ABSTRACT

The exact mathematical formulation is derived for the expected proportional coverage of a circular target from n weapons all aimed at the center of the target. It is assumed that the weapons fall in a circular normal distribution and that the lethal area of each weapon is a circle of specified radius (cookie-cutter lethality function). Tables are presented which are based on this formulation and which were computed on an IBM 7030 (STRETCH) computer. The computing time per case for coverages correct to two decimal digits is 0.25 to 0.50 seconds.

FOREWORD

The work described in this report was done in the Applied Mathematics Section of the Mathematics Research Group with Foundational Research funds No. R360FR103/2101/R0110101.

The problem was suggested to the author in May 1963 by Mr. F. C. Clodius of the Operations Research Division. The direct and inverse tables represented herein are an extension of tables requested by LTJG P. J. Mode of the Operations Research Division. The author wishes to acknowledge several stimulating discussions of the problem with Mr. Clodius and LTJG Mode.

The programming was done principally by Mr. E. L. Poole, with assistance from Mr. O. A. Thomas. Both are in the Programming Division.

Manuscript completion date was 31 August 1964.

I. DEFINITION OF THE PROBLEM

TYPICAL PATTERN FOR $n=5$

FIGURE 1

It is desired to compute the expected proportional damage to a circular target, T, of radius \bar{R} , and center at the origin of coordinates, by n weapons, each of lethal radius \bar{a} , all aimed at the center of the target, and such that their impact points are governed by a circular normal distribution with mean point at the center of the target and standard deviation σ . Figure 1 depicts a typical pattern for $n = 5$.

It is assumed that complete destruction occurs throughout the lethal area of each weapon, or circle of radius \bar{a} with the impact point of the weapon as center, and that no damage occurs outside this circle. Thus the lethality function, or conditional damage function, is the "cookie-cutter" function. Other lethality functions are considered in the literature, e.g., in [5], [8]. The damaged area of the target is shaded in Figure 1. The expected coverage, E , is by definition the expected damaged area of the target, in the sense of mathematical expectation, divided by $\pi\bar{R}^2$, the area of the target. Thus E is a fraction between zero and unity.

The problem is investigated in [3] by Germond, who derives an approximate solution under the implied assumption that the lethal radius \bar{a} is small relative to σ . This solution permits the calculations to be done in terms of either the exponential integral or the incomplete gamma function, both of which are tabulated functions, and is convenient for hand calculations. An approximation is first introduced in [3] when it is stated that the probability that a point at a distance r_0 from the center of the target is not within the lethal area of any of the bombs is $[1 - (\bar{a}^2/\sigma^2) \exp(-r_0^2/(2\sigma^2))]^n$ (where slight changes in the notation of [3] have been made to secure conformity with the present notation). This involves the assumption that the probability density function, $f(r, \theta) = [1/(2\pi\sigma^2)] \exp(-r^2/(2\sigma^2))$ for the circular normal distribution under consideration, is constant over a circle with center at (r_0, θ) and radius \bar{a} , and this assumption is not valid even approximately unless \bar{a}/σ is sufficiently small. If the density were constant over the specified circle, with the value $[1/(2\pi\sigma^2)] \exp(-r_0^2/(2\sigma^2))$, the probability that a given weapon would fall in the circle would be the product of this density and the area $\pi\bar{a}^2$, and it would follow that the probability that all of the n weapons would fall outside the circle would be $[1 - (\bar{a}^2/\sigma^2) \exp(-r_0^2/(2\sigma^2))]^n$, as stated in [3]. The final procedure derived in [3] gives a good approximation for small values of \bar{a}/σ , but is not exact except in a limiting sense as this ratio tends to zero.

The accuracy of the method of [3] depends primarily on the magnitude of \bar{a}/σ , falling off sharply as this ratio becomes significantly greater than unity, and falling off to a lesser extent as the value of n , the number of weapons, increases. Two numerical cases will be considered to indicate trends. In each case, the value given by the method of [3] will be compared with the value given by the exact method to be presented later in this report.

In Case 1 we consider the values $\bar{a} = 0.6$, $\bar{R} = 4$, $\sigma = 1$, and give n successively the values 1 and 20. When $n = 1$, the method of [3] gives $E = 0.10794$, and the method of the present report gives $E = 0.10884$, which is correct to five decimal digits. These high precision calculations are discussed in Section V. When n is increased to 20, the method of [3] gives $E = 0.87853$, and the exact method gives 0.88179, so that the agreement is not quite so good for the larger value of n .

In Case 2 we take $\bar{a} = 3$, $\bar{R} = 6$, $\sigma = 1$, $n = 6$. The method of [3] gives $E = 0.215$, whereas the exact method gives 0.483 (page 47 of the tables). The method of [3] here breaks down completely, not being valid for so large a value of \bar{a}/σ .

In Section 3, an expression is derived which is exact for all values of the parameters \bar{a} , \bar{R} , σ , n , as follows:

$$E = 1 - \frac{2}{R^2} \int_0^R [1 - P(a,r)]^n r \, dr \quad , \quad (1)$$

where the quantities \bar{R} , \bar{a} have been normalized with respect to σ to give R , a respectively; that is, $R = \bar{R}/\sigma$, $a = \bar{a}/\sigma$. Generally throughout the report, except where the contrary is indicated by the barred symbols, it is understood that $\sigma = 1$ and that the parameters R , a are the normalized ones. The function $P(a,r)$ is known as the circular coverage function, [1], [2], and is defined by

$$P(a,r) = e^{-\frac{r^2}{2}} \int_0^a e^{-\frac{x^2}{2}} I_0(xr) x \, dx \quad (2)$$

where $I_0(t)$ is the modified Bessel function of the first kind of order zero, [6]. The first partial derivatives of $P(a,r)$ are:

$$\frac{\partial P(a,r)}{\partial a} = a e^{-\frac{a^2+r^2}{2}} I_0(ar) \quad (3)$$

$$\frac{\partial P(a,r)}{\partial r} = - a e^{-\frac{a^2+r^2}{2}} I_1(ar) \quad (4)$$

where $I_1(t)$ is the modified Bessel function of the first kind of first order, [6].

II. METHOD OF COMPUTING EXPECTED COVERAGE

Although equation (1) provides an exact representation, in integral form, for the expected coverage E for all positive real values of the parameters a and R and all positive integer values of n, there is no known method, for integers n > 1, for evaluating the integral in closed form in terms of elementary functions and non-elementary functions for which efficient machine computing routines exist. For the special case n = 1, which is of interest in the study of other types of coverage problem (see [7]), a method does exist for computing E in closed form in terms of the exponential function, the circular coverage function, and the Bessel function I₁(t). This formula for the case n = 1 was deduced from the analysis of Germond in [4] and is stated in equation (5) below. A derivation is given in [7]. The formula, expressed as an expected proportional coverage of a target of radius R as in the present report, and designated here as E₀, is as follows:

$$E_0 = \frac{1}{R^2} [R^2 P(a,R) + a^2 P(R,a) - aRe^{-\frac{a^2+R^2}{2}} I_1(aR)] \quad (5)$$

where I₁(t) is the modified Bessel function of the first kind of first order, [6]. If this expression is multiplied by πR² to give the expected damaged area or average casualty area, A₀, the result makes obvious the symmetrical way in which a and R enter the formula:

$$A_0 = \pi[R^2 P(a,R) + a^2 P(R,a) - aRe^{-\frac{a^2+R^2}{2}} I_1(aR)] \quad (6)$$

The corresponding results in the analysis of the present report, taking n = 1 in equation (1) and then multiplying by πR², are

$$E = \frac{2}{R^2} \int_0^R P(a,t)t dt \quad (7)$$

$$A = 2\pi \int_0^R P(a,t)t dt \quad (8)$$

and it is proved in [7] that E₀ = E and A₀ = A.

For general positive integer values of n , the integral in equation (1) is evaluated by a method of numerical quadrature. The interval of integration, $[0, R]$, is partitioned by successive doubling of the number m of subintervals, starting with $m = 1$, then $m = 2, 4, 8, \dots$, until a preassigned criterion of accuracy is met. Rigorous upper and lower bounds, l and k respectively, for the value of E are computed at each stage. An upper bound for the error committed in taking $x \equiv (l + k)/2$ as an approximation to the value of E is then given by $(l - k)/2$. Since, as will be shown, $(l - k)/2$ never exceeds $1/m$, it can be concluded that a partition of $[0, R]$ into 2048 or fewer subintervals will always be sufficient for computing an approximation x which differs by less than 0.0005 from the true but unknown value of E , or for computing an approximation which is accurate to three decimal digits. In many cases in practice $(l - k)/2$ is much smaller than $1/m$, so that in these cases the actual number of subintervals required to compute an approximation of a specified accuracy is much smaller than the upper bound indicated by theory.

The method which is to be described for general values of n , and which has been programmed for the IEM 7030 (STRETCH) computer, is valid for the case $n = 1$, as it is for all positive integer values of n . However, for the case $n = 1$, the method referred to above, giving the result in closed form in terms of the Bessel function $I_1(t)$ and other functions for which efficient subroutines exist, is faster and more efficient than the general method, since it does not require a numerical quadrature with an unknown, possibly large, number of subintervals.

We now describe the general method of computing the expected coverage E from equation (1) by numerical quadrature. For this description, the following notation is convenient:

$$Q(r) \equiv [1 - P(a, r)]^n . \quad (9)$$

Equation (1) then takes the form

$$E = 1 - \frac{2}{R^2} \int_0^R Q(r) r dr . \quad (10)$$

It is assumed that normalized parameters a and R , and a positive integer n , have been assigned. We introduce the further notation

$$I \equiv \int_0^R Q(r) r dr \equiv \int_0^R [1 - P(a,r)]^n r dr \quad (11)$$

so that

$$E = 1 - \frac{2}{R^2} \cdot I \quad (12)$$

The principal problems are then the approximate evaluation of the integral I by numerical quadrature, and the determination of bounds for the associated error. The corresponding results for E then follow easily by equation (12).

The circular coverage function, $P(a,r)$, for fixed a , is a strictly decreasing function of r , as is shown by equation (4), and as is evident intuitively from the definition of this function as a

GEOMETRY OF INEQUALITIES (13)

FIGURE 2

probability, [1], [2]. Hence $Q(r)$ by its definition in equation (9) is a strictly increasing function of r . Hence in any interval $[r_0, r_1]$ such that $0 \leq r_0 < r_1 \leq R$, we have

$$Q(r_0) \int_{r_0}^{r_1} r dr < \int_{r_0}^{r_1} Q(r) r dr < Q(r_1) \int_{r_0}^{r_1} r dr, \quad (13)$$

or, performing the integrations of $\int r dr$,

$$Q(r_0) \frac{r_1^2 - r_0^2}{2} < \int_{r_0}^{r_1} Q(r) r dr < Q(r_1) \frac{r_1^2 - r_0^2}{2}. \quad (14)$$

To describe the method by which inequalities (14) are used to get upper and lower bounds for the value of the integral I , it is convenient to suppose for illustrative purposes that $R = 8$, and to divide $[0, 8]$ into 4 subintervals with the points $r = 0, 2, 4, 6, 8$, and subsequently into 8 subintervals. The process of halving the length of the subinterval at each stage of the numerical quadrature will then be clear.

Taking initially 4 subintervals as stated above, we define upper and lower integrals \bar{I}_4 and \underline{I}_4 as follows:

$$2\bar{I}_4 = Q(2)(2^2 - 0^2) + Q(4)(4^2 - 2^2) + Q(6)(6^2 - 4^2) + Q(8)(8^2 - 6^2) \quad (15)$$

$$2\underline{I}_4 = Q(0)(2^2 - 0^2) + Q(2)(4^2 - 2^2) + Q(4)(6^2 - 4^2) + Q(6)(8^2 - 6^2) \quad (16)$$

It is then clear from (14) that we have

$$\underline{I}_4 < I < \bar{I}_4. \quad (17)$$

We rewrite these in the forms

$$2\bar{I}_4 = + [Q(2) \cdot 2^2 + Q(4) \cdot 4^2 + Q(6) \cdot 6^2 + Q(8) \cdot 8^2] \\ - [Q(2) \cdot 0^2 + Q(4) \cdot 2^2 + Q(6) \cdot 4^2 + Q(8) \cdot 6^2] \quad (18)$$

$$2\underline{I}_4 = - [Q(0) \cdot 0^2 + Q(2) \cdot 2^2 + Q(4) \cdot 4^2 + Q(6) \cdot 6^2] \\ + [Q(0) \cdot 2^2 + Q(2) \cdot 4^2 + Q(4) \cdot 6^2 + Q(6) \cdot 8^2] \quad (19)$$

If we now divide the interval $[0,R]$ or $[0,8]$ into 8 sub-intervals by using all the points $0, 1, 2, \dots, 8$, and form the corresponding sums \bar{I}_8 and \underline{I}_8 , we find

$$2\bar{I}_8 = + [Q(1) \cdot 1^2 + Q(2) \cdot 2^2 + \dots + Q(7) \cdot 7^2 + Q(8) \cdot 8^2] \\ - [Q(1) \cdot 0^2 + Q(2) \cdot 1^2 + \dots + Q(7) \cdot 6^2 + Q(8) \cdot 7^2] \quad (20)$$

$$2\underline{I}_8 = - [Q(0) \cdot 0^2 + Q(1) \cdot 1^2 + \dots + Q(6) \cdot 6^2 + Q(7) \cdot 7^2] \\ + [Q(0) \cdot 1^2 + Q(1) \cdot 2^2 + \dots + Q(6) \cdot 7^2 + Q(7) \cdot 8^2] \quad (21)$$

The first brackets in equations (18), (19), (20), (21) are similar to each other (but no two are identical). The quantities in the first brackets in (18) and (20) are denoted as f (for $m = 4$ and $m = 8$ respectively). Similarly, the first brackets in (19) and (21) (not including the negative signs) are denoted as f_1 . Thus the quantities f, f_1 are defined for each m ($m = 1, 2, 4, 8, \dots$), and it is seen that, for a given m ,

$$f = f_1 + Q(8) \cdot 8^2 \quad (22)$$

or, in general,

$$f = f_1 + Q(R) \cdot R^2 \quad (23)$$

The second brackets in equations (18) and (20) (not including the negative signs) are denoted as h , for the pertinent value of m . The second brackets in (19) and (21) are denoted as g_1 (the notation g being reserved for a slightly different quantity to be introduced).

For general m ($m = 1, 2, 4, 8, \dots$), if R/m is denoted as δ , the sums f , f_1 , g_1 , h can be represented as follows:

$$f = \sum_{j=0}^m Q(j\delta) \cdot (j\delta)^2 = f_1 + Q(R) \cdot R^2 \quad (24)$$

$$f_1 = \sum_{j=0}^{m-1} Q(j\delta) \cdot (j\delta)^2 \quad (25)$$

$$g_1 = \sum_{j=0}^{m-1} Q(j\delta) [(j+1)\delta]^2 \quad (26)$$

$$h = \sum_{j=0}^{m-1} Q[(j+1)\delta] \cdot (j\delta)^2 \quad (27)$$

Also, for a reason which will become clear shortly, we define g as follows:

$$g = g_1 + Q(R) \cdot R^2 \quad (28)$$

From the definitions of f , f_1 , g , g_1 , h in equations (24) - (28), we have, extending equations (18) - (21) to general m , $m = 1, 2, 4, 8, \dots$,

$$\bar{I}_m = \frac{f - h}{2} \quad (29)$$

$$\underline{I}_m = \frac{g_1 - f_1}{2} \quad (30)$$

But, solving (24) and (28) for f_1 and g_1 and substituting in (30),

$$\underline{I}_m = \frac{[g - Q(R) \cdot R^2] - [f - Q(R) \cdot R^2]}{2} = \frac{g - f}{2} \quad (31)$$

and hence

$$\bar{I}_m = \frac{f - h}{2} \quad (32)$$

$$\underline{I}_m = \frac{g - f}{2} \quad (33)$$

For every value of m considered, $m = 1, 2, 4, 8, \dots$, we have

$$\underline{I}_m < I < \bar{I}_m, \quad (34)$$

as can be proved by applying inequalities (14) to each subinterval and summing.

We define upper and lower bounds, l and k respectively, for the expected coverage E , as follows:

$$l = 1 - \frac{2}{R^2} \underline{I}_m = 1 - \frac{2}{R^2} \left(\frac{g - f}{2} \right) = 1 - \frac{g - f}{R^2} \quad (35)$$

$$k = 1 - \frac{2}{R^2} \bar{I}_m = 1 - \frac{2}{R^2} \left(\frac{f - h}{2} \right) = 1 - \frac{f - h}{R^2} \quad (36)$$

Note that the upper bound l is associated with \underline{I}_m and the lower bound k with \bar{I}_m because of the minus sign in equation (12). We now have

$$k < E < l \quad (37)$$

and

$$l - k = \frac{(f - h) - (g - f)}{R^2}. \quad (38)$$

The number m of subintervals into which the interval $[0, R]$ is divided is increased by successive doubling, $m = 1, 2, 4, 8, \dots$, until we have

$$l - k \leq \epsilon, \quad (39)$$

where y is a preassigned tolerance, often taken as

$$y = 0.001 \quad (40)$$

But y is made an input parameter of the program to facilitate the use of values other than 0.001 if desired. Inequality (39) will necessarily be satisfied by taking a sufficiently large value of m , because of the relation $(l - k)/2 \leq 1/m$, as will be proved. Then if E_1 (denoted as x in the program) represents the approximation

$$E_1 = \frac{l + k}{2} \quad (41)$$

and E represents the true but unknown value of the expected proportional coverage, we will have

$$|E_1 - E| \leq \frac{y}{2}, \quad (42)$$

so that, if $y = 0.001$, the error is not greater numerically than 0.0005, as is required for three decimal digit accuracy.

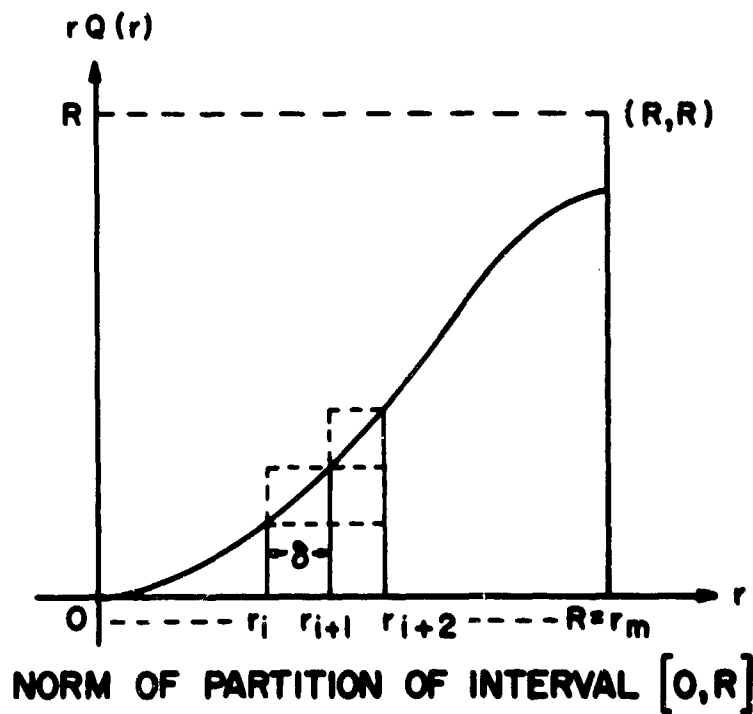

FIGURE 3

We now prove the statement that $(l - k)/2$, the upper bound for the error committed in taking $(l + k)/2$ as an approximation for the expected coverage E , is not greater than $1/m$, in the case in which the interval $[0, R]$ is divided into m equal subintervals in evaluating the integral in equation (1). This can be put in a more general form in case the interval of integration is partitioned into subintervals not all of which are of equal length, as is done in the computation of the inverse tables in the present report. Let δ denote the norm of the partition, i.e., the length of the longest subinterval. Then an upper bound for the error is δ/R , and this reduces to $1/m$ in the case in which m equal subintervals are used so that $\delta = R/m$. The upper bound will be derived in the more general form δ/R .

See Figure 3, which shows the graph of the function $r Q(r)$, the complete integrand of equations (10) and (11) (whereas in Figure 2 only $Q(r)$ is graphed). Suppose the interval $[0, R]$ is partitioned into m subintervals, not necessarily of equal length, by the points $0 = r_0 < r_1 < r_2 < \dots < r_m = R$. Since the integrand $r Q(r)$ is a strictly increasing function of r , upper and lower bounds, \bar{I}_m^* and \underline{I}_m^* respectively, for the integral I of equation (11) are provided by the expressions

$$\bar{I}_m^* = \sum_{j=0}^{m-1} r_{j+1} Q(r_{j+1}) (r_{j+1} - r_j) \quad (43)$$

$$\underline{I}_m^* = \sum_{j=0}^{m-1} r_j Q(r_j) (r_{j+1} - r_j) \quad (44)$$

These are not the same as the bounds $\bar{I}_m, \underline{I}_m$ of equations (29), (30), since here we are not performing the integration of

$\int r dr$ (see inequalities (14)) which is part of the development of

$\bar{I}_m, \underline{I}_m$. We shall show in fact that

$$\underline{I}_m^* < \underline{I}_m < I < \bar{I}_m < \bar{I}_m^* . \quad (45)$$

If bounds \bar{I}_m , \underline{I}_m , generalizing those of equations (29), (30), are worked out, based on inequalities (14), for the present situation where the subintervals are not necessarily all of the same length, they can be expressed in the forms

$$\bar{I}_m = \frac{1}{2} \sum_{j=0}^{m-1} Q(r_{j+1}) (r_{j+1}^2 - r_j^2) \quad (46)$$

$$\underline{I}_m = \frac{1}{2} \sum_{j=0}^{m-1} Q(r_j) (r_{j+1}^2 - r_j^2) \quad (47)$$

To prove that $\bar{I}_m < \bar{I}_m^*$, we have, using equations (43) and (46) and factoring $r_{j+1}^2 - r_j^2$ as $(r_{j+1} + r_j)(r_{j+1} - r_j)$,

$$2(\bar{I}_m^* - \bar{I}_m) = \sum_{j=0}^{m-1} Q(r_{j+1}) (r_{j+1} - r_j) [2r_{j+1} - (r_{j+1} + r_j)] \quad (48)$$

$$\bar{I}_m^* - \bar{I}_m = \frac{1}{2} \sum_{j=0}^{m-1} Q(r_{j+1}) (r_{j+1} - r_j)^2 \quad (49)$$

and since every term on the right is positive, it follows that $\bar{I}_m^* - \bar{I}_m$ is positive, or $\bar{I}_m < \bar{I}_m^*$. A very similar analysis shows that $\underline{I}_m^* < \underline{I}_m$, and thus (45) is established.

We next obtain a bound for the difference $\bar{I}_m^* - \underline{I}_m^*$. From equations (43) and (44),

$$\bar{I}_m^* - \underline{I}_m^* = \sum_{j=0}^{m-1} [r_{j+1} Q(r_{j+1}) - r_j Q(r_j)] (r_{j+1} - r_j) \quad (50)$$

and, denoting the norm of the partition, or $\max (r_{i+1} - r_i)$, by δ , we have

$$\bar{I}_m^* - \underline{I}_m^* \leq \delta \sum_{j=0}^{m-1} [r_{j+1} Q(r_{j+1}) - r_j Q(r_j)] \quad (51)$$

The sum now "telescopes" and gives the following results:

$$\bar{I}_m^* - \underline{I}_m^* \leq \delta[r_m Q(r_m) - r_0 Q(r_0)] \quad (52)$$

$$\bar{I}_m^* - \underline{I}_m^* \leq \delta R \quad (53)$$

since $r_m = R$, $Q(r_m) < 1$, $r_0 = 0$. Hence, from inequalities (45),

$$\bar{I}_m - \underline{I}_m \leq \delta R \quad (54)$$

Therefore, if $(\bar{I}_m + \underline{I}_m)/2$ is taken as an approximation for the value of the integral I , the upper bound $(\bar{I}_m - \underline{I}_m)/2$ for the error satisfies $(\bar{I}_m - \underline{I}_m)/2 \leq \delta R/2$. When the approximation for E is computed by equation (12), this error is multiplied by $2/R^2$. The final result is that an upper bound for the error committed in taking $(l + k)/2$ as an approximation for the value of E is $(\delta R/2) \cdot (2/R^2)$, or δ/R , as was to be proved.

It can also be shown that the use of the bounds \bar{I}_m and \underline{I}_m for the integral I , leading through equations (35) and (36) to the bounds l and k and then in equation (41) to the approximation E_1 for the expected coverage E , is in a sense better than the use of the trapezoidal rule for performing the numerical quadrature. For if the bounds \bar{I}_m^* and \underline{I}_m^* for the value of I were used, and these are cruder bounds than \bar{I}_m and \underline{I}_m as shown by inequalities (45), and if $(\bar{I}_m^* + \underline{I}_m^*)/2$ were then taken as an approximation for the value of I , one would have approximated I by the trapezoidal rule, as will be shown.

To make the argument general, suppose that it is desired to evaluate the integral

$$J = \int_a^b f(x) dx \quad , \quad (55)$$

GEOMETRY OF INEQUALITIES (56)

FIGURE 4

where $f(x)$ is a continuous monotonically increasing function of x on the interval $[a,b]$. The monotonic character of the integrand of equation (11) plays an essential role in the present discussion, and hence we impose the condition of monotonicity on the function $f(x)$. We partition the interval $[a,b]$ into m subintervals, not necessarily of equal lengths, by the points

$$a = x_0 < x_1 < x_2 < \dots < x_{m-1} < x_m = b .$$

In any subinterval $[x_j, x_{j+1}]$ we have, since $f(x)$ is an increasing function (see Figure 4),

$$f(x_j) (x_{j+1} - x_j) \leq \int_{x_j}^{x_{j+1}} f(x) dx \leq f(x_{j+1}) (x_{j+1} - x_j) \quad (56)$$

Summing over all the subintervals of the partition,

$$\sum_{j=0}^{m-1} f(x_j) (x_{j+1} - x_j) \leq \int_a^b f(x) dx \leq \sum_{j=0}^{m-1} f(x_{j+1}) (x_{j+1} - x_j) , \quad (57)$$

or, if we use the notation \underline{J} and \bar{J} for the first and last expressions, respectively, in inequalities (57),

$$\underline{J} \leq J \leq \bar{J} . \quad (58)$$

If we now denote by J_1 the approximation $(\underline{J} + \bar{J})/2$ for the value of J , we have, from the definitions of \underline{J} and \bar{J} ,

$$J_1 = \frac{\underline{J} + \bar{J}}{2} = \sum_{j=0}^{m-1} \frac{f(x_j) + f(x_{j+1})}{2} (x_{j+1} - x_j) \quad (59)$$

This is the trapezoidal rule for the approximation of the value of J using subintervals not necessarily all of the same length. If the subintervals are all equal, $x_{j+1} - x_j = h$ ($j = 0, 1, 2, \dots, m - 1$), it reduces to the familiar form

$$J_1 = \frac{1}{2} h [f(x_0) + 2f(x_1) + 2f(x_2) + \dots + 2f(x_{m-1}) + f(x_m)] \quad (60)$$

From inequalities (58) it follows that the absolute error in using J_1 as an approximation for J does not exceed $(\bar{J} - \underline{J})/2$.

Thus it has been shown that in the case of a monotonically increasing integrand $f(x)$, the approximation for the value of J

or $\int_a^b f(x) dx$ by J_1 or $(\underline{J} + \bar{J})/2$, where \bar{J} and \underline{J} are upper and

lower bounds formed in the manner shown in inequalities (57), is equivalent to the approximation obtained by the use of the trapezoidal rule. By similar methods to those used in obtaining inequality (53), it can be shown that

$$\bar{J} - \underline{J} \leq \delta [f(b) - f(a)] , \quad (61)$$

where δ is the norm of the partition or length of the longest sub-interval, and hence $(\bar{J} - \underline{J})/2$, the upper bound for the absolute error, does not exceed $\delta[f(b) - f(a)]/2$.

The foregoing analysis would apply directly if \bar{I}_m^* and \underline{I}_m^* , the bounds represented in equations (43) and (44), were used in evaluating I . The integrand $f(x)$ would correspond to $r Q(r)$, which is an increasing function of r , as has been pointed out. If $(\bar{I}_m^* + \underline{I}_m^*)/2$ were taken as the approximation for I , it would be equivalent to evaluating I by the trapezoidal rule. But the bounds \bar{I}_m and \underline{I}_m , which are actually used, are still closer, as shown by inequalities (45). It is in this sense that the method which is used can be said to be better than an alternative method in which the integral I of equation (11) is evaluated by the trapezoidal rule.

III. DERIVATION OF EQUATION (1)

In the derivation of equation (1), the first step is to get an expression for the probability that a specified point A at a distance r from the origin (center of target and aim point) is not inside the lethal area of any of the n bombs. A is inside the lethal area of any designated one of the bombs if and only if the impact point of that bomb is inside a circle with A as center and radius a . Distances here are the normalized ones $a = \bar{a}/\sigma$, etc. From the definition of the circular coverage function, [1], [2], this last probability, and hence the probability that A is inside the lethal area of the designated bomb, is $P(a,r)$. Hence the probability that A is not inside the lethal area of the specified bomb is $1 - P(a,r)$. The impact points of the bombs being independent of one another, the probability that the point A is outside the lethal areas of all of the bombs is $[1 - P(a,r)]^n$.

Now consider a small polar element of area $rdrd\theta$ of the target (Figure 5), and let (r,θ) denote any point of this element. Since, neglecting infinitesimals, every point of the element of area is at the same distance r from the origin, the probability that the element of area is outside the lethal area of all of the bombs, i.e., is not damaged, is $[1 - P(a,r)]^n$, and hence the probability that it is destroyed is $1 - [1 - P(a,r)]^n$. If it is destroyed, the contribution to the damaged area is $rdrd\theta$.

ELEMENT OF AREA OF TARGET

FIGURE 5

Hence the contribution to the expected damaged area is $\{1 - [1 - P(a,r)]^n\}rdrd\theta$. The total expected damaged area is the integral of this over the target, and the expected proportional coverage, E , is obtained by dividing this result by the area of the target, πR^2 . Thus we have

$$E = \frac{1}{\pi R^2} \int_{\theta=0}^{2\pi} \int_{r=0}^R \{1 - [1 - P(a,r)]^n\}rdrd\theta \quad (62)$$

Since the integrand is independent of θ , we can integrate immediately with respect to θ and obtain

$$E = \frac{2}{R^2} \int_0^R \{1 - [1 - P(a,r)]^n\}rdr \quad (63)$$

The first term of the integrand here can be integrated to give $(2/R^2) \cdot (R^2/2)$ or 1, and thus we have the desired result

$$E = 1 - \frac{2}{R^2} \int_0^R [1 - P(a,r)]^n r dr, \quad (64)$$

which is equation (1).

The foregoing proof is not entirely above criticism from the point of view of mathematical rigor. A completely rigorous proof, leading to the same result, has been worked out, but it would make this section excessively long.

IV. DESCRIPTION OF TABLES

There are two tables, a direct table giving expected coverage E as a function of a, R, and n, and an inverse table giving n as a function of a, R, and E; that is, the minimum number of bombs which will give at least a specified E with specified values of a and R. All values of a and R are normalized values. A total of 68 values of a and 57 values of R have been specified for both the direct and the inverse tables. These values are as follows:

$$a = 0.005(0.005)0.05(0.01)0.10(0.02)0.20$$

$$(0.05)1(0.1)2(0.2)4(0.5)10 ;$$

$$R = 0.05,0.1(0.1)4(0.5)12 .$$

For the direct tables, $n = 1(1)20$, and for the inverse tables, $E = 0.05(0.05)0.95$.

In the direct tables, n is constant on a given page, a is constant on each line and R on each column. This table was computed with the tolerance $y = 0.01$, so that the maximum error is 0.005. Nevertheless, the results are printed to three decimal digits, since the actual error in general is substantially less than the maximum possible error.

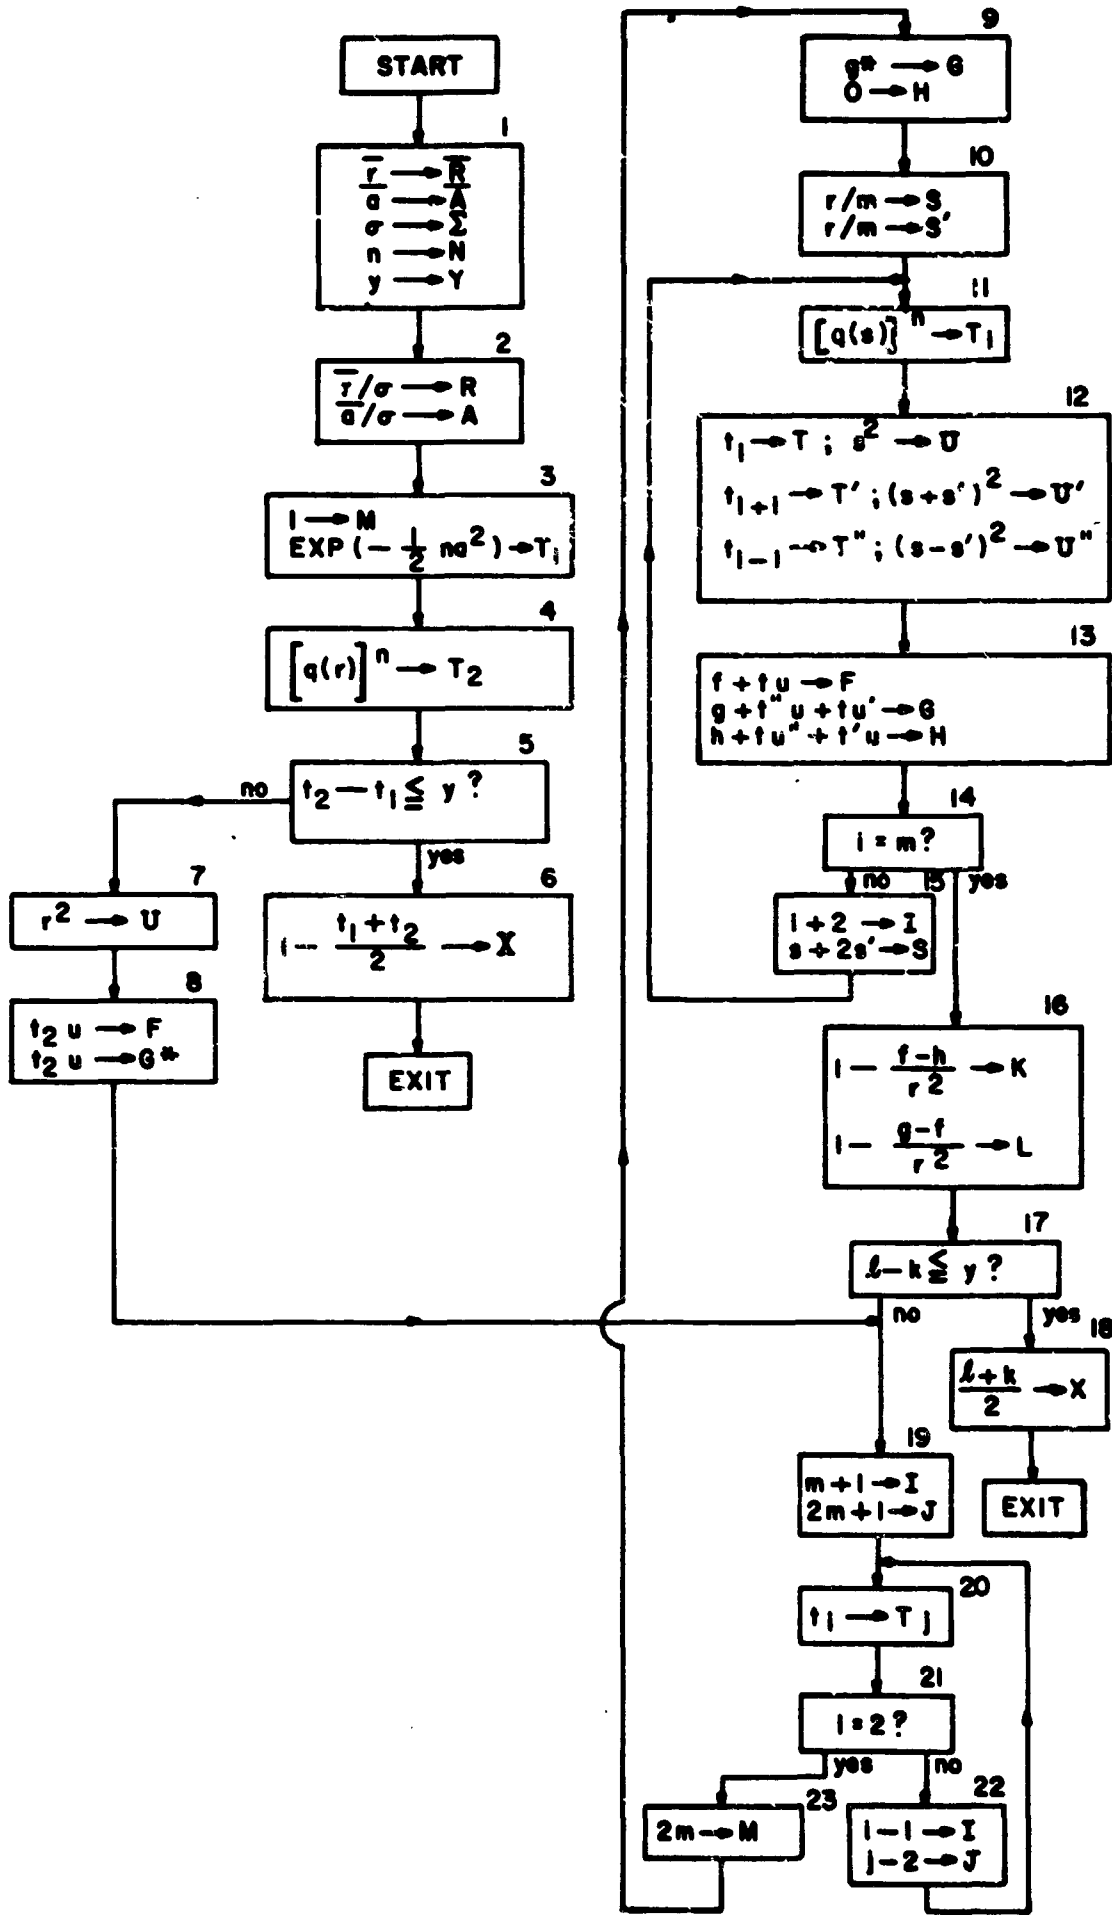

In the inverse tables, E is constant on each page, a on each line, and R on each column. The notation *** means "more than 999". If it is found that 999 bombs are insufficient to give the required E for given values of a and R, this notation is printed and no further attempt is made to determine the exact value of n. Although 68 values of a have been specified, only 60 lines of data are printed on each page in the inverse tables. If the line for some value of the lethal radius a consists entirely of the symbol ***, so will all lines for smaller values of a. If one line consists entirely of 1's, so will all lines for larger values of a. Advantage is taken of these facts to reduce the number of lines of data per page to 60 instead of 68.

V. MACHINE COMPUTING PROGRAM

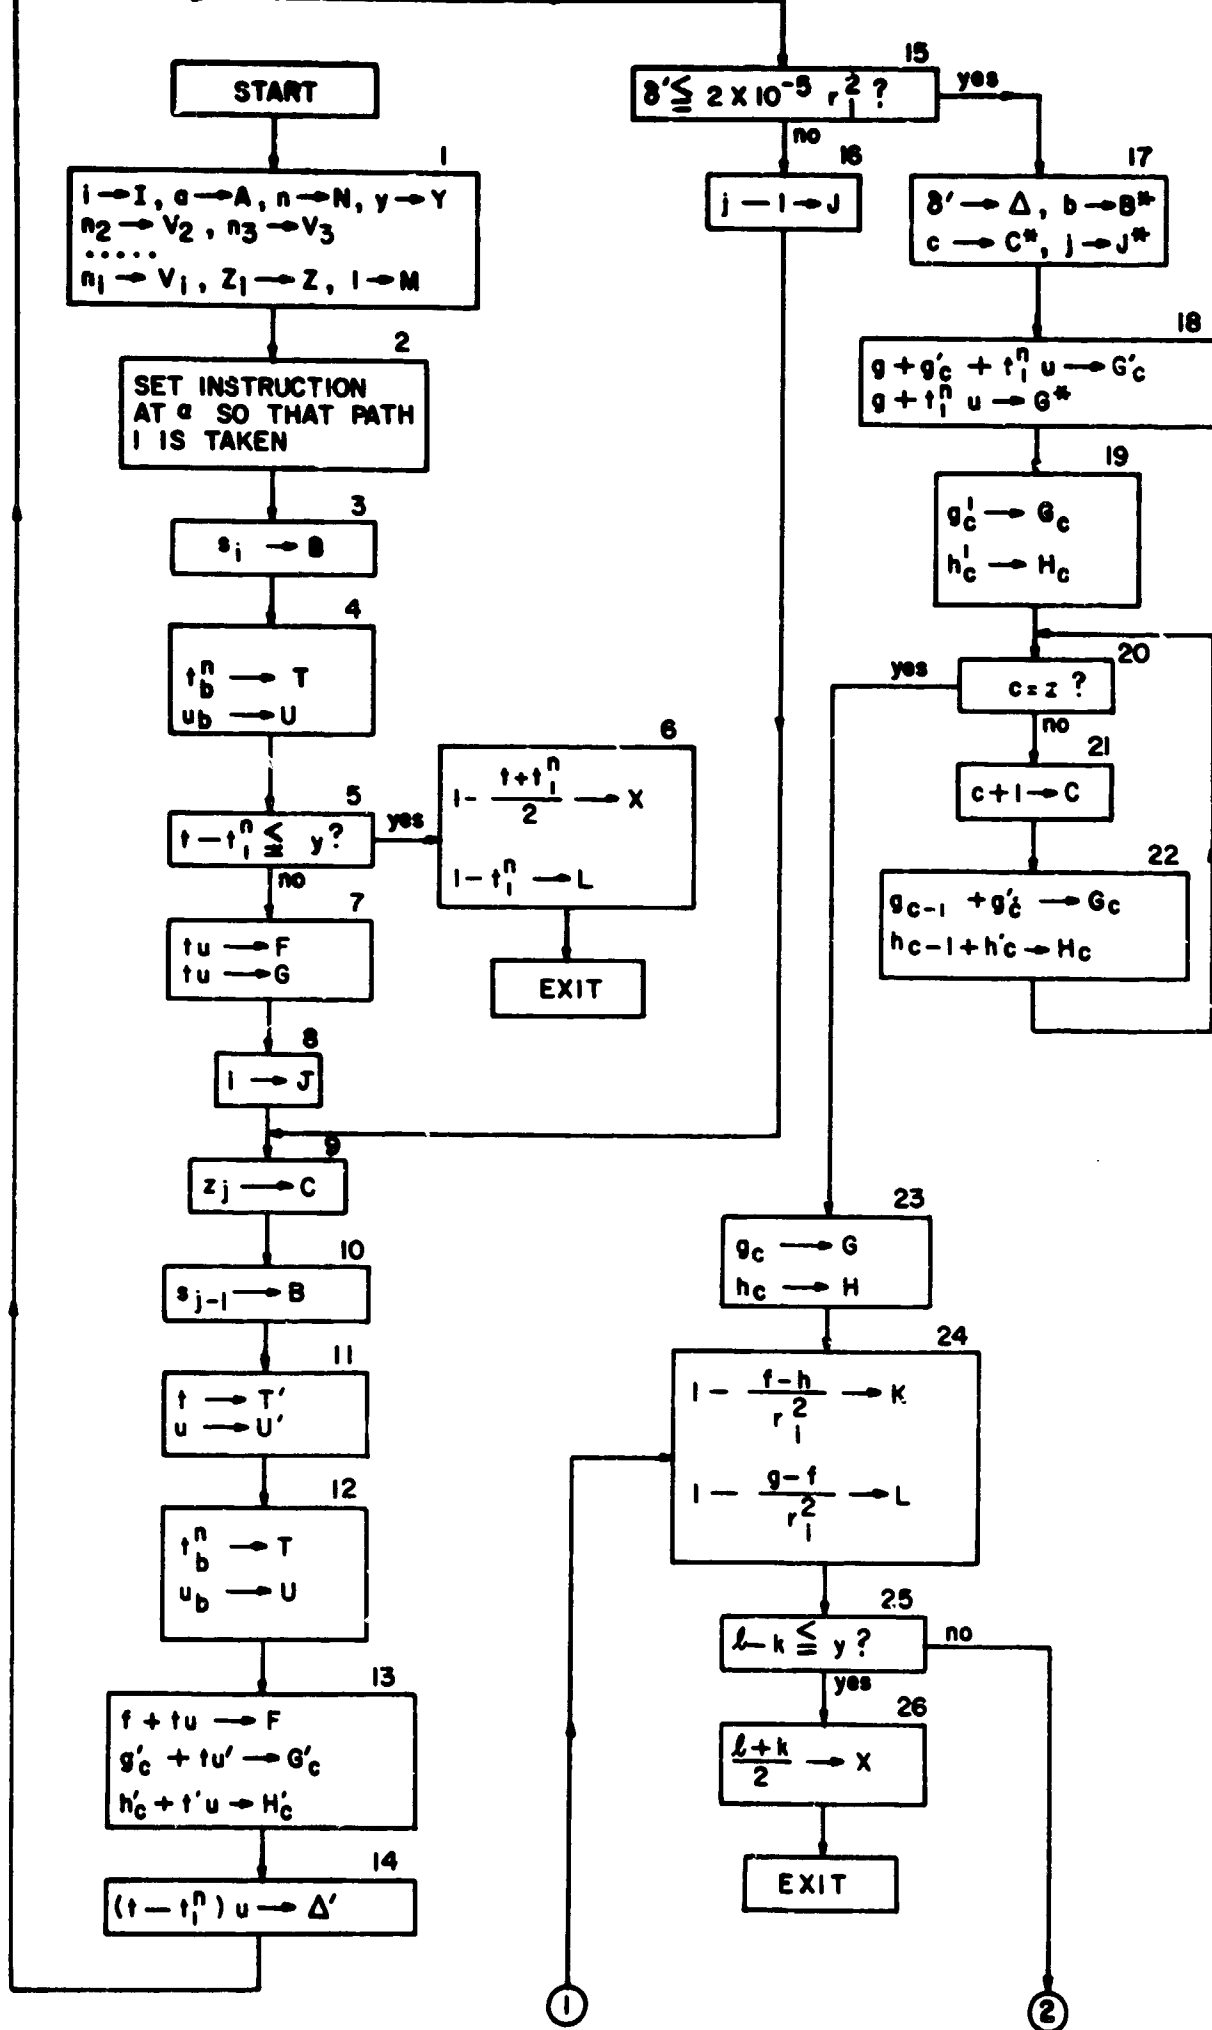

The analysis which has been given is used in a program represented in Flow Chart 1. Any positive real values of \bar{a} , \bar{R} , σ and the tolerance y can be entered at Box 1 of the flow chart, and any positive integer value of n . This flow chart follows a practice which is common in programming, of denoting a machine location by a capital letter and the number stored in the location by the corresponding small or lower case letter. Thus the numbers \bar{a} and y are entered in locations \bar{A} and Y respectively at Box 1. A special comment is required with regard to the target radius, which was denoted as \bar{R} (unnormalized) or R (normalized) in the foregoing analysis, while r was the variable of integration. In the flow chart, however, \bar{r} is the unnormalized and r the normalized target radius, and \bar{R} and R the corresponding locations, in accordance with the programming convention referred to. The normalized target radius r and lethal radius a are computed at Box 2 and stored in locations R and A .

If the tolerance is met by using only one subdivision of $[0, R]$, i.e., by taking $m = 1$, the program makes an early exit at Box 6. This is based on the following considerations. If $m = 1$, it is found that l and k , equations (35), (36), are given by $l = 1 - Q(0)$, $k = 1 - Q(R)$, where $Q(r)$ is as defined in equation (9), and hence $l - k = Q(R) - Q(0)$. $Q(0)$ and $Q(R)$ are placed in locations T_1 and T_2 respectively at Boxes 3 and 4, and the difference, $t_2 - t_1$, is compared with the tolerance y at Box 5. If the tolerance is met, the result, $(l + k)/2$ or $1 - (t_1 + t_2)/2$, is computed and placed in the output location, X , at Box 6.

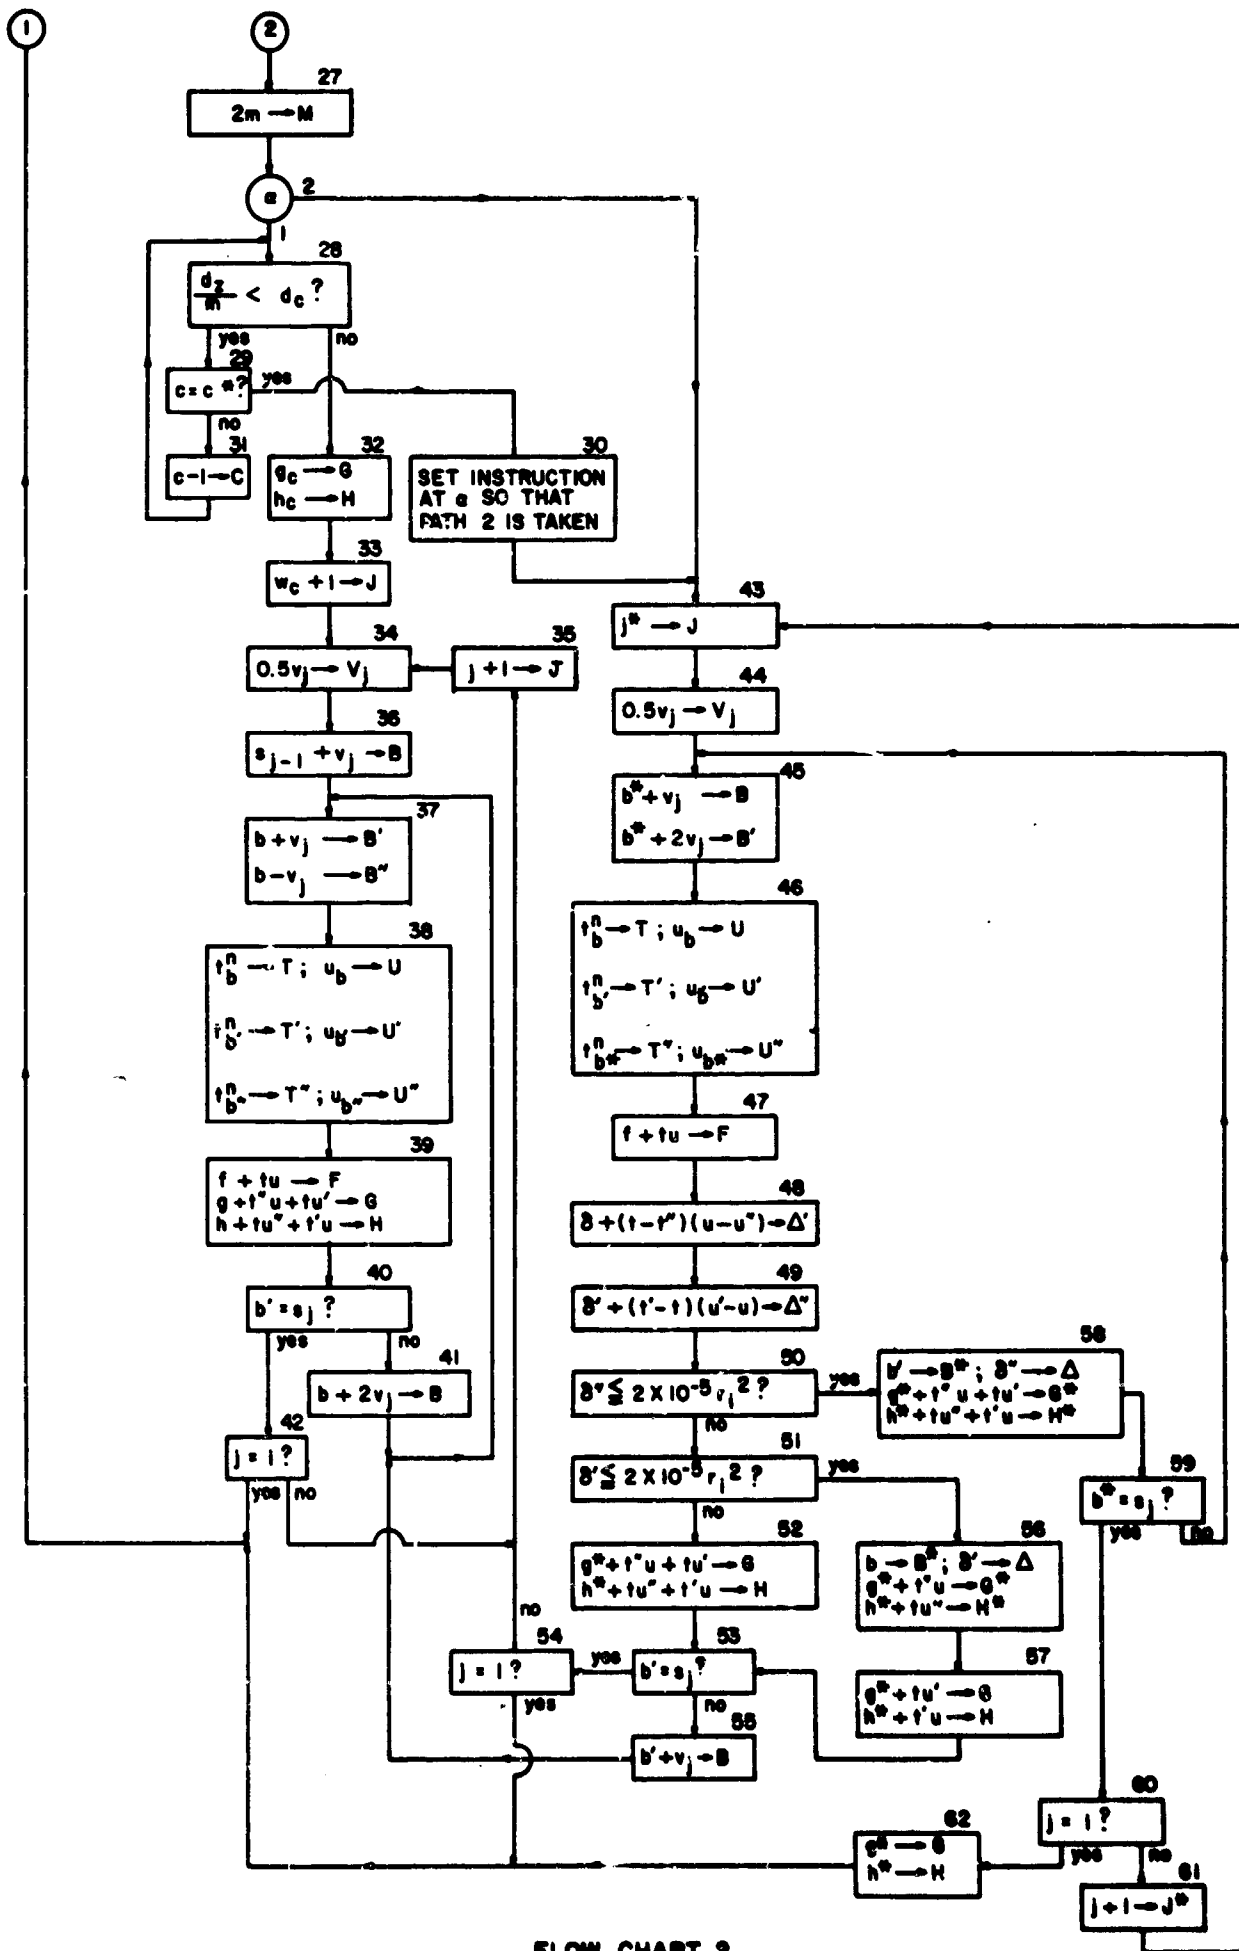

If the answer is No at Box 5, the program goes into the regular procedure of successive doubling of the number m of sub-intervals (see Box 23) until the tolerance is ultimately met at Box 17 and the approximation $(l + k)/2$ is placed in location X at Box 18. At Boxes 19-22 at each stage, in preparation for doubling the value of m , the values of $Q(r)$ which have previously been computed are spaced farther apart to make room for inserting new values. For example, when $m = 4$, values of $Q(r)$ are in locations T_1 to T_5 inclusive. Before proceeding to the detailed calculations for $m = 8$, these values are placed in locations T_1, T_3, T_5, T_7, T_9 , to clear locations T_2, T_4 , etc., for new values when $m = 8$.

FLOW CHART I
E AS A FUNCTION OF $\bar{R}, \bar{\sigma}, \sigma, n$

FLOW CHART 2
E AS A FUNCTION OF R_i, a, n

FLOW CHART 2
E AS A FUNCTION OF R_1, a, n

The values of the circular coverage function are preserved in the T_1 locations in the manner which has been indicated, as the number m of subintervals is successively increased, in order to save machine computing time, so far as machine storage permits. The circular coverage function subroutine is very time-consuming, relative to simple operations such as multiplications and divisions and even relative to simpler subroutines such as those for logarithms and exponentials. It requires an average time of about 1.6 milliseconds on the IBM 7030 (STRETCH) computer for six decimal digit accuracy, and 2.5 milliseconds for nine digits.

It was shown in Section 2 that $(l - k)/2$, the maximum possible error committed in taking $(l + k)/2$ as an approximation for the true value of E , does not exceed $1/m$. The values of m are always of the form 2^j , since m is increased by successive doubling. If we wish to guarantee that $(l - k)/2$ does not exceed 0.0005, i.e., we wish to compute E with three decimal digit accuracy, m may have to become as large as 2048 ($= 2^{11}$). If we wish to guarantee that $(l - k)/2$ does not exceed 0.00005, m may have to become as large as 32,768, as this is the smallest power of 2 which satisfies $0.00005 \leq 1/m$. This makes heavy demands on storage, but is possible on many present-day computers. If still greater accuracy is desired, the program can be modified so that values of the circular coverage function are not preserved, but are recomputed whenever required. In this case the attainable accuracy is unlimited and the storage requirements are light, but one pays a heavy price in computing time.

In computing the tables (Apps. A, B) in the present report, with all values of a and R specified in advance, a different and far more efficient scheme was used, whereby, for any given value of a , the corresponding values of $\log[1 - P(a,r)]$ are precomputed and stored, not only for all of the 57 specified values of R but also for all subdivision points which may be needed, making a total of 14785 values of $\log[1 - P(a,r)]$ for each value of a . Then when the value of $Q(r)$ or $[1 - P(a,r)]^n$ is needed for some value of n , it is obtained by computing $\exp\{n \log[1 - P(a,r)]\}$. Also, for each a , the corresponding 14785 values of r^2 are precomputed and stored. The values of $\log[1 - P(a,r)]$ are stored in locations $T_1, T_2, \dots, T_{14785}$, and the values of r^2 in locations $U_1, U_2, \dots, U_{14785}$. This program is shown in Flow Chart 2.

We do not give a complete explanation of Flow Chart 2, which would involve a very large number of details, but we give on pages 26-27 the values of r_k, n_k, s_k and z_k ($k = 1, 2, \dots, 58$),

and d_k and w_k ($k = 1, 2, 3, 4$), all of which are stored in the program. The values of r_k are simply the specified values of the target radius R , with $r_1 = 0$ to avoid zero subscripts as required by FORTRAN. The values of n_k are the maximum number of sub-intervals which may be required in the interval $[r_{k-1}, r_k]$. For example, the interval $[0.40, 0.50]$ may have to be divided into 512 subintervals, but not more, at some stage of computing the direct and inverse tables. We do not go into detail here on the s_k, z_k, d_k and w_k columns.

The average time on the IBM 7030 (STRETCH) computer for computing E as a function of a, R and n , using the method of Flow Chart 2, with precomputed and stored values of $\log[1 - P(a,r)]$, was of the order of 60 milliseconds for a tolerance y of 0.01, in computing the tables for the present report. For a tolerance of 0.001, it was of the order of 250 milliseconds or one-fourth of a second. With the program of Flow Chart 1, in which the values of $\log[1 - P(a,r)]$ are not precomputed, the time is 250 to 500 milliseconds for a tolerance of 0.01.

APPENDIX A

DIRECT TABLE

See a general description of the direct table in Section 4. The following example illustrates its use. If the unnormalized lethal radius \bar{a} is 40 yards, target radius \bar{R} is 20 yards, and standard deviation σ is 50 yards, find the expected proportional coverage E and expected damaged area for $n = 6$. Here $a = \bar{a}/\sigma = 0.8$, $R = \bar{R}/\sigma = 0.4$, $n = 6$. From page 45 of the tables it is found that $E = 0.842$. The expected damaged area is $0.842 \cdot (\pi\bar{R}^2) = 0.842 \times 400\pi$ sq. yd. = 1058 sq. yd. approximately.

APPENDIX B

INVERSE TABLE

See a general description of the inverse table in Section 4. The following example illustrates its use. Given $\bar{R} = 130$ yards, $\bar{a} = 30$ yards, $\sigma = 100$ yards, what number of bombs is required to give an expected coverage of 80%? Here $a = 30/100 = 0.3$, $R = 130/100 = 1.3$, $E = 0.80$. The result is found on page 136 of the tables, and is $n = 56$.

NUMBER OF WEAPONS OF LETHAL RADIUS A REQUIRED TO GIVE AN EXPECTED COVERAGE OF E FOR A CIRCULAR UNIFORM TARGET OF RADIUS R
(R AND A EXPRESSED IN SIGMAS AND *** INDICATES MORE THAN 999 WEAPONS)

E=.05
