beta decay and muon decay experimental data and (ii) the provisional assumption of the universal applicability of "two-component neutrino" type coupling, that a verdict may be tentatively reached in favor of a "Dirac" neutrino, operationally distinguishable from a "Dirac" anti-neutrino, and with conservation of total lepton charge valid in all neutrino interactions. THEORY OF SOLID Ne, A, Kr, and Xe at 0°K, by N. Bernardes. Apr. 1958 [6]p. incl. diagrs. tables, refs. (Technical rept. no. 12) (AFOSR-TN-58-342) (AF 18(603)108) AD 154247 Unclassified

Also published in Phys. Rev., v. 112: 1534-1539, Dec. 1, 1958.

A quantum-mechanical variational technique is applied to an Einstein model of a solid, and the heats of sublimation and equations of state of solid Ne, A, Kr, and Xe are calculated at 0°K. Mie-Lennard-Jones 8-12 potentials appropriate to the gas-phase data are used throughout, and the importance of quantum-mechanical effects is discussed; in general, good agreement with experiment is obtained. From the theoretical zero-point energies equivalent Debye temperatures, θ , are calculated, and from the dependence of these θ on volume, Grüneisen constants are computed in good agreement with experiment. Theoretical compressibility curves (at 0°K) are presented, and compared with the available experimental data; in the case of Ne, the only substance for which high-pressure data are available, the agreement is rather good up to 20° K atmosphere. THE POLARIZATION OF COSMIC RAY MUONS, by J. M. Fowler, H. Primakoff, and R. D. Sard. June 1958 [19]p. incl. diagr. tables, refs. (Technical rept. no. 10) (AFOSR-TN-58-348) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)108, Office of Naval Research, and Atomic Energy Commission) AD 154253 Unclassified

Also published in Nuovo Cimento, Series X, v. 9: 1027-1045, Sept. 16, 1958.

Also published in Proc. Conf. on Mesons and other Recently Discovered Particles, Padua-Venice (Italy), 1957, p. IV-107.

A partial longitudinal polarization of about 23% is expected for cosmic ray muons due to the falling off of the energy spectrum of the parent pions. A general theory of muon polarization for in flight decays of pions and K mesons has been worked out and applied to cyclotron and cosmic ray experiments. An experiment has been carried out to test the predictions for cosmic ray muons and it has been found that the assumptions made in the theory are correct and that muons suffer negligible depolarization while losing 2 gev energy to the atmosphere.

PROTON ANGULAR DISTRIBUTIONS FROM $^{52,53}\text{Cr}$ (d,p) REACTIONS, by A. J. Elwyn and F. B. Shull. Aug. 1958 [4]p. incl. diagrs. tables. (Technical rept. no. 7) (AFOSR-TN-58-420) (AF 18(603)108) AD 213989 Unclassified

Also published in Phys. Rev., v. 111: 925-928, Aug. 1, 1958.

Proton angular distributions from (d,p) reactions of 10 mev deuterons on 52 Cr and 53 Cr enriched targets were measured and Q values determined for four proton groups from $^{52}\text{Cr}(d,p)^{53}\text{Cr}$ and for six groups from $^{53}\text{Cr}(d,p)^{54}\text{Cr}$. All angular distributions were of type $l_n = 1$ except for $Q = 4.77$ mev in ^{52}Cr reaction, for which $l_n = 3$. The latter group is interpreted as possibly a single-particle $f_{5/2}$ state, and these data may therefore reveal the relative position of single-particle $f_{5/2}$ and $p_{3/2}$ levels.

INVESTIGATION OF $D(d,n)He^3$ NEUTRONS AT 8.4 MEV, by W. W. Daehnick and J. M. Fowler. Sept. 1958 [5]p. incl. diagrs. table, refs. (Technical rept. no. 8) (AFOSR-TN-58-496) (AF 18(603)108) AD 312989 Unclassified

Also published in Phys. Rev., v. 111: 1309-1313, Sept. 1, 1958.

The angular distribution of neutrons from the reaction $D(d,n)He^3$ has been obtained at 8.4 ± 0.1 mev incident deuteron energy for center-of-mass angles 2° to 84° . A single plastic crystal was used as a detector and deuterium gas at 200 psi as a target. The distribution is fitted by a sum of Legendre polynomials. It is also compared with the predictions of nuclear stripping theory, and adequate agreement is found with an angular distribution of the form $h_d^2 - 2/3h_d h_{d'} + h_{d'}^2$, where the h_d and $h_{d'}$ represent the simple Butler stripping distributions for the incident and target deuterons, respectively. The interaction radius $R_0 = 7 \times 10^{-13}$ cm, has been used. (Contractor's abstract)

ANGULAR DISTRIBUTIONS FROM DEUTERON BOMBARDMENT OF BERYLLIUM AND BORON, by B. Zeidman and J. M. Fowler. May 1958 [7]p. incl. diagrs. (Technical rept. no. 13) (AFOSR-TN-58-531) (AF 18(603)108) AD 158346 Unclassified

Also published in Phys. Rev., v. 112: 2020-2026, Dec. 15, 1958.

The angular distributions, from 10° to 160° , of the emergent particles from the reactions $Be^9(d,p)Be^{10,10}$, $B^{10}(d,p)B^{11,11}$, and $B^{11}(d,n)C^{12,12}$ have been investigated. The proton distributions were obtained at incident deuteron energies of 10, 9.2, and 8.1 mev while the neutron distributions were obtained with 10-mev deuterons. The proton distributions are analyzed using the Butler theory of deuteron stripping and, with the exception of the distributions from B^{11} , are in agreement with $l_n = 1$ at forward angles. The distributions from the first excited state of B^{11} are not in agreement with any curves based upon the Butler theory, indicating that stripping does not play a major part in this reaction. The neutron distributions are analyzed using the treatment of Owen and Madansky, which allows heavy-particle stripping as well as Butler stripping. Reasonable agreement between the data and this theory for

the ground state is obtained by using approximately equal amplitudes for Butler and exchange stripping and angular momenta of $l=1$ and $l=0$, respectively, for deuteron and exchange stripping. The analysis of the distribution for the first excited state of C^{12} shows $l=1$ for deuteron stripping, but does not provide a unique choice for the angular momentum in exchange stripping.

PROTON ANGULAR DISTRIBUTIONS FROM $Zn^{64,66,67,68}$ (d,p) REACTIONS, by F. B. Shull and A. J. Elwyn. July 1958 [6]p. incl. diagrs. table, refs. (Technical rept. no. 11) (AFOSR-TN-58-666) (AF 18(603)108) AD 162197 Unclassified

Also published in Phys. Rev., v. 112: 1667-1672, Dec. 1, 1958.

A summary is given of the experimental Q values and proton angular distributions from (d,p) reactions of 10 mev deuterons on a series of isotopically enriched Zn targets. The angular distributions were fitted by Butler curves for which fair agreement was obtained. Well resolved empirical distributions have been obtained for neutron orbital angular momentum quantum number from 0 to 4. Other distributions which are evidently superpositions of groups with various values of angular momentum were not resolvable. (See also item no. WAS.08:016)

Numerical values have been calculated for the scattering constant for multiply charged particles in photographic emulsion. The constant has been calculated both with and without a single scattering cut-off correction. The results are presented in graphical form and show a difference in the two calculated values of 4 to 7%. This range of difference as calculated agrees with preliminary tests on the experimental data.

SIMPLIFIED TREATMENT FOR STRONG SHORT-RANGE REPULSIONS IN N-PARTICLE SYSTEMS. I. GENERAL THEORY, by J. W. Clark and E. Feenberg. [1958] [12]p incl. refs. (Technical rept. no. 19) (AFOSR-TN-58-804) (AF 18(603)108) AD 229980
Unclassified

Also published in Phys. Rev., v. 113: 388-399, Jan. 15, 1959.

A new variational approach is developed for studying the properties of systems of particles interacting through singular short-range repulsions that give rise to strong two-particle correlations. The correlated trial function $\psi = e^{S\phi}$ results, with proper choice of S , in a simple form for the energy expectation value $\langle H \rangle$ - as well as for other matrix elements of interest - which is devoid of all reference to the strong repulsions except through e^{2S} factors and hence is particularly suited to calculation. In many cases an independent-particle type ϕ seems appropriate. The cluster evaluation of this form for $\langle H \rangle$ is discussed, both in the few-particle and many-particle cases. Using the techniques of Iwamoto and Yamada, simplified convergent cluster expansions for the energy expectation value are derived for many-fermion and many-boson systems. A program for application of this method to nuclear problems is being initiated. (Contractor's abstract)

EFFECT OF THE HYPERFINE SPLITTING OF A μ -MESONIC ATOM ON ITS LIFETIME, by J. Bernstein, T. D. Lee and others. July 1958, 6p. (Technical rept. no. 25) (AFOSR-TN-58-829) (AF 18(603)108) AD 229973
Unclassified

Also published in Phys. Rev., v. 111: 313-315, July 1, 1958.

A calculation is performed and an estimate is given of the small difference in the lifetime of the two hyperfine states of a μ -mesonic atom. A model in which a single unpaired proton exists outside a nuclear core is used to find the spin dependence between the μ -meson and this capturing proton. It is estimated that in the neighborhood of $Z = 10$, a 10% difference in lifetimes is to be expected. Possible experimental detection of this difference is discussed.

MOLECULE FORMATION IN THE INERT GASES, by N. Bernardes and H. Primakoff. Oct. 3, 1958 [20]p. incl. diagrs. tables. (AFOSR-TN-58-865) (AF 18(603)108) AD 229980
Unclassified

Also published in Jour. Chem. Phys., v. 30: 691-694, Mar. 1959.

The Schrödinger energy eigenvalue equation for the relative motion of two inert gas atoms is solved approximately by fitting a Morse interatomic potential to the generally accepted Lennard-Jones 12-6 interatomic potential. A condition for binding is derived involving the phenomenological parameters present in the 12-6 potential; from the empirical values of these parameters one can then conclude that all the inert gases, except helium, do form stable diatomic molecules. A qualitative argument is presented showing that an hexatomic helium molecule may be stable. The vibration-rotation energy spectrum of the stable inert gas diatomic molecule is discussed. Finally, the partition function for the diatomic molecule is evaluated in an approximate way, whence, using the standard form for the equilibrium constant in terms of partition functions, it follows that at reasonable values of temperature and pressure several percent of the atoms are associated in the form of diatomic molecules. ENERGY OF AN N-PARTICLE SYSTEM WITH STRONG SHORT-RANGE REPULSIONS (Abstract), by J. [W.] Clark and E. Feenberg. [1958] [1]p. [AF 18(603)108] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago U., Ill., Nov. 28-29, 1958.

Published in Bul. Amer. Phys. Soc., Series II, v. 3: 368, Nov. 28, 1958.

A simple variational method is described for calculating the energy of an N-particle system with strong short range repulsive interactions. First the Hamiltonian is

written $H = -(\hbar^2/2M)\sum_k \Delta_k + V_A + V_R$, where V_R contains all state independent singular repulsions. Then substitution of $e^S \phi$ for the wave function Ψ produces the following expression for the expectation value of H:

$$\langle H \rangle = \int e^{2S} \left\{ \frac{\hbar^2}{2M} \sum_k \nabla_k \phi^* \cdot \nabla_k \phi + \phi^* V_A \phi \right\} \int e^{2S} \phi^* \phi$$

provided S satisfied $(\hbar^2/2M)\sum_k [(\nabla_k S)^2 + (\Delta_k S)] = V_R$ and $[V_A, S] = 0$. The singular two-particle repulsions characteristic of nuclear and other systems may be removed in this fashion, by assuming S to have the form $S = \sum_{i < j} S_{ij}(\gamma_{ij})$. Three-particle interactions implied by this form for S are small in nuclear applications. For some problems an independent particle ϕ should be satisfactory, while for others a calculation to higher order in V_A , based on an orthonormal set of such ϕ 's, may be required. In this latter case, the matrix elements involved are identical with those of ordinary perturbation theory except for the presence of the correlation factor e^{2S} before each volume element.

ON DETECTION OF TRIPLET MOLECULES IN SOLUTION BY ELECTRON SPIN RESONANCE, by S. I. Weissman. [1958] [2]p. incl. table. (Technical rept. no. 27) (AFOSR-TN-58-946) (AF 49(638)464) AD 243091 Unclassified

Also published in Jour. Chem. Phys., v. 29: 1189-1190, Nov. 1958.

In order to observe paramagnetic resonance in excited triplet states in low viscosity fluids, high tumbling rates for the molecules are necessary in order to narrow the dipole coupling of the unpaired electrons. Spin-lattice relaxation times have been calculated as a function of separation of the unpaired electrons for two values of the tumbling rate. It is concluded that appropriate relaxation times are achieved if the separation of the electrons is larger than 6×10^{-8} cm or if the distribution of the electrons is highly symmetrical about one another.

[DOUBLE RESONANCE EXPERIMENTS ON THE FREE RADICAL $(SO_3)_2NO^{\cdot\cdot}$] Expériences de double résonance sur le radical libre $(SO_3)_2NO^{\cdot\cdot}$, by J. H. Burgess. [1958] [5]p. incl. diagrs. refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 49-(638)464] and Office of Naval Research) Unclassified

Published in Jour. Phys. et Radium (Paris), v. 19: 845-849, Nov. 1958.

Double resonance experiments have been carried out on dilute aqueous solutions of the paramagnetic ion $(SO_3)_2NO^{\cdot\cdot}$ in magnetic fields around 30 oersteds. This free radical exhibits a well resolved hyperfine structure with a zero field splitting of 54.7 mc. Radiation of saturating intensity was applied near the resonance frequency of one hyperfine component. At the same time the energy absorption near a second resonance frequency was observed by means of a Pound-Knight type detector operating at a low intensity level. Resonances were displayed as a function of magnetic field for various applied rf frequencies and for several

WAU.01:018 - WAU.01:021

intensities of the saturating radiation. In cases where there was an energy level common to the two transitions excited by the applied radiations, a splitting of the resonance line occurred. The positions and intensities of the two maxima depended in a detailed manner on the applied frequencies, the strength of the saturating field, the relaxation times of the disulfonate ion and on the behavior of the energy levels with dc magnetic field intensity. In cases where there is no common energy level, no effects of the saturating radiation were observed. An analysis, based on the density matrix equation $d\rho/dt = 1/i\hbar [H, \rho] - 1/T(\rho - \rho_0)$, where ρ_0 is the normalized Boltzmann factor appropriate to the energy of the system in the static magnetic fields, leads to a result for the susceptibility which agrees closely with the observations. APPLICATIONS OF CONSOLIDATED VARIATION-PERTURBATION THEORY (Abstract), by H. Shull and W. T. Simpson [1957] [1]p. [AF 18(600)375]

Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 393, Dec. 19, 1957.

Consolidated variation-perturbation theory as outlined in the previous abstract is demonstrated in its application to two-electron systems, largely to the He atom. The expansion set used is the completely discrete set of associated Laguerre functions of single orbital exponent. For this particular set, it is shown that the second-order result, $W^0 + W^1 + W^2$, is the same irrespective of the explicit choice of division of the nuclear attraction operator between the comparison Hamiltonian and the perturbation term. The explicit choice is important, however, since higher orders in the perturbation theory expansion become small only for an optimum choice. In particular, for $\psi^0 = 1s^2$, $Z = 2$, $W^0 = -4.000$, $W^1 = +1.250$, $W^2 = -0.151$; whereas for $Z = 1.6875$, $W^0 = -2.848$, $W^1 = 0.000$, $W^2 = -0.054$. The improvement becomes progressively more marked for the higher order terms. The systematic application of the remainder theorem to the variation method is shown in two examples: first, without approximation in connection with a He 20 x 20 matrix, and secondly in approximation for a much larger (136 x 136) He matrix.

ELECTRONIC SPECTRUM OF 4,4'-bis DIMETHYL-AMINO FUCHSONE AND RELATED TRIPHENYL-METHANE DYES, by F. C. Adam and W. T. Simpson. Sept. 2, 1958 [18]p. incl. diagrs. tables. (AF 18(600)375) AD 259223 Unclassified

Also published in Jour. Molecular Spectroscopy, v. 3: 363-380, Aug. 1959.

The electronic absorption and emission spectra of 4,4'-bis dimethylamino fuchsonone (BDF) and of crystal violet (CV) have been studied using a variety of solvents and experimental conditions. Analysis of the relative polarizations of the bands leads to the conclusion that for BDF the two long wavelength transitions have crossed over relative to the ordering found in the malachite green series of dyes. These results are discussed from the point of view of the low-energy structures. The absorption intensities are calculated on this basis and the values obtained are found to be in reasonable agreement with experiment. Evidence is cited for the existence of CV in nonpolar solvents as an ion pair. (Contractor's abstract)

A PRECISION ADSORPTION APPARATUS FOR THE STUDY OF THE INTERACTIONS BETWEEN GAS ATOMS AND SURFACES, by G. Constabaris, J. H. Singleton, and G. D. Halsey, Jr. Nov. 1958, 20p. diagrs. tables, refs. (AFOSR-TN-58-1048) (AF 18(600)987) AD 232046 Unclassified

Also published in Jour. Phys. Chem., v. 63: 1350-1355, Sept. 1959.

A precision apparatus for the study of the interactions between gas atoms and surfaces of low specific area is described. A low temperature adiabatic calorimeter is used as the sample cryostat and the precise techniques of gas thermometry are used for pressure measurement. The gas is metered into the system with an accurate gas transfer apparatus. Data for the measurement of known volumes, and of the apparent volume of a vessel containing a low specific area, highly graphitized carbon black, are given. These measurements, made with different rare gases at various temperatures, indicate a precision of between 1 and 2 parts per 10,000. The apparent volume data are converted to the usual quantity of adsorbed volume to give room temperature adsorption isotherms at coverages of less than 2% of the monolayer. (Contractor's abstract)

EXACT LATTICE-CLUSTER EXPANSION FOR THE FROST POINTS OF ARGON-KRYPTON GAS MIXTURES, by J. F. Walling and G. D. Halsey, Jr. [1958] 12p. diagrs. table. (AFOSR-TN-58-1098) (AF 18(600)987) AD 232047 Unclassified

Also published in Jour. Chem. Phys., v. 30: 1514-1517, June 1959.

The frost points of argon-krypton mixtures at various pressures and compositions of the gas phase have been determined. These results have been analyzed by a generalized form of regular solution theory, where the energy of mixing parameter w_{AB} has been allowed to vary with mole fraction as well as temperature. The results have been compared with an exact expansion in terms of Mayer cluster sums of the lattice-solution (Lsing) model. The model does not entirely account for the data.

Presented at Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 1957.

Also published in Jour. Molecular Spectroscopy, v. 2: 113-119, Apr. 1958.

The intensities of the molecular vibration of frequency ν_3 in C_2N_2 as well as ν'_1 and ν'_4 in the isotopically substituted, non-symmetric molecule CC^*N_2 were measured. The later measurement was carried out in a mixture containing 15.5 atomic percent of the species containing C^{13} indicated as C^* . The intensities were interpreted in standard fashion as bond moments and derivatives, after carrying out a normal coordinate calculation. This calculation yields a CN bond moment of 0.8 debye and a bond moment derivative of 0.59 debye/angstrom. This latter value fits both of the stretching vibrations, indicating that the dipole moments of the two bonds add independently with no interaction. (Contractor's abstract, modified)

MICROWAVE SPECTRUM, STRUCTURE, AND DIPOLE MOMENT OF CYCLOPROPENE, by P. H. Kasai, R. J. Myers and others. [1958] 17p. diagrs. tables, refs. (Technical note no. 2) (AFOSR-TN-58-854) (AF 18(600)1522) AD 203500
Unclassified

Also published in Jour. Chem. Phys., v. 30: 512-516, Feb. 1959.

The microwave spectra of four isotopic species of cyclopropene, $CH_2(CH)_2$, CH_2CDCH , $CH_2(CD)_2$, and $CDE(CH)_2$ were assigned and three rotational constants for each isotopic species were determined. From these data the following structural parameters were evaluated: the bond lengths C-C 1.515 A, C=C 1.300 A, C-H (methylene) 1.087 ± 0.004 A, C-H (vinyl) 1.070 A, and the intermolecular bond angles H-C-H angle $114^\circ 42' \pm 10'$ and C-C-H angle $149^\circ 55'$. The uncertainties in

the methylene values are the magnitude of a rotation-vibration interaction correction. The dipole moment of cyclopropene was found to be 0.455 ± 0.01 debye unit. (Contractor's abstract)

Also published in Jour. Amer. Chem. Soc., v. 79: 5091-5098, Oct. 5, 1957.

Dimethylvinyl-, methyldivinyl- and trivinylborane, dimethylpropenyl- and methylpropenylborane were prepared from dimethylbromoborane and vinylsodium or propenyllithium, respectively. The products in each case were separated by fractional condensation and the vinyl derivatives were separated more effectively by gas partition chromatometry. The structures were demonstrated to be as claimed through identity of the hydrocarbons formed in the reaction with silver ammonium ion. Acidity of the vinylboranes toward ammonia was diminished as would be expected if the vacant boron orbital participated in the pi-electron system belonging to the alkenyl substituents. Relative acidity was found to account for the several products obtained in the preparative reaction, for absence of reaction of trivinylborane with oxygen and the slow autooxidation of methyldivinylborane.

SLOW SPIN RELAXATION OF OPTICALLY POLARIZED SODIUM ATOMS, by H. G. Dehmelt. [1957] [3]p. incl. diagrs. [AF 18(600)653] Unclassified

Published in Phys. Rev., v. 105: 1487-1489, Mar. 1, 1957.

In order to obtain as narrow as possible paramagnetic resonance signals, it is of importance to investigate the conditions under which long relaxation times can be realized. In the present experiment on sodium atoms diffusing in argon gas, relaxation due to sodium-sodium collisions was minimized by employing very low sodium

partial vapor pressures (about 10^{-7} mm Hg). While at lower pressures the argon is serving its function well to slow down relaxation by inhibiting wall diffusion, at about 10 cm Hg relaxation due to sodium-argon collisions becomes the decisive factor. Nevertheless it was possible to realize a relaxation time of 0.21 sec for a 1-liter spherical bulb filled with 3 cm argon. About 0.02 sec was found for a 0.1-liter, 40 cm argon sample. In carrying out the experiments, optical pumping by circularly polarized resonance radiation was used to create an orientation of sodium atoms which then was monitored by measuring the transmission of the pumping radiation through the sample. By suddenly reversing a small axial magnetic field, the polarization of the atoms could be made to reverse too. From the decay rates of this inverted polarization under the combined effects of relaxation and continuing optical pumping, the experimental relaxation times were deduced. The strong signals obtained are indicative of available signal to noise ratios in future radio-frequency resonance reorientation experiments using the transmission monitoring technique. A theoretical analysis of the optical pumping process, including the dynamic aspects and allowing for collisions with argon that the sodium atoms undergo while in the excited state, was carried out and used to describe the experimental data. THE EXCITATION OF NUCLEAR SPIN TRANSITIONS IN CRYSTALS BY ULTRASONIC OSCILLATIONS, by E. A. Uehling. Final rept. Apr. 1, 1958, 21p. incl. refs. (AFOSR-TR-58-51) (AF 18(600)653; continued by AF 49(638)92) AD 154201 Unclassified

When these experiments were begun a direct connection between the orientations of nuclear spins in crystals and the lattice vibrations had not been established experimentally. The discovery of such a connection constitutes the principal achievement of this work.

Additional objectives which were realized include: (a) the measurement of the vibrational energy which is required in order to disturb the spin orientation by a known amount; (b) a study of the sensitivity of this effect in several distinctly different types of crystals; (c) an attempt to measure an acoustic relaxation parameter known as the phonon relaxation time T_p which has been

little studied in the history of physics but which is important in the interpretation of these experiments; and (d) a development of the theory of the processes which are under observation. In addition some studies of quadrupole interactions without specific reference to the interaction with lattice vibrations were made. The purpose of these studies was to investigate the nature of the electric field gradients responsible for the nuclear interaction with the lattice. (Contractor's abstract)

DETECTION OF ATOMS IN THE NITROGEN AFTERGLOW (Abstract), by R. A. Young and R. Sharpless. [1958] [1]p. [AF 18(603)36] Unclassified

Presented at meeting of the Amer. Phys. Soc., British Columbia U., Vancouver (Canada), Aug. 25-28, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 320, Aug. 26, 1958.

Using a high sensitivity ($\sim 10^5$ mm Hg atomic partial pressure), fast response (~ 1 sec), Wrede gauge measurements have been made of the atom concentration as a function of time for 2 min during the decay of the active nitrogen. The nitrogen afterglow, in a two liter glass bulb coated exteriorly with MgO, is simultaneously observed through a 5790 A interference filter by a photomultiplier (RCA 6655). The light detection and collection system has been calibrated. It was found that: (1) the atoms exhibit a three body recombination early in the afterglow ($k_n = 2.8 \cdot 10^{16}$ cc²/mol² sec, $p = 0.89$ mm Hg, (N) $\sim 2 \cdot 10^{-4}$ mm Hg partial pressure) and exponential decay during the later stages of the afterglow ($\tau = 30$ sec, $p = 0.89$ mm Hg, (N) $\sim 2 \cdot 10^{-5}$ mm Hg, accommodation coefficient $\sim 10^{-5}$); (2) the nitrogen first positive band radiation also decays exponentially but with a decay constant unrelated to that of the atoms; (3) the rate constant k_1 for the production of the nitrogen first positive band emission is $k_1 = 1.6 \cdot 10^{14}$ cc²/mol² sec derived from the early three body decay. Using this value for k_1 , the observed atomic concentration during the exponential decay would produce less emission than observed.

THE DEUTERON MAGNETIC RESONANCE SPECTRUM AND RELAXATION IN KD_2PO_4 , by J. L. Bjorkstam and E. A. Uehling. [1958] 1v. incl. diagrs. refs. (AFOSR-TN-58-996) (AF 49(638)92; continuation of AF 18(600)653) AD 205902 Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 383-384, Dec. 19, 1957.

Also published in Phys. Rev., v. 114: 961-968, May 15, 1959.

The electric field gradient (EFG) tensor at the site of the deuteron in the hydrogen bond of KD_2PO_4 and the relaxation times of the deuteron were studied. The measured quadrupole coupling constant is 119 kc/sec, the asymmetry parameter is 0.049, and the major principal axis of the tensor is along the bond direction. None of these features of the EFG tensor change appreciably with temperature over the entire range studied, which range includes the ferroelectric Curie point T_c . An interesting additional splitting in the spectral lines below T_c is observed, however. The thermal relaxation time of the deuteron was studied carefully only at room temperature. One obtains $T_1 = 6.5$ min at a particular orientation of the crystal decreasing by a factor of 2 at other particular orientations. T_2 is of the order 5×10^{-4} sec. From the point of view of orientation of the EFG tensor there are 2 distinct kinds of deuterons in the crystal. At any given orientation these deuterons differ in resonance frequency but not in the magnitude of their relaxation times or in their saturation behavior. This interdependence of the 2 kinds of deuterons and the possible causes of relaxation are discussed. (Contractor's abstract)

NUCLEAR SPIN-LATTICE RELAXATION IN KH_2PO_4 (Abstract), by J. L. Bjorkstam and E. A. Uehling. [1958] [1]p. [AF 49(638)92] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 166, May 1, 1958.

Studies of the relaxation time in the deuterated form of potassium dihydrogen phosphate have suggested a re-examination of the relaxation in the nondeuterated form. Measurements made by Newman (Jour. Chem. Phys., v. 18: 669, 1950) on the proton relaxation were interpreted by him in terms of a random jump process. He obtained relaxation times for protons equal to 1.6 sec and 0.25 sec, respectively, for crystals of KH_2PO_4 and KH_2AsO_4 . The present study resulted in relaxation times equal to 30 sec and 85 sec, respectively, under the same conditions of temperature and frequency. The phosphorus relaxation time in KH_2PO_4 , and in the deuterated form, was found to be longer. The proton relaxation showed a very striking frequency dependence. In KH_2AsO_4 , T_1 varied linearly from 32 sec at 10 mc/sec to 112 sec at 40 mc/sec. An interpretation of these results is given.

FREQUENCY DEPENDENCE OF THE NUCLEAR SPIN-LATTICE RELAXATION (Abstract), by E. A. Uehling and J. L. Bjorkstam. [1958] [1]p. [AF 49(638)92] Unclassified

Presented at meeting of the Amer. Phys. Soc., British Columbia U., Vancouver (Canada), Aug. 26-28, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 318, Aug. 28, 1958.

The relaxation time T_1 of spin 1/2 nuclei in certain crystals of KH_2PO_4 and KH_2AsO_4 is linearly dependent on frequency over a wide range of frequencies. In one case studied so far the ratio of the frequency coefficients for different nuclei in the same crystal has been obtained. In one crystal of KH_2PO_4 the relaxation time increased at the rate of 0.5 sec per mc/sec for the protons and 6.0 sec per mc/sec for the phosphorus. A semiquantitative explanation of the observed facts can be given if we make the following assumptions: (a) relaxation is due to the presence of a small density of paramagnetic ions as first proposed by Bloembergen; (b) the thermal relaxation time T_{1e} of the paramagnetic ions fulfills the condition $T_{1e} \ll 1/\nu_0$ for the smallest nuclear resonance frequency ν_0 . Under these conditions the effective volume of the region surrounding the paramagnetic ion into which spin energy must be transported by diffusion varies inversely as the frequency. Numerical analysis is required in order to explain the dependence of the frequency coefficient on the gyromagnetic ratios and crystal structure.

NOTES ON INTEGRATION I: THE UNDERLYING CONVERGENCE THEOREM, by W. F. Eberlein. [1957] [4]p. (AFOSR-TN-57-140) (AF 18(600)1534) AD 120497
Unclassified

Also published in Communications on Pure and Appl. Math., v. 10: 357-360, Aug. 1957.

Let C denote the real-valued continuous functions on a compact Hausdorff space S . An integral over S is a positive linear functional on C , that is, a mapping I of C into the real numbers. The theorem states: Let $\lim_n f_n = f$ pointwise (f_n, f in C) and $|f_n| \leq M < \infty$ for all n . Then $\lim_n I(f_n) = I(f)$. Although the theorem concerns only continuous functions on S , it is a natural basis for extending I . A new and elementary proof of the general theorem is included. It is the basis of a neogeometric approach to integration over function spaces with applications to numerical analysis and physics.

THE SPACES $K(n,p)$, by S. I. Goldberg. Sept. 20, 1957 [15]p. (AFOSR-TN-57-644) (AF 49(638)14) AD 136630
Unclassified

Abstract published in Proc. Fourth Canadian Math. Congress, Banff, Alberta (Canada) (Sept. 1-7, 1957), Toronto, Toronto U. Press, 1959, p. 87.

An n -dimensional differentiable manifold V_n of class C^k ($k \geq 3$) is considered on which there is given a positive definite metric $ds^2 = g_{jk} dx^j dx^k$, $g_{jk} = g_{kj}$ and a connection E_{jk}^i with respect to which the metric

is covariant constant. The torsion tensor is denoted by S_{jk}^i where $S_{jk}^i = 1/2(E_{jk}^i - E_{kj}^i)$. The covariant torsion tensor (tensor of type (0,3)) is antisymmetric and the symmetric part of E_{jk}^i coincides with the Christoffel symbols. It is shown that the characteristics of the space, including its Lie group, tensor symmetry, etc. properties define the geometry of a $K(n,3)$ as the natural generalization of the local geometry of a compact semi-simple Lie group.

PB 140034 Unclassified

Let M be an irreducible almost complex manifold of real dimension $n = 2m$ and denote by $F = (F^i)$ the tensorfield defining the almost complex structure. If m is even ($m = 2l$) and the restricted homogeneous holonomy group H_p at $p \in M$ is a subgroup of the real representation $QL(X, R)$ of the quaternion linear group $QL(X, C)$ then M has a quaternion structure. The group of affine transformations $A(M)$ of M is a Lie group and acts on the vector space spanned by those tensorfields of type $(1, 1)$ defining the quaternion structure as a group of rotations of 3-space. It is denoted by $C_F(M)$ the group of all affine transformations preserving F and by $Q(M)$ the subgroup of $C_F(M)$ consisting of those transformations preserving the quaternion structure. Then $C_F(M)$ is a closed subgroup of $A(M)$ and $Q(M)$ is a closed normal subgroup of $A(M)$ and $C_F(M)$. These groups are Lie groups. The main purpose is to show that $A(M)/Q(M)$ is isomorphic to $SO(3)$, if and only if, $Ap(M)$ acts as the full group of automorphisms at the algebra. Various conditions ensure this, such as (1) the factor group $C_F(M)/Q(M)$ is isomorphic to the circle group and (2) the underlying space of $A(M)/Q(M)$ can be identified with projective 3-space.

REFLECTION LAWS OF DIFFERENTIAL EQUATIONS OF MIXED TYPE, by Y. W. Chen. [1957] 25p. (AF 49(638)107) Unclassified

Presented at meeting of the Amer. Math. Soc., New York, Apr. 5-6, 1957.

Consider first the equation (*) $x^s u_{yy} + u_{xx} = 0$ with positive exponent s . The following theorem holds: Let $u(x, y)$ be a solution of (*) of class C_2 in a domain $0 < x < 1$, $a < y < b$, with continuous first and mixed second derivatives on $x = 0$. Let $u(0, y) = T_0(y)$ and $u_x(0, y) = T_1(y)$. Then (1) T_0 and T_1 uniquely determines the solution $u(x, y)$; and (2) when one of the T_i , $i=0, 1$, is zero, the other one is necessary to an analytic function of y , and $u(x, y)$ can be extended to an analytic function of two complex variables. Secondly, the same equation is considered with negative $s > -1$. Under the additional assumption that u_{xy} is continuous for $0 < x < 1$ and on $x = 0$, the above mentioned theorem is valid also in this case. The theorem generalizes the classical reflection principle of harmonic functions ($s = 0$).

HOELDER CONTINUITY AND INITIAL VALUE PROBLEMS FOR MIXED TYPE EQUATIONS, (I), by Y. W. Chen. [1958] 34p. incl. refs. (AFOSR-TN-58-607) (AF 49(638)107) AD 162135 Unclassified

The existence and functional behavior of solutions $z(W)$ with Hoelder continuous initial values on an open segment l of the y -axis are investigated. Let D be a convex domain in the positive X -half plane with l as a boundary line. Let closed subdomain D' of D be a domain which has a closed subsegment of l as a boundary and which lies otherwise in the interior of D . Take a point on l as $W = 0$. The following theorem is proved: to each regular analytic function $g(W)$ in D with the properties (1) $g(0) = 0$, and (2) in every D' $g(W)$ is Hoelder continuous with exponent μ , $0 < \mu < 1 - \alpha$, there is a solution $z(W)$ in D with the properties (1) $z(W) = 0$, and (2) $s^{-\alpha} u(W)$ and $s^{\alpha} v(W)$ are Hoelder continuous in D' respectively with exponents $\mu - \alpha$ and $\mu + \alpha$. Conversely to each solution $z(W)$ with the two properties just mentioned there is an analytic function $g(W)$ as described above. The initial values of the corresponding functions $g(W)$ and $z(W)$ are related by a simple transformation formula. By a simple device the theorem can be extended to cover the cases $0 < \mu < \alpha$ and $1 - \alpha < \mu < 1$ and also the cases of differentiable or only integrable initial data. HOELDER CONTINUITY AND INITIAL VALUE PROBLEMS FOR MIXED TYPE EQUATIONS (II), by Y. W. Chen. [1958] 19p. incl. refs. (AFOSR-TN-58-698) [AF 49(638)107] AD 162232 Unclassified

A proof is given that the initial value of u belongs to $Lip V$ and, consequently that its conjugate v^* has initial values belonging to $Lip V + 2a$, and conversely. On the basis of the generalized main theorem given, the statement is equivalent to a theorem on analyticity. If $u = 0$ on the initial line and is continuous up to the boundary, then the conjugate v^* is shown to have analytic initial values. The equation $U(x, y) = u_h(x_1, y)$ for $x < 0$ with odd integer exponent p is considered and a theorem on analytic continuation is proved.

Unclassified

Also published in *Compositio Math.*, v. 13: 173-218,
1958.

The local homology groups and the local homotopy groups of a topological space X at a point $x_0 \in X$ are defined as the (global) homology groups and the (global) homotopy groups of the tangent space $T(X, x_0)$ which is constructed. It is shown that if X is locally triangulable at x_0 , or more generally, if x_0 is a conic point of X , then these groups are isomorphic to those of Griffiths and Seifert-Threlfall. The homotopy classification is developed for an application of the local invariants to local maps and a local version of the Hopf theorem is proved. These local invariants are used to study the fibre spaces with singularities in the sense of Montgomery and Samelson, or Seifert. An application to topological semi-groups is given.

ON FIBERINGS WITH SINGULARITIES, by S.-T. Hu.
Aug. 1958, 32p. incl. diagrs. (Technical note no. 2)
(AFOSR-TN-58-611) (AF 49(638)179) AD 162139

Unclassified

Also published in *Mich. Math. Jour.*, v. 6: 131-149, 1959.

The paper provides a general definition of fiberings with singularities which includes all of the known fiberings as special cases. The singular fibers identified to points are used to prove that every fibering p with singularities can be decomposed into the composition $p_1 \circ p_2$ of two fiberings p_1 and p_2 where every singular fiber of p_1 is a singleton and every regular fiber of p_2 is a singleton and the natural projection of some topological identification. The singular fiber is studied in the extended tangent space $E(X, x_0)$ of a given space X at a given point x_0 and the natural projection $p: E(X, x_0) \rightarrow X$. The local property of any given fibering $f: X \rightarrow Y$ at an isolated singular fiber x_0 is investigated and it is proved that the fibering axiom of the local homotopy groups holds for every fibering with a single normal singular fiber.

Presented at meeting of the Amer. Phys. Soc.,
Washington, D. C., May 1-3, 1958.

Abstract published in *Bull. Amer. Phys. Soc., Series II*,
v. 3: 219, May 1, 1958.

A method is described which was developed for preparing thin single-crystal semiconductor films of uniform thickness, the crystalline properties of which are the same as those of the bulk single crystal. Single crystal n-type germanium films of thickness from 3 to 10 μ have been prepared which have thickness variations from 20 to 50% for the thicker and thinner samples, respectively. Expectations are that any semiconductor will exhibit electrolytic-etching properties similar to those of anodic n-type germanium provided the following criteria are met: (1) The rate limiting process for the electrode reaction is the flow of minority carriers to the semiconductor-electrolyte interface; and (2) the net electrode reaction is the etching of the semiconductor material. Thin films of n-type germanium were made that exhibited surprisingly good uniformity with the photoelectric etching technique.

PROTON RELAXATION IN WATER, by S. Melboom,
Z. Luz, and D. Gill. [1957] [2]p. incl. diagr. (AF 61-
(052)03)

Unclassified

Published in *Jour. Chem. Phys.*, v. 27: 1411-1412,
Dec. 1957.

Longitudinal and transverse proton relaxation times, T_1 and T_2 respectively, have been measured as a function of the solution pH and a model is presented in which hydrogen bond formation contributes to the value of T_2 . The measured values of T_2 lie consistently below those of T_1 which is inconsistent with the calculated values except for an expected minimum at pH value of 7. The minimum in the theoretical curve, as matched by experiment, is due to the formation and breaking of hydrogen bonds between the water molecules of the solution. No explanation is given of the difference between calculations and experiment at both low and high values of the pH.

KINETICS OF HYDROGEN EXCHANGE BETWEEN HYDROGEN PEROXIDE AND WATER STUDIED BY PROTON MAGNETIC RESONANCE, by M. Anbar, A. Loewenstein, and S. Meiboom. [1958] 14p. illus. (AFOSR-TN-58-169) (AF 61(052)03) AD 152196

Unclassified

Also published in Jour. Amer. Chem. Soc., v. 80: 2630-2634, June 5, 1958.

The kinetics of hydrogen exchange between H_2O_2 and water have been investigated using the PMR method in the pH range of 2.5 and 6.5. The reaction was found to be both acid and base catalyzed. In the acid region, pH < 4.5, the reaction involves H_3O^+ and H_2O_2 , while in the basic region it was found to involve HO_2^- , H_2O_2 , and H_2O . The reaction constants are $k = 1.6 \times 10^7 \text{ mol}^{-1} \text{ sec}^{-1}$, and $k = 7.3 \times 10^7 \text{ mol}^{-2} \text{ sec}^{-1}$, respectively.

The measurement of fast hydrogen exchange rates by the nuclear magnetic resonance technique is described. In the systems studied, the exchangeable hydrogens are bonded either to nitrogen (amine and amide groups) or to oxygen (hydroxyl groups). In many cases, a complete analysis of the kinetics of the exchange reaction was possible. The kinetics of hydrogen exchange was studied in the following systems: (1) aqueous solutions of ammonium chloride; (2) aqueous solutions of N-methylacetamide; (3) aqueous solutions of glycine, glycine methyl ester and sarcosine; (4) proton transfer in water; (5) aqueous solutions of hydrogen peroxide; and (6) ethanol - water mixtures. HYDROGEN EXCHANGE IN ETHANOL, by S. Meiboom, Z. Luz, and D. Gill. [1958] [9]p. incl. diagrs. table. (Bound with its AFOSR-TR-58-110; AD 201858) (AF 61(052)03) Unclassified

The rate of exchange of the hydroxyl proton in alcohols is very fast, and for this reason cannot be measured by isotope labelling. This exchange reaction can be studied by the NMR technique, and some qualitative results have been published by Arnold (Phys. Rev., v. 102: 136, 1956), and by Weinberg and Zimmerman (Jour. Chem. Phys., v. 23: 748, 1955). The reaction is both acid and base catalyzed. Concentrations of the order of 10^{-5} M acid or base accelerate the reaction to a rate corresponding to a lifetime of the alcohol molecule of about 10^{-2} sec, which is about the highest rate that can be measured by the NMR technique. Quantitative measurements of the hydrogen exchange in ethanol containing different amounts of water are described.

NUCLEAR MAGNETIC RESONANCE STUDY OF THE EXCHANGE KINETICS IN THE ACETIC ACID-ACETIC ANHYDRIDE SYSTEM, by M. Sheinblatt and S. Meiboom. [1958] 15p. incl. refs. (AF 61(052)03) Unclassified

The kinetics of the acetyl exchange reaction in acetic acid-acetic anhydride mixtures has been investigated by the NMR technique. The reaction is strongly acid-catalyzed. The reaction rate is first order in respect to hydrogen ion concentration and increases with acetic anhydride concentration. The average lifetime between exchanges is about 0.02 sec in a solution having equal concentrations of acetic acid and acetic anhydride, and containing 0.1 mol l^{-1} perchloric acid. A discussion of the possible exchange mechanisms is given. It is concluded that the dominant mechanism is a reaction between the $AcOH_2^+$ ion and the acetic anhydride molecule. NUCLEAR MAGNETIC RESONANCE STUDY OF THE PROTOLYSIS AND IONIZATION OF N-METHYLACETAMIDE, by A. Berger, A. Loewenstein, and S. Meiboom. [1958] [23]p. incl. diagra. table, refs. (Bound with its AFOSR-TR-58-110; AD 201858) (AF 61(052)03) Unclassified

Also published in Jour. Amer. Chem. Soc., v. 81: 62-67, Jan. 5, 1959.

The rate and mechanism of protolysis in N-methylacetamide in aqueous solution has been investigated by the nuclear magnetic resonance technique. The protolysis was found to be both acid and base catalyzed, the reaction rate being proportional to the amide concentration and to the hydrogen ion or hydroxyl ion concentration. It was found that in N,N-dimethylacetamide, free rotation around the C-N bond occurs on acidification. This phenomenon is closely related to the protolysis in N-methylacetamide, both being due to protonation at the nitrogen atom. It could be shown, however, from a study of the NMR spectrum in very acidic solution, that the protonation occurs predominantly at the oxygen, both ionic species being in equilibrium. A detailed mechanism for the exchange reactions is proposed. (Contractor's abstract)

PROTOLYSIS OF GLYCINE AND GLYCINE DERIVA-

TIVES, by S. Meiboom and M. Sheinblatt. [1958] [11]p. incl. diagra. (Bound with its AFOSR-TR-58-110; AD 201858) (AF 61(052)03) Unclassified

The hydrogen exchange has been investigated in aqueous solutions of the following compounds: (1) glycine (H_2NCH_2COOH); (2) glycine methyl ester ($H_2NCH_2COOCH_3$); and (3) sarcosine (N-methyl-glycine) ($H_3CHN_2^+CH_2COOCH$). In very acidic solutions the exchange in these compounds becomes slow enough for measurement by the NMR technique. This occurs above about 1N HCl for glycine and glycine methyl ester, and above 0.1N for sarcosine. Typical spectra of these compounds in very acidic solution are given. The amine hydrogen lines are very broad because of quadrupole relaxation of the N^{14} nucleus, and are not reproduced in this report. These lines are too broad and weak to be useful in the rate determinations.

SOLUTION OF AN INTEGRAL EQUATION OCCURRING IN IMPULSIVE WAVE PROPAGATION PROBLEMS, by C. L. Pekeris. May 6, 1956 [5]p. incl. refs. (AFOSR-TN-57-79) (AF 61(514)899) AD 120425 Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 42: 439-443, July 1956.

An integral equation solution for impulsive wave propagation problems in which the disturbance is propagated in a doubly or multiply refracted media is given. A summarized analysis of the equation is presented to facilitate solutions of related wave problems:

$$p \int_0^{\infty} e^{-pt} W(t, r, H) dt = \frac{p}{c} \int_0^{\infty} J_0 \left(\frac{p}{c} rx \right) f(x) e^{-(p/c)H \sqrt{x^2 + a^2}} x dx.$$

Here p = operation ($\partial/\partial t$), c = characteristic velocity of propagation of the medium, r = horizontal distance in cylindrical coordinates, H = depth of the source, J_0 = Bessel function of order zero, $f(x)$ is given, and W to be determined. Five case studies of the types of problems met illustrate the usage.

RADIATION DUE TO AN IMPULSIVE CURRENT IN A VERTICAL ANTENNA PLACED ON A DIELECTRIC

WES.01:002; WRU.01:001-003

GROUND, by C. L. Pekeris and Z. Alterman. Technical rept. Nov. 1, 1955-Oct. 31, 1956, 19p. diags. (AFOSR-TN-57-247) (AF 61(514)899) AD 126545 Unclassified

Also published in Jour. Appl. Phys., v. 28: 1317-1323, Nov. 1957.

Study is made of the electromagnetic field generated by passing an impulsive current of the form of a delta function $\delta(t)$ through a vertical antenna placed on a dielectric ground. The problem is formulated in operational form, and the Hertzian potential π is expressed as an integral over a Bessel function. This operational solution is then inverted, and the Hertzian potential $\pi(r, z, t)$ is expressed in terms of finite complex integrals over a fixed range. The integrals for π are evaluated on the electronic computer of the Weizmann Institute, and the results for the case of a dielectric constant $\epsilon = 9$ are given. The field in the air starts with a finite value at the time of arrival of the wave front, and then increases in a monotone fashion toward the steady state value. In the ground, there is a cone of angle $\sin^{-1}(1/\sqrt{\epsilon})$ centered around the downward vertical, inside which the field starts again with a finite value and then decreases toward the steady state value. Outside this cone, the direct wave in the ground is preceded by a diffracted wave originating from secondary radiation emanating from the portion of the boundary where the air wave passed in advance of the ground wave. This diffracted wave starts with zero amplitude and increases thereafter, becoming logarithmically infinite at the time of arrival of the direct wave in the ground. After that the amplitude decreases continuously toward the steady state value.

STUDY OF THE FORMATION AND DEVELOPMENT OF THE LATENT IMAGE IN PHOTOGRAPHY, by J. Gomez-Ibanez. Final rept. July 1958, 1v. incl. diags. tables, refs. (AFOSR-TR-58-93) (AF 18(600)343) AD 162134 Unclassified

This final report summarizes the work done under this contract which deals with the study of latent image formed upon exposing to light sols of silver bromide. No attempt has been made to draw conclusions from the data obtained, which, although extensive, should be considered still incomplete. One important conclusion can nevertheless be inferred from the present work: the latent image obtained in silver bromide sols does not seem to consist of metallic silver as previously postulated, but rather it appears to be a colloidal silver complex.

EVALUATION OF TWO-CENTER EXCHANGE INTEGRALS, by G. E. Tauber. Dec. 1957, 34p. incl. tables, refs. (AFOSR-TN-57-799) (AF 18(603)61) AD 148031 Unclassified

Also published in Jour. Chem. Phys., v. 29: 300-310, Aug. 1958.

The evaluation of two-center exchange integrals for any homonuclear molecules using Slater-type wave functions is reduced to the solution of Poisson's equation. An expression is obtained for the exchange integrals in terms of integrals which can be evaluated analytically. In particular, all cases which arise from 2s and 2p wave functions are discussed in detail and the auxiliary integrals evaluated. The pertinent results are collected in tables, and the final result for a particular exchange integral is given explicitly. (Contractor's abstract)

ROTATIONAL MAGNETIC MOMENT OF H_2 , by G. E. Tauber. July 8, 1958, 17p. incl. diags. refs. (AFOSR-TN-58-571) (AF 18(603)61) AD 158390 Unclassified

Also published in Phys. Rev., v. 112: 866-869, Nov. 1, 1958. (Title varies)

The rotational magnetic moment of H_2 has been calculated by considering the motion of the electrons in the presence of the two nuclei which are permitted to move themselves. The interaction is described by Breit's two-body Hamiltonian suitably generalized to this problem. The wave function is obtained by the Born-Oppenheimer method of adiabatic approximation. Calculations have been carried out for Wang's electronic wave function and up to first order in the expansion parameter give for the effective magnetic field due to rotation 23.6 gauss in good agreement with the experimental results of 27.0 gauss. ACOUSTIC DELAY LINE MEMORY FOR HUTCHINSON-SCARROTT KICKSORTER, by B. L. Robinson. Dec. 8, 1958 [5]p. incl. diags. (AFOSR-TN-58-1033) (AF 18(603)61) AD 206483; PB 140035 Unclassified

The multiple channel pulse height analyzer (kicksorter) introduced by Hutchinson and Scarrott stores the numerical results of the pulse height analysis in a serial

type computer memory commonly called the acoustic delay line memory. A quartz delay line memory unit was developed which includes transmitter, receiver and pulse shaping circuits in an inexpensive and compact plug-in package. The unit operates at a clock rate of 1.00 mcps, and requires clock pulses and input signals (about 10 v in amplitude and clamped to a reference voltage). Shaped output pulses of the same character are produced by the memory unit. This unit was adapted to the kicksorter. In the kicksorter, the clock oscillator is gated by the sweep circuit, and therefore clock pulses are not available until the sweep has started. The sweep must be started and synchronized by the output of the memory. The necessary signal is derived from output of the receiver through an amplifier stage.

Importance both in meeting the requirements that are made of an information system and in keeping costs at the lowest possible level. Other things being equal the simplest code that is effective in meeting requirements is to be preferred. Any elements of complexity in a code must justify themselves by providing benefits commensurate with costs. (Contractor's abstract)

THE STEREOSPECIFIC RADICAL ADDITION OF HYDROGEN BROMIDE TO CIS- AND TRANS-2-BROMO-2-BUTENE, by H. L. Goering and D. W. Larsen. [1957] 4p. (AFOSR-TN-57-143) (AF 18(800)1037) AD 128432
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 2853-2854, May 20, 1957.

Experiments were conducted to show the stereospecificity of the radical addition of hydrogen bromide in an acyclic system. Mixtures of anhydrous liquid hydrogen bromide with, in one case, *cis*- and in another *trans*-2-bromo-2-butene were irradiated, after which the hydrogen bromide was allowed to evaporate and the composition of the residual reaction mixture determined by gas chromatographic and infrared analysis. That the additions were radical rather than ionic was clear from the orientation. When a mixture of *cis*-2-bromo-2-butene and liquid hydrogen bromide was allowed to stand in the dark at -80° for 1 hr the reaction mixture was found to contain 8.5% of bromobutene and 91.5% 2,2-dibromobutane. Under similar conditions using *trans*-2-bromo-2-butene the reaction mixture consisted of 10% unreacted bromobutene, 87% 2,2-dibromobutane, and 3% di-2,3-dibromobutane. It was determined from these observations that the radical addition is indeed stereospecific and results in almost complete *trans* addition.

ADDITION OF HYDROGEN BROMIDE TO 1-HALOCYCLOHEXENE AND THE REARRANGEMENT OF DIHALOCYCLOHEXANES IN THE PRESENCE OF FERRIC CHLORIDE, by H. L. Goering and L. L. Sims. [June 24, 1957] 19p. incl. tables, refs. [Rept. no. 6] (AFOSR-TN-57-280) (AF 18(800)1037) AD 132351
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 6270-6274, Dec. 5, 1957.

The ionic addition of hydrogen bromide to 1-chlorocyclohexene and 1-bromocyclohexene in excess liquid hydrogen bromide in the presence of a small amount of ferric chloride gives 1-bromo-1-chlorocyclohexane and 1,1-dibromocyclohexane, respectively. In the presence of larger amounts of ferric chloride the initially formed gem dihalide undergoes halogen exchange and rearrange-

ment. Thus both 1-chlorocyclohexene and 1-bromocyclohexene can be converted to *trans*-1,4-dibromocyclohexane in good yields. Examination of products from a series of experiments in which the amount of ferric chloride was varied indicates the following sequence for the conversion of 1-chlorocyclohexene to *trans*-1,4-dibromocyclohexane: 1-chlorocyclohexene - 1-bromo-1-chlorocyclohexene - 1,1-dibromocyclohexane - *cis*-1,2-dibromocyclohexane - 1,3-dibromocyclohexane - *trans*-1,4-dibromocyclohexane. Apparently, *trans*-1,2-dibromocyclohexane is not involved as an intermediate in this process. Under appropriate conditions 1-chlorocyclohexene can be converted to 1-bromo-1-chlorocyclohexane, 1,1-dibromocyclohexane or *trans*-1,4-dibromocyclohexane in good yields.

THE SOLVOLYSIS OF CIS AND TRANS-2-CHLOROCYCLOALKYL ARYL SULFIDES IN 80% AQUEOUS ETHANOL, by H. L. Goering and K. L. Howe. Sept. 10, 1957, 19p. incl. diagrs. tables, refs. (AFOSR-TN-57-495) (AF 18(800)1037) AD 136485
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 6542-6548, Dec. 20, 1957.

The rates of solvolysis of *cis*- (Ia) and *trans*-2-chlorocyclohexyl phenyl sulfide (IIa) and *cis*- (IIIa) and *trans*-2-chlorocyclopentyl phenyl sulfide (IVa) and para substituted derivatives of these β -chlorosulfides in 80% aqueous ethanol have been determined. In both the cyclohexyl and cyclopentyl systems the *trans* isomers, in which the neighboring sulfide group can participate in the ionization step, are more reactive than the corresponding *cis* isomers by factors of 10^5 to 10^6 . Electron-withdrawing substituents retard the rate of solvolysis of the *trans*-2-chlorocycloalkyl phenyl sulfides (II and IV) but do not affect the reactivity of the *cis* isomers (I and III). At 118° the *cis*-2-chlorocyclohexyl aryl sulfides (I) are 6 times less reactive than cyclohexyl chloride and the *cis*-2-chlorocyclopentyl aryl sulfides are 15 times less reactive than cyclopentyl chloride. Similar values of ρ_{Hoe} and $k_{\text{trans}}/k_{\text{cis}}$ for the cyclohexyl and cyclopentyl chlorosulfides show that sulfur participates about equally well in the two systems. THE EFFECT OF SOLVENT ON SPECTRA. 1. A NEW EMPIRICAL MEASURE OF SOLVENT POLARITY: Z-VALUES, by E. M. Kosower. [1958] [8]p. incl. diagrs. tables, refs. [AF 49(638)282]
Unclassified

WIS.05:002, 003; WIS.06:001, 002

Published in Jour. Amer. Chem. Soc., v. 80: 3253-3260, July 5, 1958.

The position of the charge-transfer (c-t) absorption band of 1-alkylpyridinium iodide complexes is remarkably sensitive to the nature of the solvent in which it is measured. The transition energies derived from the band positions are linear in the Winstein-Grunwald Y-value (a kinetic measure of solvent ionizing power) over a wide range of methanol-water, ethanol-water and acetone-water mixtures. The c-t bands can be measured in solvents for which it is not possible or convenient to seek a Y-value. It is proposed that the transition energies, in kcal/mol, be adopted as empirical measures of solvent polarity, and that they be called Z-values. The complex formed from 1-ethyl-4-carbomethoxy-pyridinium iodide was selected as a standard and pyridine-1-oxide was used to extend the Z-value scale to iso-octane, in which the salt is insoluble. As an initial check on the validity of the Z-values, the transition energies for the c-t bands of the 1-ethyl-4-cyanopyridinium iodide complex in six solvents have been found to be linear in Z. A theoretical analysis of the data based on a reasonable model for the 1-alkylpyridinium iodide complex provides the free energy of solution of the complex dipole. The difference in free energy of solution of the 1-ethyl-4-carbomethoxy-pyridinium iodide complex dipole between iso-octane and water is 17.3 kcal/mol. Using the apparent absorption coefficient as a measure of the effect of the solvent on the association of the pyridinium and iodide ions into complex, it is found that certain solvents (dimethylformamide, dimethyl sulfoxide) are dissociating, and others associating (acetic acid), in comparison with "normal" solvents (chloroform, alcohols, etc.). (Contractor's abstract)

THE EFFECT OF SOLVENT ON SPECTRA. II. CORRELATION OF SPECTRAL ABSORPTION DATA WITH Z-VALUES, by E. M. Kosower. [1958] [7]p. Incl. diagrs. tables, refs. [AF 49(638)282] Unclassified

Published in Jour. Amer. Chem. Soc., v. 80: 3261-3267, July 5, 1958.

A number of electronic transitions in different solvents are compared with Z-values, an empirical measure of solvent polarity based on the c-t band of 1-ethyl-4-carbomethoxy-pyridinium iodide. It is possible to identify certain specific interactions between solute and solvent by this means. With the aid of several reasonable assumptions, and a knowledge of the difference in the free energy of solution of the pyridinium iodide dipole between iso-octane and water, it is possible to estimate the excited state dipole moments resulting from certain electronic transitions. The effect of solvent on the spectra of several cyclopropyl ketones has been investigated, and a band resulting from cyclopropyl conjugation un-

quivocally identified in this way. Methyl cyclopropyl ketone has a maximum at 1931 Å in water; this information casts doubt on previously reported maxima attributed to the interaction of a cyclopropyl ring with a carbonyl group. (Contractor's abstract)

THE EFFECT OF SOLVENT ON SPECTRA. III. THE USE OF Z-VALUES IN CONNECTION WITH KINETIC DATA, by E. M. Kosower. [1958] [4]p. Incl. diagrs. table, refs. [AF 49(638)282] Unclassified

Published in Jour. Amer. Chem. Soc., v. 80: 3267-3270, July 5, 1958.

The correlation of solvent effects on reaction rates can be extended to non-hydroxylic solvents with Z-values, which are based on the position of the charge-transfer band of 1-ethyl-4-carbomethoxy-pyridinium iodide in a given solvent. In the case of the exchange of radioactive iodide ion with methyl iodide, specific interaction between iodide ion and acetone, in the transition state and initial state accounts for the unusually rapid reaction observed in acetone. The Z-value correlations offer an opportunity of separating electrostatic and specific solvent effects. The analogy between the "intimate ion-pair" solvolysis intermediate and the pyridinium iodide complex is discussed, and the value of this point of view is illustrated by application to some data for tri-(p-nitrophenyl)-methyl derivatives. THE ACID STRENGTH OF TRIPHENYLSILANOL, by R. West and R. H. Baney. July 18, 1958 [2]p. (AFOSR-TN-58-686) (AF 49(638)285) AD 162220 Unclassified

Also published in Jour. Inorg. and Nuclear Chem., v. 7: 297-298, Oct. 1958.

Triphenylsilanol may be titrated in pyridine solution, using tetrabutyl NH_4OH in benzene-methanol as titrant.

The following reproducible half-neutralization voltages are found: phenol-0.68; p-methoxyphenol-0.73; triphenylsilanol-0.80; and p-nitroaniline-0.90; all $\pm 0.01\text{v}$, at 0.01 to 0.02 M. This is the first direct measurement of the Brønsted acidity of a silanol compared to other weak acids.

HYDROGEN BONDING OF PHENOLS TO OLEFINS, by

by R. West. Sept. 2, 1958 [13]p. incl. diagrs. tables, refs. (AFOSR-TN-58-805) (AF 49(638)285) AD 202360
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 81: 1614-1617, Apr. 5, 1959.

Evidence was obtained for the formation of weak intermolecular H bonds between phenols and olefins in solution by IR spectral studies in the 3400 to 3800 cm^{-1} region. A new O-H absorption band characteristic of the H-bonded complex appeared at 60 to 130 cm^{-1} lower frequency than the absorption due to unassociated phenol hydroxyl groups. Relative basicities of olefins were measured by determining the frequency shift on H bonding. The basicities were increased by increasing the alkyl substitution at the double bond, and decreased by conjugation. Intramolecular H bonding to ethylenic π -electrons was observed in *o*-allylphenol. Phenol was used as the principal hydroxyl compound along with the slightly more acidic compound *p*-fluorophenol. Phenols have the following advantages as reference acids in H bonding studies: (1) the greater acidity of phenols leads to larger shifts of absorption position on H bonding; (2) phenols have a higher absorbency for O-H vibration, so that the bands in question can be observed conveniently; and (3) phenols have less tendency to self-association than aliphatic alcohols, which minimizes complications resulting from intermolecular association of hydroxyl groups with one another. At 0.20 M or less in CCl_4 the self-association of the phenols used was negligible. (ASTIA abstract)

THE REDUCTIVE COUPLING OF TRIPHENYL-CHLOROSILANE: EVIDENCE FOR THE TRIPHENYLSILYL GRIGNARD REAGENT, by T. G. Selin and R. West. [1958] [2]p. (AFOSR-TN-58-806) (AF 49(638)-285) AD 202361
Unclassified

Also published in Tetrahedron, v. 5: 97-98, Jan. 1959.

A novel coupling of 2 mol of a chlorosilane by a Grignard reagent to produce the Si-Si linkage probably involved the formation of the first known example of an organosilylmagnesium compound. Ph_3SiCl (0.05 mol) refluxed 18 hrs or more with 0.10 mol $\text{C}_6\text{H}_{11}\text{MgBr}$ in 250 ml tetrahydrofuran yielded 67% $\text{Ph}_3\text{SiSiPh}_3$ (I), m 365-6°, together with 1 mol each of cyclohexene (II) and C_6H_{12} . Under the same conditions PhMgBr and 2 - $\text{Me C}_6\text{H}_{10}\text{MgBr}$ gave 51 and 62% yields of I, respectively, though no disilane was obtained in the less basic Et_2O . Me_3SiCl was not coupled under the above

conditions but a mixture of Ph_3SiCl and Me_3SiCl yielded 14% Ph_3SiSiMe , m 106.8°, suggesting the reaction of the intermediate Ph_3SiMgBr with Me_3SiCl .

Apparently aromatic groups on Si are necessary for stabilization of the intermediate as they appear necessary for the formation of organosilylalkali compounds. Ph_3SiCl and $\text{C}_6\text{H}_{11}\text{MgBr}$ may undergo a 4-center reaction with formation of Ph_3SiMgBr , II, and HCl. The Ph_3SiMgBr would couple with Ph_3SiCl and the by-product HCl would react with $\text{C}_6\text{H}_{11}\text{MgBr}$ with formation of C_6H_{12} . This mechanism is consistent with experiments showing that the reduction of Ph_3SiCl to Ph_3SiH is not a part of the coupling reaction, and that the coupling reaction proceeds by a polar rather than a free radical reaction.

SMALL-ANGLE X-RAY SCATTERING FROM COLD-WORKED METALS (Abstract), by W. W. Beeman, R. [H.] Neynaber and others. [1957] [1]p. [AF 18(600)698]
Unclassified

Published in Acta Crystallographica, v. 10: 825, Dec. 1957.

Studies of the temperature dependence and polarization of the x-ray scattering at small angles from cold-worked Cu, Ni and Al are described. There is very little evidence for cavity scattering except, perhaps in diffusion couples. Most of the scattering can be explained as the result of two successive Bragg scatterings either from two subgrains of the same original grain or a double process within a single subgrain, the resulting forward beam, in this case, being physically broadened. In annealed materials a sharp diffracted beam at angles too small to allow a single Bragg reflection has been observed occasionally. Such diffractions are the result of a double Bragg reflection from two grains accidentally so oriented as to permit the reflection. In cold working the number of independent reflecting domains is greatly increased and the continuous small-angle scattering is assumed to be the unresolved sum of a large number of double scattering processes.

[STUDY OF LATTICE IMPERFECTIONS IN CRYSTALS] by W. W. Beeman. Final rept. Dec. 31, 1958, 3p. (AF 18(600)698)
Unclassified

WIS.04:005 (continued)

The true small angle single scattering from cold worked metals is a very small fraction of the observed scattering, which appears at small angles, but which is really the result of two large angle Bragg scatterings successively from two subgrains which are slightly tilted with respect to one another. Therefore, it is not possible to use small angle x-ray scattering as a direct probe of the defect structure of cold worked metals. Long wavelength neutron studies may be useful since the wavelength can be made so great that no Bragg scattering is possible. However, there are intensity difficulties with neutrons. The discovery of the double Bragg scattering mechanism is of considerable

x-ray interest but the possible applications to solid state physics have not been thoroughly explored. The scattering curve gives a measure of the tilt angle distribution of the subgrains in a cold worked grain. Measurement of the rate of disappearance of the scattering at elevated temperatures is a convenient way of studying the kinetics of recovery and recrystallization. Dr. Sharp in his thesis work investigated the small angle scattering from Cu-Ni diffusion couples. In this case there is clear evidence for single scattering from cavities but mixed with it is a quite appreciable amount of double Bragg scattering presumably caused by the lattice distortions which accompany diffusion.

THE LEAST EIGENVALUE OF HILL'S EQUATION, by R. A. Moore. [1957] [14]p. [AF 18(600)1127] Unclassified

Published in Jour. Analyse Math. (Jerusalem), v. 5: 183-196, 1956/1957.

The functional dependence of the least eigenvalue $(-a)$ of Hill's equation $y'' + (-a + bq(x))y = 0$ on the parameter b is investigated. Here q is a periodic function of period one with mean zero, and y is required to be periodic with period one. By using various Sturmian theorems, the author proves the following and other similar properties of the function $a(b)$: $a(b)$ is convex, $a(0) = a'(0) = 0$, and

$$a(b) \leq \begin{cases} mb - m^2 w^{-2} & (b \leq 2mw^{-2}) \\ \frac{1}{2} w^2 b^2 & (2mw^{-2} \leq b \leq 2Mw^{-2}) \\ Mb - m^2 w^{-2} & (b \geq 2Mw^{-2}) \end{cases}$$

where m and M are the minimum and maximum values of q , while w is the maximum value of

$$\left| \int_{\xi_1}^{\xi_2} q(x) dx \right| \text{ for } 0 \leq \xi_1 \leq \xi_2 \leq 1. \text{ (Math. Rev. abstract)}$$

[CAUCHY'S PROBLEM: EXISTENCE AND UNIQUENESS OF THE SOLUTIONS] Probleme de cauchy: existence et unicite des solutions, by E. Hille. [1957] [AF 18(600)1127] Unclassified

Published in Bull. Math. Soc. Sci. Math. Phys. R. P. Roumaine, v. 1: 31-53, 1957.

Cauchy's abstract problem is studied in a Banach space for reason of precision. The conditions imposed assume A to be a linear operator whose domain $D[A]$ and counterdomain $R[A]$ are subspaces of X , a complex B space. An element f_0 of X is given with the intent of finding an application $t \rightarrow y(t; f_0)$ of $0 \leq t < \infty$ in X such that: (1) $y(t; f_0) \in D[A]$, (2) $y(t; f_0)$ possesses a derivative strongly continuous with respect to t , (3) $y'(t; f_0) = A[y(t; f_0)]$, and (4) $\lim_{t \rightarrow 0^+} \|y(t; f_0) - f_0\| = 0$. The analogous problem, designated as PACⁿ, for the equation $y^{(n)}(t) = A^n[y(t)]$ where the initial values of $y(t)$, $y'(t)$, ..., $y^{(n-1)}(t)$ are given for $t = 0$ as elements of X , is studied by means of an analysis of relations pertaining to the theory of semi-groups and a concomitant association to equations of higher order.

NOTE ON A CLASS OF DIFFUSION EQUATIONS, by R. H. Geeslin. [1958] [4]p. [AF 18(600)1127] Unclassified

Published in Proc. Nat'l. Acad. Sciences, v. 44: 788-791, Aug. 1958.

This paper is an abstract of the author's dissertation which discusses the Cauchy problem for the diffusion equation (1): $(b(x)T_x)_x - T_t = 0$ in the space $L(-\infty, \infty)$, $b(x)$ being positive and continuous. Suggested by a paper of E. Hille [Jour. Analyse Math., v. 3: 81-196 (1954)], two cases are considered: Case 1, $B(-\infty) < \infty$ and $B(\infty) = \infty$; and case 2, $B(-\infty) = B(\infty) = \infty$; where $B(x)$ denotes $\int_0^x sb(s)^{-1} ds$. Let $\{w_n(x)\}$ and $\{\lambda_n\}$ be the characteristic values of the equation $Lu(x) = (b(x)u'(x))' = \lambda u(x)$. Then, in case 1,

$$(2): T(t)f(x) = \int_{-\infty}^{\infty} K(x,s,t)f(s)ds,$$

$$K(x,s,t) = \sum_{n=1}^{\infty} w_n(x)w_n(s)\exp(\lambda_n t),$$

gives the solution of the Cauchy problem for every $f \in D(L)$. Under the further restrictions:

$$\int_{-\infty}^{\infty} |w_n(x)| dx < C_1 |\lambda_n|^p \text{ and } \sup_x |w_n(x)| < C_2 |\lambda_n|^p$$

($p > 0$), (2) is the solution of the Cauchy problem for every $f \in L(-\infty, \infty)$. If it is assumed that L is the infinitesimal generator of a semi-group of positive contraction operators on $L(-\infty, \infty)$ — such as the case in the case 2 — and the resolvent of L has the representation

$$R(\lambda, L)g(x) = \int_{-\infty}^{\infty} G(x,s,\lambda)g(s)ds \text{ (Re}(\lambda) > 0) \text{ with}$$

symmetric and continuous kernel G , then $G(x,s,\lambda)$ is completely monotonic and $K(x,s,t) =$

$$\lim_{\sigma \rightarrow \infty} (2\sigma)^{-1} \int_{-\sigma}^{\sigma} G(x,s,\lambda) e^{\lambda t} d\lambda \text{ for } t > 0 \text{ and for any fixed } c > 0. \text{ If } \left| \int_{-\infty}^{\infty} \lambda G(x,s,\lambda) ds \right| < 1$$

($\text{Re}(\lambda) > 0$), then (2) gives the solution of the Cauchy problem for every $f \in L(-\infty, \infty)$. (Math. Rev. abstract)

[REMARKS ON THE SYSTEM OF LINEAR DIFFERENTIAL EQUATIONS FOR AN INFINITE NUMBER OF UNKNOWNNS] Remarques sur les systemes des equations differentielles lineaires a une infinite d'inconnues, by E. Hille. [1958] [9]p. [AF 18(600)1127] Unclassified

Published in Jour. Math. Pures Appl., v. 37: 375-393, Oct.-Dec. 1958.

YAL.02:011; YAL.06:001, 002; YAL.07:001

Linear differential equations with an infinity of unknowns are treated in the paper. Some of the phenomena are presented in some simple cases applicable to the theory of random variables when the possible values of the variable form a denumerable set. Two special systems are studied which present a variety of striking singularities. The two systems are: $z'(t) = z(t)A$ (a differential system) and, $z_0(t) = \{z_k(t) = e^{-kt} - e^{-(k+1)t}\}$ (which is examined for zero solutions).

ON ROOTS AND LOGARITHMS OF ELEMENTS OF A COMPLEX BANACH ALGEBRA, by E. Hille. [1958] [12]p. (AF 18(600)1127) Unclassified

Published in Math. Ann., v. 136: 46-57, 1958.

Let B be a non-commutative Banach algebra having unit element e and let G be the group of regular or invertible elements of B. The paper is concerned with kth roots and logarithms of elements of G, i.e., solutions x of $x^k = a$, and $\exp x = a$. If x_1 and x_2 are distinct kth roots of a such that $\sigma(x_1) \cap \sigma(\omega^j x_2) = \emptyset$ for $j = 1, \dots, k-1$ and $\omega = e^{2\pi i/k}$ ($\sigma(b)$ = the spectrum of b), the x_1 and x_2 commute, and there exist k idempotents e_j , some of which may be zero, which commute with x_1 and x_2 and are such that $e_i e_j = \delta_{ij} e_j$, $\sum_j e_j = e$ and $\sum_j \omega^j e_j = x_1 x_2^{-1}$. The proof is based on properties of the spectrum of the operator $S(b)[x] = b^{-1}xb$ for b in G. Further, if $b^k = a$, and $\sigma(b) \cap \sigma(\omega^j b) = \emptyset$, $j = 1, \dots, k-1$, then there exists a neighborhood of a of which all points are kth powers of the elements in a neighborhood of b. The condition $\sigma(b) \cap \sigma(\omega^j b) = \emptyset$ can be weakened. Similar theorems are proved for logarithms; the operator $T(a)[x] = ax - xa$ replaces the operator $S(b)$ in their derivation. (Math. Rev. abstract)

A NOTE ON NONCOMMUTATIVE JORDAN ALGEBRAS, by L. J. Paige. May 1957 [4]p. (AFOSR-TN-57-230) (AF 18(603)58) AD 126527 Unclassified

Also published in Portugaliae Math., v. 16: 15-18, 1957.

Let L be an algebra over a field F of characteristic $\neq 2$, such that $x^2 = 0$ (all x in L) and such that there is a bilinear form $f(x,y)$ with values in F satisfying $f(x,y) = f(y,x)$, $f(x,yz) = f(xy,z)$ (all x, y, z in L). With t,

s in F, an algebra $A = A(L, f, t, s)$ is constructed as follows. A consists of matrices $\begin{pmatrix} a & \alpha \\ \beta & b \end{pmatrix}$ (a, b in F; α, β in L); addition and scalar multiplication of such matrices are defined in the obvious way, and multiplication by the rule

$$\begin{pmatrix} a & \alpha \\ \beta & b \end{pmatrix} \begin{pmatrix} c & \gamma \\ \delta & d \end{pmatrix} = \begin{pmatrix} ac + f(\alpha, \delta) & a\gamma + \alpha d + t\beta\delta \\ c\beta + b\delta + s\alpha\gamma & f(\beta, \gamma) + b^2 \end{pmatrix}.$$

Then A is flexible, of degree 2, and hence is a non-commutative Jordan algebra. A is simple if and only if the form f is non-degenerate on L. In particular, if L is a semisimple Lie algebra of characteristic 0 and f is its Killing form, A is simple. (Math. Rev. abstract)

ON JORDAN ALGEBRAS WITH TWO GENERATORS, by N. Jacobson and L. J. Paige. [1957] [12]p. (AF 18-(603)58) Unclassified

Published in Jour. Rational Mech. and Anal., v. 6: 895-906, Nov. 1957.

A proof is given that the free non-associative Jordan algebra J_0 with two generators is special. The sub-algebra relative to Jordan multiplication generated by two generators in a free associative algebra F is used to develop a basis for an inductive definition. From the procedure used for J_0 , a basis is determined for J, a free Jordan algebra, which defines a set S in J in 1 - 1 correspondence with the J_0 basis. A sufficiency proof for the basis is given by showing that $\{S\}^2 \subset \{S\}$, where $\{S\}$ is the space spanned by S.

SPECTRAL REPRESENTATION OF SEMIGROUPS OF NORMAL OPERATORS, by C. I. Tulcea. [1958] [2]p. (AF 49(638)153) Unclassified

Published in Proc. Nat'l. Acad. Sciences, v. 44: 44-45, Jan. 1958.

Let G be a locally compact group with Haar measure μ ; S a subset of G with: (1) $xy = yx \in S$ for all x, y in S; (2) $\mu(U) > 0$ for all non-void $U \subset S$ open in S. Let E be the space of characters on S endowed with the topology of uniform convergence on compact sets. If \mathcal{Z} is a class of relatively open and compact sets in S which covers S and $R = \{r(X) \mid X \in \mathcal{Z}\}$ is a set of real numbers not less than one, let $E(R)$ be the subspace of characters $\chi \in E$ with $|\chi(t)| \leq [r(X)]^{1/2}$ for $t \in X, X \in \mathcal{Z}$. Let H be a

YAL.08:001 - YAL.08:004

Hilbert space and let $\alpha(t) = U_t$ be a weakly continuous map of S into the set of bounded normal operators on H such that $U_t U_s = U_{ts}$ for $t, s \in S$ and $\|U_t\| \leq [r(X)]^{1/2}$ for $t \in X, X \in \mathcal{U}$. The following theorem is stated. There exists a unique spectral family of measures $(\mu_{x,y})_{x,y \in H}$ on $E(R)$ such that for $t \in S, x, y \in H$, we have $(\alpha)(U_t x | y) = \int E(R) X(t) d\mu_{x,y}(X)$; $(\beta) \|\mu_{x,x}\| = \|x\|^2$ for all $x \in H$, if and only if for every $x \neq 0$ there is a $t \in S$ with $U_t x \neq 0$. If E itself is locally compact and S has a non-void interior and is separable, then a similar theorem holds for the integral taken over all of E . (Math. Rev. abstract)

THE STRUCTURE OF SPECTRAL LINES FROM PLASMAS, by H. Margenau and G. W. Landwehr. Jan. 1, 1957, 1v. Incl. diagrs. tables, refs. (AFOSR-TN-57-56) (AF 18(603)15) AD 115095 Unclassified

Also published in Rev. Modern Phys., v. 31: 569-615, July 1959.

A fairly detailed summary and an incisive critique of the present state of the plasma broadening problem is presented. The state is shown to be unsatisfactory in several minor respects (the treatment of the cooperation of electrons and ions is still rather intuitive and is not based on a rigorous analysis; approximations connected with the use of sum rules in the section) and a major one (under study), the quantum theory of second-order Stark broadening by electrons. The statistical theory and impact-theory, velocity-broadening or phase-shift broadening theory of plasma line-broadening theory are surveyed.

THE BALMER LINES AS INDICATORS OF THE PHYSICAL STATE OF A PLASMA (Abstract), by H. Margenau. [1957] [1]p. [AF 18(603)15] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 85, Jan. 30, 1957.

This paper reports new results of a theoretical study concerning the structure of the Balmer lines emitted in a plasma of high ion density. Reliance on the Holtsmark theory leads to two errors: (1) the theory itself requires modifications, and (2) the effect of the electrons becomes important and must be included. It is to be

shown particularly how point (2) can be treated and how the electrons modify the Holtsmark shape. The departures from that shape depend on the temperature as well as the density of electrons and should provide, in principle, an independent measure of the electron temperature. Point (1) is to be left for casual discussion.

PRESSURE INDUCED SATELLITES (Abstract), by L. Klein. [1957] [1]p. [AF 18(603)15] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 54, Jan. 30, 1957.

A qualitative suggestion by Preston and others is utilized in an attempt to formulate a quantitative theory of the side bands accompanying the absorption lines of the alkali spectra. In accordance with that hypothesis a suitable set of interaction energy curves for the radiating atom-perturber configuration were chosen; and the statistical theory as formulated by Margenau was used. It is shown that a very general set of potential energy curves cannot lead to results in agreement with the data of Ch'en or Robin. It is suspected that the statistical theory (in its present formulation) does not account for the satellite band phenomena, no matter how peculiar the interaction curves may be, and that a model including the perturber motions (now under study) is required to explain the facts.

STARK EFFECTS IN LINE BROADENING, by H. Margenau and M. B. Lewis. [Jan. 1957] 23p. [AF 18(603)15] Unclassified

Presented at Internat'l. Colloquium on the Optical and Acoustical Properties of Compressed Fluids and Molecular Interactions, Laboratoires de Bellevue, France, July 1-6, 1957.

Also published in Phys. Rev., v. 106: 244-250, Apr. 15, 1957.

Earlier calculations, based on customary radiation theory, fail to yield a meaningful finite answer for the second-order Stark effect upon line broadening (Part I). The reason for this occurrence is found in the assumption that, at some definite time, the radiating atom, as well as the perturbing electron, is in a precise energy state. When the electron is represented in a suitable way by a wave packet, a finite line width results

YAL.08:005, 006; YAL.03:007, 008

(Part II), and this answer agrees within reasonable limits with that of the classical impact theory, provided certain conditions, enumerated at the end of Part II, are satisfied. (Contractor's abstract)

STATISTICAL BROADENING OF SPECTRAL LINES EMITTED BY IONS IN A PLASMA, by M. [B.] Lewis and H. Margenau. [1958] [4]p. incl. diagr. tables. (AF 18(603)15) Unclassified

Published in Phys. Rev., v. 109: 842-845, Feb. 1, 1958.

The Holtsmark theory of line broadening omits the factor $e^{-V_{ij}/kT}$ in the evaluation of probabilities, where V_{ij} is the Coulomb interaction between the i th and the j th ions. This leads to serious errors in the wings of a line where frequency shifts arise from close encounters which are inhibited by the Boltzmann factor. In part I of the present article a consistent binary approximation to the line shape is given, the assumption being made that only a single perturber is involved in a collision. Part II treats the case of many particles, retains V_{ij} for all perturbers j interacting with a single radiating ion i , but ignores forces between the perturbers themselves. Comparison is made with other treatments. (Contractor's abstract)

FINE STRUCTURE PRESSURE EFFECTS (Abstract), by L. Klein and H. Margenau. [1958] [1]p. [AF 18(603)15] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 214, May 1, 1958.

The Van der Waals dipole-dipole perturbation energy is calculated for the fine structure levels of an alkali atom interacting with noble gas atoms. A general expression for the interaction energy caused by n simultaneously acting perturbers is developed for the $^2P_{1/2}$ and $^2F_{3/2}$ levels of the alkali atom. Shift and broadening of these two components are calculated as functions of noble gas density by the use of a statistical theory. It is found that the theory predicts a red shift which is nearly linear with density, the $^2F_{3/2}$ compo-

nent being shifted slightly more than the $^2P_{1/2}$. This is in agreement with the experimental data for heavy noble gases. The half-widths predicted are slightly less than the experiments indicate, but the discrepancy is within the limits of accuracy of the theory. Because of neglect of exchange effects and higher than dipole interactions, the treatment is restricted to densities below 100 rd.

STRUCTURE SENSITIVITY OF THE LOW-TEMPERATURE IONIC CONDUCTIVITY OF NaCl CRYSTALS, by D. B. Flachbach and A. S. Nowick. Jan. 1957 [16]p. incl. diagr. refs. (Technical note no. 5) (AFOSR-TN-57-22) (AF 18(600)850) AD 115056 Unclassified

Also published in Jour. Phys. Chem. Solids, v. 2: 226-231, 1957.

Measurements of the steady-state ionic conductivity of synthetic crystals of NaCl in the temperature range from 20° to 100°C are reported. It is found that annealing increases the conductivity over the value in the "as-received" condition, while plastic deformation followed by low-temperature recovery reduces it. Neither treatment affects the activation energy, which is found to be 1.07 ± 0.05 ev. The results further indicate that the structure sensitivity of the steady-state conductivity is not related to the space-charge polarization phenomenon. Comparison of the present data with earlier results on the structure sensitivity of the x-ray coloration of similar crystals suggests that in both cases the effects of thermal and mechanical treatment are probably due to changes in the state of dispersion of impurities.

RECOVERY OF INTERNAL FRICTION AND ELASTIC CONSTANTS, by A. S. Nowick. [1957] [30]p. incl. diagr. tables, refs. (AFOSR-TN-57-447) (AF 18(600)850) Unclassified

Also published in "Creep and Recovery"; a Seminar, Cleveland, Ohio (Oct. 6-7, 1956), Cleveland, Amer. Soc. for Metals, 1957, p. 146-175.

A freshly cold-worked metal shows a modulus defect and a relatively high value of internal friction due to the presence of dislocation loops which are capable of bowing out under an applied stress. Recovery of the damping and modulus after deformation is extremely rapid, so that minutes after deformation at room temperature (even of a high melting point metal) large

changes in these properties already have taken place. The modulus defect and internal friction in heavily deformed metals are attributed to the relatively free dislocations within the subgrain structure, and are regarded as not influenced by dislocations that form the subgrain boundaries. The dependence of damping and modulus defect on deformation temperature is such that (for equivalent anneals) the effects are larger the higher the deformation temperature. Two theories of the recovery of the damping and modulus are discussed. The first theory assumes that point defects created by the deformation pin the dislocation segments to produce recovery, while the second considers that dislocation rearrangement is responsible for the recovery.

SOME TRANSIENT ELECTRICAL EFFECTS OF PLASTIC DEFORMATION IN NaCl CRYSTALS, by D. B. Fischbach and A. S. Nowick. Aug. 1957 [41]p. incl. diagrs. refs. (Technical note no. 6) (AFOSR-TR-57-55) (AF 18(600)850) AD 136474 Unclassified

Also published in Jour. Phys. Chem. Solids, v. 5: 302-315, 1958.

Transient electrical effects of plastic deformation in NaCl crystals have been investigated. Two such effects have been observed: (1) a temporary increase in the ionic conductivity; and (2) a deformation-induced charge flow with no applied electric field. The first effect, which is observable for about an hr at room temperature, is attributed to excess vacancies freed by moving dislocations. It is suggested that an important source of these vacancies may be the break-up of associated complexes between cation vacancies and multivalent cation impurities. The second effect is observed only following inhomogeneous plastic deformation, and ceases abruptly when the stress increment producing it is removed. Possible sources for this deformation-induced charge flow are discussed and an explanation is offered in terms of electrically charged dislocations. (Contractor's abstract)

LATTICE IMPERFECTIONS IN METALLIC AND IONIC CRYSTALS, by A. S. Nowick. Final rept. July 1, 1953-Aug. 31, 1957, 6p. (AFOSR-TR-57-56) (AF 18(600)850) AD 136504 Unclassified

The work completed under this contract concerns the interaction between point defects and dislocations. This study was originally begun with the objective of utilizing certain properties of the alkali halide crystals which are uniquely adapted to the study of such

interactions as their electrical and optical properties. The work subsequently branched out into a study of the pinning of dislocations by x-irradiation through the use of precision elastic modulus measurements (obtained from resonant frequencies) and internal friction measurements. Finally, the work was further expanded to include the study of the modulus and internal friction of metals in relation to the pinning of dislocations by quenched-in defects. Each of the above mentioned branches of the work are described in further detail.

INFORMATION OBTAINABLE ON POLARIZATION OF μ^+ AND ASYMMETRY OF e^+ IN MUONIUM EXPERIMENTS, by G. Breit and V. W. Hughes. Mar. 13, 1957, 12p. incl. tables. (AFOSR-TN-57-117) (AF 18(600)771 and AF 18(600)1565) AD 120470 Unclassified

Also published in Phys. Rev., v. 106: 1293-1295, June 15, 1957.

The formation of the compound $\mu^+ + e^-$ (muonium) is considered as a tool for gaining information regarding the polarization of the μ^+ before their capture by the e^- and the asymmetry of the e^+ emission in the disintegration $\mu^+ \rightarrow e^+ + \nu + \bar{\nu}$. The detection of asymmetry effects is supposed to take place through the counting of e^+ . The effect of constant magnetic fields and of microwave induced transitions among magnetic substates of muonium is calculated with the conclusion that all of the experiments considered here determine in different ways the same combination of parameters describing the initial muon polarization and the asymmetry of e^+ emission in muon decay. VACUUM POLARIZATION EFFECTS IN PROTON-PROTON SCATTERING, by L. Gaurand, III. [1957] [51]p. incl. diagrs. tables, refs. (AFOSR-TN-57-420) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)771 and Office of Ordnance Research) AD 132499 Unclassified

Also published in Phys. Rev., v. 108: 1597-1610, Dec. 15, 1957.

The problem of vacuum polarization scattering of protons by protons is treated to first order in the vacuum polarization interaction. The phase shifts caused by the interaction are calculated, and the corresponding addition to the p-p scattering matrix is constructed, including exactly the effects on the phase shifts and scattering. Other electromagnetic and relativistic modifications

YAL.04:020 - YAL.04:023

of the Coulomb scattering amplitudes are also examined in the limit of low energies. Numerical results are given for the vacuum polarization contributions to the p-p scattering cross section over the energy range 1.4 to 4.2 mev. It is found that vacuum polarization scattering may easily be confused with nuclear p wave scattering.

THEORY OF THE ISOTOPE SHIFT, by G. Breit.
Jan. 8, 1958, 33p. diagrs. refs. (AFOSR-TN-58-30)
(AF 18(600)771) AD 148069 Unclassified

Also published in Rev. Modern Phys., v. 30: 507-516,
Apr. 1958.

Existing theories of the spectroscopic isotope shift are reviewed and the assumptions made in them are examined. In the early development of nuclear physics the existence of agreement as to order of magnitude between expectation and experiment was of interest in corroborating general views regarding nuclear structure. Later more difficult attempts to obtain quantitative agreement naturally suffer from arbitrariness in the assumptions regarding the effect on the nuclear charge distribution of adding a neutron to those already present. There is no doubt regarding the correlation between the variations of the intrinsic quadrupole moment of the collective model and the magnitude of the isotope shifts, but the quantitative aspects of this interpretation are not settled. Similarly it is not clear which of the various proposals for the understanding of even-odd staggering has the closest bearing on the observed phenomenon and the smallness of the isotope shift in comparison with expectation on the incompressible fluid model with the $A^{1/3}$ proportionality of the nuclear radius is understood only qualitatively. There appears to be no reason for believing, however, that the observed facts will not agree with currently accepted models of nuclear structure when these are developed to the point of making it possible to perform the necessary calculations. The main reason for the difficulty in providing a quantitatively reliable treatment is the extreme smallness of the change in nuclear charge distribution which often corresponds in order of magnitude to a change in the nuclear radius by 1/600 of its value.

Unclassified

Also published in Phys. Rev., v. 111: 1597-1603, Sept. 15, 1958.

The effects of including vacuum polarization scattering in angular momentum states with $L > 0$ and the effects of employing the relativistic value of the Coulomb scattering parameter η_r rather than its non-relativistic value η have been considered in the analysis of low-energy p-p scattering data. It has been found that about half of the apparent mean p wave phase shift present in published data, in the energy range 1.8 - 4.2 mev, should be attributed to this vacuum polarization scattering. A further decrease in magnitude of the p wave is obtained when η_r is employed, rather than η . Both the vacuum polarization scattering in states with $L > 0$ and the employment of η_r rather than η result in a contribution to the f function which does not vary linearly with energy. The effects of these contributions on the coefficients of a polynomial expansion of $f(E)$ are ascertained with reference to p-p scattering data in the energy range 0.2 to 7.5 mev. The object of the work is more that of investigating the possible magnitude of effects on conclusions drawn from data due to applying the various corrections than that of deriving final phase shift values. EFFECTS OF ATOMIC ELECTRONS ON p-p AND n-p SCATTERING, by G. Breit. Aug. 15, 1958, 6p. (AFOSR-TN-58-730) (AF 18(600)771) AD 162265 Unclassified

Also published in Phys. Rev. Letters, v. 1: 200-203,
Sept. 15, 1958.

Consideration is given to the possibility that the screening effect, hitherto assumed to be small, may prove to be non-negligible at low energies (<10 mev). Coulomb excitation of the molecular electrons and acceleration of the target atoms are considered. These effects interfere with the employment of low energy data for p-wave anomaly detection and increase the relative importance of higher energy work.

NATURAL LINE WIDTH FOR TRANSIENT EXCITATIONS, by G. Breit and M. H. Hull, Jr. Sept. 25, 1958, 26p. diag. (AFOSR-TN-58-906) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)771 and Atomic Energy Commission under AT(30-1)1807) AD 204516

Unclassified

Also published in Astrophys. Jour., v. 129: 456-467, Mar. 1959.

The absorption of a photon by a material system with 4 participating levels A B C D is studied with special attention to the case in which the levels are the result of combining excitations of separate systems from a - a' and from b - b' with the identification of A B C D with (a,b), (a,b'), (a',b), (a',b') respectively. The absorption width of the BD transition is shown to approach the limit expected for the decoupled system as the parameters corresponding to the decoupled condition are made to approach their special values. It is similarly shown how the formulas for rescattering by the general system approach those for the decoupled system. It is found that the procedure of folding the radiation widths of upper and lower levels in a radiation transition in order to obtain the width of an absorption or emission line must be used with care, and that the circumstances entering the excitation of the levels need consideration. Correlations in photon magnitudes in double photon emission and absorption enter some of the considerations. The consideration of the double photon emission solution is used as an illustration of the role of the ratio of the strength of coupling between electrons to the natural line width. Also published in Phys. Rev., v. 114: 830-837, May 1, 1959.

In connection with a proposed explanation of the anisotropy observed in the scattering of neutrons from various elements at energies of a few hundred kev, the order of magnitude of the neutron polarizability is estimated making use of data on photopion production. A

polarizability α greater than $\sim 2 \times 10^{-42} \text{ cm}^3$ appears unlikely on this basis. There remains an unexplained factor of ~ 50 which has to be accounted for either in the polarizability or by providing another explanation of the neutron scattering anisotropy. The possibility of explaining the anisotropy on the basis of ordinary scattering theory does not appear to be excluded. The exact proportionality of the coefficient of $\cos \theta$ to the neutron momentum does call for an r^{-4} type of potential, but it is not clear whether the energy dependence of the coefficient is sufficiently well determined by the data and whether the compound nucleus features of the interaction are capable of explaining the observations. Nevertheless a few less usual effects are estimated. These are the interaction of the neutron moment with the vacuum polarization charge and with the external electric field of the nucleus as well as its interaction with the electric charge density at the nuclear surface. The latter is hard to distinguish from other nuclear effects. The former two effects are small and do not resemble the observed effects. (Contractor's abstract)

PRODUCTION OF TRIPLET P STATES OF HELIUM IN A BEAM (Abstract), by J. A. White, V. W. Hughes and others. [1957] [1]p. [AF 18(600)1565] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 37, Jan. 30, 1957.

The $M = +1$ magnetic substate of a refocused beam of metastable 3S_1 He atoms was selected by use of a wire stop in an atomic beam magnetic resonance apparatus. Unpolarized light from a low voltage, 60-w helium arc lamp (Osram spectral lamp) caused a defocusing of about 10% of the refocused beam, which corresponds to a detected signal of 2×10^{-14} amp. The defocusing (light flop) is interpreted as due to a change in M value which can be associated with the process of excitation of a 3S_1 atom to a 3P state and its subsequent decay back to the 3S_1 state. The use of optical filters indicated that the excitation is primarily to the $1s\ 2p\ ^3P$ states, which occurs at a wavelength of 10 830 Å. The amount of defocusing agrees in order of magnitude with the theoretical estimate. The production of the $n = 2, ^3P$ states of He in a beam should allow a high precision measurement of the fine structure separations of these states by a combined optical-microwave atomic beam magnetic resonance method.

ZEEMAN EFFECT OF NEON AND ARGON IN METASTABLE 3P_2 STATE (Abstract), by C. Drake, V. W. Hughes, and A. Lurio. [1957] [1]p. [AF 18(600)1565] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 37, Jan. 30, 1957.

The electronic g_J values of neon and argon in their metastable 3P_2 state have been measured by the atomic beam magnetic resonance method. The metastable atoms were produced in a glow discharge and detected by electron ejection from a wire. The magnetic field of about 550 gauss was calibrated by use of a Zeeman transition in the metastable 3S_1 state of helium. The theoretical g values were calculated to the experimental precision taking into account quantum electrodynamic and relativistic contributions and state perturbations. The experimental and theoretical results agree and are

	g_J (exptl.)	g_J (theoret.)
Ne	1.5009 ± 0.0001	1.5009 ± 0.0001
Ar	1.5009 ± 0.0001	1.5010 ± 0.0001

The Zeeman transition in the metastable 3P_2 state of krypton was observed with an intensity considerably less than that for Ne and Ar.

REMARKS ON FORMATION OF MUONIUM IN GASES (Abstract), by V. W. Hughes. [1957] [1]p. [AF 18(600)-1565] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 205, Apr. 25, 1957.

The existence of polarized μ^+ mesons from the π^+ decay and the angular asymmetry in the distribution of e^+ decays from μ^+ , which are associated with parity non-conservation, may make possible studies of the hyperfine structure (hfs ≈ 4500 mc/sec) of the bound state of a μ^+ meson and an electron (muonium). With this motivation estimates have been made of cross sections relevant to the formation of muonium in gases. At kinetic energies of order $(e^2/a_0)(m_\mu/m_e)$, for which the μ^+ meson's velocity is comparable to the velocities of electrons in a gas molecule, the cross section for the capture of an electron by a μ^+ meson is of the order πa_0^2 ; the cross section for the ionization of muonium is of similar magnitude. At sufficiently low kinetic energies so that the breakup of muonium is energetically forbidden the cross section is several orders of magnitude smaller. For a gas with an ionization energy less than the binding energy of muonium (13.5 ev) muonium formation competes with decay of the free μ^+ meson and with attachment of μ^+ to a gas molecule. For a gas with ionization energy

greater than 13.5 ev the μ^+ meson may fall below the threshold for muonium formation due to inelastic and elastic collisions and will then decay without forming muonium.

ATOMIC g_J VALUES FOR NEON AND ARGON IN THE METASTABLE 3P_2 STATE (Abstract), by A. Lurio, C. Drake and others. [1958] [1]p. [AF 18(600)1565] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 8, Jan. 29, 1958.

The ratios of the electronic g_J values of Ne and A in their metastable 3P_2 state to the g_J of He in its metastable 3S_1 state have been redetermined by the atomic beam magnetic resonance method using separated oscillatory fields. At a magnetic field of 550 gauss transitions between Zeeman levels of Ne or A and of He are observed at frequencies of approximately 1157 mc/sec and 1543 mc/sec. If the known value $g_J(\text{He}) = 2[1.001183(8)]$ is used, the results obtained are $g_J(\text{Ne}, ^3P_2)_{\text{exptl}} = 1.500888(5)$ and $g_J(\text{A}, ^3P_2)_{\text{exptl}} = 1.500964(8)$. Relativistic corrections to the Lande g_J value of 1.5 for a 3P_2 state have been computed using Slater wave functions. If these corrections are combined with the spin g_s value for the electron of $g_s = 2(1.0011596)$, the following theoretical values are obtained: $g_J(\text{Ne}, ^3P_2)_{\text{theoret}} = 1.50088$ and $g_J(\text{A}, ^3P_2)_{\text{theoret}} = 1.50106$. The agreement of the experimental and theoretical g_J values for Ne is excellent; the discrepancy for A may be due to the effects of configuration interaction which are not included in the theoretical value.

DEPOLARIZATION OF POSITIVE MUONS IN GASES; SEARCH FOR MUONIUM (Abstract), by V. W. Hughes, A. Lurio and others. [1958] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)1565], Office of Naval Research, and Atomic Energy Commission) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 51, Jan. 29, 1958.

The depolarization of positive muons stopped in various gases has been studied in an experiment similar to that of Garwin, Lederman, and Weinrich. The gases at pressures from 20 to 60 atmos were contained in a thin-walled stainless steel cylinder 12 in. in length and 6 in. in diameter. The peak and valley gated positron counting rates were measured at the appropriate values of the magnetic field which causes the precession of the muon spins. The fraction of the total counts which arises from muons stopping in the gas is between about 1/3 and 2/3. The following values are obtained for the ratios of peak counts (P) to valley counts (V):

YAL.09:008, 009

Gas and cylinder	Pressure (psi)	P/V
Cylinder alone	...	1.79 ± 0.09
A	825	1.25 ± 0.05
SF ₆	300	1.49 ± 0.06
SF ₆ + Xe	300(Xe-2)	1.54 ± 0.09
SF ₆ + NO	225(NO-90)	1.38 ± 0.18

FURTHER EVIDENCE FOR MUONIUM FORMATION IN N₂O (Abstract), by D. McColm, V. W. Hughes and others. [1958] [1]p. [AF 18(600)1565] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 229, May 1, 1958.

In a previous paper the particularly large depolarization of positive muons stopped in N₂O gas was reported for an experiment similar to that of Garwin, Lederman, and Weinrich. One explanation for the low observed value of (peak counts)/(valley counts) is the abundant formation of muonium. To test this possibility further the effect of a small magnetic field H_z along the direction of the incoming muon beam on the positron counting rate parallel to this direction has been measured. The positron counting rate arising from μ-meson decays is observed under two field conditions: (i) H_z = 0 and a vertical field H_y = 2 gauss, (ii) H_z = 15 gauss; H_y = 2 gauss. A change in counting rate by a factor 1.09 ± 0.02 is found without correction for background. If π mesons are stopped in the gas, the corresponding measurement gives 1.01 ± 0.01. With the assumptions that all muons form muonium in its ground state and that the magnetic substates are unequally populated as expected for

initially polarized muons, a ratio of counting rates equal to about 1.16 is expected due to the retention of the polarization of the m = -1 magnetic substate in the H_z field. It is felt that the result of this experiment adds considerable support to the view that muonium formation occurs for muons stopped in N₂O.

MAGNETIC MOMENT OF MU-MESONIC ATOMS (Abstract), by V. W. Hughes and V. L. Telegdi. [1958] [1]p. [AF 18(600)1565] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 229, May 1, 1958.

Nonconservation of parity in the decay of π and μ mesons may make possible precise measurements of the magnetic moment of mu-mesonic atoms in their ground S_{1/2} state by the observation of Zeeman transitions. The magnetic moment, m, of the μ meson attached to a nucleus of charge +Ze and spin I = 0 differs from the magnetic moment, m_μ, of the free μ meson by a relativistic binding factor which can be calculated from the Dirac equation for the mu-meson atom. For a point charge model of the nucleus m = m_μ[1 - α²Z²/3], in which α is the fine structure constant. For an extended spherically symmetric nucleus, m = m_μ[1 - 2⟨T⟩/(3m_μc²)], in which m_μ = mass of mu meson and ⟨T⟩ is the expectation value of the kinetic energy of the mu meson in the mesonic atom. For lead, α²Z²/3 = 0.12. Since the radius of a mu-mesonic atom with large Z is of the order of the nuclear radius, the two expressions for the correction to the magnetic moment give values which differ by a substantial fraction of the correction itself (~1/2 for Pb). Hence, the precise measurement of these magnetic moments may offer a useful tool for the study of nuclear structure.

ALGEBRA

Algebras:

Lie algebras

CAL.09:009; RIA.01:001

Non-associative algebras

BCU.03:004; YAL.06:002

Non-associative rings and algebras; Lie Rings and algebras

BCU.03:001, 005; CHI.18:003; YAL.06:001, 002

Fields, Rings:

Valuations

HAR.10:003

Groups and Generalizations:

Classical groups, linear groups

NOR.07:003, 005

Finite groups

BCU.03:003

Group theoretic constructions, free groups, extensions

CHI.08:009; OSU.08:024

Matrix groups, representations, characters

CAL.03:024

Homological algebra

CHI.08:008; CHI.18:001, 002; COU.22:002

Linear algebra:

Eigenvalues and eigenvectors

BCU.02:002, 003, 008, 010; NCU.03:003-005

Forms and transformations

BCU.02:004-006, 009

Inequalities for matrices

BCU.02:004-006

Linear equations, matrix inversion, determinants

HAR.09:006; NCU.04:043

Matrices

BCU.02:002, 009, 010; CAL.09:007; COU.10:032, 033; COR.05:074; FRE.04:006; PIB.09:020; THM.03:002

Miscellaneous inequalities

BCU.03:002

Non-associative Rings and Algebras:

General

WAS.02:031

Polynomials:

Algebraic equations, roots

MIT.12:227

FOUNDATIONS, THEORY OF SETS, LOGIC

Applications of logic

NEU.01:015

Logical calculi, many-valued, modal

COR.05:065

GEOMETRY

Algebraic Geometry:

General theory of varieties, surfaces

HAR.10:001, 002, 004

Group varieties, Abelian, equivalence theories

MIT.02:002; NOR.02:005, 008

Complex Manifolds

IAS.05:016

Convex Domains, Distance Geometries:

Convex sets and geometric inequalities

IAS.11:001; MDU.01:004

Distance geometries

MDU.01:004

Theory of games

IAS.05:020

Convex Domains, Integral Geometry:

Extremum properties and geometric inequalities

MDU.09:062

Differential Geometry:

Classical differential geometry

LEH.02:001

Differential geometry in the large

WAY.04:002, 004

Vector and tensor analysis

WAY.04:001, 003

Differential Geometry, Manifolds:

Affine connections

PEN.11:001, 002

Deformation, rigidity

LEH.02:003, 004

Holonomy groups

PEN.11:002

Motions of manifolds

CAL.09:005; MIT.02:004; MIC.15:001

Riemannian manifolds

LEH.02:002; NOR.02:007

Manifolds, Connections:

Riemannian geometry

MIC.15:001

MATHEMATICAL ANALYSIS

HEB.01:009; NYU.06:027

Approximations and Expansions:

Approximate quadratures

PEN.04:008

Asymptotic approximations and expansions

HAR.09:006

Continued fractions

COL.06:001

Convergence, rate of convergence

HAR.05:014, 015

Degree of approximation, best approximation

HAR.05:003, 021

Orthogonal systems, expansions

WAS.02:028-030

Calculus of Variations:

Applications

NCU.05:025; NOR.08:002

Estimation theory (parametric case)
MIS.01:010, 016; NCU.04:033, 039, 042, 050;
NOR.08:001

Multistage decision procedures, sequential analysis
COR.13:013, 017; COU.06:027

Multivariate analysis
NCU.04:033, 036, 038-040, 044, 045, 055;
NCU.06:002, 003

Non-parametric methods and order statistics
NCU.04:039, 050; NCU.05:023, 025

Order statistics
MIS.01:015

Statistical engineering, quality control
COU.06:024, 025

Testing of hypotheses (parametric case)
MIS.01:010; NCU.04:034, 036, 037, 056;
NCU.05:022

THEORY OF NUMBERS

Theory of Numbers: Analytic
Zeta function, L-function, Dirichlet series
COR.05:061, 062, 067

Theory of Numbers: General
CHI.19:001

Diophantine equations
MIT.18:001

TOPOLOGICAL ALGEBRAIC STRUCTURES

Functional Analysis:
Commutative algebras
MIN.16:001

Infinite matrices
COR.05:074

Lie Groups and Algebras:
Lie groups
IAS.05:014, 024; JHU.08:002

Miscellaneous Topological Algebra:
Topological lattices
LSU.01:004

Topological semi-groups
LSU.01:002, 004-007, 009, 010

Topological Groups:
Semigroups and other generalizations
LSU.01:003

Topological Groups and Lie Theory:
Algebraic Lie theory
CHI.08:005

Groups of transformations
JHU.08:004, 005; PEN.03:005-007

Topological Groups and Lie Theory: (cont'd)

Lie algebras of groups, exponential mapping
CAL.09:006

Lie groups
LSU.01:008

Lie groups, real or complex fields
IAS.05:017, 022

Lie theory: general fields
NOR.07:001, 002, 004

Representations, group algebras
CAL.09:011; IAS.05:022; JHU.08:003, 006

Topological Vector Spaces, Functional Analysis:
Algebras of linear operators, representations of
groups and algebras
VRU.02:003; YAL.02:011

Applications of functional analysis; analysis of
differential and integral operators
MDU.01:009

Banach spaces
HEB.01:002, 004, 006; MDU.01:003

Function spaces: general
