Motion sickness was investigated by placing the 5 in a barany chair in which the 110-120 Hz head was flexed on his chest and then extended. Motion sickness was produced in susceptible 5s with the motion sickness limited to the feeling of nausea. It was noted that a physiological response could be measured which would act as an end point rather than a nauseating feeling. Continuous physiological recordings were made to ascertain if certain measures may serve as an index to motion sickness. A questionnaire test for motion sickness was also devised that would correlate with susceptibility to motion sickness. The following 6 recordings of the test situation were made: revolution of the table, skin temperature, swallowing movements, onset of sweating, breathing rate and depth, arterial blood pressure, head movements, feeling of lateral tilting, feeling of closing-diving, feeling of turning, signal for nausea. It was found that acute motion sickness can be produced in susceptible subjects, seated in a barany chair, rotating at 16 rpm and flexing their heads in a controlled manner; there is a positive association between motion sickness susceptibility and test reaction ($p < 0.001$); there is a positive association between onset of sweating and onset of nausea ($p < 0.001$); in all subjects who were severely nauseated on the test procedure there was a secondary nausea lasting from 2 to 12 hours. Spitz, H. A TECHNIQUE FOR THE ANALYSIS OF THE BEHAVIOR OF A SYSTEM. App. Math. Statistics.

2743

This paper shows how the specification and analysis of these sequences may be applied to the description and evaluation of a given man-machine system. The concept of sequential analysis is extended and a modified procedure suitable of system description and evaluation is presented. The procedure is applied to two different kinds of system problems: a communication network and a hypothetical traffic system.

Rawlins, J.S.P. DEVELOPMENT OF A FLYING HELMET AND OF A PROTECTIVE HELMET. RPRC 847, Aug. 1953. 19pp. Flying Personnel Research Committee, RAF Institute of Aviation Medicine.

2742

This report describes the development of a new (inner) flying helmet giving improved noise-exclusion (Type 2) and a new crash-protective helmet to be worn over it. A telephone, a connector for use with the ejection seat, and an oxygen mask attachment were also investigated in association with the helmet. The theory of protective helmets is discussed and experimental results of direct comparison of the impact-absorption of British and United States helmets are given.

Faucett, R.E. THE EFFECT OF DRAMAMINE ON VISUAL AND AUDITORY ACUITY. Proj. NM 002 015.09.01, Rep. No. 222, April, 1953. 13pp. Medical Research Laboratory, U.S. Naval Submarine Base, Bureau of Medicine and Surgery, Navy Dept. New London.

2743

The effects of Dramamine on visual acuity, color perception, stereoscopic vision, flicker fusion, and auditory acuity was investigated. Each of fifty-eight subjects was tested under three experimental conditions: when taking Dramamine, when taking a placebo, and when no drug or placebo was being given. The differences between conditions are evaluated so that certain conclusions about the effect of Dramamine on visual efficiency can be stated.

Carterette, E.C. LOUDNESS ADAPTATION FOR BANDS OF NOISE. J. Acoust. Soc. Amer., 1956, 28 (5), 865-871. Contract AF 18(600)-571, AFRCR-TH-55-57, Operational Applications Laboratory, AFRCR. (Indiana University).

2744

To determine the extent of adaptation to bands of noise as a function of their level, band width, and duration, two experiments were performed by the method of dichotic loudness balances. In the first experiment one ear of each of 36 listeners was exposed to a 100-5000 cps tone for 6 minutes during which they turned up the same noise in the opposite ear until it matched the adapting tone in loudness. The adapting tone was presented at 40, 70, 90, 100 and 105 db SPL. In the second experiment 12 subjects balanced the loudness of the following bands of noise--1280-1720, 1075-2600 and 100-4900 cps--presented at 50, 70 and 90 db SPL and of a 1500 cps tone at the same SPLs. The results are presented in terms of the diminution of loudness as a function of time and the SPL of the adapting stimulus. T. O. R 7

Copewell, J.E. EFFECTS OF A STEREOSCOPIC SOUND MOTION PICTURE ON THE LEARNING OF A PERCEPTUAL-MOTOR TASK. Contract N60MR 269, Rep. 269 7 3 2, Sept. 1952, 13pp. USN Special Devices Center, Port Washington, N.Y. (Pennsylvania State College, State College, Penn.).

2747

To ascertain whether the stereoscopic sound motion picture contributes significantly to the learning of a perceptual-motor task as compared to the conventional sound motion picture, three different experimental treatments were given to three equated groups. One group saw a stereoscopic film (wearing polaroid viewing spectacles). The other two groups saw the same film except that it was not stereoscopic; one of these groups wore the polaroid viewing spectacles. A performance test was given immediately following the film showing. Speed scores and percentage of subjects completing task successfully in a ten-minute period were analyzed for differences due to experimental treatment. Implications for use of training films are indicated.

Stein, J.J. THE EFFECT OF A PRE-FILM TEST ON LEARNING FROM AN EDUCATIONAL SOUND MOTION PICTURE. Contract N60MR 269, Rep. SDC 269 7 35, Nov. 1952, 15pp. USN Special Devices Center, Port Washington, N.Y. (Pennsylvania State College, State College, Penn.).

2748

To ascertain the effect of a pre-film test on learning from an educational sound motion picture, approximately 3500 United States Navy seamen recruits were tested. Pre-film tests were constructed to cover film content and were given to three different groups with no knowledge of results, with partial, and with complete knowledge of results. Following the film showing, an immediate and a delayed (one week) retention test were given. Several control groups were used: 1) took post tests only, 2) saw film once and took post tests, and 3) saw film twice and took post tests. The test data from two different films were analyzed for effect of pre-film test, knowledge of results, and content of pre-film test.

Rubinstein, M.K. & Loeb, M. INTERACTION BETWEEN VISION AND AUDITION. Proj. No. 6-95-20-001, Rep. No. 151, July 1954, 14pp. Army Medical Research Lab., Office of the Surgeon General, Research and Development Division, Dept. of the Army.

2749

Visual acuity was determined during exposure to several levels of sound; auditory thresholds were measured during exposure to several levels of illumination. Results indicated that visual acuity is significantly impaired by auditory stimulation; auditory acuity is not influenced by visual stimuli.

2750

Loeb, M., Kane, W.H., Roberts, E.E. & Samelson, M.L. A FURTHER INVESTIGATION OF THE INFLUENCE OF WHOLE-BODY VIBRATION AND NOISE ON TENSION AND VISUAL ACUITY. Proj. No. 6-95-20-001, Rep. No. 163, Oct. 1954, 19pp. Dept. of the Army, Army Medical Research Lab., Office of the Surgeon General, Research and Development Division, Fort Knox, Kentucky.

2750

To determine the nature and extent of changes in visual acuity, manual tremor, and aiming tremor as affected by intense noise, and/or vibration, measurements were made on 15 subjects before, during, and after exposure to two amplitudes of sinusoidal vibration at three different frequencies (15, 25, 35 cycles per second), broad band noise (115 decibels), and a control condition (no vibration, no noise). The data are analyzed for differential effects in the three functions. In addition, threshold measurements of "annoying" and "barely tolerable" vibration (inches of amplitude of platform vibration) were determined. Further research is recommended.

Hartman, R.C. & Page, R.E. PERFORMANCE WITH LIGHT-WEIGHT GRENADES AS A FUNCTION OF WEIGHT AND DISTANCE. Proj. 6-95-20-001, Subtask AMEL S-1, MEDEL, Rep. 176, Feb. 1955, 73pp. USN Medical Research Lab., Fort Knox, Ky.

2751

To investigate the effect of weight and distance on weight throwing, five weights of grenades (from two to ten ounces) were thrown at targets located 15, 20, 30, and 35 yards from the subject. Five throws of each weight grenade at every distance were made by each of 12 subjects. Performance was measured by accuracy scores (radial distance from target center) and consistency of scores (dispersion of throw) and analyzed in terms of the weight and distance factors. Recommendations for design of light-weight hand grenades are included.

Justus, G.M., Noble, H.A. & Gross, W.A. RANGE AND SPEED ESTIMATION. Proj. TT2-689, Third Report, Dates of Test: July 18 to July 28 1952, Oct. 1953, 40pp. Aberdeen Proving Ground, Md.

2753

To investigate accuracy of range and speed estimations of the untrained eye as affected by range and speed of target and use of binoculars, data were obtained from 800 ROTC cadets observing moving trucks as targets. Speed of operation varied from three to 27 miles per hour and ranges from 500 to 1650 yards. The error data were analyzed for speed and for unaided eye versus binoculars. The potential or systematic error for untrained observers is discussed in relation to training in tank gunnery.

2756 Kennedy, J.V. THE PARTIAL PRESSURE SUIT IN HIGH ALTITUDE ESCAPE. Report from "Conference on Problems of Emergency Escape in High-Speed Flight, 29-30 Sept. 1952, Wright-Patterson AFB, Dayton, Ohio". USAF Wright Air Development Center, Aero-Medical Lab., Wright-Patterson AFB, Ohio.

Described is the partial pressure suit and the physiological principles incorporated into its design. It is felt to have fulfilled the requirements for emergency protection at extreme altitudes and is the only practical altitude suit available for widespread use. However, there are some shortcomings: including: a) restricted visibility when inflated; b) requirement for other protective clothing; and c) uncertain windblast protection afforded by the helmet. Perfection and mass production of a different type altitude suit in the next 3-5 yrs. is unlikely; therefore, the partial pressure suit must be considered in any system of high altitude escape. The partial pressure suit may also eliminate the requirement for an e-escape capsule or pod, and in case of e-b'n pressurization. (HMAS)

2757 Belding, H.S., Minard, D., Wiebers, J.E., & Ross, J.W. HEAT STRESSES AND STRAINS OF SUMMER TRAINING AT THE MARINE CORPS RECRUIT DEPOT PARRIS ISLAND, SOUTH CAROLINA. Contract ONR 115-406, Rep. 1, Jan. 1956, 22pp. ONR, University of Pittsburgh.

2757 To study various problems resulting from conduct of military training in hot weather, a Heat Study Team spent four summer weeks at the Marine Recruit Training Depot, Parris Island, South Carolina. Observations were made on a squad of eight recruits. Physiological responses of these men were observed and their exposure to heat measured while they engaged in normal training activities and in standardized marches. Data on heat production, elevations of heart rate, rectal temperature and sweating are reported. Present provisions of the Parris Island Heat Directive were critically examined and suggested modifications made.

2760 Lee, D.H.K., Katin, J.G., Woodcock, A.H., Goddard, W.L., et al. STUDIES ON CLOTHING FOR HOT ENVIRONMENTS--DEATH VALLEY, 1950. PART I. EXPERIMENTS AND RESULTS. Rep. 178, June 1951, 70pp. Department of the Army, Office of the Quartermaster General, Environmental Protection Section, Washington, D.C.

In July and August, 1950, a group of scientists from the Research and Development Branch, QMC, with cooperation from the Quartermaster Board, conducted a series of experiments in Death Valley, California, to test principles of clothing design for protection against hot desert environment stresses. As a result of these experiments, the following conclusions were reached: a) Under the conditions experienced, both the operating efficiency and the physiological welfare of the individual may be jeopardized after less than 2 hours of moderate activity. b) Under these circumstances, almost any reduction of the heat load upon the individual is important. c) Foot ventilation, such as is obtained by air-permeable uppers, or ventilating insoles, keeps feet cooler. d) Thick socks are desirable. e) A cap was found to be a generally acceptable form of headgear; but this requires a large visor, adjustable headband, and a crown which stands away from the head. f) The use of a headcloth is very desirable, as a protection against solar radiation, hot winds, and dust; more work is required on the optimum form and method of use. g) There is need for body clothing for men working in the sun, at least up to an activity level equivalent to walking at 3 mph. h) There is an outstanding advantage to be gained from having the outer body clothing of loose design, with controllable ventilation openings at the neck, waist, wrists, and ankles. i) There is a definite requirement in the design of outer body clothing for a method of preventing the entry of sand when the wearer is crawling. j) Where other considerations indicate the need for fairly thick fabrics, there are no physiological objections to their use. k) There are, at present, no indications for controlling the use of underwear.

2761 Liebowitz, H.M. & Kaestner, N. THE EFFECT OF GRID LINES IN THE FIELD OF VIEW UPON PERCEPTION OF MOTION. Contract AF 18(600) 54, WADC TR 54 221, March 1954, 8pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (University of Wisconsin, Madison, Wisc.).

2761 To investigate the effects of reference stimuli in the field of view on perception of motion, the minimum discriminable target velocity was determined by eight untrained Ss for exposure durations of 1/4 and 16 sec., luminance values of .016 and 500 cd, both with and without vertical grid lines in the field of view. Threshold data are plotted as a function of practice for the various parameters and implications for perceptual training are discussed.

Lund, D.W. EFFECTS OF POSITIVE G ON SUBJECTS STUDIED AT THE MAYO AND AIR MATERIEL COMMAND CENTRIFUGES. TSEA: 595 69, E.O. 695 67, Sept. 1946, 28pp. USAF Air Materiel Command, Aero Medical Lab., Wright-Patterson AFB, Ohio.

The responses of 12 Ss to positive acceleration on the Mayo and Air Materiel Command centrifuges were compared. The average G-tolerances of the group, appraised by assay using visual symptoms and equivalent ear pulse amplitude changes as end points was 0.5 and 0.9, respectively, lower on the Mayo than on the Air Materiel Command centrifuge. The basic pattern of the cardiovascular response was the same at both Laboratories. The sequence of the measured physiological events which occur in response to positive acceleration and, with one exception, the timing of these events, was repeated on the 2 centrifuges. The data suggest that the difference in G-tolerances observed on the 2 machines is more related to differences in psychological factors associated with exposure to G than to any physical differences between the 2 centrifuges. Lutz, C.C. STANDARDIZATION OF ALTITUDE SUITS, TYPES T-1 AND S-2. Tech. Memo Rep. WARD 52 121, Nov. 1952 12pp. USAF Wright Air Development Center, Aero Medical Lab., Wright-Patterson AFB, Ohio.

Summarized are the data concerning the development of the Air Force altitude suits, Type T-1 and S-2, for the purpose of standardizing this garment. An altitude pressure suit which consists of 3 main components: a pressure oxygen helmet, a counter-pressurizing garment, and an emergency oxygen cylinder and regulating assembly, has been developed. This complete assembly provides emergency protection against the effects of low barometric pressure, which occur in the event of loss of cabin pressurization extremely high altitudes. The development of the counter-pressure garment portion of the assembly, known as the partial-pressure suit and designated as Suit Altitude, Type T-1 and Type S-2 is fully described in the report. (HEIAS)

Smith, P.K. EFFECTS OF SOME CENTRAL NERVOUS SYSTEM DEPRESSING DRUGS ON INTELLECTUAL AND PSYCHOMOTOR PERFORMANCE AT 18,000 FEET WITH AND WITHOUT SUPPLEMENTARY OXYGEN. Proj. 221, Rep. 1, Jan. 1944, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

To determine the effects of some CNS depressing drugs on intellectual and psychomotor performance at 18,000 ft. with and without supplementary oxygen, 93 Ss were given moderate doses of morphine sulfate, codeine phosphate, Demerol, or Army Motion Sickness Preventive. Ss were given an addition test, code substitution test, steadiness aiming test, and compensatory pursuit test. The tests were performed with added oxygen and after a period of anoxia varying from 15 to 45 min. It was found that: a) Morphine sulfate in 10 mg. doses given subcutaneously approximately one hr. before testing had no demonstrable effect on performance; b) Demerol in 100 mg. doses given by mouth approximately 2 hrs. before testing had no demonstrable effect, but the same dose given subcutaneously approximately an hr. before testing adversely affected performance; c) Codeine phosphate given in 130 mg. doses by mouth approximately 2 hrs. before testing had no demonstrable effect on performance; d) Army Motion Sickness Preventive given in 2 capsule doses by mouth had a small but not statistically significant effect on performance both with and without supplementary oxygen. Smith, P.K. ATTEMPTS TO FIND A REMEDY SUPERIOR TO HYOSCINE FOR MOTION SICKNESS. Proj. 333, Rep. 1, Aug., 1945, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

This study was conducted to find a more suitable remedy for airsickness than hyoscine. The drugs tested were atropine sulfate in doses of 1.0 mg., Pavatrine in doses of 250 mg., hyoscine hydrobromide; and hyoscine hydrobromide in combination with prostigmine bromide, chlorobutanol, benzedrine sulfate, and V-12. The Ss were given a drug or placebo about 50 to 100 minutes before swinging on a swing of 14 ft. radius. The Ss were swung in a sitting position with their heads upright. They were observed for pallor, sweating and vomiting and questioned to determine the extent of nausea and dizziness after the test. Neither the atropine sulfate nor Pavatrine are superior to 0.75 mg. doses of hyoscine hydrobromide in preventing swinging sickness. Combinations of hyoscine and prostigmine bromide, of hyoscine and chlorotone and benzedrine or of hyoscine and V-12 were not superior to hyoscine alone for the prevention of swing sickness. (HEIAS)

Thorne, M.W. QUESTIONNAIRE ANALYSIS OF THE PROBLEM OF AIRSICKNESS AS IT IS MET WITH IN STATIONS IN THE CONTINENTAL UNITED STATES. Proj. 83, Rep. 1, Sept. 1942, 5pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Reported is the analysis of a questionnaire concerning the subject of airsickness which was disseminated to Air Force stations throughout the continental United States to obtain information regarding the experience with airsickness of the Flight Surgeons at these various stations. 177 Air Force stations reported on the occurrence and other features of airsickness as it existed at the respective stations reporting. It was found that: the incidence of airsickness is greatest in primary flying training, the navigation school at Hondo and in casual passengers. At other stations airsickness has not been common. In the opinion of the Flight Surgeons reporting the contributing causes of airsickness are: (in order of prominence): a) apprehension, b) acrobatics, c) turbulent air, d) dietary factors, e) cabin odors and poor ventilation. The treatment of airsickness best suited in the opinion of those reporting is: a) psychological approaches, b) diet control, c) preflight sedation.

2774

Thorne, M.W. AUTONOMIC REACTIONS TO STARTLE: I. PHOTOELECTRIC PLETHYSMOGRAPH. Proj. 135, Rep. 1, Nov. 1943, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The construction of a photoelectric capillary plethysmograph using a condenser coupled amplifier and inductor recorder is described. Its advantages include rugged construction, ease of operation, and availability for use in the low pressure chamber. Its usefulness is demonstrated as: a) A detector of some autonomic nervous system activities; and b) An adjunct in the study of capillary activity in various breathing mixtures. (MEIAS)

Tobias, C.A. RADIATION HAZARDS IN HIGH ALTITUDE AVIATION. Proj. ADO 695 72, Tech. Rep. 52 119, May 1952, 36pp. USAF Wright Air Development Center, Aero Medical Lab., Wright-Patterson AFB, Ohio. (University of California, Berkeley, Calif.)

A comprehensive review and summary is given of what is known today of the hazards of natural radiation at high altitudes. On the basis of existing physical data and biological knowledge, estimates were made of the dosage delivered by cosmic radiation at very high altitudes. It was concluded that even extensive high altitude flying would have very little effect on health and would constitute only a small hazard compared with other commonly accepted radiation dangers from artificial sources. Nevertheless, there is continued need for further physical investigations of the distribution of cosmic ray ionization, actual biological assays of their effects at high altitudes, and for ground level studies using artificial sources of radiations.

Torndorf, J. AUDITORY PERCEPTION IN AIRCRAFT NOISE. Proj. 21 27 001, Rep. 1, Dec. 1951, 23pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The problem of communication in noise was explored from the listener's standpoint. In normal Ss perception of pure-tone and speech signals was measured at 6 intensity levels of simulated aircraft noise (conventional and jet types) under a variety of test conditions. Curves were established depicting levels of threshold and of comfortable listening for both pure-tone and speech, and that of optimum speech perception. They allow demonstration of the width of the useful auditory area in noise and of the operational level which offers the most satisfactory perception under each condition. Conclusions and specific recommendations are presented.

Blackston, M.W., & Rabine, E.N. ELECTRONICS TROUBLESHOOTING TRAINER. Keesler 56-1, Final Proj. Rep., Feb. 1956, 28pp. Training Analysis and Development Division, 3380th Technical Training Group, Keesler AFB, Miss.

2779

This report describes the development and use of the Electronics Troubleshooting Trainer for training in the "split-half technique" in troubleshooting and the "developmental" approach to training. Several examples of the Trainer are given to illustrate levels of development from basic to advanced. Methods for using the Trainer, variations in form to satisfy different objectives, and evaluation possibilities are discussed.

2780

Weiss, R.A. VARIABILITY IN THE ENERGY COST OF SELECTED EXERCISES. Proj. 374, Rep. 1, Nov. 1945, 5pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The oxygen consumption of 30 Ss was tested by a closed circuit metabolism apparatus during rest, exercise, and recovery. Each S was tested 3 times with each of 5 exercises to determine energy cost variability. In a comparison of 2 measures of energy expenditure, net oxygen consumption and energy cost in multiples of the resting metabolic rate (RMR), the latter was selected as more desirable because of greater independence from body size, and because it is expressed in units which are more easily understood. The measure of cost in RMR was found to have a high degree of reliability (0.86-0.90). There was a significant variation in cost in RMR between the 30 Ss for each of the 5 exercises studied in this investigation. Accordingly, cost in RMR obtained from testing one S cannot be used to predict accurately the cost for other Ss. Variation between Ss was not related to any of the anthropometric measurements studied in this investigation, since correlations between cost in RMR and various anthropometric measurements were found to be significant in only one instance, between length of arm and exercise C. For exercises to be ranked in the same order, according to cost in RMR, for nearly all Ss, the differences between the means of the exercises must exceed a certain minimum, which increases with an increase in strenuousness of the exercises. When the cost of the less strenuous of 2 exercises is between one and 10 RMR, the minimum differences at which the exercises are ranked in the same order for 95% of the Ss ranges from 0.99 to 6.97 RMR. For 99% of the Ss, this range will be from 2.00 to 10.50 RMR.

2784

White, C.S., Hume, Jane M., Armstrong, Elizabeth D. & Lundgren, K.T. HUMAN TOLERANCE TO ACUTE EXPOSURE TO SIX PERCENT CARBON DIOXIDE IN AIR AND IN OXYGEN. Contract AF33(035) 13244, Proj. 21 1402 0001, Rep. 1, March 1953, 13pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Human Ss in 50 experiments were exposed for 15 minutes to 6 percent CO₂ in air and in O₂ at a ground level altitude of 5,000 ft. Performance of a card-sorting test was not significantly influenced by breathing CO₂, although one of 31 Ss was unable to complete the experiment. Dyspnea, smell and taste sensations, headache, and sweating were the most common symptoms. The increase in expiratory minute volume was significantly greater in the CO₂ in air than in the CO₂ in O₂ group. The percentage of rise in tidal air was much greater than the percentage of increase in respiratory rate. The average rise in the alveolar pCO₂ determined during the 16th minute of inhaling CO₂ was 11 mm. Hg above the average of 32 mm. measured after 5 minutes of breathing air. The advisability of requiring air crew indoctrination in the effects of acute CO₂ inhalation was emphasized.

Zeidner, J., Gordon, B.A. & Goldstein, L.G. DARK-ADAPTATION TIME FOR TESTING NIGHT-VISION ABILITY. Proj. 29562000, Tech. Res. Note 25, April 1954, 37pp. Department of the Army, Personnel Research Branch, Washington, D.C.

The objective of this study was to determine the optimal period of dark adaptation for the administration of mesopic (moonlight) tests. The interest was in the dark adaptation time required by a soldier who is taken from a well-lit waiting room, dark adapted in a more or less light-tight room, and examined with acuity targets administered at a mesopic brightness. The experiment used a pre-adaptation brightness of 753 millilamberts (11.88 log micromicrolamberts); the dark-adapting brightness was at the testing level itself--6.67 log micromicrolamberts. 100 examinees were tested binocularly on the Modified Landolt Ring and Chevron Contrast Mesopic test at varying intervals of dark adaptation. The last 20 examinees were retested 5 weeks later. The Landolt Test was developed as a measure of retinal resolution; the Chevron Test was developed as a measure of brightness-contrast sensitivity. Threshold values showed that almost complete (for practical purposes) dark adaptation to the 6.67 micromicrolamberts mesopic level was attained in 10 minutes. The test-retest reliability coefficients of acuity and of contrast sensitivity scores were, in general, slightly higher for the later intervals than for the initial periods of adaptation. There was evidence that, under carefully controlled conditions, 5 minutes of dark adaptation is sufficient for testing at mesopic brightness levels. However, for large-scale testing in the operational situation, 10 minutes of dark adaptation is a more careful choice. Mesopic visual acuity after 10 minutes of dark adaptation would be close to terminal acuity; small variation in adapting time would not critically affect scores.

Spector, H., Peterson, M.S. & Friedemann, T.E. METHODS FOR EVALUATION OF NUTRITIONAL ADEQUACY AND STATUS--A SYMPOSIUM. Dec. 1954, 313pp. National Research Council, Advisory Board on Quartermaster Research and Development, Committee on Foods, Washington, D.C.

This report is a summary of a symposium on methods for evaluating nutritional adequacy and status held in 1954. The program was organized into the following general categories: a) evaluation of protein adequacy; b) evaluation of vitamin adequacy; c) evaluation of mineral adequacy; d) evaluation of military rations by animal experimentation; e) evaluation of nutritional status of populations; f) body composition. In these categories, existing methods were critically evaluated, and the need and possibilities for new methods emphasized. (HEIAS)

Spector, H. & Peterson, M.S. NUTRITION UNDER CLIMATIC STRESS--A SYMPOSIUM. May 1954, 204pp. National Research Council, Advisory Board on Quartermaster Research and Development, Committee on Foods, Washington, D.C.

This is a report of a symposium on nutrition under climatic stress held in 1952. The program was organized into the following general categories: a) practical problems of service operations under climatic stress; b) physiological responses of men to heat and cold; c) animal experimentation; d) human experimentation. Concluding feature of the program was a summary of present knowledge and a survey of areas in which more research is needed. (HEIAS)

Scobee, R.G. & Moss, H.L. A COMPARISON OF TESTS FOR HETEROPHORIA: EFFECT OF LIGHT AND DARK ON THE SCREEN-MADDOX ROD TEST. Proj. 375, Rep. 3, July 1945, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Lateral and vertical heterophoric determinations were made at a distance of 20 ft. on 60 Ss using the screen-Maddox rod test under 2 conditions: a) the testing room in complete darkness; and b) the testing room lighted with a 60-Watt, frosted Mazda bulb above S's head. No significant differences in the heterophoric measurements when made in a lighted room vs. a dark room were found. (HEIAS)

Scobee, R.G., Green, E.L. & Moss, H.L. A COMPARISON OF TESTS FOR HETEROPHORIA: VARIATIONS IN THE SCREEN-MADDOX ROD TEST DUE TO OCULAR DOMINANCE, ROD COLOR, AND SCREENING. Proj. 375, Rep. 4, July 1945, 10pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A study was made of possible variations in heterophoria measurements made at testing distances of 20 ft. and 13 in. with the screen-Maddox rod test depending upon whether: a) screening is performed or not; b) the rod is placed before the dominant or non-dominant eye; c) a white or a red Maddox rod is used. Significant differences were found for condition -a- at both distances and regardless of conditions b and c. No differences were found due to condition -b-. Significant differences were found for condition -c- at 20 ft. but not at 13 in., regardless of conditions a and b. It was recommended that determination of the dominant eye should be dropped from the present AAF physical examination for flying. On the basis of these and other results, it was recommended that the screen-Maddox rod test be abandoned in favor of the Maddox rod alone. (HEIAS)

Scobee, F.G. & Rowland, W.M. A FILTER FOR THE RED LENS TEST IN THE "64" EXAMINATION. Proj. 322, Rep. 1, Dec. 1944, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

This report attempts to specify a given red lens to be used in Form "64" of the examination for flying. The need for a standardized red lens is felt for 2 reasons: a) a standardization of the test is badly needed, and b) a number of perfectly normal individuals might be unjustly eliminated from flying by virtue of having seen 2 images when a dark red lens is used to perform this test. The primary purpose of the red lens in the present "64" examination is to enable the subject to identify accurately true and false images. The fact that a certain amount of fusion is disrupted by the difference in color of the images thus produced is, and should be, of secondary importance. There is no specified density for the red lens used in the test and, as a result, a wide variety of lenses are in use throughout the Army Air Forces. In view of this situation, the fact that a fairly dense red lens will produce diplopia in even the normal individual becomes extremely important. A satisfactory color for the test is the Polaroid Unicolor Red - XR12 or any lens of similar density. The adoption of this or a similar lens is strongly recommended since standardization of any and all portions of the "64" examination is highly desirable.

Senturia, B.H. DETERMINATION OF AUDITORY ACUITY FOLLOWING VARIOUS PERIODS OF EXPOSURE IN THE ALTITUDE CHAMBER. Proj. 129, Rep. 1, March 1943, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

3 of 8 members of the personnel of an altitude chamber who had been exposed to marked pressure changes over a period of 14 months, showed a maximum loss of 15 db of auditory acuity in some portion of the auditory spectrum. In the main, losses were confined to the frequencies 5792, 8192, and 11584 cps. No significant permanent loss of acuity occurred as a result of attacks of aerotitis or aero-otitis in 3 Ss. (HEIAS)

2796

Senturia, B.H. AUDITORY ACUITY OF AVIATION CADETS. Proj. 239, Rep. 1, May 1944, 5pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Auditory acuity tests were performed on 500 enlisted trainees between the ages of 18 and 27 years (mean age 21.1 yrs.). 34% of right ears and 32% of left ears showed threshold curves which did not deviate more than 10 db below the audiometric zero-line from 1024 to 1584 cps. Tonal dips of 15 db or more occurred in 23% of right ears and 29% of left ears, prior to any recent exposure to aircraft noise. 49.2% of the Ss showed bilateral similarity of hearing types. Comparison of results of 5 examiners show some deviations but fairly uniform results are obtained.

Senturia, B.H. A SURVEY OF AUDITORY ACUITY AMONG PILOTS AND ENLISTED TRAINEES. Proj. 171, Rep. 1, Sept. 1943, 5pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Auditory acuity thresholds were obtained on 150 Students and Instructors (300 ears) who had 100-2500 logged hours and who were flying daily. These were compared with thresholds obtained from 100 Enlisted Trainees (200 ears) who had less than 25 logged hours and had no exposure to aircraft noise for the preceding 30 days. All audiograms were empirically divided into 4 types and 4 grades of losses according to the configuration of the threshold curve and the severity of the hearing loss. Only 23% of the Instructors and Students and 33% of the Trainees were found to have normal hearing over the entire range of frequencies tested. There is a significantly greater incidence of Type "I" (high-tone) deafness and a smaller number of normals among the Instructors than among the Trainees. A remarkably high incidence of Type "V" tonal gaps in the regions of 2896 and 4096 cps occurs among Trainees, prior to aircraft noise exposure. Attention is directed to the losses of auditory acuity which exist prior to aircraft noise exposure but which are frequently interpreted as occupational defects resulting from airplane noise.

Senturia, B.H. THE EFFECT OF EXPOSURE TO AIRPLANE NOISE ON AUDITORY ACUITY. Proj. 205, Rep. 2, May 1944, 4pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Audiograms were obtained on 64 enlisted trainees who had passed the flight physical, and who had no known exposure to aircraft noise in the preceding 30 days. Following the completion of approximately 135 hrs. of flying time (primary - 50 to 70 hrs. - and basic - 50 to 70 hrs. - pilot training), 19.5% of ears showed hearing losses greater than 10 db, at 1 or more of the frequencies tested. The greatest percentage of clinically significant losses occurred at the higher frequencies (2048 - 5792 cps). This should be interpreted in light of the fact that retests were made 2 - 8 hrs. after exposure to aircraft noise. (HEIAS)

Senturia, B.H. THE EFFECT OF EXPOSURE TO AIRPLANE NOISE ON AUDITORY ACUITY. Proj. 205, Rep. 3, Aug. 1944, 4pp. USAF School of Aviation Medicine, Randolph Field, Tex.

54 of the original 100 Ss examined at preflight successfully completed advanced pilot training. 40 of these Ss were then given audiometric retests following a period of freedom from noise of 24 hours or more ("rested" group). 14 Ss had 1/2 to 8 hours rest from aircraft noise prior to retest ("non-rested" group). Among the "rested" ears, mean hearing losses sustained during primary or basic pilot training were partially or completely recovered following advanced training. In striking contrast, the "non-rested" ears of the advanced group showed mean hearing losses which were widespread, involving the frequencies 1024 to 5792 cps inclusive. It may be concluded that hearing losses incurred during primary, basic, or advanced pilot training are, on the whole, temporary losses which are partially or completely recovered following 24 hours of rest.

Smith, D.E. COMPARISON OF AUDITORY ACUITY OF FLYING PERSONNEL AND NON-FLYING PERSONNEL. Proj. 514, Rep. 1, July 1948, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Audiograms were obtained for 227 Ss with a mean flying experience of 1400 hrs. (range 100 - 4000) and for 211 Ss who had no flying experience except for occasional commercial transport flights. Ss without flight experience showed a high tone loss of 10 to 12 db vs. Ss with flight experience who showed a high tone loss of 17 db. Ss were between 20 - 30 yrs. of age. This difference in acuity was significant and indicates that the loss of high tones in flying personnel is not due simply to aging, but that there is an additional factor of acoustic trauma. (HEIAS)

Smith, P.K. THE USE OF HONEY TO INCREASE ANOXIA TOLERANCE. Proj. 79, Rep. 1, June 1942, 14pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Using 28 Ss, a diet of honey and milk was compared with a sucrose and milk diet. The ratio of added carbohydrate was essentially the same in both diets: 56 gms. of honey vs. 40 gms. of cane sugar per pint of milk. Ss were given code tests and addition tests at ground level and at 10,000 ft. There was no significant difference between performance following a honey-milk diet vs. a sucrose-milk diet. However, performance on both these diets was superior to performance following a normal diet. (HEIAS)

Smith, P.K. EFFECT OF SULFONAMIDE DRUGS ON ANOXIA TOLERANCE: EFFECTS OF PROPHYLACTIC DOSES OF SULFANILAMINE, SULFATHIAZOLE, SULFADIAZINE AND SULFAPYRAZINE. Proj. 76, Rep. 1, Feb. 1943, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

18 Ss performed intellectual and psychomotor tests at simulated altitudes either with or without added oxygen and with a 4 gm. dose of sulfanilamide, sulfadiazine, sulfathiazole, sulfapyrazine, or a placebo. The doses were given 4 to 6 hrs. before testing. Sulfanilamide, both with and without supplemental oxygen, adversely affected performance on both types of tasks. Sulfadiazine, sulfathiazole, and sulfapyrazine had no measurable effect on performance. (HEIAS)

2804

Smith, P.K. EFFECT OF SULFONAMIDE DRUGS ON ANOXIA TOLERANCE: EFFECT OF THERAPEUTIC COURSES OF SULFATHIAZOLE AND SULFADIAZINE. Proj. 76, Rep. 2, Feb. 1943, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Using 14 Ss, the effects of sulfonamide drugs on oxygen tolerance. Before the administration of the drug was begun, each S made 5 ascents in the high altitude chamber and took the psychomotor tests with and without supplementary oxygen. Ss were divided into 3 groups, 1 being given sulfadiazine, 1 sulfathiazole and 1 placebo. The doses were 1 gm. 4 times a day for 5 days. The ascent in the high altitude chamber was made about 1:30 P.M. on the fifth day the drug was given. Daily blood samples were taken and determinations made of the free and total sulfonamide, total hemoglobin, methemoglobin and sulfhemoglobin. Pulse rates were taken after approximately 30 to 40 min. without added oxygen at 10,000 ft. and then again 5 min. after the oxygen was turned on. About 5 days after the last dose of sulfonamide, the entire procedure was repeated this time with each S getting another sulfonamide or a placebo. No differences in performance between the Ss receiving different sulfonamides or a placebo was found. Sulfonamide blood levels after doses of sulfadiazine were 2 to 3 times as high as the levels found after similar doses of sulfathiazole. This was due to the smaller excretion of sulfadiazine. (HEIAS)

2805

Smith, P.K. EFFECTS OF MORPHINE AT HIGH ALTITUDE. Proj. 181, Rep. 1, Sept. 1943, 1p. USAF School of Aviation Medicine, Randolph Field, Tex.

To determine the effects of one-half grain doses of morphine tartrate at 38,000 feet, 6 individuals were taken to 38,000 feet and readings made at 15 minute intervals of their arterial saturation as revealed by the oximeter. They exercised at 10 minute intervals. After a period of rest pulse rates were observed and respiratory rates were obtained merely by observing the regulator diaphragm. This gave only rate with no indication as to depth, etc. One entire "Syrrette" containing one-half grain of morphine tartrate was then given and the Ss observed for one hour at 38,000 feet. The results indicated that morphine in doses of one-half grain of the tartrate given subcutaneously was well tolerated at 38,000 feet simulated altitude.

Smith, P.K. THE EFFECTIVENESS OF SOME MOTION SICKNESS REMEDIES IN PREVENTING AIRSICKNESS IN NAVIGATION STUDENTS. Proj. 261, Rep. 2, Jan. 1945, 6pp. USAF School of Aviation Medicine, Randolph Field, Tex.

274 navigation students were chosen who had been airsick 3 or more times regardless of the number of flights. They were then given 1 of the remedies, Army Motion Sickness Preventive (A), Royal Canadian Navy Seasickness Remedy (C), hyoscine (H), or a placebo of lactose (L), or nothing at all (O). All drugs were given in number 1 pink capsules. The order of administration was rotated in successive students so that approximately equal numbers would take the drug in each of the following sequences: ALCOH, LCOHA, COHAL, OHALC, and HALCO. The drugs were given 1/2 to 1 hr. before the flight began. The results indicated that Army Motion Sickness Preventive, Royal Canadian Navy Seasickness Remedy and hyoscine are all moderately effective in preventing airsickness. Some evidence was obtained that hyoscine was more effective than the Army Motion Sickness Preventive or the Royal Canadian Navy Seasickness Remedy. There was no evidence that the administration of placebos affects the incidence of seasickness. (HEIAS)

2807

Smith, P.J. USE OF HYOSCINE HYDROBROMIDE FOR THE PREVENTION OF AIRSICKNESS IN FLEXIBLE GUNNERY STUDENTS. Proj. 251, Rep. 3, Dec. 15-5, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

To study the effects of hyoscine hydrobromide (HM) on airsickness 560 Ss were given 3.75 mg. doses of HM and 479 were given a placebo (lactose). Assignment of HM was random. Ss (Jannille gunnery students) were given the drug immediately before a mission. A questionnaire, indicating 5 degrees of airsickness (none to extreme) was filled out by S immediately upon completion of the mission. The data was analyzed in 2 ways: a) incidence of airsickness of all degrees; and b) vomiting or extreme airsickness. Using the former criterion significantly fewer Ss became airsick following HM vs. a placebo. Using the latter criterion there was no difference between the numbers of Ss becoming airsick following HM vs. placebo. (MEIAS)

Parant, G.N. & Whittingham, B.G.V. A SURVEY OF MEASUREMENTS OF FEET AND FOOT-WEAR OF ROYAL AIR FORCE PERSONNEL. F.P.R.C. & L. July 1952, 36pp. Medical Research Council, Flying Personnel Research Committee, Farnborough, Hants, England.

This report is concerned with a survey providing foot measurements of 200 men in the RAF (100 flying personnel and 100 ground staff) and measurements of the boots and shoes they were wearing. Comparisons are made between this series and one of 5566 United States soldiers, with the object of discovering how far data of the latter can be used in dealing with the sizing of new types of footwear for British Service communities. Following particulars of both surveys, topics treated are: a) the clinical examination of the feet of the RAF personnel; b) the accuracy of the measurements of feet and footwear; c) a reduction and comparison of the foot measurements of the 2 surveys; d) the measurements of footwear (RAF survey) and their relations to foot measurements; e) the grading of measurements for different sizes and fittings of footwear; f) the use of data for foot measurements in developing new footwear, with reference to the development of a flying boot.

Peckard, J.M. TEN YEAR FOLLOW UP STUDY OF THE PHYSICAL STATUS OF 1000 AVIATORS. A STUDY OF THE DEATHS OCCURRING IN THE PAST TWELVE YEARS. Proj. MM 001 057-05-02, Nov. 1952, 10pp. USAF School of Aviation Medicine, Pensacola Air Station, Fla.

An analysis is presented of the deaths occurring over a 12 yr. period among 1056 white males all of whom were in the naval air training program at Pensacola, Florida from July 1940 to May 1941. Over 99% of this group have been traced. 220 of the 1056 Ss (21%) are now dead, and of this number 185 deaths occurred during World War II. The date and cause of death is known in all but one case. 192 deaths (87% of all deaths) were associated with aviation, 1/3 of them in aerial combat. The 27 non-aviation deaths included 16 in combat, 7 from disease, and 4 as a result of non-aviation injuries. Study of the mortality among the Ss when divided according to flight status reveals that the men who completed flight training only after difficulty during some phase of the program have a higher aggregate mortality (27%) than the better students and instructors (21%). The men who did not complete the training program have a significantly lower mortality (15%). When the Ss are divided according to military status during flight training, it is found that the officer students have a mortality of 32% which is more than double the mortality of 15% among the enlisted students. The cadets have a mortality of 20%. The death rates for our Ss still active in military aviation, for military pilots, for commercial pilots, and for non-flying military officers since 1945 are also examined. It is found that military aviators even in peace time have a death rate 5 times that of non-flying officers. Commercial pilots have a lower aviation accident death rate than military pilots but higher than the general population.

Peugnet, H.B. MEASUREMENTS OF NOISE IN AIRCRAFT. Proj. 296, Rep. 1, Feb. 1945, 7pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Noise levels were measured in the B-29, B-24, and B-17 airplanes. The principal emphasis was given to the B-29, as such measurements have not previously been reported. Low frequency noise in the B-29 at normal cruising speed was much less than in the B-24 and B-17. The average level at 4 B-29 positions was 96 db overall noise, as compared with about 110 db in the other 2 types. High frequency noise in the B-29 was from 20 to 30 db lower than in the B-24 and B-17, except when the flight compartment fans and defrosters were in operation. Flight compartment fans raised the noise level of the 1600-3200 cps band from 65 db to about 90 db. The high frequency hiss of the fans made speech communication very difficult. In the sound spectrum of the B-29, a noise peak of about 90 db intensity at the 150-300 and 200-400 cps bands was probably caused by inverters and generators. This "hum" did not seriously interfere with speech. Noise levels in the B-29 were approximately the same at low and high altitudes, except for the high frequency hiss of defrosters.

Rose, H.V. STUDY OF ACCLIMATIZATION DURING A TWO-WEEK EXPOSURE TO MODERATE ALTITUDE (10,000 FEET). EFFECT OF ALTITUDE ADAPTATION ON NIGHT VISION AND OCULAR MUSCLE BALANCE. Proj. 21 02 029; Rep. 1, March 1949, 16pp. USAF School of Aviation Medicine, Randolph Field, Tex.

9 to 12 Ss have been examined before, during, and after staying 2 weeks at an altitude of 3,000 m. (10,000 ft.). The twilight visual acuity, which after a short stay at a simulated high altitude in the decompression chamber shows a marked decline, is restored to normal within 24 hours at actual altitudes of about 2,000 to 3,000 m. (6,500 to 10,000 ft.). This normal value was maintained throughout the following 2 weeks sojourn at this altitude. The brightness threshold in night vision was likewise restored to normal or better values after staying 24 hours at actual altitudes of about 2,000 to 3,000 m. (6,500 to 10,000 ft.)--in contrast to the deterioration observed in decompression tests. In those cases where the improvement was above the normal values, a recession was observed during the 2 weeks period at these altitudes. The examination of the ocular muscle balance after the first 24 hours revealed a tendency to esophoria, which in the course of the following 2 weeks at high altitude shifted to a tendency to exophoria. These processes, depending on the extent and moment of their manifestations, may gain importance in long distance flights. They may be induced in pressure cabin aircraft in which the prevailing pressure is less than that at ground level.

Farnsworth, D. THE FARNSWORTH-MUNSELL 100-HUE AND DICHOINOUS TESTS FOR COLOR VISION. J. Opt. Soc. Amer., 1943, 33, 10, 568-578. Paper presented at Symposium on Color-Blindness at the meeting of the Optical Society of America, March 4-6, 1943, New York.

2813

The Farnsworth-Munsell 100-Hue test was developed as a laboratory technique for the analysis of color anomaly. From data obtained in this manner new types of color vision tests can be created for specific purposes. The Dichotomus Test, B-20, for code-color discrimination was thus derived. Principles upon which these tests are constructed are described and preliminary results presented.

Rowland, Louise S. SELECTION AND VALIDATION OF TESTS FOR COLOR VISION--RELATIONSHIP BETWEEN DEGREE OF COLOR DEFICIENCY AND ABILITY TO IDENTIFY SIGNALS FROM A "BISCUIT GUN". Proj. 137, Rep. 7, Nov. 1943, 4pp. USAF School of Aviation Medicine, Randolph Field, Tex.

32 normal Ss and 84 color deficient Ss were given a battery of color vision tests before taking part in 1 or more field tests involving the recognition of the red, green and white signals from a "biscuit gun". Of the 6 tests studied, only the Color Threshold Lantern was adequate in selecting those color deficient individuals who were able to distinguish signals from the biscuit gun. When biscuit gun signals were shown from a distance of 1 mi., the visibility of the signals was much greater at night than at dusk or in the daytime. In the experiments made at night, all the normal and all the color deficient Ss identified the color correctly. At dusk all the normals and about 1/2 the color deficient Ss made perfect scores. In the experiments made in the daytime, some of the normals and all the color deficient made errors. (HEIAS)

2817

Rowland, Louise S. A LANTERN FOR MEASURING CHROMATIC THRESHOLDS. Proj. 97, Rep. 1, Dec. 1942, 6pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A lantern for measuring chromatic thresholds is described. Its purpose is to provide a quantitative test for ability to recognize aviation signals and to provide a basis for selecting those color deficient individuals who can be considered "color safe" insofar as recognition of signals is concerned. Determinations made with a color lantern using signal colors of varying intensity show definite and reproducible differences in the scores of color anomalous Ss. 33 normal and 27 color deficient Ss were tested. Approx. 10% of those with anomalous color vision make scores equalling those of normal Ss. Since the test approximates closely the actual conditions involved in the recognition of signal colors, the normal scores made by some color anomalous Ss indicate that their defect is not sufficient to cause any significant impairment in ability to identify signal colors. (HEIAS)

Rowland, Louise S. AN ABRIDGED EDITION OF THE AMERICAN OPTICAL COMPANY PSEUDO-ISOCROMATIC PLATES FOR TESTING COLOR PERCEPTION. Proj. 68, Rep. 1, July 1942, 5pp. USAF School of Aviation Medicine, Randolph Field, Tex.

26 Ss were examined by means of 3 pseudo-isochromatic tests: a) The American Optical Company series containing 46 plates; b) The 8th edition of the Ishihara charts containing 32 plates; and c) An abridged edition of the Ishihara charts (7th edition) containing 11 plates. The tests were given according to the standard procedure outlined in the regulations. A study was made of individual records to determine which charts gave results consistent with the results of the entire series. It was concluded that: The American Optical Company Pseudo-Isochromatic Plates contain a number of charts which should be omitted. Those include: a) charts which are read by a majority of color deficient subjects; b) charts in which normal subjects frequently make minor errors not related to color deficiency. An abridged version of the test composed of 23 of the more reliable charts was proven. In a group of 26 Ss, to provide a much more definite differentiation in the scores of normal and color defective Ss than does the complete test. It is recommended that further studies be made to confirm the advantages of the abridged version of the test described in this report.

Russell, R.W. THE EFFECTS OF HIGH ALTITUDES (DECREASED BAROMETRIC PRESSURE) ON SIMPLE MENTAL WORK. Proj. 20, Rep. 1, March 1942, 4pp. USAF School of Aviation Medicine, Randolph Field, Tex.

2 experiments were conducted to determine the effects of high altitude with and without O₂ on the level of proficiency of simple mental work. A simple addition test consisting of single digits was administered prior and after the "flight", and at altitudes of 35, 38, and 40,000 ft. In Exp. I, the effect of anoxic conditions on test behavior was studied. A series of runs in a low-pressure chamber were made in which 56 Ss were tested at an altitude of 18,000 ft. without O₂. The behavior studied was affected significantly by anoxia at 18,000 ft. No decrement in proficiency level occurred at 35, 38, and 40,000 ft. when O₂ was available. Exp. II tested the effects of high altitudes (35, 38, and 40,000 ft.) on the test performance when the Ss were supplied with regulation O₂ equipment and supply. No control groups were run. It was concluded that practice effects were not a significant factor, although a "let down" effect proved to be significant. The effects of altitude were negative. There was no decrease in performance between the samples taken at 35, 38, and 40,000 ft. (HEIAS)

Schaefer, H.J. EXPOSURE HAZARDS FROM COSMIC RADIATION BEYOND THE STRATOSPHERE AND IN FREE SPACE. Proj. MM 001 059.13.03, March 1952, 9pp. USN School of Aviation Medicine, Pensacola Air Station, Fla.

The ionization dosage from cosmic radiation increases from its sea level value of 0.1 milliroentgen-equivalent-physical per 24 hours to a maximum of 15 mrep/d at 75,000 ft. for northern latitudes. It then decreases and levels off to a value of 9 mrep/d which is reached at about 140,000 ft. At larger distances from the earth the ionization dosage can be expected to increase again to twice the last mentioned value due to the gradually vanishing shadow effect of the earth. The actual ionization dosages in larger absorber masses (air, planes, rocket ships) will be considerably higher due to the transition effect. The multiplication factor which equals about 2.0 for the rarified air at 75,000 ft. altitude will be substantially larger for denser materials. The deflecting influence of the geomagnetic field excludes low-energy primaries from the equatorial belt. The thin-down phenomenon is limited to northern latitudes. The exposure hazard, therefore, can be expected to be substantially greater in the polar cap. For larger distances from the earth it can be theoretically derived that the equatorial zone of total exclusion of low-energy heavy nuclei extends to about 1,000 miles altitude and the zone of partial exclusion (i.e., of the gradual build-up of the full intensity) to about 8,000 miles altitude.

Schmidt, Ingeborg. NEW TESTS FOR THE EXAMINATION AND TRAINING OF COLOR VISION. I. PSEUDO-ISOCROMATIC PLATES. Proj. 517, Rep. 1, July 1948, 11pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Hsu-Pen Wu's and 3 other sets of pseudo-isochromatic plates are tested to find whether the Wu plates are adequate for selection purposes and how they compare with the other tests. 100 normal Ss and 62 color defective Ss were tested. Wu's pseudo-isochromatic plates proved a good screening test, since it permits an especially definite differentiation between color normal and color deficient. This classification is more accurate than that afforded by the Ishihara plates, stilling plates, and AOC charts. However, the Wu plates are rather unreliable in determining quantitatively the red-green defect. An investigation of the precision of differentiation provided by each individual plate showed that some plates are very satisfactory, whereas others were of only little value, having been interpreted incorrectly by a high percentage of color normals. It is recommended that the pattern and color of some plates be modified and that some plates should be omitted. Also, the illumination of the plates should be standardized. (HEIAS)

Scobee, R.G. & Chinn, H.I. THE EFFECT OF CARBON MONOXIDE ON NIGHT VISUAL EFFICIENCY. Proj. 234, Rep. 1, Jan. 1944, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The effect of low blood concentrations of CO on night visual efficiency was investigated. The following functions were tested before and after CO inhalations: light and form perception thresholds, visual acuity, contrast discrimination, muscle balance, depth perception, color vision, and accommodation. A blood concentration of CO up to 20% has no constant demonstrable effect on night visual efficiency. It is possible that muscle balance and depth perception are affected in CO anoxia. (HEIAS)

2826

Scobee, R.G. & Green, E.L. A COMPARISON OF TESTS FOR HETEROPHORIA: RELIABILITY OF THE SCREEN-MADDOX ROD TEST. Proj. 375, Rep. 2, July 1945, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The reliability of heterophoria measurements made at a testing distance of 20 ft. with the screen-Maddox rod test, as it is used in the AAF Physical Examination for Flying, was determined. 50 Ss were tested for lateral phoria and 49 Ss for vertical phoria by 2 examiners, each of whom repeated his examination on a subsequent date. A r of 0.95 was found for lateral heterophoria and a r = 0.92 for vertical phorias. (HEIAS)

Karpovich, P.V. THE RELIABILITY OF THE AAF PHYSICAL FITNESS TEST. Proj. 184, Rep. 1, Oct. 1943, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

122 Pre-Flight Aviation Students at the San Antonio Aviation Cadet Center were tested and retested with the AAF Physical Fitness Test. The test possessed a high degree of reliability as shown by the coefficient of correlation of +0.85 for the Physical Fitness Ratings.

2828

Karpovich, P.V. EFFECT OF AGE UPON THE PHYSICAL FITNESS RATINGS. Proj. 191, Rep. 1, Jan. 1944, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Physical Fitness Ratings were collected for 8,712 AAF enlisted men between the ages of 18 and 38. Physical Fitness Ratings include sit-ups, pull-ups, and the 300 yd. shuttle-run. Lines of best-fit were calculated for each of these 4 indices vs. age. The slopes of these lines were significantly different from zero, indicating a definite effect of age upon the scores. (HEIAS)

2829

Karpovich, P.V. EFFECT OF AGE UPON THE PHYSICAL FITNESS RATINGS. Proj. 191, Rep. 2, July 1944, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

AAF Physical Fitness data on 10,550 enlisted men were gathered. The number of pull-ups and sit-ups, time for shuttle-run, and Physical Fitness Ratings (composite index derived from previous 3 scores) were each fitted to a line of best fit against age (range of 18 to 38). All 4 lines indicated a significant decrease with increasing age. (HEIAS)

Karpovich, P.V. THE EFFECT PRODUCED ON THE SCORES OF THE AAF PHYSICAL FITNESS TEST BY THE WEARING OF THE FATIGUE UNIFORM. Proj. 179, Rep. 1, Oct. 1943, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

2 series of experiments on the effect produced on the scores of the AAF Physical Fitness Test by the wearing of the fatigue uniform are reported. In the first, 267 Ss were divided into 2 groups, group A and group B. Each group was tested twice, once in fatigue uniforms and G.I. shoes and once in athletic uniforms and tennis shoes. In the second series, 445 Ss were divided into 3 groups, group C, group D, and group E. Groups D and E were tested the same as groups A and B; group C, a control group, wore athletic uniforms for both tests. In both experiments wearing the fatigue uniform instead of the athletic uniform slightly lowered the score obtained. There were inconsistencies in performance obtained with the component parts of the AAF Physical Fitness Test, particularly in running. That the inconsistencies were caused by inadequate supervision of the test was indicated because when the experiment was later repeated under more rigid supervision, the inconsistencies disappeared completely. The difference in the Physical Fitness Ratings obtained with the fatigue uniform and with the athletic uniform is of statistical significance, but it is not sufficient to be of practical importance in mass testing nor to warrant construction of special scoring tables. However, in following the progress of an individual, care should be taken that the same type of uniform is worn for all tests.

2832

Karpovich, P.V. THE EFFECT OF REVERSE AND FORWARD GRIPS UPON PERFORMANCE IN CHINNING. Proj. 178, Rep. 1, Sept. 1943, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

3830 Aviation Students were tested for chinning using the forward (overhand) grip. The mean value was 8.7 chinings per man. 4781 Aviation Students were tested using the reverse grip. The mean was 8.9 chinings per man. The difference was 0.2 chinings per man in favor of the reverse grip. This difference is significant from a statistical point of view. In order to avoid errors in scores, the AAF Physical Fitness Test regulations should be followed; namely, that the forward grip should be used during the test. From the standpoint of training, one should pay more attention to practicing the forward grip because this grip is more useful for a soldier in overcoming obstacles he may have to scale. A experimental kinesiological analysis of both types of chinning should be made for a better understanding of the action of the muscles involved.

2833

Karpovich, P.V. THE EFFECT OF FORWARD AND REVERSE GRIPS ON CHINNING AT VARIOUS PERFORMANCE LEVELS. Proj. 189, Rep. 1, Dec. 1943, 5pp. USAF School of Aviation Medicine, Randolph Field, Tex.

To determine the effect of forward and reverse grips on chinning at various performance levels, 7000 Ss, after classification according to performance level, were given 2 chinning tests. Ss were divided into 2 groups, A and B. In the first test, Group A used the forward grip and Group B, the reverse grip; in the second test, the grips were reversed. The data indicated that differences between chinning scores with the reverse and forward grips exist and become greater with increases in the level of performance. It was concluded that in fitness testing the reverse grip should not be indiscriminately substituted for the forward grip. (HEIAS)

Loucks, R.B. A METHOD FOR REDUCING MUSCLE ACTION POTENTIALS TO QUANTITATIVE INDICES OF TENSION FOR USE IN AIR CREW CLASSIFICATION TESTS. Proj. 44, Rep. 1, Oct. 1942, 9pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A method is described which makes possible a comparison of one individual with another on the basis of the AP activity which underlies the muscular tension involved in the performance of a particular task. The technique provides a numerical score for muscular tension immediately upon completion of a particular task. The application of this method to the measurement of muscular tension involved in the performance of a standard psychomotor test results in scores of such high reliability ($r = .95$) that individuals can be differentiated from each other with a marked degree of precision. The method may have value as a general technique for measuring the effect of drugs, fatigue, anxiety, etc., on muscle tension. The required equipment for the recording of muscular AP. (HEIAS)

Loucks, R.B. IMPAIRMENT IN PSYCHOMOTOR PERFORMANCE WITH THE TYPE A-13 PRESSURE DEMAND OXYGEN SYSTEM AT 45,600 FEET SIMULATED ALTITUDE. Proj. 308; Rep. 1, Aug. 1944, 59pp. USAF School of Aviation Medicine; Randolph Field, Tex.

A group of 50 subjects were employed in an investigation of the amount of decrement in psychomotor performance at 45,600 ft. simulated altitude while utilizing the Type A-13 pressure demand oxygen system at 8 in. of pressure. In spite of a preliminary indoctrination run and denitrogenation procedures, 30% of the Ss had to be brought down to ground level within the first few minutes after reaching elevation, because of circulatory collapse or gas pains. For the Ss who completed their tests, the average of the individual decrements in performance at 45,600 ft. is almost as great as that shown at 18,000 ft. without the use of oxygen masks, but control measurements on a group of 40 Ss who performed the psychomotor test at ground level with pressure breathing indicate that the pressure breathing in and of itself causes sufficient distraction to produce an appreciable impairment in psychomotor performance. If the loss in efficiency due to the distraction effect of pressure breathing at ground level is subtracted from the impairment in performance with pressure breathing at 45,600 ft., the residual loss, which represents that portion of the decrement which is due to anoxia, is approximately the same as that produced at 15,000 ft. when the subjects do not wear oxygen masks.

2840
Masland, R.L. ALTITUDE TOLERANCE WHEN BREATHING OXYGEN AND WHEN BREATHING OXYGEN SUPPLIED UNDER POSITIVE PRESSURE. Proj. 213; Rep. 1, Aug. 1944, 12pp. USAF School of Aviation Medicine; Randolph Field, Tex.

This report is a review of a series of experiments undertaken at the School of Aviation Medicine to determine the gain in altitude tolerance obtainable by the use of oxygen and of oxygen supplied under positive pressure. 2 conclusions were reached: a) With adequate denitrogenation, using either demand or pressure breathing equipment, flights to 40,000-41,500 ft. may be continued for periods of half an hour, with a descent rate of less than 10% and with performance on the part of those who do not descend equivalent to that exhibited by individuals at altitudes of 12,000-17,000 ft.; b) With ascent above 43,000 ft. using pressure breathing, there is a rapid increase in descent rate, from 15% at 43,500 ft. to 36% at 45,600 ft. This descent rate is probably sufficiently high to make flights to such altitudes unwarranted, except in great emergency. However, where the tactical situation requires, such flights, it is probable that those individuals who do not suffer an unfavorable reaction will retain useful consciousness up to approximately 48,000 ft. (arterial oxygen saturation equivalent to 20,000 ft.) at least for short periods of time.

Mann, C.W. VISUAL FACTORS IN THE PERCEPTION OF VERTICALITY. Contract N70NR 434 TO1, ONR Proj. NP 143 455 & BuMedSurg. Proj. NM 001-063, Cl. 29, Joint Proj. Rep. 29, Aug. 1952, 6pp. USN School of Aviation Medicine; Naval Air Station, Fla. (Tulane University).

2838
To investigate Gibson's hypothesis that errors in the perception of verticality will be less under consistent visual-proprioceptive stimulation than under discrepant conditions, nine subjects were required to set a target-rod in alignment with the gravitational vertical under 15 conditions of room and body tilt. Mean constant errors and mean average errors in rod-setting were analyzed in terms of the above hypothesis. The results are discussed in terms of the respective roles of visual and proprioceptive factors in judgments of verticality.

Marcks, C.A. HOW DOES EQUIPMENT AND CLOTHING AFFECT THE PROBLEMS OF EMERGENCY SYSTEMS DESIGN. Sept. 1952, 7pp. USN Bureau of Aeronautics, Washington, D.C.

2839
This brief paper views the rapid growth in personal equipment components and in the complexity of protective clothing for aircraft operations during and since World War II. These trends are discussed in terms of their effects on emergency escape provisions, as affecting the safety of the pilot and as affecting the design of equipment and aircraft. The dangers of the present course are pointed out and a preferred approach is discussed.

2841
Mayo, A.W. ESCAPE DEVICES REQUIRED FOR FUTURE AIRCRAFT. Sept. 1952, 14pp. Douglas Aircraft Company, El Segundo, Calif.

Considerations involved in aircraft escape devices are surveyed. Safety and escape requirements should be based on a study of the particular conditions applying to the aircraft under consideration rather than on an attempt to arrive at them by generalization. In objectively analyzing the application of escape and safety devices to an aircraft, 3 considerations appear to be fundamental in determining the objective requirements of the system: these are moral, morale, and economic considerations. Safety is not an absolute, as it is possible to reduce indefinitely any defined risk by increasing expenditures of effort. Once the objective requirements are established, studies of specific conditions are in order. 2 general types of variables require consideration: a) Environmental control--control of the composition, pressure, and temperature within the escape device; b) Force control--control of the variations in magnitude and directions of accelerations of forces. It is emphasized that the maximum use of statistics should be made in order that excessive consideration not be given to extreme and unusual conditions of flight. (MEIAS)

McDonald, R.K. & Kelley, V.C. STUDY OF ACCLIMATIZATION DURING A TWO-WEEK EXPOSURE TO MODERATE ALTITUDE. SOME OBSERVATIONS ON THE EFFECTS OF ALTITUDE ON METABOLISM. III. HEMOGLOBIN METABOLISM AND ERYTHROCYTOSIS. Proj. 21 02 029, Rep. 3, Oct. 1949, 13pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The investigations are concerned with the alterations in hemoglobin metabolism and erythropoiesis that occurred in a group of 26 Ss during a 2 week period of acclimatization at an elevation of 10,000 ft. There is an initial rapid rise in hemoglobin concentration and erythrocyte count which is attributable to release of stored red cells under the stimulus of anemia. This is followed by a more gradual rise attributable to formation of new cells. The hemoglobin levels attained during exposure to altitude are maintained for a considerable period of time after return from altitude. Hemoglobin destruction as judged by fecal urobilinogen excretion is increased during the early phase of exposure to anoxia but decreased below baseline values during the latter part of the exposure. Urine urobilinogen excretion increases progressively with time at altitude but returns to within normal limits immediately upon return from altitude indicating that there is inadequate liver function during anoxic stress of this degree but that this inadequacy rapidly disappears following termination of the stress.

Grether, W.F. EFFECTIVE TARGET DIAMETER AS A FACTOR IN DETERMINING DIFFICULTY OF THE S.A.M. TWO-HAND COORDINATION TEST. Proj. 304, Rep. 1, July 1944, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

In the use of the S.A.M. Two-Hand Coordination Test for selection of aircrew personnel differences have been noted in the difficulty of different test units. In order to find the cause of these differences in difficulty, and thus be able to eliminate them, measurements of effective target diameter were made on the test units currently in use at Medical and Psychological Examining Units No. 6, 8, and 10. These measurements were then related to the current mean scores on the different units of this apparatus and found to give a correlation coefficient of +.457. This coefficient indicates that the effective target diameter is a significant factor in determining the difficulty of the S.A.M. Two-Hand Coordination Test. It is suggested that these differences in difficulty could be significantly reduced by maintaining a standardized effective target diameter on all test units.

2850

Hemingway, A. THE EFFECT OF ENVIRONMENTAL TEMPERATURE ON MOTION SICKNESS. Proj. 170, Rep. 3, Nov. 1943, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

971 Ss in the AAF were given a 20-min. swing test to determine whether or not a cool environment would reduce the incidence of swing sickness. The tests were conducted out of doors throughout one summer and winter under all types of weather conditions. Temperatures between 5 and 35°C had no effect on the incidence of swing sickness. In a small group of 11 Ss tested in an environment above 35°C the incidence of swing sickness was higher than in other groups. This is suggestive that a hot environment may favor motion sickness; but the group is too small for a definite conclusion to be drawn. (HEIAS)

Karpovich, P.V. APPRAISAL OF THE PRESENT PHYSICAL TRAINING PROGRAM FOR AVIATION CADETS. Proj. 15, Rep. 1, April 1942, 6pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

2851

This report presents an appraisal of the system of physical training of aviation cadets at various types of flying schools (as of April 1942). It describes such aspects as organization of the physical training program, conduct of classes, "research" claims, facilities, etc., and presents suggestions for improvement of such programs.

2852

Karpovich, P.V. DEVELOPMENT OF SPECIAL AVIATION EXERCISES. Proj. 26, Rep. 1, April 1942, 6pp. AAF School of Aviation Medicine, Randolph Field, Tex.

2852

This is a report of the development of special calisthenics drills symbolizing a plane and pilot in action to stimulate interest among flying cadets and flying personnel in such physical exercises. The reaction to these exercises is presented along with a detailed and illustrative description of the exercises.

2853 Karpovich, P.V. A SPECIAL TAPE FOR THE MEASUREMENT OF CHEST EXPANSION. Proj. 24, Rep. 1, Oct. 1942, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Research conducted by the Department of Statistics of the School of Aviation Medicine revealed frequent and great errors in measurements of the chest girth of the flying cadets. The newly designed tape described in the body of this report is recommended, because: a) It is easier to use; b) Results obtained by different observers in chest measurement of 99 student flight surgeons and 10 enlisted men were more consistent when the new tape was used than with the ordinary tape.

2854 Karpovich, P.V. RELATION BETWEEN BREATH HOLDING TESTS AND THE ENDURANCE IN RUNNING AND HARVARD STEP-UP TEST SCORES. Proj. 373, Rep. 2, Nov. 1945, 4pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A group of 48 aviation students was used for this study. The breath holding times obtained with 5 different tests were correlated with the maximum treadmill running times and the Harvard step-up test scores. Since the coefficients of correlation thus obtained are statistically not significant, the breath holding ability cannot be used for prediction of either running endurance or Harvard step-up test score. It is recommended that breath holding tests described in this report should not be used in assessing physical fitness of normal men.

Karpovich, P.V. STUDIES IN THE AAF PHYSICAL FITNESS TEST: SIT-UPS AND LEG-LIFTS. Proj. 245, Rep. 4, Aug. 1945, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

223 aviation cadets were used to study the correlation between and the reliability of the number of sit-ups and the number of leg-lifts. Ss were divided into approximately equal groups, A and B. On the first day of testing Group A did sit-ups and Group B did leg-lifts. 4 days later, Group A did leg-lifts and Group B did sit-ups. For establishing the reliability of the leg-lift an additional group of 101 Ss were used. The reliability of the sit-up had been found previously and no additional data were required. The reliability of sit-ups is +.71 and that of leg-lifts is +.72; yet, in spite of the large degree of kinesiological similarity between the two exercises the coefficient of correlation is only +.38, and therefore these two exercises cannot be used interchangeably for testing purposes.

2859

Karpovich, P.V. STUDIES OF THE AAF PHYSICAL FITNESS TEST: SELECTION OF A TIME LIMIT FOR SIT-UPS. Proj. 245, Rep. 3, July 1944, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

To determine if a time limit may be validly substituted for an unlimited period of time in performing sit-ups 5 groups of Ss performed sit-ups with either a 1, 2, 3, 4 or 5 min. time limit. One week later each group performed sit-ups with an unlimited time limit. The Ss were 2,478 AAF personnel--602 mechanics, 532 basic trainees, and 1,344 aviation cadets. The 3-min. time limit correlated highest with an unlimited period of time in sit-ups performance. However, the correlation coefficient of +.70 (the highest) is too low to justify substituting a 3-min. time limit for an unlimited period of time in individual testing.

2862

Karpovich, P.V. STUDIES OF THE AAF PHYSICAL FITNESS TEST: TRAINING CURVES IN CHINNING. Proj. 245, Rep. 1, April 1944, 3pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

To determine the rate of improvement in chinning performance, a study was conducted on the effect of training on the chinning performance of 98 aviation students, half of whom were of low ability and the others of high ability. Both groups had half the members utilizing a forward grip and the other half a reverse grip. Results were presented in terms of comparison of the chinning test scores and training curves obtained from the various groups.

Gallagher, J.R., Gallagher, Constance D. & Sloane, A.E. A BRIEF METHOD OF TESTING COLOR VISION WITH PSEUDO-ISOCROMATIC PLATES. Amer. J. Ophthalmol., Feb. 1943, 26(2), 178-181. (Massachusetts Eye & Ear Infirmary, Boston, Mass.).

A brief method for testing color vision, utilizing the pseudo-isochromatic charts published by the American Optical Company, is suggested. This method requires less time to administer, is attended with much less difficulty in interpreting results, avoids the introduction of eye fatigue as a factor in the individual's response, and yet efficiently detects individuals whose color vision is impaired. It is recommended that 10 of the plates (plus three Malingers plates) be used, and that the failure of more than one of these tests be considered evidence of color-vision deficiency.

2866

Chinn, H.I. MOTION SICKNESS. Special Report, Dec. 1951, 8pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The incidence and etiology of motion sickness are reviewed. The efficacy of various drug preparations as prophylactics is considered. The most promising preventive is the antihistaminic Lorgigan. A mixture of Benadryl and hyoscine gives excellent results against airsickness but produces undesirable side effects when taken for 2 or 3 days. Similarly, hyoscine alone or hyoscine aminoxide shows good protection against airsickness but produces side effects during frequent administration. The antihistaminics Dramamine, Trimerton, and Wellcome Preparation 47-83 give good protection. A number of other compounds are listed which give only fair or poor protection.

2868 Dempster, W.T. SPACE REQUIREMENTS OF THE SEATED OPERATOR. GEOMETRICAL, KINEMATIC, AND MECHANICAL ASPECTS OF THE BODY WITH SPECIAL REFERENCE TO THE LIMBS. Contract AF 18(600) 43, Proj. 7214, Tech. Rep. 55 159, July 1955, 254pp. USAF Aero Medical Lab., Wright Air Development Center, Dayton, Ohio.

The structure of the limb joints and the range and type of their motions were studied on cadaver material, with supplementary work on living subjects, in order to clarify geometric, kinematic and engineering aspects of the limb mechanism. Plans for the construction of manikin joints which showed normal ranges of limb movement were developed from this information. Specifications were also worked out for drafting board manikins which show correct limb ranges for seated postures. Subjects comparable to the model physique of Air Force flying personnel and highly selected small samples of muscular, thin, and rotund builds supplied information on the range of possible hand and foot movements which was consistent with the seated posture. Maximum dimensions of the work space for seated individuals were determined; a study of the kinematic factors involved permitted an evaluation of the potential utility of different regions within reach. Eight cadavers were dismembered to provide data on such physical constants as mass of parts, segment centers of gravity, density and moments of inertia. This work was supplemented by data on the distribution of body bulk in the living subjects studied. Applications of the above information to analyses of horizontal push and pull forces in terms of couples permitted an evaluation of the effectiveness of body mass, leverages and support areas.

2867 Gilbert, G.H. INTER-SENSORY FACILITATION AND INHIBITION. J. Gen. Psychol., 1941, 25, 381-407. (Psychology Dept., Connecticut College for Women, New London, Conn.).

This paper reviews the effects of heteromodal stimulation on sensitivity--the "dynamic" effect--of auxiliary stimulation. The experimental evidence available to date justifies the following tentative conclusions concerning the effect of heteromodal stimulation on sensitivity to stimulus intensity: Under conditions of momentary heteromodal stimulation a) a sufficiently intense stimulus will momentarily reduce sensitivity in another modality, and increase it after an optimum interval (about 1/2 sec.); b) a less intense heteromodal stimulus will momentarily increase sensitivity. Under conditions of prolonged stimulation, there is some evidence that the quality of the heteromodal stimulus may determine the direction of the effect, some stimuli acting as excitants, others as depressants. The effect will be limited by the lability of the sensation affected and individual differences in the susceptibility to heteromodal influence. The reported effects of heteromodal stimulation in space, color, and pitch discrimination may be regarded for the most part as secondary effects, depending on the effect of heteromodal stimulation on intensive sensitivity. From studies of more complex properties--flicker-fusion and phi-phenomenon--it is evident that on the complex level of stimulation we must also reckon with total field properties. Some of the theoretical implications are briefly discussed.

2870 Dinamore, Ruth A. & DuBois, P.H. A PRELIMINARY STUDY OF LEARNING IN THE B-500 FLIGHT SIMULATOR. Memo. Rep. 26, July 1952, 18pp. USAF Human Resources Research Lab., Bolling AFB, Washington, D.C. (Washington University, St. Louis, Mo.).

2870

To evaluate the training proficiency of the B-500 Flight Simulator, the performance of 47 crews during progressively more difficult simulated flights was analyzed. Performance of the aircraft commander, flight engineer, and the entire crew functioning as a team was evaluated by instructors' observations recorded in Simulator Flight Check booklets. The results are presented and discussed in terms of the number of errors evidenced throughout the training course. Progress in certain specific training areas (e.g., emergency procedures, basic flying techniques) is also discussed.

2874 Gagne, R.M. & Smith, P.K. CRITERIA OF ANOXIA TOLERANCE: III. EVALUATION OF A GROUP OF PSYCHOLOGICAL TESTS FOR USE AS INDICES OF ANOXIA. Proj. 89, Rep. 3, Nov. 1943, 14pp. USAF School of Aviation Medicine, Randolph Field, Tex.

An experiment was conducted to determine the effectiveness of a number of intellectual and psychomotor tests in revealing decrements in performance under conditions of anoxia. The tests employed were as follows: a) Addition Test; b) Code Substitution Test; c) Speediness Aiming Test; d) Compensatory Pursuit Test; e) a revised form of the Peg Moving Test; and f) Discrimination Reaction Time Test. All tests were found to have satisfactory reliability. The reliability of the Peg Moving Test was comparable to values obtained for the other psychomotor tests. Significant differences in performance under anoxia were shown to occur in the case of the Addition Test, the Pursuit Test, the Steadiness Aiming Test, and the Peg Moving Test. The Code Substitution Test and the Discrimination Reaction Time Test did not reveal significant differences. According to the distribution of differences under the control and experimental conditions, none of the tests in its present form could be used for indoctrination purposes to reveal individual decrements. The Compensatory Pursuit Test shows the most promise in this respect.

Gray, J.S. & Green, E.L. VOLUNTARY VENTILATION CAPACITY: NORMAL VALUES AND RELIABILITY OF MEASUREMENT. Proj. 449, Rep. 1, Dec. 1945, 11pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Standardization data for a method of measuring the voluntary ventilation capacity of human subjects is presented. The method consists of measuring the ventilation during a brief period of maximum voluntary hyperpnea. Repeated tests in 89 aviation students revealed the reliability coefficient of the test to be 0.90. The mean ventilation capacity was found to be 168 L/min. with a standard deviation of 22 L/min. The ventilation capacity was found to be correlated with surface area, but not with age, height, or weight. A regression equation was obtained from which the normal ventilation capacity may be predicted from a knowledge of the surface area with a standard error of estimate of 15 L/min. This test should be clinically useful as a ventilatory function test of the respiratory system.

2876
Greenberg, R.J. THE INCIDENCE OF AIRSICKNESS IN AAF TRAINING AND COMBAT. A MEDICAL EVALUATION PROGRAM REPORT AAF AS M43. Proj. 467, Rep. 3, ca. 1946, 9pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Data concerning the problems of airsickness were obtained by means of individual interrogation of 1488 combat returnee flying personnel. The interrogation was designed to obtain an estimate of the incidence of airsickness in training and combat, the number of combat missions during which airsickness had interfered with the performance of duty, the flyer's opinion as to the cause of his airsickness, and any remedy he had found effective. The data were compared with other surveys of the incidence of airsickness during training and with the incidence of suspension from flying duty for airsickness during combat. The over-all incidence of airsickness during training was 25.7%. There were 10.2% sick on three or more flights and 2.9% on ten or more. All completed their training and tour of combat duty. The over-all incidence of airsickness during combat was small, 5.4%, comprised of 3.7% who had been airsick during training and 1.7% who had not. The rate of interference with the performance of duty during a combat mission because of airsickness was very low, 0.2% per one thousand man-missions for 29,501 man-missions. The remedies most frequently found to be effective in overcoming airsickness were "relax in the aircraft, continue to fly, stick with it until the symptoms no longer occur, eat moderately, don't eat foods that disagree with you, direct your attention, keep busy, think of something else".

2877
Greenberg, R.J. AN EVALUATION OF THE ALTITUDE TRAINING PROGRAM. A MEDICAL EVALUATION PROGRAM REPORT AAF-AS-M 43. Proj. 467, Rep. 1, ca. 1946, 7pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

2877
The AAF Altitude Training Program was evaluated by means of questionnaires administered to 1485 men, combat flying returnees, who received their training between 1941 and 1945. From the data were estimated the amount of training received and the general effectiveness of the program. Ratings given to three aspects of the program—lectures, training aids, and preparation for combat—and to more specific portions of the program (e.g., emergency procedures) were analyzed according to aircraft type, year of training, and number of combat missions undergone by the respondent. Recommendations for improving the program were made.

2878
Grether, W.F. CRITERIA OF ANXIA TOLERANCE: I. DEVELOPMENT OF PSYCHOLOGICAL TESTS FOR USE IN THE ALTITUDE CHAMBER. Proj. 89, Rep. 1, Dec. 1942, 12pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

2878
Seven psychological tests to be used for the measurement of intellectual and motor functions in an altitude chamber are described and evaluated. Criteria for evaluation include the effect of practice on performance, range of scores, and reliability. The tests were administered to groups of Ss, which included from 15 to 24 persons, on five different occasions. Learning curves are constructed and test-retest and odd-even reliability coefficients are computed on the basis of the scores. Each test is described briefly. Instructions and, for the three apparatus tests, wiring diagrams are reproduced.

Grether, W.F., Connell, E., & Bjornstad, Jeanne M. EXPERIMENTAL EVALUATION OF THE NEW LONDON NAVY LANTERN FOR TESTING COLOR PERCEPTION. Rep. MCREXD 694 218, March 1949, 11pp. USAF Wright Air Development Center, Aero Medical Lab., Wright-Patterson AFB, Ohio

An evaluation was made of the New London Navy Lantern by testing and retesting 10 color deficient and 71 color normal adults on the lantern, 3 Pseudo-Isometric Charts, 2 Anomalous Scope, and a Neutral Point test. The findings concerning the Navy Lantern may be summarized as follows: a) 5 of the 10 color deficient Ss made no errors on the Navy Lantern on the first test, and 3 of these 5 made no errors on the retest. This indicates that many color deficient individuals will not be detected by one trial on this lantern. Whether those not detected may be considered "color safe" for aircrew training was not determined by this investigation; b) 7 out of 71 color normal individuals made 1 or more errors on the Navy Lantern during either the test or the retest. This indicates that unless supplemented by another color vision test or administered by an exceptionally cautious and skillful examiner some individuals will be falsely diagnosed as color blind by the Navy Lantern; c) The general design of the Navy Lantern was found to be very excellent for convenience as a color testing device. A number of mechanical difficulties were experienced which could be corrected easily in future models.

Grodins, F.S. THE EFFECT OF SEVEN HOUR EXPOSURE TO A PRESSURE ALTITUDE OF 10,000 FEET ON PSYCHOMOTOR PERFORMANCE. Proj. 402, Rep. 1, June 1945, 4pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The psychomotor performance of 15 Ss was tested continuously on the SAM single dimension pursuit meter during a 7-hr. exposure to an altitude of 10,000 ft. A control group of 19 Ss was tested at an altitude of 1,500 ft. No significant differences were found between the average performance, measured by time on target at 30 min. intervals, of the control and test groups during the 7-hr. period. The negative results obtained mean either a) that there was no impairment of psychomotor efficiency or b) that there was impairment in efficiency but that sufficient reserve was available to compensate for it. Thus, the results obtained permit no conclusion as to whether or not a decrease in psychomotor efficiency occurred. (HEIAS) R 9

Hemingway, A. AN APPARATUS FOR MEASURING THE ONSET OF SWEATING DURING THE DEVELOPMENT OF MOTION SICKNESS. Proj. 92, Rep. 1, Nov. 1942, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A galvanometric method which indicates the onset of sweating during motion sickness is described. The method described has been used on more than 100 swing tests for measuring susceptibility to motion sickness. It predicts with a high degree of accuracy the onset of sweating. In a few cases, as a rough estimate of 10% or less, Ss will become sick without sweating. The method is simple in operation and the circuit is easily assembled. (HEIAS)

2882

Hemingway, A. RESULTS ON 500 SWING TESTS FOR INVESTIGATING MOTION SICKNESS. Proj. 31, Rep. 2, Nov. 1942, 9pp. USAF School of Aviation Medicine, Randolph Field, Tex.

500 swing tests have been performed on glider pilots, cadets and airborne infantry. The incidence of swing sickness in 438 men--selected pro-glider pilots is 28.5% with half of these being mild and the other half severe cases of swing sickness. In a group of 16 cadets and navigators who were hospitalized for airsickness, the incidence of swing sickness was 100%. In a group of 35 airborne infantry who were airsick on recent maneuvers, the incidence of swing sickness was 80%. Blood pressures, pulse rates, and body temperatures were measured before and after swinging for all individuals tested. There were no significant changes. The incidence of swing sickness has been related to the history of motion sickness as determined by a questionnaire. A standardized scoring system was developed for the swing test. This standardized system is recommended as a means of measuring susceptibility to motion sickness.

Hemingway, A. SPEECH INTELLIGIBILITY AT HIGH ALTITUDE IN THE COLD UNDER CONDITIONS WHICH CAUSE ICE FORMATION IN THE MASK. Proj. 398, Rep. 1, Aug. 1945, 13pp. USAF School of Aviation Medicine, Randolph Field, Tex.

13 altitude chamber flights were performed to determine the usefulness of mask heaters for the prevention of ice formation in oxygen masks at high altitudes and to investigate the effect of the heaters on speech intelligibility. 15 Ss with heated and 15 Ss with unheated masks read word lists at 60°F and 20,000 ft. altitude. Recognition of the recorded readings was tested the next day. Using heated masks there were significant increases in speech intelligibility as indicated by the reduction in errors of word recognition, and by the reduction in equipment failure after 3 hrs. (HEIAS)

Rowland, Louise S. SELECTION OF A BATTERY OF COLOR VISION TESTS. Proj. 108, Rep. 1, Feb. 1943, 8pp. USAF School of Aviation Medicine, Randolph Field, Tex.

5 tests of color perception were given to 160 Ss. The purpose was to evaluate these tests as to their suitability for rapid screening of all color deficiencies, quantitative tests of degree of defect, or as adjunct tests for obtaining further information. Not all Ss were given all 5 tests. The Rabkin (Russian) is proved to be the best and simplest screening test of all those studied. It is not now available in quantity and the abridged version of the A.O. charts (S.A.M. Res. Proj. 68, Rep. 1 & 2) is the next best choice. According to the present data, the threshold lantern (S.A.M. Res. Proj. 97, Rep. 1) provides the best means of estimating the degree of defect: first, because it distinguishes 6 different degrees of color deficiency, whereas, the other tests provide only 3; second, it bears a close relationship to one of the more important field requirements in that it employs Aviation Colors as defined by the Bureau of Standards. It is recommended that further studies be made with these and additional tests on larger groups of normal and color deficient Ss. It is further recommended that test which prove most suitable as quantitative tests be studied in relation to actual performances such as the identification of flares, signals, etc. and other operational duties which may be indicated after a "job analysis" is completed.

Smith, R.B. STUDY OF ACETATE HOODS USED TO SIMULATE BLIND FLYING. Proj. 511, Rep. 1, Feb. 1948, 5pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

2887

To determine whether the use of acetate filters on cockpits in simulated blind flying constitute a cause of headaches, the specifications of the filters used by the USAF were examined. A clinical examination of 20 men having approximately equal vision in the two eyes was made as follows: 1) visual acuity was determined at distance of 20 ft. without a filter, through neutral gray, red, and blue filters, and 2) muscle balance was tested under the same conditions. Both types of readings were converted to continuous variables and studied by analysis of variance.

Cibis, P.A. & Halperin, H. FAULTY DEPTH PERCEPTION CAUSED BY CYCLOTORSION OF THE EYES. Proj. 21 24 013, Rep. 1, Sept. 1951, 10pp. USAF School of Aviation Medicine, Randolph Field, Tex.

100 Ss were examined for cyclotorsion in 2 different tests. 70 gave evidence of marked cyclotorsion significant on a 5% probability level when the illumination or state of adaptation was changed. The investigation revealed, furthermore, that cyclofusional compulsions during bright adaptation continued, although gradually attenuating, up to 15 minutes during the period of dark adaptation. The effect of general oxygen deficiency and alcoholic intoxication on cyclotorsion was studied in a limited number of Ss.

Strughold, H. INVESTIGATIONS ON THE USEFULNESS OF CONTACT LENSES IN FLIGHT. i. THE SENSIBILITY OF CORNEA AND CONJUNCTIVA OF THE HUMAN EYE. Proj. 21 24 005, Rep. 1, May 1951, 7pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The sensations and their topographical distribution on the cornea and conjunctiva of the human eye are reviewed. The purpose of the review is to provide a summary of this data as a basis for the construction and use of contact lenses. The cornea and conjunctiva, bulbi of the human eye respond to mechanical stimuli with pain sensation only. The pressure sense is not represented in these areas. The center of the cornea is the most pain-sensitive spot of the whole body. The border of the cornea is 10 times, and the corneal border of the conjunctiva bulbi is about 150 times, less sensitive than the center of the cornea. This zonal difference in the sensitivity to mechanical stimuli is of significance in the problem of fitting contact lenses. Finally, for comparison, a review is given of the topography of the temperature sense on the cornea and conjunctiva.

Rowland, W.M. THE EFFECT OF SULFATHIAZOLE AND SULFADIAZINE ON VISUAL FIELDS, OCULAR MOTILITY, AND DEPTH PERCEPTION. Proj. 99, Rep. 1, Dec. 1942, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Data was collected from 8 Ss to study the effect of sulfathiazole and sulfadiazine on visual fields, ocular motility and depth perception. From the data obtained it was concluded that: a) The visual fields for white, red, and blue of Ss who had taken 4 grams a day of sulfathiazole or of sulfadiazine over a period of 5 days were not affected by these drugs; b) Ocular motility as measured by adduction and abduction was not significantly affected by the administration of similar doses of these drugs; c) Depth perception was not adversely affected in Ss who had such therapy.

2891

Keil, F.C. THE EFFECTS OF LOW BAROMETRIC PRESSURE ON THE FIELD OF VISION. Proj. 158, Rep. 1, June 1943, 4pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Visual field defects of sufficient severity to be observed subjectively occurred as a result of ascent to a simulated altitude above 33,000 feet in 1.8 per cent of 500 subjects studied. These defects were a part of a more or less characteristic syndrome, i.e., joint pains, "chokes", headaches, visual symptoms, and collapse. In the 9 cases studied, no permanent damage resulted.

2892

Campbell, P.A. POSSIBLE EFFECTS OF SMALL DAILY DOSES OF SULFADIAZINE ON FLYING PERSONNEL. Proj. 293, Rep. 1, July 1944, 37pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Daily doses of 1 gm. of sulfadiazine were given to 19 Ss for 6 weeks. Plasma levels of free sulfadiazine averaged from 2 to 5 mgm. per cent depending on the time after the administration of the drug. No decrement in performance was found on a battery of psychological tests (3 psychomotor and 3 paper and pencil), either at ground level or without supplementary oxygen at 18,000 ft. simulated altitude, was found. No significant effects were found on: a) physical fitness; b) blood morphology or hemoglobin concentration; c) bacteriological flora of the nose and throat; d) auditory acuity; e) visual functions including light threshold and foveal visual acuity; f) ability to equilibrate while blindfolded; and g) susceptibility to motion sickness. It is recommended that flying personnel be permitted to fly whether or not they are receiving daily doses of 1 gm. of sulfadiazine unless it is demonstrated that they are unusually sensitive to the drug. Bernage, J.J., Norrishan, R. & Ellison, B.C. AN EXPERIMENTAL EVALUATION OF THE APPLICATION OF HARMONIC ANALYSIS TO THE TRACKING BEHAVIOR OF THE HUMAN OPERATOR. Contract AF 18(600) 16, RDB 694 39, Tech. Rep. 53 304, May 1954, 36pp. USAF Wright Air Development Center, Aero Medical Lab., Wright-Patterson AFB, Ohio.

5 experiments were carried out to determine the applicability of harmonic analysis to the tracking behavior of the human operator for the purpose of obtaining descriptions of the behavior useful to systems design engineers. The results indicate that the behavior is non-stationary and nonlinear in all the visual tracking situations. However, under the condition of an auditory input, neither equally equivalent to and presented simultaneously with the visual input the behavior is stationary. The error behavior in this case resembles low power, random noise.

Bernage, Isabel R. THE RELIABILITY OF HEIGHT, WEIGHT, CHEST, AND ABDOMINAL MEASUREMENTS OF AVIATION CADETS. Proj. 18, Rep. 1, July 1942, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Measurements of height, weight, chest, and abdomen of 230 aviation cadets were examined for reliability by comparing the dimensions recorded on WD AGO Form 63, Physical Examinations, and on WD AGO Form 64, Physical Examination for flying. From this data it was concluded that: a) Measurements of height and weight as recorded on WD AGO Form 63 and on WD AGO Form 64, are highly reliable; b) Independent judgments of height are correlated to the extent of .97; of weight, .96. (The coefficient of correlation may vary from 1.00 for perfect inverse relationship through 0 for random relationship, to 1.00 for perfect positive relationship); c) The dimensions of the chest at expiration and of the abdomen as recorded show moderately high reliability. The correlation between successive measurements is .76 for chest at expiration and .76 for abdominal circumference; d) Chest expansion as recorded demonstrates low reliability. The correlation between chest expansion as reported on WD AGO Form 63 and WD AGO Form 64 is .37; e) With rare exception, measurements of height and of chest are now recorded to the nearest half inch, rather than the nearest quarter inch as directed in par. 25, AR 40 105 and par. 27, AR 40 105. It is recommended that steps be taken to increase the reliability of chest expansion measurements.

Buettner, K. EFFECTS OF EXTREME HEAT ON MAN. 1. PROTECTION OF MAN AGAINST CONFLAGRATION HEAT. Proj. 21 02 103, Rep. 1, Feb. 1950, 1Epp. USAF School of Aviation Medicine, Randolph Field, Tex.

Large scale conflagration and the heat flash of the atomic bomb not only add to the known dangers of fire, but also produce entirely new hazards. The laws of heat exchange from fire to man and those of his main physiological responses are briefly discussed. In addition to CO poisoning and the many hazards caused by the vastness of the destructions, radiant heat is of utmost importance. It can be thoroughly averted by using aluminum protective clothing.

Burchell, H.B. REPORT OF ACCIDENTS RESULTING FROM ANOXIA IN AIRCRAFT. Proj. 206, Rep. 2, April 1944, 11pp. USAF School of Aviation Medicine, Randolph Field, Tex.

42 fatal and 139 non-fatal cases of anoxia occurring in heavy bombardment aircraft have been reviewed. Since the most frequent cause of anoxia with demand equipment has been the inadvertent disconnection of the mask-to-regulator tubing, continued emphasis in indoctrination on this hazard should be given to flying personnel. Freezing of the continuous flow mask was the outstanding cause of anoxia when this type of equipment was used. Freezing of demand masks of both the A-10 and A-14 types is being reported in increasing numbers and continued investigation on methods of preventing this is indicated. Anoxia due to poor indoctrination has practically disappeared from the recent reports. If indoctrination is to be improved further the only suggestions are that more practical teaching be given on handling of specific emergencies. There is enough evidence in the reports received that is worthwhile to teach crew members how to perform artificial respiration. 3 lives were apparently saved in combat aircraft by continued artificial respiration. A few suggestions concerning how the reports of anoxic deaths should be written are given. Questionnaire forms have been less useful in teaching than letter reports which give a running account of the anoxic accident. Sufficient data on accidents resulting from anoxia in aircraft are now available to make a training film covering the subject.

2902

Campbell, P.A. A PRELIMINARY REPORT ON THE STUDY OF AIRSICKNESS. Proj. 31, Rep. 1, Aug. 1942, 28pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A number of methods were tried in order to find which tests are most efficient for the determination of susceptibility to airsickness before flight. The methods used were the questionnaire, the swing test, vestibular tests, and gastrointestinal studies. Of 150 men given the swing test, 112 had no symptoms of swing sickness, 17 had mild symptoms, and 21 had severe symptoms. Analysis of the swing tests show that 43% of airsickness susceptibles were swingsick in 20 min. of supine swinging, while only 11% of non-susceptibles were swingsick. The vestibular tests (vertigo, nausea, sweating, and pallor) show a similar order of predictability value. Combining the 2 tests does not add appreciably to predictability. Partial analysis of the questionnaire method indicates that history of motion sickness is fairly dependable in predicting that airsickness will occur. The gastrointestinal survey shows that in most individuals the motion of swinging depresses gastric motor function as measured by tone and peristalsis. None of the Ss who maintained some gastric peristalsis showed any evidence of motion sickness. (HEIAS)

Garvey, W.D., Knowles, W.B. & Newlin, E.P. PREDICTION OF FUTURE POSITION OF A TARGET TRACK ON FOUR TYPES OF DISPLAYS. Proj. NR 592 030, NML Rep. 4721, April 1956, 9pp. USAF Research Lab., Washington, D.C.

2906

Tracking on a search radar scope or vertical plotting board often requires the prediction of future positions of a target based on its past history. Accuracy of prediction was measured in terms of deviations in range and bearing between estimated and actual position plots of four different displays: linear and non-linear Plan-Position Indicators, linear and non-linear E-scan. Sixty problems were presented to 32 subjects. Signals were presented at the rate of six per minute; after the second signal, the subject indicated the estimated position of the next signal by a mark, and so on through the track. Accuracy of performance was compared for the four displays.

Immergluck, L. THE ROLE OF SET IN PERCEPTUAL JUDGMENT. J. Psychol., 1952, 34, 181-189. (Dept. of Psychology, Sarah Lawrence College, Bronxville, N.Y.).

2913

Some aspects of the role of set in the area of perceptual judgment were investigated--specifically, the extent to which simple perceptual responses are subject to routinization and how such routinization will affect perceptual judgment. Two series of cards, each containing a pair of simple geometric designs (one of which was a more perfect geometric example), were prepared; one series contained the more perfect figures on the right side, the other used a mixed order. The final card for both series placed the more perfect figure on the left. One group of 16 subjects responded to the set series, the other to the mixed series. Errors on the final card were recorded and compared in terms of the initial questions posed.

Grinstead, A.D. & Ambler, Rosalie K. A STUDY OF THE DISTRIBUTION OF AIRCRAFT ACCIDENTS IN NAVAL AIR TRAINING. Proj. Rep. NM 001 059 20-01, April 1951, 9pp. USN School of Aviation Medicine, Pensacola Air Station, Fla.

This study was undertaken to determine whether accidents occur more frequently than chance allows at any particular time of day. Data were taken from the flight and accident records of 9TU-1 for the period 15 October 1949 through 14 October 1950. During this year 69,911 hops were flown and 43 accidents due to causes other than material failure occurred. There were 9 flight training periods beginning at 0730, 0830, 0930, 1030, 1130, 1230, 1430, and 1500 respectively. The total number of hops and "non-material" accidents was recorded for each of the daily flight training periods. Since all periods overlapped, a plane was assigned to a training period on the basis of take-off time. The 2 diurnal curves plotted from the data closely approximated each other in shape; this suggested that accident occurrence was a function of the number of planes in the air at a given time. To examine this possibility, the ratio of the number of accidents to the number of hops was calculated for each period and compared with the theoretical ratio of accidents to hops based on chance expectancy for each period. The observed ratio of the number of accidents to the number of hops was not significantly different from the theoretical ratio based on chance. Further, the difference between accident occurrence in each training period and accident occurrence for the remainder of the day was not significantly different. The data were analyzed in the same manner for days of the week instead of periods of the day; similar results were obtained. It was concluded that, within the limits of this data, periods of the day when accidents occur more frequently are simply the periods when there are more planes in operation; and that no systematic factor is in operation in the distribution of these accidents by days of the week.

Lovell, G.D. & Morgan, J.J.B. PHYSIOLOGICAL AND MOTOR RESPONSES TO A REGULARLY RECURRING SOUND: A STUDY IN MONOTONY. *J. exp. Psychol.*, June 1942, 30(6), 435-451. (Northwestern University, Evanston, Ill.).

An experiment was devised to determine in part the behavior displayed by Ss in response to a regularly recurring tone of 60 cps. The tone rate was set both faster and slower than the normal respiration of each S and changes in his breathing were recorded, as he sat quietly in a Morris chair for 40 min. Pulse rate and palmar skin resistance were recorded and Ss were observed by E for any overt accompaniments to the sounder. Each of the 38 Ss filled out a questionnaire relating to his attitude during the experiment and to his relaxation habits. The results indicate the following conclusions: a) the respiration rate of Ss approximates that of the sounder, and breathing becomes rather regular; b) Ss relax significantly during a period of such stimulation whether the rate is faster or slower than normal respiration rate; c) Ss given definite instructions and suggestions to relax did not show any difference in relaxation from Ss which had no such instruction; d) since respiration changes were noted in all Ss, and motor accompaniments to the regularity of the sound, such as bobbing the head, were observed in most Ss, the inference was drawn that such responses aid in the relaxation that was observed. It was proposed that these motor responses help to discharge surplus energy or tension in the body and thus allow a greater degree of relaxation than would otherwise be attained. (MEIAS)

Peters, R.V. THE RELATIVE INTELLIGIBILITY OF SINGLE-VOICE AND MULTIPLE-VOICE MESSAGES UNDER VARIOUS CONDITIONS OF NOISE. JOINT PROJECT REPORT. Proj. #M COI 104 500.56, July 1955, 9pp. USN School of Aviation Medicine, Pensacola Air Station, Fla. & Ohio State University Research Foundation, Columbus, Ohio.

The purpose of the present experiment was to test the hypothesis that continuity of voice during a message transmission contributes to listener efficiency. Evaluations were made of the intelligibility of single-voice and multiple-voice transmissions under a) 5 conditions of white noise and b) 3 conditions of speech babble. 48 speakers served as experimental Ss. The voice transmissions were multiple-choice intelligibility test word groupings. The following conclusions may be drawn on the basis of the experimental results: a) Continuity of voice during a message transmission contributes to listener efficiency. Under conditions of both white noise and speech babble, single-voice transmissions were consistently more intelligible than were multiple-voice transmissions; b) The contribution of continuity of voice to listener efficiency may vary according to the particular listening conditions as was indicated by the fact that the mean values of intelligibility did not follow the same trend for single-voice and multiple-voice transmissions under the 5 conditions of white noise.

Peters, R.W. STUDIES IN LISTENER RECEPTION OF VOICE MESSAGES: THE PERSISTENCE OF THE EFFECTS OF LISTENING CONDITIONS. JOINT PROJECT REPORT. NM 001 104 500.55, June 1955, 7pp. USM School of Aviation Medicine, Pensacola Air Station, Fla. & Ohio State University Research Foundation, Columbus, Ohio.

The purpose of the present experiment was to test the effect of various S/N ratio listening conditions upon the reception of subsequent materials. Listeners were tested following indoctrination listening at +8 db, 0 db, or -8 db S/N ratios. All listeners were tested at a 0 db S/N ratio. Testing and indoctrination materials were written down intelligibility words presented with white noise at the various S/N ratios. Three groups of listeners, with 38 persons in each group, served as experimental subjects. The results indicate a persistence effect of an adverse listening condition upon the reception of subsequent materials. Mean reception values were significantly lower for listeners indoctrinated at -8 db S/N ratio prior to their response to test materials than were the reception values for the listeners indoctrinated at either +8 db or 0 db S/N ratios.

Peters, R.W. LISTENER PERFORMANCE AS A FUNCTION OF LISTENING TIME FOR VARIOUS SIGNAL-TO-NOISE CONDITIONS. JOINT PROJECT REPORT. NM 001 104 500.55, June 1955, 8pp. USM School of Aviation Medicine, Pensacola Air Station, Fla. & Ohio State University Research Foundation, Columbus, Ohio.

Listener reception was evaluated, with respect to values earned at the end of 8 cumulative time intervals during an hour of continuous testing, for several signal-to-noise conditions. The noise was babel, prepared by superimposing 2 voices on a single recording. Mean values of listener reception did not follow the same trend for each listening condition. As the signal-to-noise ratio was decreased, a temporary decrement in listener reception followed after approximately one-half hour of listening. This decrement became more pronounced and more lasting as the signal-to-noise ratio was decreased.

Reynolds, B. & Adams, J.A. PSYCHOMOTOR PERFORMANCE AS A FUNCTION OF INITIAL LEVEL OF ABILITY. *Amer. J. Psychol.*, June 1954, 67(2), 266-277. (USAF Perceptual & Motor Skills Research Lab., Lackland AFB, Tex.).

2926

In an investigation of the learning of a motor task as a function of level of initial ability, two groups of 480 subjects (basic airman trainees) were given 80 and 60 20-second trials on the Rotary Pursuit Test with massed or with distributed practice (with a 5-second or a 30-second intertrial interval). Each group was subdivided into deciles on the basis of performance on the first five trials. Learning curves (time on target over trials) for the various subgroups are compared, and the scores are analyzed statistically.

2931

To study the influence of area on foveal (cone) intensity discrimination, threshold determinations were made by two subjects for six circular areas varying in radius from 2 to 28 minutes of visual angle at a constant exposure duration (0.03 seconds), and over a range of 4.6 log units of adapting intensity. The data are presented graphically and discussed in terms of visual theory.

2932

To investigate the role of mediated stimulus generalization in sensory pre-conditioning, four groups of ten subjects each were assigned to one of the following conditions: 1) a verbal response to paired stimuli (a tone and light); 2) a verbal response to the same stimuli presented independently; and 3) a verbal response to one but not the other stimulus (with two groups of subjects assigned here). The results are presented and discussed in terms of the frequency of response transfer manifested under each condition of sensory pre-conditioning.

Graham, C.H. VISUAL SPACE PERCEPTION. *Fed. Proc.*, June 1943, 2(2), 115-122. (Psychology Lab., Brown University, Providence, R.I.).

This paper is a brief summary of the cues, monocular and binocular, used in visual space perception. Stereoscopic range finding is then considered, both from the standpoint of the instrument and the operator. Next, coincidence range finding is considered. These 2 types of range finding illustrate the use of monocular cues (coincidence range finding) and of binocular cues (stereoscopic range finding). This leads to a brief consideration of perceptual constancy. Lastly the perception of movement and speed is briefly considered.

Minograd, L. & Van Dyke, R.D., Jr. FLIGHT DETERMINATION OF THE EFFECTS OF RUDDER-PEDAL-FORCE CHARACTERISTICS ON THE AIMING ERROR IN AZIMUTH OF A CONVENTIONAL FIGHTER AIRPLANE. NACA Res. Memo. RM A50006, July 1950, 32pp. National Advisory Committee for Aeronautics, Washington, D.C. (USAF Aces Aeronautical Lab., Moffett Field, Calif.).

Flight tests were conducted to study the effect on the aiming error in azimuth of a change in the rudder-pedal-force characteristics of a conventional fighter airplane equipped with an illuminated fixed gunsight. Simulated gunnery runs were made on both ground and aerial targets with the normal rudder and with a rudder so modified that the rudder-pedal-force variation in sideslip was approximately zero. The effect of the modification on the mean azimuth tracking errors was insignificant (less than 1 mil); however, the pilots noted that with the modified rudder it was fatiguing to fly the airplane for any length of time.

Bousfield, W.A., Esterson, J., & Whitmarsh, G.A. THE EFFECTS OF CONCOMITANT COLORED AND UNCOLORED PICTORIAL REPRESENTATIONS ON THE LEARNING OF STIMULUS-WORDS. Contract Nonr-651(00), Tech. Rep. 18, June 1956, 8pp. ONR, University of Connecticut.

2941

To investigate the effect upon learning of providing additional cues to the stimulus, 165 subjects were given two successive presentations of 25 stimulus words (nouns) in five categories either as to concept or color under three conditions: (1) words alone, (2) words presented simultaneously with their uncolored picture, or (3) words presented simultaneously with their colored picture. These conditions represented varying degrees of compound-ness of signs represented by the object. The number of stimulus words recalled correctly immediately after presentation was evaluated by analysis of variance techniques for differences due to experimental conditions. Errors (words not in stimulus list, repeated words) were analyzed separately for the three conditions. A theoretical rationale of the study is presented. T. R 3

Belwin Company. FREQUENCY RANGE RESTRICTION EFFECTS UPON AN/AIC-10(VA-1) ARTICULATION SCORES IN 120 DB AMBIENT NOISE LEVELS WITH VARIOUS LEVELS OF STATIC INTERFERENCE. Contract AF 33(038) 23313, Rep. AFAC-5, May 1952, 16pp. Engineering and Research Department, Belwin Company, Cincinnati, Ohio.

The word articulation performance of Intercommunication Set AN/AIC-10(VA-1) was studied experimentally under controlled conditions of reduced bandwidth, simulated electrical noise and ambient acoustical noise such as would exist when listening in an aircraft to radio communication from another aircraft under marginal reception conditions. It was found that in a 120 db jet-aircraft type of noise spectrum the full frequency range of which AN/AIC-10(VA-1) is capable (approximately 300-6500 cps) is required for best intelligibility. This requirement holds for a wide variety of static interference conditions. In 120 db propeller-driven aircraft type of noise spectrum, degradation of intelligibility is quite severe for cutoff frequencies below 1500 cps.

Brown, J.L., & Woodward, Lois K. ROD-CONE INTERACTION IN THE DARK-ADAPTED EYE. NADCHA-5604, Proj. NM 001 110 300, Rep. 1, April 1956, 32pp. (U.S.N. Aviation Medical Acceleration Laboratory, NADC, Johnsville, Pa.).

2949

To investigate the transition from cone function to rod function which occurs with changes in the criterion threshold when adaptation is held constant, the amount of light required to identify correctly the orientation of a pattern of parallel lines was measured with a variety of wavelength distributions of test light. Grating patterns ranged from very fine to coarse (0.143 to 0.0130 inch). Measurements were made with eyes of observers adapted to darkness and with short flash presentations (0.015 second). Threshold data (luminance) were plotted as a function of visual acuity (grating size) for each wavelength. Implications for practical use of the data are discussed.

Harris, J.D. THE EFFECT OF SENSATION-LEVELS ON INTENSIVE DISCRIMINATION OF NOISE. Amer. J. Psychol., July 1950, 53, 409-421. (USN Medical Research Lab., New London Submarine Base, Conn.)
This paper explores intensive discrimination for random frequency noise and describes the gradual increase in BL near stimulus threshold. 3 different procedures were used. In 1 procedure, two-category reports ('loud'-'soft') were required for each item; in the other 2, S reported only when he apprehended a stimulus change. These 2 procedures yielded comparable results throughout. The first procedure yielded the finest index of sensitivity and was much less affected by decrease in intensity. It was argued that this procedure allows cues below the level of apprehension to aid in the determination of reporting behavior and therefore lends itself to the discovery of sensitivity presumably nearer to the physiological limit of the organism. The differential intensive threshold for noise increments, under optimal conditions, ranges from 0.42 to 0.70 db. This range includes variations arising from psychophysical method, training of Ss, and manner of dealing with probably invalid reports. The threshold for decrements is about 0.1 db larger. A knowledge of the effect of psychophysical method is especially important in studies on the relation between intensity and differential intensive sensitivity. One method at 5 db above stimulus threshold yielded a differential threshold of 0.63 db; another method yielded 1.22 db. Differential sensitivity cannot become infinitely coarse as intensity decreases, but reaches a limit imposed by the fact that the noise vs. noise-increment judgment ultimately is transformed to a noise vs. no-noise judgment. A supplementary experiment places the coarsest possible differential intensive threshold at between 2.5 and 3.5 db; for intensities right down to stimulus threshold.

Harris, J.D. AN EVALUATION OF EAR DEFENDER DEVICES: TWO EARPLUGS, FOUR CUSHIONS, AND THREE COMBINATIONS. Proj. NM 003 041 56.06, R 1, 271, Dec. 1955, 11pp. USN Medical Research Lab., New London Submarine Base, Conn.

Since the standard ear defender available for Navy use is unsatisfactory in some respects, a search for additional devices for protection against high intensity noise was undertaken. The following devices were investigated: 2 earplugs--the V-51R Ear Warden, and M005; 4 ear muffs: Grason-Stadler Type 001, "Noisefoam", and David Clark Company Models 124, and 372 1/4. Various combinations of the earplugs and muffs were also investigated. The M005 earplug, a cylinder of foam rubber impregnated with wax, was found to be as effective as the V-51R and to give more protection to those individuals for whom the V-51R is not suitable for anatomical reasons. The ear muffs were evaluated by the use of the Binural Free Field Bkeshy Threshold Shift Technique. The Model 372 1/4 adjustable-tension muff was found to be significantly better than the others and to be equal or superior to a good earplug at all frequencies from 300 to 4,000 cps. Due to its bulk, the Model 372 1/4 cannot be employed in all situations; maximum protection can, however, be achieved by wearing a good earplug plus any of several small lightweight earmuffs in combination.

Burnett, W.A., Bogar, J.E., & Konhauser, J.D.E. QUEUEING THEORY APPLIED TO MILITARY COMMUNICATION SYSTEMS. Contract DA 49-025-SC-150, DA Proj. DA-3-99-01-001, SC Proj. 102'E, SC Tech. Requirements SCEL-2101E, HRB Proj. 57, Feb. 1956, 193pp. Signal Corps Evaluation and Analysis Group, Haller, Raymond and Brown, Inc., State College, Penn.

2957

To study the behavior of the building blocks of military communication systems, the theory of probability is applied to the problem of a waiting line (queue). Both single channel and multiple channel problems are considered: general formulation of the problem of single channel with Poisson arrivals, ordered queueing, and arbitrary call lengths; and multiple channel problems for Poisson arrivals, ordered queueing and exponential call lengths. Two methods are used to obtain solutions to these problems: one required setting up state probabilities, the other (Lindley) does not require this. Solutions are given in the form of graphs and formulas or in terms of equations not yet solved for practice. F. R 5

Sandberg, K.O.W. & Lipshultz, H.L. MAXIMUM LIMITS OF WORKING AREAS ON VERTICAL SURFACES. Rep. 166-18, April 1952, 19pp. USN Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Baltimore, Md.).

This experiment measured the maximum area which can be reached on a flat vertical surface by the 2 arms of 8 male Ss seated at varying viewing distances away from the surface. The paper discusses the influence of some of the variables: viewing distance, arm length, and body distance between pivot centers. It was found that each arm described an approximate circle whose diameter decreased as the distance between the S and the flat vertical surface was increased. The 3 viewing distances of 10 in., 15 in., and 20 in. were selected as representative of actual operating practice. At the distance of 20 in. from eye to vertical panel, the average S described a circle of 40.4 in. diameter with each arm. The 2-circle centers were approximately 12 in. apart, horizontally. When adjusted for the average anterior arm reach for almost 3000 AAF cadets, the circular diameter is 43.5 in. The area enclosed by 2 such 43.5 in. circles is the maximum area of reach for operators of approximately average size. When a manual task requires both hands to be at the same place simultaneously, the points which can be reached without a posture change are then limited to the common area of the 2 overlapping circles.

Switzer, R.E. THE HUMAN SIDE OF AIRCRAFT ACCIDENTS. Publ. H 36, Oct. 1951, 35pp. (A Presentation by Medical Safety Div., Flying Safety Officers.) - USAF Directorate of Flight Safety, Research, Norton AFB, Calif.

Approximately 60% of Air Force accidents result from failure, physical and psychological of the human element. The problems of the Medical Safety Division are: to discover the causes of human error in aircraft accidents, to determine the underlying factors, and to determine the causes of death and injury and their relationship to design and equipment. A detailed analysis of pilot errors indicate that 60% are due to judgment errors, 20% to attention errors, 15% to manipulation errors, and 5% to navigation errors. The causes are: insufficient knowledge, emotional factors, habit interference, stresses. An analysis of natural and variable stresses is given. Protective equipment is designed in the light of the analysis of the accidents. The greatest difficulty is the lack of knowledge on the part of the users about the equipment. (HEIAS)

Haxe, H.W. & Averbach, E. APPARENT AND REAL RESOLUTION IN RADAR VISIBILITY. Contract AF 33 (038) 22642, Proj. 7192, Task 71598, Tech. Rep. 55-459, Sept. 1955, 10pp. USAF Wright-Air Development Center, Aero Medical Lab., Wright-Patterson AFB, Ohio. (Johns Hopkins University, Baltimore, Md.).

Differential sensitivity for luminance differences existing in 2 spatially separated homogeneous fields was measured under 3 conditions of viewing. In the first the comparison fields, presented on a cathode ray tube face, were separated by darkness; in the second the fields were joined by a transition area in which luminance increased linearly from the value presented in the darker field to that presented in the lighter field. A third condition controlled for the decrease in size of the fields which occurred with increasing separation of them. In all viewing conditions the darker field was presented to the left and the right of the lighter field equally often; and the observer's task was to detect the darker side of the display. Detection was significantly better with the gradient present than with the fields separated by darkness. The results, which suggest that the visual system can reform and sharpen the gradient of light separating a return from the background illumination on a radar screen, indicate that visual resolution for radar returns cannot be predicted in a simple way from facts known about the resolving power of the radar system. The factors which appear to determine visual resolution are not those which are affected critically by changes in the scale of the display alone.

Fleishman, B.A. PREDICTING ADVANCED LEVELS OF PROFICIENCY IN PSYCHOMOTOR SKILLS. Proj. 7703, Task 77083, AFPRC-TN-56-10, Jan. 1956, 20pp. Skill Components Laboratory, AFPRC, Lackland AFB, San Antonio, Tex.

2977

This paper reviews recent work on the relations between aptitude variables and progress at different stages of learning on complex psychomotor tasks with a view to establishing the kinds of abilities and measures which best predict higher levels of proficiency in such skills. The typical design of the studies was to give samples of 200-300 subjects extended practice on the task and a selected battery of printed and apparatus tests. Correlations among scores taken from various segments of practice and from the reference tests were then studied by factor analysis. Criterion tasks were visual-reaction discrimination, visual-discrimination reaction, and tracking (rotary pursuit). The results are presented graphically and discussed in relation to psychomotor learning and prediction. T. C; R 6

Case, H.W., Michael, J.L., Mount, G.E., & Brenner, R. ANALYSIS OF CERTAIN VARIABLES RELATED TO SIGN LEGIBILITY. 44-58. Department of Engineering, University of California.

2981

To study some aspects of legibility of highway destination signs, black letters on a white background and white letters on a black background were compared in outdoor, daylight conditions. Both closely spaced (between letters, half the letter height; between rows, 2/3 letter height) and widely spaced (1 1/3 letter height between letters and rows) letters (two rows of four letters each) were used. On the basis of an initial screening of visual acuity, subjects were assigned to a distant range (five equally spaced positions between 295 and 355 feet) or a close range (220 to 280 feet) for testing letter recognition. Scores (number of letters correctly identified for each of the four stimuli) were studied by analysis of variance for effects of letter-background colors, spacing, and interactions. T. R 18

University of Illinois. HUMAN PERFORMANCE IN INFORMATION TRANSMISSION: IV. FLASH RECOGNITION OF FAMILIAR DISPLAYS. Contract DA 36 039 SC 56695, Rep. R 69, Jan. 1956, 91pp. Control Systems Lab., University of Illinois, Urbana, Ill.

2982

To investigate the problem of how much information a man can assimilate visually in a brief flash, a series of experiments were performed using familiar objects (alphabet letters and playing cards). Variables were: exposure duration (ten to 2000 milliseconds), stimulus complexity (two to eight letters or cards), response complexity (whole or single-ali), display geometry (one or two lines) and time (pattern of variation either known or unknown to subject). Three subjects responded as directed; if initial response was wrong they were required to guess until correct or for four additional responses. Amount of information transmitted was estimated by the method of standard matrix, error magnitude, or of hints. Discussion is in terms of capacity, filtering, time, and interaction characteristics of the data-gathering process. R 21

USAF Operational Test Center. OPERATIONAL SUITABILITY TEST OF APPRENTICE JET ENGINE MECHANIC GRADUATES OF TTA COURSE NUMBER AB433230-2. FINAL REPORT. Proj. APG/CSC/916 A, March 1956, 16pp. USAF Operational Test Center, Eglin AFB, Fla.

2983

To determine the ability of apprentice jet engine mechanic graduates of Technical Training Air Force Course Number AB43230-2 to perform the duties of their Air Force specialty, eight representative graduates were studied during a 90-day on-the-job situation. Procedures included assignment to normal routine duties without explanation or demonstration until capability to perform the task was established; observation; and daily ratings of performance by the supervisor immediately responsible for performance of the job. The data were used to make a critique of the training program, of the job description, and of job training standards. Recommendations are included.

Ford, J.W. THE BINAURAL PRESENTATION OF GUIDANCE DATA. Rep. OM 368 P 2 Rev., May 1949, 11pp. Cornell Aeronautical Laboratory, Inc., Buffalo, N.Y.

2985

To determine the possibility of using the binaural direction-discriminating sense to convey both lateral and vertical guidance data to an airplane pilot, a laboratory model of such a system was constructed and demonstrated in conjunction with the Link Trainer. Lateral flight is controlled by means of a varying phase intensity relation reaching the pilot's ears through earphones and vertical flight by a tone of varying pitch. Tests of the system were made by qualified instrument pilots from commercial airlines, Civil Aeronautics Administration, Armed Services and the Cornell Aeronautical Laboratory. In addition, the system was flight-tested in a Boeing 247-D airplane in five "blind" approach landings. Recommendations for further development are included.

2986

Hermanns, T.G. FACTORS DETERMINING THE DIRECTION OF THE VISUAL AFTER-IMAGE DRIFT. J. exp. Psychol., Feb. 1941, 28(2), 187-198. (University of Washington, Seattle, Wash.).

A series of experiments are reported which demonstrate that there are at least 2 factors involved in the determination of visual after-image drift. One is the point of fixation relative to the object used to produce the retinal effects necessary for the production of the after-image; or we might say, the position of the retinal effects relative to the fovea which we have called the retinal factor. The other factor is the pattern of muscular stresses during retinal stimulation which leave their after effects persistent during the experiencing of the after-image; this we have referred to as the muscular factor. The retinally determined drift is demonstrated when the point of fixation is to one side of the object fixated, and the drift ensuing tends to be in the direction of the object relative to the point of fixation; this drift is dependent upon the locus of retinal stimulation and within the limits of the durations of retinal stimulation used is independent of the duration, and also independent of the muscular factors. The muscularly determined drift is demonstrated when the eyes during retinal stimulation are in a position of left or right orientation with fixation centered upon the object; this drift tends to be in the direction of the preceding muscle tensions.

USAF Operational Test Center. OPERATIONAL SUITABILITY TEST OF JOINT USAF-CAA OVERRUN AND APPROACH LIGHTING. FINAL REPORT. Proj. APG/CSC/994 A, April 1956, 12pp. USAF Operational Test Center, Eglin AFB, Fla.

2988

To determine a recommended standard airfield lighting system for joint Air Force-Civil use, three systems were evaluated: U.S. Standard Configurations A (centerline system) and B (side lighting of overrun with centerline extension) and Configuration X (combination of A and B). The test aircraft made 274 night approaches. Of these, 151 were made by fighter aircraft and 123 by jet bombers. System evaluation was based on pilot preference and an analysis of adaptability of system to different types of Air Force aircraft. Recommendations are included. T. 1.

Yarcho, W.B. FLOTATION TESTS OF LIFE PRESERVER INFLATED BENEATH THE PARACHUTE HARNESS. Proj. R-670-417, Tech. Memo Rep. WCRD 53-151, Dec. 1953, 13pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio.

2991

To establish the flotation characteristics of a pneumatic life preserver when inflated under a parachute harness, tests were conducted in a swimming pool. The subject wore a lightweight summer flying suit, a standard B-5 pneumatic life preserver, and a Class III quick-release canopy parachute harness. The harness was adjusted by experienced personnel to approximate service condition tightness prior to each trial. Trials were conducted with several arrangements of equipment, such as: parachute harness secured and one cell of life preserver inflated; parachute harness chest strap loosened with both cells of life preserver inflated; etc. The adequacy of the life preserver to supporting the subject was evaluated by observation. Recommendations for further testing are included. T. 1.

Cartography Division, Aeronautical Chart and Information Center. THE G S R MODEL: GRAPHICALLY SIMULATED RELIEF BY GRADIENT DISTRIBUTION OF DETAIL ON LAYERS OF TRANSPARENT PLASTIC. ACIC Tech. Rep. 67, May 1955, 20pp. Aeronautical Chart and Information Center, Air Photographic and Chart Service, USAF, St. Louis 18, Mo.

2992

This report presents a method of depicting areas and objects, at predetermined scale, graphically and in three dimensions, by use of an assembly comprised of a number of layers of transparent plastic sheeting. Scale and size relationships, materials and equipment, construction steps, and the method of depicting such items as natural features, roads, railroads, transmission lines, bridges and other features are discussed. The effectiveness of this principle of presentation has been demonstrated through the construction of experimental models and prototypes. X

Wilbanks, W.A., Webb, W.B., & Tolhurst, G.C. A STUDY OF INTELLECTUAL ACTIVITY IN A NOISY ENVIRONMENT. Rep. 1, Res. Proj. NM 001 104. 100, Oct. 1956, 7pp. U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Fla.

2993

To investigate how a noise environment affects individual performance of an intellectual task, four tests from the Differential Aptitude Tests were selected as the task to be used: Mechanical Reasoning, Abstract Reasoning, Clerical Speed and Accuracy, and Numerical Ability. The tests were administered twice to 92 naval cadets divided randomly into two groups, once in noise (110-115 decibels) and once in quiet—using counterbalanced order for the two groups. The data were studied by analysis of variance for differences among individuals, sessions, orders, and sound conditions. Rank order correlation coefficients were computed for each group to check the reliability of individual behavior under quiet and under noise. Implications for selection procedures are discussed. T. R 4

2994

Briggs, G.E., & Fitts, P.M. TRACKING PROFICIENCY AS A FUNCTION OF VISUAL NOISE IN THE FEEDBACK LOOP OF A SIMULATED RADAR FIRE CONTROL SYSTEM. Contract AF 18(600)-1801, Proj. 7718, Task 77292 and 37050, Res. Rep. AFPTTC-TN-56-134, Dec. 1956, 7pp. Interceptor Pilot Research Laboratory, AFPTTC, Tyndall AFB, Fla.

2994

To determine the functional relation between visual noise in radar fire control system and tracking proficiency, four well-practiced subjects received 12 40-second trials on each of seven amplitude levels of visual noise. The Ohio State University Pilot Training Research Simulator served as the skill task. This apparatus provides a two-dimensional compensatory tracking situation simulating that of the F-86D aircraft at 35,000 feet and at 500 knots. Time-on-target scores (summed over the final three seconds of each trial) were analyzed as a function of noise level. Further discussion related percent of performance level under noise to maximum level of effectiveness.

Cohen, J.D., & McKelvey, R.K. THE BEHAVIOR OF INDIVIDUALS AND PERSONNEL SYSTEMS IN THE SURVEILLANCE FUNCTIONS OF AN AIR DEFENSE DIRECTION CENTER: IV. OPERATIONAL PERFORMANCE CRITERIA. Proj. 7712, Task 77207, Res. Rep. AFPTTC-TN-56-117, Sept. 1956, 18pp. Crew Research Laboratory, AFPTTC, Randolph AFB, Tex.

2995

To obtain a description of surveillance activity (Aircraft Control and Warning) in terms of measurable aspects of behavior considered critical for effective system (Air Defense Center) operation, observations were collected from 24 airman operators whose experience ranged from ten to 36 months. The operators, selected at random from four teams, were rotated systematically through four positions in the surveillance section. Each team was observed under normal operational conditions for two 24-minute periods on three successive days. Response variables were selected which could be related to system criteria and standard operating procedures and analyzed in terms of traffic condition and load carried, accuracy, delay, currency of display, and adherence to crew operating procedure. Implications for research and training are discussed. T. I. R 3

Conrad, R. SOME PSYCHOLOGICAL FACTORS IN SORTING LETTERS BY MACHINE. A.P.U. 271/56, Oct. 1956, 7pp. Applied Psychology Research Unit, Medical Research Council, Cambridge, England.

2996

This is an analytical discussion of the psychological (or human engineering) problems in letter sorting by machine. Current designs of letter sorting machines (England) with their operators are considered a bio-mechanical system and as such the following problems are discussed: deciphering, coding, keying, fatigue, and training. Problems still to be solved are listed.

2997

Broadbent, D.E. FALLACIES IN THE DESIGN OF INDUSTRIAL WORK. A.P.U. 275/55, 1955, 5pp. Applied Psychology Research Unit, Medical Research Council, Cambridge, England.

2997

This paper treats the relation of laboratory experiments on human behavior to applications in the field of work design. Three general assumptions frequently made in work design are considered in relation to experimental evidence from the laboratory: that the effect of prolonged work is to produce a steady decline in performance; that a man involved in movement tasks is more subject to fatigue than is the inactive man with a perceptual task, such as inspection; and that there is an unchanging optimum for working conditions. The manner in which laboratory findings should be applied in the field is further discussed.

2998

Begbie, G.H. ACCURACY OF AIMING IN LINEAR HAND-MOVEMENTS. A.P.U. 261/56, Aug. 1956, 41pp. Applied Psychology Research Unit, Medical Research Council, Cambridge, England.

2998

To study accuracy of aiming in linear hand movements six subjects were first given practice in drawing lines from a starting point towards a target followed by two experimental sessions. In the first the eyes were open; in the second the eyes were closed just prior to and during movement. Four line lengths (16, 20, 24, and 32 centimeters) and eight directions (0, 35, 90, 145, 180, 215, 270, 325 degrees) were drawn (128 per session). Error (distance of each line from target in millimeters) and bias (line passing clockwise or anti-clockwise of target point) were studied by analysis of variance of the influence of direction, extent and visual conditions. A simple theory of movement control was used to explain the results.

Leonard, J.A. PERCEPTION AND THE USE OF VISUAL AIDS. A.P.U. 274/56, 1956, 7pp. Medical Research Council, Applied Psychology Research Unit, Cambridge, Eng.

2999

This paper is based on a talk given to an Audio-Visual Aids Conference at Oxford, 1955. Attention is drawn to a possible effect of the use of visual aids; namely, the resulting greater uniformity of performance. Evidence for and against this effect is examined. Three practical aims of research in visual aids are discussed: presenting information for immediate use (as in piloting aircraft); presenting information for specific use for rapid mass learning (assembling a gun); and presenting information for purposes of education. The important role of the worker in investigations of the last type is stressed.

Broadbent, D.E. THE CONCEPT OF CAPACITY AND THE THEORY OF BEHAVIOR. A.P.U. 257/56, Aug. 1956, 12pp. Applied Psychology Research Unit, Medical Research Council, Cambridge, England.

3001

This paper presents the case for a qualitative application of information theory in psychological studies of human behavior in addition to the more common quantitative one. Reasons for distrusting quantitative theory in psychology are presented and discussed. The use of concepts from information theory in forming non-quantitative models is developed using as an example the extinction of conditioned responses. The advantages of such an approach are discussed.

Bowen, H.M., & Woodhead, M.M. ESTIMATION OF TRACK TARGETS AFTER PRE-VIEW. Canad. J. Psychol., 1955, 2 (4), 239-246. (Applied Psychology Research Unit, Medical Research Council, Cambridge, England).

3002

To explore differences among four types of navigational display for a track prediction task, twelve subjects predicted from immediate experience (complete tracks were observed prior to prediction) the targets of initiated tracks (1/3 of track was given). The four grids were exponential and linear polar coordinates and exponential and linear cartesian coordinates. The deviation of estimate from true termination of track was calculated as (1) distance in inches, (2) distance translated into miles, and (3) direction of error. The data were analyzed for differences due to type of grid and length of track. Findings are discussed with reference to interpretation of rectangular and polar systems.

Mackworth, N.H., & Mackworth, J.F. REMEMBERING ADVANCE CUES DURING SEARCHING. A.P.U. 258/56, Nov. 1956, 20pp. Applied Psychology Research Unit, Medical Research Council, Cambridge, England.

3004

To investigate a form of receptor anticipation in which future events are identified on a visual display, and then this identification is removed so that advance cues must be remembered during decision-taking, 22 subjects were given an "search task consisting of four three-digit numbers representing objectives in each of 20 columns and required to move counters at timed intervals to bring them to the right place at the right time. Variables were (1) number of advance cues (zero to four); (2) speed (eight and four decisions per minute); and (3) grouping of advance cues. Two experiments were conducted. The data (percent correct decisions) were studied by analysis of variance techniques. Discussion is in terms of anticipation span.

Mackworth, N.H., & Mackworth, J.P. VISUAL SEARCH FOR SUCCESSIVE DECISIONS. A.P.U. 234/56, Nov. 1956, 16pp. Applied Psychology Research Unit, Medical Research Council, Cambridge, England.

3018

To identify some of the factors affecting decisions taken from information supplied by multi-source displays, a laboratory task was devised to provide a mass of detail from which the subject had to pick out the one objective that was appropriate at any given time. Variables were: (1) average demand speed of decision (from 2.4 to 12 decisions per minute); and (2) display load (five to fifty columns through which visual search had to be made to find the objective). Two experiments (four and forty-four subjects, respectively) were conducted. The data (errors per min per 100 moves) were studied by analysis of variance techniques for effects of increased speed and load factors and their relationships.

3021

This paper describes an exploratory study into the utility of some auditory-perceptual tests (not now used by the Air Force) for predicting proficiency in telegraphic code reception. The tests evaluated included measures of discrimination of pitch, of loudness, of rhythm, of time, and of timbre; a test of tonal memory, and two new experimental tests. The criterion of success used was speed of code reception (number of groups per minute) at the end of the fourteenth week of training. The tests were administered to 400 entering radio operator trainees. The test scores were analyzed by correlational techniques.

Ward, D.W. THE METHOD OF "SINGLE DESCENT" IN GROUP AUDIOMETRY. Contract Nonr-1151(02), Proj. Designation Nr 146-092, BuMed & Surgery Proj. NM 001 102 502, Rep. 2, Oct. 1956, 15pp. U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Fla.

3024

To find a method for determination of auditory threshold that would lend itself to group testing, two methods were compared: (1) adjustment (both direct and indirect), in which each listener sets an attenuator to his own threshold, and (2) "single descent," in which the level of the test tone decreases steadily and listeners press a button "just when the beeps disappear." The reliabilities of both methods were tested and the method of "single descent" was studied further as a function of rate of descent, for effects of short term auditory fatigue, and for validity using standard clinical techniques as the criteria. The usefulness and limitations of the group methods are discussed.

Smith, W.M. SENSITIVITY TO APPARENT MOVEMENT IN DEPTH AS A FUNCTION OF "PROPERTY OF MOVEMENT." J. exp. Psychol., Aug. 1951, 42(2), 143-152. (Princeton University, Princeton, N.J.).

Using response time as the measure of sensitivity, the hypothesis was tested that sensitivity to apparent movement in depth would vary with the presence or absence of the property of movement characterizing a particular stimulus. The property of movement was defined as that characteristic of an object which describes its usual behavior pertaining to movement. This hypothesis was not confirmed by the results. However, from the data it was concluded that: a) The response time to apparent movement in depth varied as a function of different conditions of observations; b) Very wide differences were found among Ss in sensitivity to this kind of apparent movement; c) Significant interactions were discovered between conditions and stimuli, and also between conditions and Ss.

Duncan, C.P. & Underwood, B.J. TRANSFER OF TRAINING IN MOTOR LEARNING AS A FUNCTION OF DEGREE OF FIRST-TASK LEARNING AND INTER-TASK SIMILARITY. Contract 33(038) 11396, NADC TR 52 64, April 1952, 37pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Northwestern University, Evanston, Ill.).

3033

This is an experimental study of transfer of training as a function of degree of first-task training and inter-task similarity. Three hundred Ss trained on the Star Discrimeter (requiring movement of a lever from a center position into the appropriate one of six radial slots in response to one of six signal lights). First-task training varied from 10-180 trials; inter-task similarity was varied by changing light-slot relationships (2, 4, or 6 changes). Evidence of transfer to the second task is discussed regarding implications for training and equipment design.

Bridgman, C.S., Libby, J.E.P., & Solomon, R.L. KNOWLEDGE OF RESULTS AS IT AFFECTS TRACKING ACCURACY IN A MODIFIED E-14 TRAINER WITH THE B-29 PEDESTAL SIGHT. Contract OEXR-1171, Proj. AC-94, OSRD Rep. 6050, Rep. 8, Oct. 1945, 31pp. OSRD, NDRC, Applied Psychology Panel, (University of Wisconsin).

3035
To determine the effect of knowledge of results upon the framing accuracy of B-29 gunners, two groups of 12 students each were required to track and frame, on each of 20 days, 16 attacks (from a P-7 film) in a modified E-14 trainer. While one group received immediate knowledge of results, the other group received no information of performance. An additional group of ten graduate gunners performed under each condition. The findings are presented in terms of a comparison of mean absolute errors obtained under each condition of knowledge of results. An air phase using the Firing Error Indicator is also described.

Simpson, R.G. UTILIZATION OF JOB PROFICIENCY MEASUREMENT IN RELATION TO TRAINING PROBLEMS IN STRATEGIC AIR COMMAND. Contract AF 33(038) 10524, HRL Memo. Rep. 20, March 1952, 20pp. USAF Human Resources Research Lab., Bolling AFB, Washington, D.C.

3036
This article, based on studies of on-the-job proficiency, presents a re-evaluation of training and research problems existing in the strategic air command (see HRL Reports No. 14 and 16). It is concerned with job proficiency evaluation, measurement, administration planning, and evaluation of training, and other problems primarily oriented to the establishment of a job proficiency program. Suggestions are offered concerning such aspects as the improvement of training programs, the provision of proficiency research, and the facilitation of inter-organization training information.

Brown, G.E., Jr. GENERALITY OF TRACKING TRAINING. Contract OEXR 591, Proj. SCS 6, Rep. 4508, Memo. 7, Dec. 1944, 4pp. Tufts University, Medford, Mass.

3040
This report investigates the transfer of tracking proficiency to a different tracking task. The seven groups of trackers included an inexperienced group, a group trained on the Tufts trainer, and groups composed of men regularly assigned to tracking on the Director 17, Director 15, Height Finder, Radar SCR 263, and 40 in Gun. All groups performed the same tracking task on the Tufts trainer. The distribution of scores for individuals within each group is presented graphically, and the differences in group means are statistically evaluated.

Abrams, W.H., Miller, J., Mallory, L.A., Hibbet, G.W., et al. A PROJECT FOR STANDARDIZING SUBMARINE PHRASEOLOGY AND DEVELOPING A TRAINING PROGRAM IN SUBMARINE VOICE COMMUNICATIONS. FINAL REPORT. Service Control N 118, OSRD Rep. 4795, Feb. 1945, 31pp. US Office of Scientific Research & Development, National Defense Research Council, Washington, D.C.; Harvard University Psycho-Acoustic Lab., Cambridge, Mass.; Psychological Corporation, Washington, D.C.; & Columbia University Div. of War Research, New York, N.Y.

In the program of standardizing phraseology, a systematic catalog was first made of alternative forms of all commands in common use, arranged according to the ship's operation involved. Then experimental tests were conducted to determine the intelligibility over sound-powered phones in the presence of noise of alternative station names and of key words frequently used in messages. Based on these tests and upon conformity with submarine usage, detailed uniform voice procedures and specific wordings for all important submarine commands were prepared and submitted for criticism to officers throughout the submarine service. The development of the training program proceeded concurrently with work on standardized phraseology. This covered a basic course in the fundamentals of telephone talking, an intermediate course emphasizing the use of standard phraseology, and an advanced course covering the combat team stage. Plans for the layout of a training room were developed and the necessary equipment designed. A text (Submarine Telephone Talkers' Manual) and an instructor's manual for the basic course were prepared.

EFFECT OF VARIOUS DURATIONS OF RED ADAPTA-
TION ON THE COURSE OF SUBSEQUENT DARK ADAP-
TATION. Proj. NM 003 041.58.01, Rep. 246,
Apr. 1954, 9pp. U.S. Naval Medical Research
Laboratory, New London, Conn.

3049
To ascertain the usable limits of red adaptation as
a substitute for dark adaptation in operational situa-
tions, observers were preadapted to white light (325
foot lamberts) for ten minutes, then donned red goggles
(two, five, or ten minutes), neutral goggles (ten minutes)
or moved to total darkness. Threshold measurements were
made throughout course of adaptation following the
second adapting period. Adaptation curves are compared
for the various conditions and findings related to
practical usage.

Berkshire, J.R. FIELD EVALUATION OF A TROUBLE-
SHOOTING AID. Proj. 7714, Task 77253, AFFTC TR
54 24, June 1954, 8pp. USAF Personnel & Training
Research Center, Lackland AFB, Tex.

3050
The development and preliminary evaluation of a set
of trouble-shooting materials by means of which a me-
chanic can trace symptoms of malfunction to the under-
lying cause or causes are discussed. The experimental
materials included color-coded schematics of the bomb-
release chain of the AN/APQ-24 radar set with written
directions called "trouble locators". Six different
malfunctions were studied by 24 mechanics, one group of
whom were experienced and another with little or no ex-
perience. Each mechanic identified two malfunctions,
using his own methods for one and the trouble-shooting
materials for the other. Length of time and number of
components removed were compared for the two methods and
for the two groups.

3055 Schaefer, K.E. STUDIES OF OXYGEN TOXICITY: 2. A WARNING SIGN OF ACUTE SYMPTOMS OF OXYGEN TOXICITY. Proj. NM 002 015-03-09, Rep. 232, Aug. 1953, 23pp. USN Medical Research Laboratory, LX, New London, Conn.

12 trained underwater swimmers from an underwater demolition unit swam at an average speed of 0.98 mi. per hr. at various depths (surface, 20 ft., 30 ft., 40 ft.) over a period of 93 min., with rest periods every 15 min. Average pulse rate and respiratory rate at the end of swims which were terminated because of symptoms were significantly higher than at the end of normally terminated swims--a fact which is believed to indicate that an increased sympathetic activity accompanies symptoms of oxygen toxicity. In contrast to resting conditions at high pressures of oxygen, dyspnea is the most frequent symptom during underwater swimming while breathing oxygen at higher than atmospheric pressures. Besides these 2 known phases of oxygen effects, another phase was discovered; a complete parasymphathetic dominance in regard to heart rate, as shown by a fixation of pulse rate, nonresponsiveness of pulse rate to change in activity from exercise to rest and from rest to exercise. This sign preceded the development of symptoms in 78% of all cases and in 100% of grave symptoms, e.g., convulsions. Therefore, it is felt that this sign can be used as a warning of symptoms of oxygen toxicity.

3056 Weybrew, S.B. Q-METHODOLOGY IN CRITERION RESEARCH, Proj. NM 003 041-53-01, Rep. No. 239, Oct. 1953, 28pp. USN Medical Research Laboratory, USN Submarine Base, New London, Conn.

This report is designed to investigate the general possibilities of Q-technique in criterion research. A brief discussion of Q-methodology, including limitations, is presented together with the empirical results from a study applying Q-technique to the specific problem of constructing criteria of an efficient submariner. In raters, 7 submarine medical officers, 6 submarine line officers and one civilian psychologist described an ideal submarine enlistee "man" by the Q-sorting method, the trait population being derived from previous research. The resulting Q-correlation matrix was computed and 3 centroid factors extracted. Categorical rating scales were then constructed for the "trait dimensions" rated relevant by the Q-sorter defining each factor. The results show a) gross 2-ratings provide a highly tenable description of the ideal submariner, b) there is closer agreement as to what constitutes an ideal submariner within the medical group as compared to the submarine line officer group, c) there is one generally agreed-on-Q-description (with the present Q-trait population) of the ideal submariner as the 2 other factors could not be differentiated from the first general factor.

3057 Hixson, W.C., Harter, G.A., Warren, C.E. & Cowan, J.D., Jr. AN ELECTRONIC RADAR TARGET SIMULATOR FOR AIR TRAFFIC CONTROL STUDIES. Contract AF 33(616)-43, Proj. 7192, Task 71596, MACC TR 54 569, Dec. 1954, 83pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3057 The radar simulator described in this report was designed for research on air traffic problems arising from the need to control large numbers of aircraft in the vicinity of a landing field. The simulator provides independent control of speed and heading for 30 radar aircraft targets which are displayed on a Plan Position Indicator-type radar display with simulated ranges of either ten or 50 miles. The accuracy of target course generation, the flexibility of display system, and method of operation are discussed. Other uses of the device for general air defense problems are suggested.

3058 OSRD Staff. MEMORANDUM ON RADAR OPERATOR TRAINING: RESULTS OF STUDY OF SCR 270-71 OPERATORS-IN-TRAINING AT DREW FIELD. Contract OEXar-919, Proj. SC-70, NS-146, OSRD Rep. 1737, Res. Rep. 1, Aug. 1943, 6pp. OSRD, NDRC, Applied Psychology Panel, Yerkes Laboratories of Primate Biology, Orange Park, Fla.

3058 A study of SCR 270-71 radar operators-in-training based upon observations of approximately 500 operators for a period of approximately one month, was conducted to determine the effectiveness of the radar operator training program. Accuracy of range and azimuth reading proficiency were measured by means of the Philco Trainer. The results were presented and discussed in terms of the proficiency scores exhibited by the operators and the factors which appear to be relevant to improvement of the training program, e.g., student morale, course material, knowledge of results, training schedule arrangement, and so forth.

3061 Lindsley, D.B., et al. A STUDY OF THE FOXBORO TRAINER AS A TRAINING DEVICE FOR LEARNING TO TRACK BY MEANS OF PIP-MATCHING. Contract OEXar-919, Proj. SC-70, NS-146, OSRD Rep. 3102, Res. Rep. 5, Dec. 1943, 15pp. OSRD, NDRC, Applied Psychology Panel, Yerkes Laboratories of Primate Biology, Orange Park, Fla.

3061 The Foxboro Trainer (BC-968-A), a training device for learning pip-matching tracking ability, was studied to determine its value as a tracking trainer and more specifically, to determine the degree of skill obtained at different stages of practice. Ss (25) were given three runs each day for 12 successive days with motivation being maintained by verbal encouragement and competition within the group. Tracking scores were plotted against Veeder error scores and the results were discussed in terms of the relative increment in tracking ability at specific stages of practice as well as the overall tracking improvements reflected by use of this device.

Saidoor, J.C., Mallory, L.A., & Hearsey, E.L. METHODS OF TRAINING TELEPHONE TALKERS FOR INCREASED INTELLIGIBILITY. Contract OENr-680, Proj. F-109(1), SC-67, OSRD Rep. 3178, Rep. 4, Jan. 1944, 41pp. OSRD, NDRC, Applied Psychology Panel, Psychological Corporation, N.Y.

3062

To evaluate methods of instruction in talking over sound-powered telephones, 14 methods were employed with approximately 650 recruits. Four general types of methods were specified: 1) instruction by reading materials silently, 2) instruction using phonograph records, 3) instruction by teachers over phones, and 4) instruction in teacher-classroom situation. Each man's speech was tested for intelligibility before and after training. The results were discussed in terms of the relative gains in intelligibility produced by each method.

Kaufert, E.B., Spragg, S.D.S., & Taylor, H.A. VALIDATION OF THE MODIFIED ARMY BC-968-A RADAR TRAINER AS A TRAINING DEVICE FOR AERIAL TRACKING OF THE MARK 37 GUN DIRECTOR WITH MARK 4 RADAR. Contract OENr-1171, Proj. N-114, OSRD Rep. 4476, Rep. 15, Feb. 1945, 18pp. OSRD, NDRC, Applied Psychology Panel, University of Wisconsin.

3063

The BC-968-A Radar Trainer (Foxboro Trainer), ordinarily used to train men in the operation of SCR-268 radar equipment was utilized in training Navy personnel in pointer's and trainer's tasks in tracking the Mark 37 gun director with Mark 4 radar. Its efficacy in this function was evaluated by selecting two groups of matched Ss (on the basis of a tracking test) and training one group on the BC-968-A trainer while the other group received no training. After 12 days, both groups were tested in the gun director. The results were discussed in terms of the comparative performance of each group.

Ratliff, F. & Riggs, L.A. INVOLUNTARY MOTIONS OF THE EYE DURING MONOCULAR FIXATION. J. exp. Psychol., Dec. 1950, 40(6), 687-701. (Brown University, Providence, R.I.). (ONR).

The purpose of this experiment was to measure rapid involuntary movements of the eye during steady monocular fixation of a stationary, object. A photographic method of recording was used. 4 main types of movements were observed: a) Small rapid motions with a median extent (peak to trough) of about 17.5 sec. angle of rotation, and frequencies ranging from 30 to 70 cycles per sec. b) Slow motions of irregular frequency and extent. c) Slow drifts in one direction or another upon which the motions mentioned above are superimposed. d) Rapid jerks with an average extent of about 5.6 min. of arc occurring at irregular intervals, at times apparently compensating for the drifts. Total movement due to the combined effects of these motions over a period of 3 or 4 sec. was usually less than 10 min. of arc during the steadiest fixations. On the basis of the above results conclusions were drawn regarding the motions of the retinal image of the object being fixated. a) During a fixation period of 3 or 4 sec. the image of the object being fixated may move across a total of 25 to 50 receptors. b) The slower motions, drifts, and jerks may carry the retinal image across about a dozen receptors. c) The small rapid motions move the retinal image across 2 or 3 receptors at most. However, the median extent of these motions is so small that the movement of the retinal image under optimal conditions of fixation is not likely to exceed the width of one receptor. The results of this experiment indicate that small rapid motions of the eye do occur during 'steady' fixation, but that the magnitudes of these motions are extremely small.

Johnson, E.P. & Riggs, L.A. ELECTRORETINAL AND PSYCHOPHYSICAL DARK ADAPTATION CURVES. J. exp. Psychol., Feb. 1951, 41(2), 139-147. (Brown University, Providence, R.I.). (ONR).

Psychophysical procedures have been employed in experiments designed to match an earlier study of dark adaptation in which human electroretinal responses were used. The level of pre-adaptation was kept low enough to involve principally the scotopic system of the eye, since it was known that the retinal responses were primarily scotopic in origin. It was found that the extent of dark adaptation, measured as a lowering of the light intensity necessary to arouse a response, was roughly comparable in the absolute threshold experiments and in the electrical ones. The 2 sets of dark adaptation curves are not, and cannot be expected to be, identical. Their general similarity does, however, support the conclusion that human dark adaptation takes place largely at the retinal level, and that the scotopic visual system is responsible for the phenomena observed in both sets of experiments.

3069
This paper reports the results of the administration of a questionnaire on simulated blind flying equipment to 143 Navy pilots. Replies to questions are tabulated and analyzed to evaluate the equipment in terms of usage, comparisons of various systems, and difficulties and needed improvements. Appendices include a copy of the questionnaire and the comments of respondents (critical incidents, equipment difficulties, recommendations, etc.).
T.

3071
This article described an optical-mechanical trainer for the Plan Position Indicator which was developed to supplement an improved system, called the "Flash-Reading Method," of training in radar plot reading. The training device, the PPI Flash Reading Trainer, simulates all aspects essential to the task of learning to read plots. The system of training in which it is used emphasizes training in maximum speed in reading individual and successive target echoes and the standardization of problem situations. Potential applications of the trainer and training methods were discussed along with the results of their experimental application to radar plot training.

Wapner, S., & Witkin, H.A. THE ROLE OF VISUAL FACTORS IN THE MAINTENANCE OF BODY-BALANCE. Amer. J. Psychol., 1950, 62, 385-408. (Clark University, Worcester, Mass. & Brooklyn College New York). (ONR).

Maintenance of balance on an unstable platform was studied under 4 conditions of the visual field: a) full visual field (highly structured); b) limited field (of weak structure); c) no visual field (S blindfolded); and d) an unstable (moving) field. As the visual field was weakened, eliminated, and finally made unstable, balance became progressively poorer for both men and women. It was found, however, that women showed differentially poorer balance than men when presented with unstable visual surroundings. There were marked and sustained individual differences in performance for each tested condition examined, both in pattern of scores from one condition to another and in rate of improvement. By controlling the condition of the visual field in both steadiness and balance, and by introducing a mechanism for adjusting the difficulty of the task to the weight of S, a significant relationship was found between steadiness and balance, greater steadiness being associated with better balance. The highest correlations between these stated were obtained for trials carried out under identical conditions of the visual field. The results of this and related studies suggest that individuals differ notably from each other with respect to extent of dependence on the visual field in their bodily orientations.

Luneburg, R.K. THE METRIC OF BINOCULAR VISUAL SPACE. J. Opt. Soc. Amer., Oct. 1950, 40(10), 627-642. College of Physicians & Surgeons, Columbia University, New York, N.Y. (ONR)

Attention is given to some problems concerning stimulus and response in the psychophysical experiment. The role of instructions, classification of stimuli, and limitations of the S's verbal response are discussed. An examination is made of the stimulus-response relations of the following psychophysical methods: constant stimuli, single stimuli, limits, adjustment, sense-ratio, and reaction time. Representative stimulus-response functions are described. It is concluded that the behavior-evidenced in the psychophysical experiment is discriminating. Some historical aspects of psychophysical theory are considered and criticized. An attempt is made to relate the data of the psychophysical experiment and perception to the field of behavior theory. It is shown in equation (10) that psychophysical functions are describable as special cases of the general behavior function of equation (9). In the special case a specific aspect of a stimulus is the essential variable, and terms representing number of presentations of stimuli, time, and specific conditions of the organism are constant. In certain treatments that involve several psychophysical functions (e.g., intensity discrimination), one variable aspect of the stimulus is treated in equation (11) as a function of another aspect of the stimulus, the response and all other variables remaining constant. R 40

The aim of this paper is to show that the so-called visual space has a uniquely determined non-Euclidean metric, or psychometric distance function, the numerical parameters of which depend on the individual observer. Certain well-known phenomena of space perception, such as the horopter, the alley experiment and size constancy, are explained on the basis of the distance function. Methods of measuring the personal parameters of the metric are developed, and applications of the theory to the field of binocular instruments and pictorial representation of space are suggested. Ryan, T.A., Cottrell, C.L. & Bitterman, M.E. MUSCULAR TENSION AS AN INDEX OF EFFORT: THE EFFECT OF GLARE AND OTHER DISTURBANCES IN VISUAL WORK. *Amer. J. Psychol.*, July 1950, 53, 317-341. (Cornell University, Ithaca, N.Y. & University of Texas, Austin, Tex.). (ONR)

Using a controlled rate of presentation of a letter checking-test and holding constant the visual relations between the work-area and the glare-source, muscular action potentials (MAP) were measured from 4 diverse regions of the body. Significant increments in MAPs were found when glare was introduced. There was no evidence of differential effects in different regions of the body. Combination of changes occurring at several points produced more significant results than those obtained from a single area. The total electrical activity for a period of work is thus shown to have validity, inasmuch as it reflects the effects of severe glare in group averages. The reliability and sensitivity of this index must be investigated further, however, since not all individuals in the group showed patterns similar to the group-averages. The fact that a given individual shows no increase in potentials during work under glare may reflect a real lack of effect in that particular individual or it may only mean that this index is not sufficiently reliable to measure effects in the single day's record.

Murray, Elsie. MASS-TESTING OF COLOR VISION: A SIMPLIFIED AND ACCELERATED TECHNIQUE. *Amer. J. Psychol.*, 1946, 51, 370-385. (Cornell University, Ithaca, N.Y.).

A mass-testing procedure used on Cornell University entering students in the fall of 1947 is described, along with analysis and discussion of results. The regulations for testing were a) speed (1:1 min. per 5), b) setting (small table in open space in a large gymnasium), c) examiners (students trained by physician in charge), and d) testing hours (8-12 AM and 2-6 PM for 5 consecutive days). The test materials were 13 pseudo-isochromatic plates (Ishihara, 5th ed.), 10 correct was the score adopted for color normal and a record was kept of errors. It was found that of the 1866 men tested 144 or 7.7% scored 3-12 errors; out of 468 women, 11 were scored color deficient or 2.4%. These percentages compare favorably with those generally reported. Some discussion of certain doubtful plates is presented. Even though the procedure throughout was tentative, the writer feels that the results demonstrate that any institution interested in the future of its students, however pressed for time, will find it profitable to run a color-test along with its medical examination of entrance. Harvard University. THE PROBLEM OF SELECTING AND TRAINING COMMUNICATIONS PERSONNEL. Contract GEMR 658, OSRD Rep. 987, MFR Rep. 27, Nov. 1942, 24pp. Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.

3087

This report is concerned with the problems of adequate selection and training of personnel for communication in aircraft, ships, and tanks. It presents the results of experiments dealing with individual differences among communications personnel (e.g., differences in listening ability and articulation), the validation of tests of individual differences (e.g., the comparison of laboratory with actual flight performance), the efficiency of tests used to select communications personnel (e.g., acuity of hearing tests, etc.), and the use of equipment and particular types of instructions in the training of listeners and speakers (e.g., equipment information, resonant vs. non-resonant interphone system, etc.).

Spragg, S.D.S. A STUDY OF THE TRACKING PROFICIENCY OF STUDENT OPERATORS DURING TRAINING ON AERIAL TRACKING OF THE MARK 37 GUN DIRECTOR WITH MARK 4 RADAR. OSRD Contract GEMR 1171 & Rep. 4049, MRC Proj. N 114 & Rep. 10, Aug. 1944, 16pp. University of Wisconsin, Madison, Wisc.

3088

To evaluate the proficiency of students trained to track the Mark 37 Gun Director with Mark 4 radar, and to study the effect of knowledge of results (or coaching) on such performance, two groups of Fire Controlmen students were compared. While one group was trained in the usual manner, the other group was coached during and following tracking runs. Performance was recorded on a Pointing and Training Record Sheet and by using a Mark 79 telescope as a check sight. Results are discussed in terms of the comparative performance of each group and the general proficiency evidenced by all of the subjects.

Lit, A. THE MAGNITUDE OF THE PULFRICH STEREO-PHENOMENON AS A FUNCTION OF BINOCULAR DIFFERENCES OF INTENSITY AT VARIOUS LEVELS OF ILLUMINATION. *Amer. J. Psychol.*, 1949, 62, 159-181. (Columbia University, New York, N.Y.).

The present investigation is concerned with the effect of differences in intensity at different base levels of illumination on the Pulfrich stereophenomenon. Determinations were made of the relationships existing between a) the magnitude of the near and far displacements, and b) the differences in retinal illumination existing between the 2 eyes for c) many basic levels of illumination. The following relationships were found: a) displacement and latency-difference increase as the difference in retinal illumination increases; b) displacement and latency-difference approach maximal values as the difference in retinal illumination increases; c) the rate of increase depends on level of illumination; slopes of the curves increase as level-of-illumination decreases; d) for a given difference in retinal illumination, displacement and latency-difference increase as level of illumination decreases; and e) the difference in retinal illumination necessary to produce a constant displacement or latency-difference becomes smaller as level of illumination decreases. The results obtained may be accounted for on the assumption that the absolute visual latent period and the logarithm of the stimulus-intensity are inversely related. The results are analyzed in terms of laws of space-perception, and additional experiments have been performed to test the relations.

Graham, C.H., Hammer, E.J., Mueller, R.D., & Note, F.A. STEREOSCOPIC SETTINGS WITH RETICLES PROVIDING MULTIPLE REFERENCE ANGLES: THE PERCEPTION OF SPATIALLY REPEATING PATTERNS. PSYCHOLOGIA, 1949, 27, 209-216. (Psychology Dept., Columbia University, New York, N.Y.). (GMR).

It is shown theoretically that, under certain conditions, a stereoscopic observer may align a target with a reticle at more than a single value of apparent range. Theory predicts that multiple alignments may occur when the visual angle, α , existing between adjacent equally spaced reticle marks is sufficiently small. If we designate the angular difference existing between a given alignment setting and the "true" alignment setting as n , then the condition for alignment is fulfilled when $\sin n = n$. An integral number, n , represents the degree of "false" fusion. Experimental data, obtained with the stereoscope and reticles described in the text, are in accord with theory.

Kobrick, J.L. QUARTERMASTER HUMAN ENGINEERING HANDBOOK SERIES: II. DIMENSIONS OF THE UPPER LIMIT OF GLOVED HAND SIZE. Proj. Reference 7-83-01-004; Tech. Rep. EP-41, Dec. 1956, 185pp. Environmental Protection Research Division, Quartermaster Research & Development Center, Natick, Mass.

3096
This report presents human engineering information on the hand size of the soldier wearing various ensembles of Quartermaster protective gear. It is intended for use as a handbook by engineers for establishing size and space allowances in the design and sizing of hand-operated equipment. The criterion employed is the bare hand size that is equal to or bigger than the hand size of 95 percent of the Army personnel (95th percentile of the Army hand size distribution). The information is presented in pictorial form with index scales, so that dimensions can be measured on the pictures and referred to the index scale to establish actual size.

Davis, H. THE ARTICULATION AREA AND THE SOCIAL ADEQUACY INDEX FOR HEARING. LARYNGS, 1948, 58(8), 761-776. (Research Laboratory of the Central Institute for the Deaf, St. Louis, Mo.). (GMR).

The Social Adequacy Index (SAI) is a single number that indicates how well a person hears speech under average everyday conditions. The SAI is based on 2 different kinds of speech tests. One kind of speech test measures the hearing loss for speech in db. This is a measure of auditory acuity. The other kind of test measures the discrimination loss, i.e., the inability to recognize difficult words even when they are spoken loudly. Several tests are available for measuring auditory acuity; however, the only quantitative tests available at present for measuring discrimination loss are the phonetically balanced (PB) word lists given at high intensity levels. From the results of one test of each kind the SAI may be found either graphically or from a table. The Threshold of Social Adequacy, where a person still "gets by," but with considerable difficulty, is at SAI -- 33; meaning that he understands an average of 1/3 of the (PB) monosyllables that he hears under average conditions. Difficulty in social situations begins, however, when the index falls from normal (94-100) to 67, i.e., when 2/3 of the PB monosyllables are still understood. Hearing becomes socially useless at an SAI of 10 or 15 when simple sentences spoken in a very loud voice are no longer understood.

Davis, T.R.A., Johnston, D.R. & Bell, F.C. SOME CHARACTERISTICS OF SHIVERING IN MAN. Proj. 6 64 12 028, Task USAFHL T 1, MEDEA, Rep. 383, May 1959, 14pp. USA Medical Research Lab., Fort Knox, Ky.

3100
To determine the relative roles of core and peripheral temperatures not only regarding the stimulation of shivering but also concerning the maintenance and regulation of shivering subsequent to its onset, ten human subjects (22 to 26 years of age) were studied. After one hour of stabilization at room temperatures (30 degrees C) in supine position on mesh cot and wearing shorts, each subject was wheeled into a cold room (14 degrees C) for one hour. Measurements included motor activity, rectal and surface temperatures in both warm and cold rooms. Immersion experiments used sea water. Onset of shivering was analyzed in relation to body size, surface area, latitude of origin, skin temperatures and rectal temperatures. The shivering pattern was also studied.

3102 Falconer, G.A., & Davis, H. THE INTELLIGIBILITY OF CONNECTED DISCOURSE AS A TEST FOR THE "THRESHOLD FOR SPEECH." LEARNINGS, 1947, 27(9), 581-595. (Central Institute for the Deaf, St. Louis, Mo.). (ONR).

A recorded test for the threshold of intelligibility for connected discourse (TICD) is described. The listener selects his own threshold by adjusting the volume control. The advantages claimed for this test are: a) speed (about 2 min.); b) interest for the listener and lack of fatigue; c) high face validity. (It uses a sample of an actual radio broadcast); d) satisfactory reliability; e) negligible learning effects. The chief disadvantage of the test is the subjective nature of the end-point. An occasional subject gives an erratic threshold. The TICD test was compared experimentally with Auditory Test No. 9 (syndetic words), using 50 normal and 94 hard-of-hearing ears. The thresholds obtained by the two tests were nearly identical. The normal and the hard-of-hearing were about equally reliable, with a slight advantage in favor of the hard-of-hearing.

3103 Day, R.H. & Baxter, J.R. A COMPARISON OF TWO TYPES OF VISUAL APPROACH AID. Note ARL/IE-4, Jan. 1959, 38pp. Dept. of Supply, Aeronautical Research Labs., Melbourne, Australia. (Dept. of Psychology, University of Sydney, Sydney, Australia).

3103 To compare the principles of glidepath guidance used in the British Angle of Approach Indicator and the Australian Precision Visual Glidepath, twelve experienced airline captains made three approaches on each system during conditions of clear visibility on moonless nights. Preferences under a variety of conditions and from a number of aspects were determined by questionnaire; flight profiles were also recorded. The data were analyzed for differences between the two systems. T. G. I. R 5

3104 Dearborn, W.F., Johnston, P.W. & Carmichael, L. IMPROVING THE READABILITY OF TYPEWRITTEN MANUSCRIPTS. Proc. Nat. Acad. Sci., Oct. 1951, 37(10), 670-672. (Tufts University, Medford, Mass.).

3104 This paper reports some of the results from an investigation of ways to improve the readability of typewritten manuscripts. Some of the features which were tried out experimentally were 1) the use of a "peak stress" format (capitalizing in each sentence the word to which the author would give maximum oral stress), 2) two-column arrangement, 3) single-spaced lines, 4) other spatial arrangements which break up the article into more comprehensible units of thought, and 5) blackening (by retyping over original) certain sections deemed by the writer to be of particular importance.

3105 This report covers the design and construction of a dynamic simulator of an aircraft in flight with which "human frequency responses" to visual signals may be measured for the purpose of determining optimum characteristics of an aircraft's controls. The simulator comprises an aircraft cockpit, a program unit that presents visual input stimuli on a cathode-ray tube in view of the pilot, an electronic analog computer that computes the aircraft equations of motion and resultant stimuli (target) motions, and a recorder for pilot responses and other desired quantities. Validation of the simulator is given in a separate report.

3106 Davis, H., Silverman, S.R., & McAuliffe, D.R. SOME OBSERVATIONS ON PITCH AND FREQUENCY. J. Acoust. Soc. Amer., 1951, 21(1), 40-42. (Central Institute for the Deaf, St. Louis, Mo.). (ONR).

"Tone-pips" were produced by brief rectangular electrical pulses being delivered through 2 sound-effects filters in cascade with both high and low cut-offs set at 2000 cps. Nearly all of the acoustic energy of the final signal was found to be concentrated in a band about an octave wide and centered at 2000 cps. The pulsing frequency was varied independently between 50 and 150 pips per second. Listeners describe the resulting sound as a "metallic buzz." Listeners vary greatly in their ability to identify the 2 "pitches" present in this sound and in the accuracy with which they match with a pure tone either the pulsing frequency (about 130 per second) or the band-pass frequency (2000 cps in the present series). Errors of exactly one octave are particularly common. In the theoretical discussion we argue that the "pitch" of a pure tone is a double attribute compounded of "buzz" (correlated with frequency of volleys of nerve impulses) and "body" (correlated with position of maximum stimulation on the basilar membrane).

Staats, A.W., Staats, Carolyn K. & Heard, W.G. PSYCHOLOGICAL PROCESSES IN LANGUAGE COMMUNICATION. LANGUAGE CONDITIONING OF MEANING TO MEANING USING A SEMANTIC GENERALIZATION PARADIGM. Contract NMR 2305 (00); Tech. Rep. 4, May 1958, 8pp. Arizona State College, Tempe, Ariz.

3109

This study tests the hypothesis that a word meaning response can be conditioned to the meaning response of another word. Two types of stimuli were used: 1) words presented on a screen (conditioned stimulus--CS) and 2) words presented orally (unconditioned stimulus--UCS). The visually presented words were shown 14 times in random order. On each presentation the CS-word was paired with a different UCS-word. The CS-words ROCK and CARPET were always paired with UCS-words of positive or negative evaluative meaning. The order of pairing was reversed for two groups. Finally, all subjects rated a series of words including STONE and RUG on a semantic differential scale of pleasant-unpleasant. The scores were analyzed for mediated conditioned meaning to synonym words.

Hirsh, I.J. & Webster, F.A. SOME DETERMINANTS OF INTERAURAL PHASE EFFECTS. J. acoust. Soc. Amer., Sept. 1949, 21(5), 496-501. (Psycho-Acoustic Laboratory, Harvard University, Cambridge, Mass.). (Rep. PNR 68)

A 250-cycle tone was presented against 4 different kinds of background. The masking sounds were: a) pure tones; b) regular pulses (125 pps); c) random pulses (average 125 pps); and d) random noise. Combinations of filters permitted the presentation of these maskers in frequency bands that were varied in width and center frequency. The results indicate that the threshold for the tone in the presence of a regular, periodic masker does not depend to any significant degree upon interaural phase relations. A necessary characteristic of the masker that produces interaural phase effects is randomness or irregularity. Both masking and the interaural phase effects increase as the frequency band of a random masker approaches the frequency of the tone. Band width alone does not contribute to the interaural phase effects except as widening a band tends to bring one cut-off nearer the frequency of the tone. Wide and narrow band maskers, both of which contain the frequency of the tone, produce the same effects.

Pollack, I. LOUDNESS AS A DISCRIMINABLE ASPECT OF NOISE. *Amer. J. Psychol.*, April 1949, 62, 285-289. (Harvard University, Cambridge, Mass.).

2 experienced listeners and 1 relatively inexperienced listener attempted to match a narrow band of noise-signal in terms of a) loudness, b) volume, c) annoyance, d) density, and e) force. The data was analyzed in terms of the difference between an equal-loudness adjustment and an adjustment in terms of each of the other judgments. It was found that: a) the low-frequency bands of noise are relatively more voluminous than high-frequency bands, b) both the very low and very high frequencies were relatively more annoying than the middle-noise frequencies, d) the relations obtained for volume are reversed for density, d) of all the criteria employed, force was the most poorly differentiated from loudness.

Fortes, T.W. AUDITORY SIGNALS FOR INSTRUMENT FLYING. *J. Aeronautical Sciences*, March 1946, 13(3), 255-258. (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.).

3126

This study is concerned with the applicability of auditory signals to instrument flight. Several investigations were undertaken to determine the following aspects of auditory signals: (1) the most discriminable types of signals; (2) the degree of accuracy with which such signals could be utilized; and (3) the number of simultaneous auditory signals which could be followed successfully. The experimental results of each aspect of this investigation are presented and discussed in terms of their application to Link Trainer flights. The general degree of accuracy of performance with various types of auditory signals and various modes of presentation is presented along with the inherent implications for application of this technique to training in flight.

3128 Pollack, I. THE EFFECT OF WHITE NOISE ON THE LOUDNESS OF SPEECH OF ASSIGNED AVERAGE LEVEL. *J. Acoust. Soc. Amer.*, May 1949, 21(3), 255-258. (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.).

Continuous recorded speech passages were presented against a background of white noise and against a quiet background. The effect of the noise on the loudness of speech was determined by having listeners adjust the level of speech heard in quiet to sound equal in loudness to an assigned average level of speech presented against selected levels of background noise. In general, it was found that a) low noise levels produce a proportionately lower depression in the loudness level of speech than higher noise levels; b) as a first approximation, however, the effect of noise on the loudness of speech is a function of the speech-to-noise ratio rather than of the level of the speech alone or of the noise alone, and c) under none of the experimental conditions did white noise actually increase the loudness of speech (the "Egan effect"). The assumption that a given level of noise subtracts a constant number of loudness-units from speech (regardless of the level of the speech) was found to be fairly adequate in describing the experimental results.

R 6

3129 Thomas, G.J. EQUAL-VOLUME JUDGMENTS OF TONES. *Amer. J. Psychol.*, April 1949, 62, 182-201. (University of Chicago, Chicago, Ill.).

The present investigation demonstrates the nature of equal-volume contours throughout a large part of the auditory area (100 to 8350 cps.). In general, the contours indicate that at high intensities and high frequencies, a given change in frequency produces less change in volume than it does at lower intensities and frequencies. Throughout the middle portion of the contours, the procedure of adjusting the intensity of 1 or 2 tones which differ in frequency seems to yield essentially the same equal-volume contour as the procedure of adjusting the frequency of 1 or 2 tones which differ in intensity. However, when the method of intensity-adjustment is used, a tendency appears for the contours to flatten out at the extremes, thus giving a sigmoid shape to the contour and causing it to deviate at either end from the contour determined by the method of frequency-adjustment. Psychologically unophisticated subjects can learn with relative ease to make transdimensional equal-volume matches that are subjectively satisfying and consistent. Inter-individual differences appear to be greater than intra-individual differences from trial to trial. The equal-volume contours are considered to be reliable because contours determined at different times but with the same standard tone were found to be very similar.

3131 Pullack, I. SPECIFICATION OF SOUND-PRESSURE LEVELS. *Amer. J. Psychol.*, July 1949, 62, 412-417. (Harvard University, Cambridge, Mass.).

This note describes the more important conversion factors for transferring from one set of auditory intensity measurements to another. The most satisfactory specification of level developed by an earphone is in terms of the SPL at the face of a calibrated condenser microphone in a standard artificial ear. The conversions considered here are: calibration under an earphone cushion; calibration at eardrum-closed ear; real-ear response; calibration at eardrum-open ear and calibrations at eardrum-open ear with random incidence. 3134 Wallach, H., Newman, E.B. & Rosenzweig, M.R. THE PRECEDENCE EFFECT IN SOUND LOCALIZATION. *Amer. J. Psychol.*, July 1949, 62, 315-336. (Swarthmore College, Swarthmore, Penn.).

This paper was concerned with what an S hears when 2 nearly identical sounds reach his ears from different directions and one follows the other after a slight delay. The conclusions were: a) 2 such brief sounds will be heard as a single sound if the interval between is sufficiently short -- the upper limit was found to be about 5 msec. for single clicks and apparently much longer, perhaps as much as 40 msec., for complex sounds; b) if 2 such sounds are heard as a single sound, the localization of the total sound is determined largely by the location of the first sound -- a precedence effect. Limitations of this precedence effect include: discontinuous or transient type sound, conditions around second sound relative to localization of total location and time interval, intensity, and similarity of second relative to first. 3131 Cotzin, M. & Dallenbach, K.M. "FACIAL VISION:" THE ROLE OF PITCH AND LOUDNESS IN THE PERCEPTION OF OBSTACLES BY THE BLIND. *Amer. J. Psychol.*, Oct. 1950, LXIII, 485-515. (University of Texas, Austin, Tex.).

3131.

This study, the last of three investigations on the perception of obstacles by the blind, concerned the auditory dimension (pitch or loudness) involved in the perception. Four subjects (two blind and two with normal vision wearing a blindfold) were tested on their ability to perceive an obstacle under the following conditions: 1) a continuous sound (thermal noise containing all audible frequencies at high level intensity) was moved toward an obstacle at a rate controlled by the subject; and 2) a continuous sound (pure tones varying by octave relationship from 125 to 8000 cycles and at 10,000 cycles) was moved as before. Stimulus-limens were determined for each subject at distances varying from zero to six feet from the wall and the data were analyzed for the critical dimension. T. G. I.

3132 Dancher, J.W., Colman, K.W. & Courtney, D. THE SIMULATOR PILOT IN A DYNAMIC AIR TRAFFIC CONTROL SIMULATOR: AN ACTIVITY ANALYSIS. INTERIM REPORT. Contract FAA/ERD 27, Proj. N, Rep. 23, Feb. 1959, 54pp. Courtney and Company, Philadelphia, Penn.

3132

A dynamic Air Traffic Control (ATC) system simulator is currently being developed for the Federal Aviation Agency, Bureau of Research and Development. This report is concerned with an analysis of the simulator operator's activities. Included are a detailed description of the operator's task and its relationship to the over-all simulator system for personnel concerned with the conduct of ATC studies, an optimal set of procedures and sequences for accomplishing the various operations, a basis for a detailed specification of the requirements of the task as an aid in selecting operators, a basis for determining training needs and criterion measures of proficiency, and feedback for future simulator development to improve simulator console design.

3135 Bekey, G. von. THE MOON ILLUSION AND SIMILAR AUDITORY PHENOMENA. *Amer. J. Psychol.*, Oct. 1949, 62, 540-552. (Harvard University, Cambridge, Mass.).

In this paper auditory phenomena similar to the moon illusion are described: the optical vs. acoustical size of an orchestra from different locations in a large theater (just opposite to the moon illusion), and sound-image observations in an anechoic room (apparent distance as a function of observational angle--again inverse to the moon illusion). Existing theories of the moon illusion are briefly reviewed and the phenomenon of visual size constancy is then used to interpret this illusion. Also a kinesthetic spatial illusion is described.

Minkins, J.E., Jr. & Stevens, S.S. THE MASKING OF PURE TONES AND OF SPEECH BY WHITE NOISE. *J. Acoust. Soc. Amer.*, Jan. 1950, 22(1), 6-13. (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.).

This report presents the results of a study of the monaural masking of pure tones by white noise at 8 sensation levels (SL) from 20 to 90 db. The observed values of masking were employed to determine 2 basic functions: a) the critical band width of a masking noise, i.e., the ratio, in decibels, between the level of a pure tone and the level per cycle of the noise that is just able to mask the tone; b) the function relating the amount of masking to the effective level of the masking noise. With the aid of these 2 functions, a set of contours was constructed to represent the masked threshold for pure tones heard monaurally against a background of white noise having an ideal flat spectrum at the ear of the listener. A study was also made of the masking by white noise of speech in the form of continuous discourse. Measurements of the threshold of detectability and of the threshold of intelligibility were made at the same 8 noise levels used to mask pure tones.

Larue, H.A., & Sklodowski, V.A. EFFECTIVENESS OF SCALD GRID MARKINGS ON TARGET LOCATION. May 1956, 23pp. Cracley Division, Avco Manufacturing Corp., Evendale Plant, Cincinnati, Ohio.

3127

To determine if the physiological changes induced by acclimatization in animals also takes place in man, six subjects (22 to 26 years of age) were studied for a period from October through February. Each subject received one hour of deliberate cold exposure (room temperature, 14 degrees C) per month preceded by one hour stabilization to 30 degrees C. Measurements for both conditions included resting metabolic rate, rectal and skin temperatures, and baseline motor activity. Shivering activity was measured by integrating muscle action potentials from right thigh. Heat acclimatization was obtained by eight-hour daily exposures to 49 degrees C, for three weeks with 20 minutes of exercise each hour.

3139

To investigate the effect of radar scope overlays on operator performance, a rectangular three-sector scope (target appearing in any one of the three sectors) was simulated on cards and presented tachistoscopically for 0.5 seconds. The task (20 subjects) was to report the location of the target by sector. Display variables were 1) type of sector separation (color, thin lines, thick lines, and thin lines with arrow) and 2) number of scaled grid markings (four degrees of "clutter"). Performance (per cent accuracy) was analyzed as functions of type and number of grid markings.

3138 Bekesy, G.V. VIBRATION OF THE HEAD IN A SOUND FIELD AND ITS ROLE IN HEARING BY BONE CONDUCTION. *J. Acoust. Soc. Amer.*, Nov. 1948, 20(6), 749-760. QMC. (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.). (Rep. PNR 56).

In a sound field the head is set into forced vibrations, and the vibrations are sometimes heard by bone conduction. For clinical purposes it is important to know the magnitude of these vibrations of the head so that, in cases of partial deafness, the roles of air conduction and bone conduction can be understood. The pattern of the head vibrations and the velocity of the deformation waves traveling along the bony wall of the skull were measured. For the velocity we found $c=570$ m/sec. In the course of the experiments, a new method of calibrating a vibration pick-up with a sound level meter was developed. It was found possible to construct an earphone that reduces the amount of "cross-hearing" to a very low value. With this earphone, hearing thresholds can be measured in many cases without using noise to mask the ear with the better hearing, even though the difference between the sensitivities of the 2 ears is greater than 40 db. It is shown that the maximal sound insulation that can be obtained with an ear plug is determined by the elastic forces acting between the skin of the ear canal and the bony wall of the ear canal.

3140 Hirsh, I.J. THE INFLUENCE OF INTERAURAL PHASE ON INTERAURAL SUMMATION AND INHIBITION. *J. Acoust. Soc. Amer.*, July 1948, 20(4), 536-544. (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.). (Rep. PNR 51).

The difference between the binaural and monaural thresholds varies within fairly large limits. Although this binaural-monaural difference does not vary as a function of frequency when pure-tone thresholds are measured in the quiet, the difference does vary with frequency which has been used in the past to refer to the phenomenon in which the binaural threshold is lower than the monaural, obtained for masked thresholds only when the phase angles between the two earphones are opposite for the tones and the noise. If the tones and the noise have the same interaural phase angle the binaural threshold is higher than the monaural. This phenomenon, called interaural inhibition, as well as its antipode, interaural summation, is most marked at low frequencies and increases as the intensity of the masking noise is increased. The discussion considers some implications of these findings for the theory of masking and of interaural summation.

HILLER, G.A. & LICKILDER, J.C.R. THE INTELLIGIBILITY OF INTERRUPTED SPEECH. *J. Acoust. Soc. Amer.*, March 1950, 22(2), 167-173. (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.). (Rep. PNR 50).

This paper concerns the effects of interrupting speech waves--turning them on and off intermittently or masking them with intermittent noise--upon their intelligibility. The effects were studied with various rates of interruption and with the speech left undisturbed various percentages of the time. Tests were conducted a) with speech turned on and off in quiet, b) with continuous speech masked by interrupted white noise, and c) with speech and noise interrupted alternately, the speech wave being turned on as the noise wave was turned off, and vice versa. a) When the speech wave is turned on and off infrequently, the percentage of the message that is missed is approximately the same as the percentage of time the speech is off. When the interruptions are periodic and occur more often than 10,000 times per second, the interruptions do not interfere with the reception of the message. b) The quiet it is easy to understand conversational speech so long as the interruptions occur more than 10 times per second. c) When continuous speech waves are masked by noise that is interrupted more than 200 times per second, intelligibility is independent of the interruption frequency and of the percentage of time the noise is on, provided the ratio of average speech power to average noise power is held constant. Interrupted masking noise impairs intelligibility least if the frequency of interruption is about 15 per second. c) When interrupted speech and interrupted noise alternate at frequencies below 10 alternations per second, the noise does not impair intelligibility. At higher frequencies of alternation the temporal spread of masking becomes appreciable. The general features of these results are approximately the same whether the interruptions occur periodically or at random.

3144

HOWES, D.H. THE LOUDNESS OF MULTICOMPONENT TONES. *Amer. J. Psychol.*, Jan. 1950, 62(1), 1-30. (Harvard University, Cambridge, Mass.).

The loudness (in sones) of complex tones consisting of from one to 11 equally loud components is equal to the sum of the loudnesses of the several components. Unequally loud components are also shown to be additive with respect to loudness. Additivity begins to break down when the components mask each other; this point has been determined for components separated by equal pitch-distances. The decrease in the loudness of a complex tone due to intercomponent masking can be measured as the difference between its observed loudness and a theoretical value based on the hypothesis that the loudness of a complex tone is the sum of the loudnesses of its components. Measured in this way, the masking per component is invariant with respect to frequency, but depends on the loudness of the components and the pitch-separation between them. From these results a simple formula for the calculation of the loudness of multicomponent tones has been devised. This formula predicts accurately the results of previous experimentation with multicomponent tones. These simple relations in masking appear only when psychological units (sones and mels) replace the physical ones (decibels and cycles per second). The discovery of simple relations by means of these psychological scales constitutes a strong confirmation of the procedure by which they were established. The results for the masking of loudness apparently do not hold for masked thresholds of audibility. The possibility that loudness and audibility thresholds are different processes is discussed. Finally, a model based on the results is suggested, and its characteristics are compared with the known physiological properties of the auditory system.

3141

KIRSH, I.J. THE RELATION BETWEEN LOCALIZATION AND INTELLIGIBILITY. *J. Acoust. Soc. Amer.*, March 1950, 22(2), 196-200. (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.). (Rep. PNR 67).

The binaural masked threshold for speech depends upon the relation between the interaural phase angles of the speech and those of the noise. When these phase angles are the same, the threshold is high, and both speech and noise appear to be in the same place. When the interaural phase angle of the speech is reversed relative to that of the noise, the threshold is low and the speech and noise appear to be in different places. These relations have been clearly demonstrated with earphones, and they suggest that in free-field listening the threshold of intelligibility might be affected by the relative locations of the sources of speech and of masking noise. It was found that when the azimuths of the sources of speech and of noise are changed relative to each other, the threshold of intelligibility changes by small but consistent amounts. When the sources are close together, the threshold is high; when the sources are far apart, the threshold is reduced. Although this relation is partially confounded by the effect of azimuth on the sound pressure levels at the ears, the factor of localization appears to play a significant role, especially when two ears are used and when the head is allowed to move. In order that the head-of-hearing may take advantage of these effects, they must have a hearing aid with two separate microphones mounted near the ears and connected each to a separate earphone.

SMITH, M.H. & LICKILDER, J.C.R. STATISTICAL BIAS IN COMPARISONS OF MONAURAL AND BINAURAL THRESHOLDS: BINAURAL SUPPLEMENTATION OR BINAURAL SUPPLEMENTATION. *Psychol. Bull.*, July 1949, 46(4), 278-284. (Harvard University, Cambridge, Mass.). (PNR 72).

This paper examines the magnitude of the bias (supplementation effect) in the monaural-binaural comparison and whether it is influenced by the step of equating the monaural thresholds before determining the binaural threshold. It was found that further information on 3 main points is required to finally prove the existence of a summative process or reject the hypothesis of statistical bias: a) to what degree are the momentary sensitivities of the 2 ears correlated; b) to what degree are successive momentary monaural thresholds correlated; and c) how does the precision of a threshold determination depend upon the length of time spent in making it. Miller, G.A. & Garner, W.R. THE MASKING OF TONES BY REPEATED BURSTS OF NOISE. J. Acoust. Soc. Amer., Sept. 1948, 20, 691-696. (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.).

The masking of tones by continuous and interrupted noise was determined for 3 noise intensities, 3 noise-time fractions and rates of interruption varying from 0.5 to 512 interruptions per second. The decrease in masking effectiveness as a result of the discontinuity of the masking noise depends principally upon the duration of the silent interruption, and secondarily upon the frequency of the masked tone and the intensity of the noise. A computational device is presented which will permit a first approximation of the masking produced by interrupted noises.

3150

This report summarizes accomplishments during the year 1957 on a research project on human visual capacities as a basis for safer design of vehicles. The total behavioral field of vision has been studied by obtaining fields of fixation, standard fields of vision, fields with intermediate and maximum eye deviation, and field of maximum head rotations. Apparatus was developed and constructed for measuring peripheral acuity and form perception in a dynamic situation. Visibility areas of 16 contrasting vehicles were measured, analyzed, and rated. An analysis of conspicuity characteristics of motor vehicles was made. A general literature survey was completed.

Neff, W.D. INTERNATIONAL ASSOCIATION OF GERONTOLOGY THIRD CONGRESS. Tech. Rep. ONRL-82-54, Sept., 1954, 19 pp. ONR. American Embassy, London, England.

3167

This is a report of the Third Congress of the International Association of Gerontology, held July 1954 in London, England, and prepared by W.D. Neff. Brief summaries are presented of papers representing research under the general headings of changes in the EKG in psychiatric illness of old age, neurology of the aged, and studies of intelligence, learning, and special skills (e.g. speed of writing, language function, etc.) in the aged. A list of authors and papers is included.

3168

Mitkin, H.A. STUDIES IN GEOGRAPHIC ORIENTATION. Yearb. Amer. Phil. Soc., 1946, 152-155. (Brooklyn College, Brooklyn, N.Y.).

3168

A series of experiments investigating the way in which orientation toward the north-south-east-west axes of space is normally maintained is summarized. For most of the experiments the ability of the subject to remain oriented through a series of movements was tested. The variables were as follows: without the aid of vision, with a visual frame of reference, and with suggestion of illusory body motion (postural autokinetic effect). A paper-and-pencil test was devised to investigate further the nature of individual differences in orientation.

3169

Mitkin, H.A. THE EFFECT OF TRAINING AND OF STRUCTURAL AIDS ON PERFORMANCE IN THREE TESTS OF SPACE ORIENTATION. Rep. 80, Oct. 1948, 25pp. Division of Research, CAA, Washington, D.C. (Brooklyn College, Brooklyn, N.Y.).

3169

To determine the effect of training and of structural aids on performance in three tests of space orientation (Stability of Orientation Test, Dark-Room Test, and Rotating-Room Test), each test was administered twice to 196 subjects. Four groups of 49 subjects each were tested under the following conditions: 1) training given between first and second administrations, 2) structural aids varied between the two administrations, 3) additional testing given between administrations, and 4) test and retest with no interpolated activity. The test data were analyzed by methods of covariance to determine the effect of the differential treatment.

Lightfoot, D., Carhart, R., & Jerger, J.F. EFFICIENCY OF IMPAIRED EARS IN NOISE: C. PERCEPTION OF SPEECH AT SUPRA-THRESHOLD LEVELS. Proj. 21-1203-0001, Rep. 6, Dec., 1953, 10 pp. USAF School of Aviation Medicine, Randolph Field, Texas.

3170

Standard speech discrimination tests were administered to normal and hard-of-hearing subjects at three suprathreshold levels, in quiet and in two levels of thermal noise. The general conclusion was that noise was not observed to exert a systematically detrimental effect on discrimination of monosyllabic words by hard-of-hearing subjects. There was, however, substantial variation among individuals.

Lerner, D. COMMUNICATION SYSTEM MODELS. Report from: "Paper given at AAAS Meeting, Boston, December 1953." 5pp. Sociology Dept., Massachusetts Institute of Technology, Cambridge, Mass.

This paper is concerned with the segment of communication whereby public information is disseminated among the members of a political community. Regularities of behavior interrelating the 4 variables: channel, audience, source, message, are what is meant by a communication system. 2 main systems are distinguished: media and oral. The degree to which a society utilizes one or the other is descriptive of its social system. Interrelations among economic, political, and cultural variables are then hypothesized and described. Data from UNESCO sources were used and several correlation coefficients computed. (HEIAS)

Black, J.W. AN APPLICATION OF SIDE-TONE IN SUBJECTIVE TESTS OF MICROPHONES AND HEADSETS. Joint Rep. NM 001 064, Rep. 20, Feb., 1954, 5 pp. U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Florida. (The Ohio State Univ., Acoustic Lab.)

3174

Twenty-four experimental subjects attempted to repeat a phrase and to establish by control of the vocal level a level of side-tone that matched the level of the stimulus phrase that was heard. The experimental procedure followed the Method of Average Error. Alternative headset-microphone combinations represented broad-band and narrow-band transmission. The subjects tended to speak at a higher level than they should have to match the stimulus. The error was greater in noise than in quiet and greater in broad-band equipment than with narrow-band.

3175

Black, J.W., & Tollhurst, G.C. THE RELATIVE INTELLIGIBILITY OF LANGUAGE GROUPS. Joint Rep. NM 001 064.01, Rep. 21, May, 1954, 4 pp. U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Florida. (The Ohio State Univ.)

3175

French, British, and American listeners heard recorded intelligibility tests spoken by French, British and American speakers. The American speakers were the most intelligible to the American listeners. The French speakers were the least intelligible to all groups. The intelligibility of the French and British speakers was improved for American listeners when the listeners were indoctrinated for one hour in the dialects of the speakers.

Hartman, E.B. THE INFLUENCE OF PRACTICE AND PITCH-DISTANCE BETWEEN TONES ON THE ABSOLUTE IDENTIFICATION OF PITCH. Proj. NM-003 041-22.05, Rep. 206, June 1952, 14pp. USN Medical Research Lab., New London Submarine Base, Conn. (Reprinted from: Amer. J. Psychol., March 1954, 67(1), 1-14).

3176

To investigate the influence of practice and pitch-distance between tones on the absolute identification of pitch, 12 observers were asked to identify nine pure tones 48 times a week for eight weeks. The tones were separated by equal appearing pitch-intervals (either 50, 100, 200, or 300 mels). Correction of the judgment was made during the first seven weeks but not during the last. Results are presented and discussed in terms of learning as a function of pitch-intervals and the amount of retention of pitch identification following a duration of two months.

 Morris, Ailene, & Dimmick, F.L. VISUAL ACUITY AT SCOTOPIC LEVELS OF ILLUMINATION. MRL Rep. No. 162, 1950, 9, 157-183. Bullied Proj. NR 003 041.04.03, U.S. Naval Submarine Base, Medical Research Laboratory, New London, Conn.

3177
 To investigate visual acuity at scotopic levels of illumination, acuity thresholds on checkerboard type target were obtained for six observers at eight levels of illumination between 3.7 and 6.7 log micro micro lamberts. The 50% lines were plotted in units of reciprocal visual angle against log brightness. Comparison is made with classic studies of the function covering higher ranges of illumination. Measurements of pupil change with illumination were made with an infra-red pupillometer.

 Mitchell, R.T., Morris, Ailene, Dimmick, F.L. THE RELATION OF DARK ADAPTATION TO DURATION OF PRIOR RED ADAPTATION. MRL Rep. 166, 1950, 9, 258-277. Bullied Proj. NR 003 041.49.01, U.S. Naval Submarine Base, Medical Research Laboratory, New London, Conn.

3178
 To investigate the effect of duration of preadaptation upon the immediate threshold and upon the course of dark adaptation, measurements were made following seven adaptation periods (zero to 40 minutes) wearing red goggles under a preadapting brightness of 150 millilamberts. Threshold data are plotted as a function of time in the dark following different durations of red adaptation. Sensitivity levels after five seconds in the dark after the varying periods of red adaptation and comparable periods of dark adaptation, are obtained. Operational interpretation of the data is made.

 Woodward, A.A. Jr., Cornish, E.R. Jr., Blevins, W.V., Cain, S.M., et al. PHYSIOLOGICAL EVALUATION OF A DIFFUSION BOARD PROTECTIVE SHELTER (U). Proj. 4 08 02 019 01, Rep. 2177, Sept. 1957, 48pp. USA Chemical Warfare Labs., Army Chemical Center, Md.

3179
 To ascertain whether human occupants of a diffusion board protective shelter are subjected to intolerable physiological stresses during occupancy up to two days, a prototype shelter was constructed and evaluated. A total of 18 subjects served in nine different tests. Physiological measurements were body temperatures, heart rates, respiratory activity, metabolic rates (calculated), and observations by an inside observer of various activities and signs of developing strain. Environmental data collected were air temperatures, relative humidity, barometric pressure, and gas composition of shelter air and outside air. These data were analyzed in terms of tolerable conditions of carbon dioxide concentration and temperatures.

 Ziegenruecker, G.H. & Magid, E.B. SHORT TIME HUMAN TOLERANCE TO SINUSOIDAL VIBRATIONS. Proj. 7231, Task 71786, WADC TR 59 391, July 1959, 13pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3180
 Short time human tolerance criteria for sinusoidal vibration from one to 15 cps were determined using ten healthy male subjects ranging in age from 23 to 34 years. At each frequency, the amplitude was increased at a constant rate from zero to the point where the subject stopped the run because he thought that further increase might cause actual body harm. Lower and upper tolerance limits were established. Subjective tolerance limits were found to be caused by one or more of seven specific sensations or symptoms. Physiological observations during vibration exposure were also made.

 Hanes, R.H. THE CONSTRUCTION OF SUBJECTIVE BRIGHTNESS SCALES FROM FRACTIONATION DATA: A VALIDATION. J. exp. Psychol., Oct. 1949, 41(5), 719-728. (Johns Hopkins University, Baltimore, Md.). (Rep. 166, 11-97).

An attempt has been made to validate the fractionation technique for the construction of sensory scales by statistical comparison of the results obtained from estimates of 1/2 and 1/3 as bright and 2 and 3 times as bright. The results for 20 Os. each of whom made each type of estimate, were subjected to an analysis of variance. Since the differences between the 1/2 and 1/3 estimates and between the double and triple estimates were found to be significant, the construction of scales based on these different ratios was possible. In addition, the order in which the different types of estimates were made, the brightness level, individual differences and the various interactions of these factors were found to be significant. The individual subjective scale values, obtained for each type of estimate by each O, were also treated by the analysis of variance. The variance due to individuals was again significant, but the variance for type of estimate was not significant.

 Hanes, R.H. SUPRATHRESHOLD AREA BRIGHTNESS RELATIONSHIPS. J. opt. Soc. Amer., Jan., 1951, 41, 28-31. Contract NS-ori-166, T.O. I, Proj. Design. NR-784-001, Rep. 166-I-110, ONR, Special Devices Center, Port Washington, L.I., N.Y. (Johns Hopkins Univ., Inst. for Cooperative Research.)

3182
 To investigate size-brightness relationships for supra-threshold levels of brightness, eight observers made equal brightness matches of two test areas separated by 4-1/2 inches as seen against a dark background. Four test intensity levels (0.1, 1.0, 10.0, 100.0 millilamberts) and five different stimulus sizes (9, 18, 36, 144 minutes of visual angle) were investigated. Luminances of the variables required to match the standard luminance at each size were studied by analysis of variance method for each intensity level. Discussion relates the findings to visual theory and practical usage.

Leyzorek, M. TWO-POINT DISCRIMINATION IN VISUAL SPACE AS A FUNCTION OF THE TEMPORAL INTERVAL BETWEEN THE STIMULI. J. exp. Psychol., May 1951, 41(5), 364-375. ONR, Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Baltimore, Md.). (Rep. 166 1 125).

4 Ss were asked to judge the position of the second of a pair of light flashes with respect to the first when the distance and the temporal interval between these stimulus points were varied systematically. The temporal intervals were .25, .57, 1.32, 3.03, 6.96, and 16.0 sec. 4 conditions of observation were used: a) Foveal observation of stimulus points presented on a brightly lighted screen with no control of the Ss' fixations. b) Peripheral observation of stimuli presented on a lighted screen with the Ss' eye movements controlled by a fixation point 5 deg. to the right of the stimulus area. c) Foveal observation of stimulus points presented in complete darkness, fixation not controlled. d) Peripheral observation in complete darkness, fixation controlled as in b). The range of thresholds obtained, from the shortest time interval, .25 sec., to the longest, 16.0 sec., was as follows: a) Condition a) gave the lowest thresholds, 2.2 to 11.6 min. of arc. b) Conditions b) and d) gave approximately the same thresholds, from 7.4 to 14.2 min. of arc. c) Condition c) gave the highest thresholds, from 7.5 min. to 3 deg. 4 min. of arc. d) The variability of the Ss' judgments was inversely proportional to their precision.

Carmichael, L. PERCEPTUAL ASSIMILATION IN A STEREOSCOPIC ILLUSION. Amer. J. Psychol., Jan. 1950, 63(1), 112-113. (Tufts University, Medford, Mass.).

3186

This note describes a stereoscopic illusion observed when observing a scene in nature with one eye and with the other eye a transparency of the same scene. The transparency had two objects (boats) not in the natural scene at the moment of observation. A perceptual assimilation of the boats into the natural scene was noted. The significance of this phenomenon for an understanding of distance perception is suggested.

3187

Gebhard, J.W. & Halsey, R.M. DISCRIMINATION OF SMALL TIME INTERVALS BETWEEN A VISUAL AND AN AUDITORY SIGNAL. Contract NSORI 166, Proj. NR 784 001, SDC Proj. 20 F 1, SDC TR 166 1 60, Jan. 1949, 14pp. USN Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Baltimore, Md.).

In these experiments 1 or 2 dots were employed and the audio signal was given at positions preceding, following, or on the dots. S's task was always to judge when the click occurred with respect to the visual patterns. The conditions tested included effect of 2 dots vs. 1 (click given randomly with either dot), effect of radial position of dots, effect of position on circumference of the display, and effect of angular separation. Ss varied markedly in the fineness of their ability to detect the coincidence of auditory and visual signals and did not show evidence of learning after the first few trials. Their thresholds were very stable and could be readily reproduced. 90% correct judgments of coincidence can be obtained from practiced Ss when the time separations are as little as 15 to 45 msec. The applications to performance on audio-visual displays are indicated. (HEIAS)

Head, H. MANEUVERABLE TARGET POSITIONING UNIT. SDC Rep. 166 1 73, March 1949, 19pp. ONR, Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Engineering Lab., Baltimore, Md.).

One phase of psychological research into the effectiveness of various radar display equipment calls for laboratory simulation at the radar indicator of conditions which exist when a friendly aircraft is maneuvered in accordance with instructions from radar observers. A Maneuverable Target Positioning Unit was developed to fulfill this requirement. The machine drives one point (maneuverable aircraft) with respect to another (radar observer), and provides controls for speed and course as selected by the operator. These motions are used to position the shafts of range and bearing potentiometers. The potentiometers control the output of a separate target generating system which, in turn, produces the maneuverable target on the radar indicator under consideration. One unit is complete and 2 additional units are under construction. Preliminary tests show satisfactory performance and indicate that the machine may be expected to function as intended in the projected research program.

Flottorp, G. PURE-TONE TINNITUS EVOKED BY ACOUSTIC STIMULATION: THE IDIOPHONIC EFFECT. Acta Oto-laryngol., Aug.-Oct. 1953, 43, 396-415. ONR. (Harvard University, Cambridge, Mass.). (Rep. PNR-130).

When an ear is stimulated with a pure tone of a certain frequency and intensity, some persons may perceive an extra tone called an idiotone in addition to the stimulus tone. The perception may be in the form of beats, roughness, or distinct double tones, and it may be followed by a more-or-less rapidly decaying after-tone after the stimulus tone has been turned off. The pitch of this evoked tinnitus is nearly unaltered by the various frequencies that are used as eliciting stimuli. The frequency corresponding to the idiotone is characterized by an inability to elicit an idiotone for any intensity, and this frequency is extremely stable. No change was found during 3 years of experimentation. The influence of various aspects of the stimulus tone upon the evocation and the character of the idiotone are described. A correlation is found between an idiophonic effect and a localized threshold change but no increase in resolving power seems to accompany the idiotone. The source of the idiophonic effect is discussed. It is concluded that the idiophonic effect cannot be used to support a theory of high-tuned circuits (high Q electromechanical elements) in the cochlea, but rather that it points to some kind of time-consuming process, such as biochemical action in sensory elements and nerve cells.

Shaw, M.E., & Rothschild, G.H. SOME EFFECTS OF PROLONGED EXPERIENCE IN COMMUNICATION NETS. *J. Appl. Psychol.*, 1956, 40 (5), 281-286. Contract W5-ori-166, Rep. 166-I-202, Proj. Designation NR 145-089, Task Order 1, ONR, Johns Hopkins University.

3191
To study the effects of different communication nets upon group behavior when the groups operated in the same net over a period of days, eight groups (four subjects) were assigned to each of three nets (star, slash, and common) and were required to solve two simple arithmetic problems each day for a ten-day period. Questionnaires were answered at end of period asking for job satisfaction ratings (over-all and day-to-day), group leader, and system of communication, if any. Time scores for solving the problems, number of message units, errors, ratings of satisfaction, emergence and leadership were analyzed for differences due to type of communication net and for changes attributable to experience. The extent of agreement with previous similar experiments is discussed. T. G. I. R 14

Beidler, L.M. A THEORY OF TASTE STIMULATION. *J. Gen. Physiol.*, Nov. 1954, 28 (2), 133-139. (Office of Naval Research, Washington, D.C. & Physiology Dept., Florida State University, Tallahassee, Fla.)

The treatment in this paper of available quantitative data on the response of taste receptors to sodium salt stimulation clearly indicates that the ions of the chemical stimulus are loosely bound to some substance of the taste receptor. This can be thought of as an initial reaction which ultimately leads to stimulation of the receptor and an eventual depolarization of the associated sensory neuron. The speed of the total reaction suggests that the receptor substance is located on or near the surface of the receptor. The recently proposed enzymatic reactions for chemoreceptors do not appear plausible for sodium salt stimulation of the taste receptors of the rat. R 7

Research has been conducted to determine if objective and reliable measures can be developed to evaluate shipboard performance of Navy enlisted men. Adequate measures of performance are necessary to determine proper qualifications for advancement and to determine the effectiveness of selection and training programs. A series of Practical Performance Tests, designed to measure the practical factors of shipboard performance, has been developed. These tests have been administered to Electrician's Mates and Engineers serving aboard submarines. They have been shown to be valuable additions to existing performance measures. Information about the usefulness and importance of performance tests is presented in this report. The reliabilities and interrelationships of the tests are discussed, and observations are made on the construction of performance tests. Results of correlational studies with other measures of shipboard performance are also given. R 100 (approx.)

Broadbent, D.E. EFFECTS OF NOISES OF HIGH AND LOW PITCH ON BEHAVIOUR. A.P.U. 222/54, Sept. 1954, 11pp. Applied Psychology Research Unit, Medical Research Council, Cambridge, England.

Three groups of subjects worked for two sessions in noise at a five-choice serial reaction task. On one day the noise was restricted to frequencies above 2000 cps, and on another to frequencies below that frequency. The high-pitched noise gave more errors in performance, the difference being most important at the highest intensity of 100 db. When reaction times were measured to the same noises, the first reaction of a series with the same type of stimulus was slower when the stimulus was low intensity and low pitched. With high pitched or high intensity stimuli this was not so. It thus appears that sounds more likely to interfere with work also produce a faster reaction when themselves acting as signals, confirming a view already advanced about noise effects; that the effect is due to competition between various stimuli to control response.

Westheimer, G. MECHANISM OF SACCADIC EYE MOVEMENTS. A.M.A. Arch. Ophthalmol., 1954, 52, 710-724. (Ohio State University).

3208

To study the nervous and muscular mechanisms subserving saccadic eye movements, a photographic method was developed for recording horizontal eye movements with a high degree of precision for both time and extent. The subject was instructed to fixate a neon light bulb and to change fixation to another target light when it became visible. Responses were obtained for symmetrical positioning of the two targets on either side of a median plane and for angular separations at nodal point of eye of two to thirty degrees. The recordings were studied for typical characteristics of movement pattern--position, velocity, and acceleration. The findings are related to physiological evidence from other sources and a mathematical treatment of the system is described. G. I. R 26

Judson, A.J. & Cofer, C.N. THE EFFECT OF A REINFORCED RESPONSE IN A SIMPLE VERBAL PROBLEM. Contract N7ONR 397, Tech. Rep. 8, ca. 1950, 5pp. University of Maryland, College Park, Md.

3213

This paper reports two experimental studies of associative strength. In one experiment, 20 Ss made 10 associations to each of 10 stimulus words, and recognition of the words they selected was tested six weeks later, with the associated words each appearing with three unrelated words. The second experiment duplicated this pattern to some extent, but with nonsense syllables. Correct responses (recognition of words with associative strength) are analyzed and interpreted regarding the effect of reinforcement on response potential.

Judson, A.J. & Cofer, C.N. A FURTHER ANALYSIS OF DIRECTION IN A SIMPLE VERBAL PROBLEM. Contract N7ONR 397, Tech. Rep. 7, ca. 1950, 18pp. University of Maryland, College Park, Md.

3214

To study the effects of serial order, unambiguous stimuli, and response potential in forming verbal associations, 321 college students took a 48-item test. Each item consisted of two unambiguous and two ambiguous words, such that either unambiguous word might equally logically be selected as not associated with the other three words; Ss selected what they considered the unrelated word. Serial order of items and of words in items varied among 12 forms of the test. Twelve items had one alternative that could be selected on a religious criterion. Ss' choices are analyzed as functions of word order, unambiguous stimuli, and Ss' religion.

Judson, A.J. & Cofer, C.N. THE ROLE OF INCREASED ASSOCIATIVE STRENGTH IN REASONING. Contract N7CNR 397, Tech. Rep. 5, ca. 1947, 12pp. University of Maryland, College Park, Md.

3216

To investigate the transfer of verbal associations to the solution of a novel problem, 397 college students were tested. Initially, three groups learned word associations, including "rope-swinging" associations with one group, "twine-rope" and "word-rope" with the other two. A fourth (control) group learned no associations. All four groups were then tested with a problem that could be solved by swinging a string. Number of "swinging" solutions to the problem are compared for the four groups to evaluate the effect of the learned associations. Results are interpreted in light of Hull's theories of association reinforcement and response generalization.

Cofer, C.N. VERBAL BEHAVIOR IN RELATION TO REASONING PERCEPTION AND LEARNING. I. INTRODUCTORY STATEMENT. Contract N7CNR 397, Tech. Rep. 4, ca. 1950, 3pp. University of Maryland, College Park, Md.

3217

This is an introductory statement establishing the theoretical viewpoint for a series of experiments reported elsewhere. Consideration is given to the possibility that certain stimuli which function within the organism to mediate behavior are verbal and/or symbolic in character. Two situations are described to illustrate this viewpoint.

Farnsworth, D. TRITANOMALOUS VISION AS A THRESHOLD FUNCTION. Proj. NM 002 014 09 06, XV(3), Rep. 274, July 1956, 12pp. USN Medical Research Lab., Naval Submarine Base, Conn. (Reprinted from Die Farbe, 1955, (4), 185-196).

3218

This is a critical survey of tritanomalous and tritanopic color vision. Tritanomalous color vision can be interpreted in terms of the ratio of the blue to the green plus red physiological tristimulus values. There are conditions for which this ratio appears to be constant for any fixed product of retinal area and illumination. The degree of tritanomalous vision is related to the absolute value of this product and to other constants of vision. In particular, tritanomalous vision is not exclusively a foveal or small field phenomenon. Inherited and threshold tritanopia display the same symptoms; tritanopia and tritanomalous vision are different degrees of the same type of color deficiency.

Rogers, O.E. ANALYSES OF BASIC TRAINING STAGE GRADES FOR MULTI-ENGINE AND SINGLE-ENGINE AVIATORS. Proj. NM 001 109 102, Rep. 3, Aug. 1956, 14pp. USN School of Aviation Medicine, Naval Air Station, Fla.

3219

This report presents three analyses of basic training stage grades for a randomly selected sample of 199 officers who had completed advanced training for multi-engine and single-engine aviators. Factor analyses were made to determine whether the same or different factors account for variance in the two types of aviators. Other analyses were made to determine differences in grades between the two and differences in standard partial regression coefficients (beta weights) for predicting performance during advanced training.

Dupertuis, G.W., Pitts, G.C., Osserman, E.F., Walham, V.C., et al. THE RELATION OF SPECIFIC GRAVITY TO BODY BUILD IN A GROUP OF HEALTHY MEN. Proj. NM 004 066 03 06, June 1950, 6pp. USN Medical Research Institute, Bethesda, Md. (Western Reserve University School of Medicine, Cleveland, Ohio).

Specific gravity determinations by underwater weighing, calculation of per cent body fat, and descriptions of physique by Sheldon's somatotyping technique were carried out on a group of 81 healthy male subjects selected to include representatives of the extremes of body build. The average age of this group was 26.6 years and the average weight, 165 pounds. The data reveal that people of different body types vary enormously in specific gravity. Soft, round, fat individuals have a low body density, whereas lean people, whether heavily muscled or delicately built, are uniformly of higher body density. An equation is presented which makes it possible to predict body specific gravity with an average deviation of 0.007 from the figures obtained by immersion. From these predictive values the average error for estimation of body fat is only $\pm 3.5\%$.

Gelfan, S. EXPLOSIVE DECOMPRESSION AT HIGH ALTITUDE. Amer. J. Physiol., July 1950, 162(1), 37-53. (School of Medicine, Yale University, New Haven, Conn.).

Rats were explosively decompressed to simulated altitudes of 35,000 to 75,000 ft. in air and in 100% oxygen. The survival time at altitude becomes progressively shorter with higher final decompression altitudes until about 52,000 ft. is reached, after which it becomes constant and independent of altitude, whether in air or in oxygen. Below this critical altitude the difference between the survival times in oxygen and air widens sharply. In terms of duration of respiration following decompression, this minimal time which becomes constant above 52,000 ft. is on the average about 18 sec. when decompressed from 20,000 ft. in air, 30 sec. when decompressed from sea level in air and 40 sec. in 100% oxygen (including 20 min. preoxygenation). Rapid decompression per se, even up to 75,000 ft. is not fatal for rats. Unless recompressed quickly enough, however, they die at altitude from anoxic anoxia. The rate or chances of survival of rats, when recompressed at free-fall rate following decompression to altitudes of as high as 75,000 ft. is given for both oxygen and air. The considerably better chances of survival from the higher altitudes in oxygen are due to the preoxygenation and the fact that the increase in pressure during recompression becomes quickly significant below 52,000 ft. in oxygen. Some of the pathological changes resulting from the decompression and concomitant anoxia are briefly described.

Peters, H.W. LISTENER RESPONSES TO VOICE MESSAGES AS A FUNCTION OF SIGNAL-TO-NOISE RATIO AND EXPERIENCE WITH SIMILAR MESSAGES. Contract N60NR-22525, ONR Proj. Designation NR 145-923, BuMed & Surgery Proj. NM 001 104 500, Joint Proj. Rep. 64, July 1956, 9pp. U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Fla.

3227

To evaluate the combined effect of amount of exposure to training messages and noise level for test message reception upon listeners' test responses, highly similar training and test messages were constructed. Listeners (twelve groups of 18 subjects each) responded to test messages heard at one of four signal-to-noise ratios (+10, +5, 0, and -5 decibels) after exposure to 0, 4, or 12 periods of training messages. Number of correct responses and number of incorrect responses corresponding to training lists were analyzed for differences attributable to familiarity with training messages and for noise levels of reception. Morris, A., Katz, M.S., & Bowen, Jane D. REFINEMENT OF CHECKERBOARD TARGETS FOR MEASUREMENT OF VISUAL ACUITY LINES. J. Opt. Soc. Amer., 1955, 45 (10), 834-838. (U.S.N. Medical Research Laboratory, Naval Submarine Base, New London, Conn.).

3228

To evaluate the checkerboard target for its applicability to visual acuity experimentation, the standard target was modified to eliminate all cues other than resolution, produced in varying sizes and mounted on both black and white. The targets were validated by psychophysical measurements of the acuity thresholds and chi-square techniques of analysis. Two methods for varying the visual angle were compared: varying target size and varying target distance. The range of stimuli required to establish an acuity limit was determined. T. G. I. R 9

Moeller, G., Fooks, G., Sperling, H.G., Farnsworth, D., et al. DARK ADAPTATION AND THE NEAR ULTRAVIOLET. Contract Nonr 1276(00), Proj. NM 002 014.09.05, MRL Rep. 268, Oct. 1955, 12pp. USN Medical Research Lab., New London Submarine Base, Conn.

2 studies of the effects of exposure to the near ultraviolet (principally 334, 365, and 396 mμ) upon subsequent dark adaptation are reported. For the first study, a Hecht-Shlaer adaptometer was modified so that radiation from a mercury lamp or incandescent lamp (control) could be added to the light adaptation field of the adaptometer. 4 conditions of light adaptation were employed. 3 Ss produced 20 dark adaptation curves each, 5 under each condition. No differences were found between the ultraviolet and the control conditions. Exposure to the higher brightness raised the threshold at 25-30 minutes by 0.12 log units. In the second experiment the ultraviolet and control light adaptation fields differed from each other in both color and spectral composition, and were much brighter than in the first experiment. Again there was no reliable evidence that exposure to the near ultraviolet affects subsequent dark adaptation deleteriously. The source of discrepancy between these negative findings and the positive results reported by others has not been identified. (HEIAS) R 15

Miller, J.W., & Ludvig, E. THE RESULTS OF TESTING THE DYNAMIC VISUAL ACUITY OF 1000 NAVAL AVIATION CADETS. Contract Nonr-586(00), ONR Proj. NR-142-023, BuMed and Surgery Proj. NM 001 110 501, Rep. 10, Aug. 1956, 15pp. U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Fla.

3231

To examine the dynamic visual acuity of a large population, threshold measurements were made on 1000 young men (naval aviation cadets) having a static visual acuity of 20/20 or better uncorrected. A rotating mirror apparatus presented a test object traveling at horizontal angular velocities of 20 and 110 degrees per second. Frequency distributions of obtained thresholds and the parameters characteristic of the dynamic acuity of the individual were presented and tested for normality. The possibility of classifying the subjects into distinguishable groups on the basis of threshold values was explored. Applications to pilot selection are discussed. T. G. R 13

Schafer, T.H. INFLUENCE OF THE PRECEDING ITEM IN MEASUREMENTS OF THE NOISE-MASKED THRESHOLD BY A MODIFIED CONSTANT METHOD. J. exp. Psychol., June 1950, 40(3), 365-371. (USN Electronics Lab., San Diego, Calif.).

The entire psychometric function for 3-sec. tonal signals presented at 5-sec. intervals in a background of thermal noise varies with the intensity of the preceding signal. Within 1 db of threshold the number of equally intense signals detected varies by approximately 25% as a function of the preceding signal. A relatively intense preceding signal reduces the percentage detected, a moderately intense preceding signal increases it, and a preceding signal at the same intensity slightly reduces it. Following a suggestion of Fernberger's for mitigating the influence of the preceding item, a sequence of a chosen set of signal intensities is given in which each precedes all of the others and itself very nearly the same number of times. Steele, R.J. A STATISTICAL ANALYSIS OF ELECTRONIC
EQUIPMENT FAILURES IN EDUCATION. SE 06472 (SE 21 1),
Ecol. Rep. 261, Feb. 1955, 18pp. USN Electronics Lab.,
San Diego, Calif.

3239

Forty-two published reports of the Evaluation Branch,
U.S. Navy Electronics Laboratory, were examined and the
failures reported therein were analyzed statistically.
The equipments covered a wide range of functions and in-
cluded radar sets, radio receivers and transmitters,
sonars, and other electronic equipments. The relative
frequency of 28 common categories of failure was plotted
as a bar graph. Descriptive statements of the type of
failure for each category were given. Recommendations
are made for the benefit of Bureau of Ships contractors.

Lincoln, M.M. NOISE LEVEL LIMITS FOR THE AVOIDANCE
OF DEAFNESS IN SHIPBOARD MACHINERY SPACES. Code 371,
Rep. 371 X 27, Nov. 1955, 31pp. USN Bureau of Ships,
Washington, D.C.

3241

In this report a set of octave band noise level
limits for machinery spaces of naval vessels is pro-
posed. The noise limits were arrived at by examining
a previously proposed spectrum in the light of the
American Standards Association report "Relations of
hearing loss to noise exposure". The noise in machi-
nery spaces is limited so that the unprotected ear of
the watch stander, assigned to machinery spaces over
his entire naval career, does not suffer hearing loss
over that normally expected due to aging. Noise
levels actually encountered in naval machinery spaces
are presented with results of application of noise
control measures.

Miller, J.W. THE MEASUREMENT OF DYNAMIC VISUAL
ACTIVITY WHILE THE OBSERVER IS ROTATING.
Contract Nour-606(OC), ONR Proj. NR-162-023,
Bull. 9 Surgery Proj. NR 001 110 501, Rep.
11, Oct. 1946, 12pp. U.S. Naval School of
Aviation Medicine, Naval Air Station, Pensacola,
Fla.

3247

To determine the effect on visual acuity of rotating
the observer with the target in a fixed position, three-
fold determinations were made with the subject (a) re-
rotating at five different angular velocities from 20 to
120 degrees per second. The data were compared with data
taken previously when the observer was stationary and
the target motion was produced by a rotating mirror and
with static acuity measurements. The results of a num-
ber of experiments reported in the literature, in which
ocular pursuit was examined, were related to the findings.

Chitt, R.L. & Oberst, F.W. EFFECTIVENESS OF VARIOUS DRUGS IN PREVENTION OF AIRSICKNESS. I.
EFFECTS OF CHEMICAL COMPONENTS OF DRAMAMINE. Proj. 21 32 014, Rep. 1, Aug. 1950, 50p. USAF
School of Aviation Medicine, Randolph Field, Tex.

The relative effectiveness of Dramamine and Benadryl in the prevention of airsickness
was determined. No significant difference was found between Benadryl (50 mg.) and Dramamine
(100 mg.) in protecting subjects from airsickness during simulated turbulence in an airplane.
8-chlorotheophylline gave no significant protection. A combination of hyoscine-hydrobromide
(0.65 mg.) and Benadryl (50mg.) was found to be more effective than either drug alone. A
combination of 1/2 if doses of hyoscine-hydrobromide (0.33 mg.) and Benadryl (25 mg.) gave an
effectiveness 1/2 to that of a full dose of hyoscine (0.65 mg.) but inferior to the full
dose mixture.

Miller, J.W. THE EFFECT OF ALTERED ILLUMINATION ON VISUAL ACUITY MEASURED DURING OCULAR PURSUIT. Contract Nour-50C(00), ONR Proj. NR-142-023, BuMed & Surgery Proj. NR 001 110 501, Rep. 12, Sept. 1956; 15pp. U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Fla.

3252
To investigate the effect of intensity of target illumination on dynamic visual acuity, threshold determinations were made by six subjects while being rotated at angular velocities from 25 to 120 degrees per second. Six levels of target (Landolt ring) were used (0.04, 0.20, 1.0, 5.0, 25.0, 125.0 footmilles) at each velocity. Static acuity was then determined with the subject stationary and 0.7 second target exposure. The data (threshold of arc) were analyzed as a function of intensity of illumination. An interpretation of the results is presented.

Foster, R. & Hardy, J.O. THE REACTION TO PAIN AS DETERMINED BY THE GALVANIC SKIN RESPONSE. CHAPTER V. Reprinted from Life Stress and Bodily Disease, 1950, XVII, Proceedings Association for Research in Nervous & Mental Disease, 1949, 16pp. Russell Sage Institute of Pathology, Cornell University Medical College, New York, N.Y.

3253
A study of the GSR as a reaction to graded, standard intensities of pain were carried out on four normal Ss. The pains were induced by intense thermal radiation and were graded from threshold to eight dols in steps of two dols. Three series of experiments were performed. 1) The Ss, in a relaxed state, were exposed daily over a six-month period to pains presented in a fixed order from zero, threshold, two, four, six, and eight dols; the GSR to each pain was recorded. 2) The Ss were similarly studied in hot and cold environments. 3) Studies were made before, during, and after events calculated to induce anxiety. Differences between pain sensations and pain reactions were discussed.

3255
Chinn, H.L., Oberst, F.W. & Wilks, S.S. EFFECTIVENESS OF VARIOUS DRUGS IN PREVENTION OF AIR-SICKNESS. III. STUDY OF ADDITIONAL ANTIHISTAMINICS IN AIRPLANE AND SWING. Proj. 21 32 014, Rep. 3, Aug. 1950, 7pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The study examined the effectiveness of antihistamines in protection against motion sickness. The antihistaminics Decapryn and Chlor-Trimecon exert only a slight protection against airsickness induced by artificial turbulence. Artone, an antispasmodic, protects against airsickness but to a lesser degree than hyoscine. Chlor-Trimecon and Thephorin do not protect against swing sickness. It is concluded that antihistaminic potency is not related to motion sickness prophylaxis.

Rand, G.W. & Ray, J.T. EVALUATION OF THE NEW LONDON NAVY LANTERN COLOR VISION TEST. Contract NTRC 434, T.O. 1, Joint Memo, Rep. 1, May 1950, 17pp. Office of Naval Research, Washington, D.C. Tulane University, New Orleans, La.

The evaluation of the New London Navy Lantern test was conducted in terms of the American Optical Company's Pseudo-Isochromatic Plates, 1940 edition, as the independent criterion. 372 consecutive patients (civilian, officers, and enlisted personnel) of the Department of Ophthalmology, School of Aviation Medicine, Pensacola, Florida, served as the experimental population. Of the 372 subjects, 41 (11.02%) were judged as color-deficient by the A.O. plates, and 148 (39.78%) were judged as color-deficient by the N.L. test. For each subject the A.O. plates were administered in an illuminated room, of the 372 subjects, N.L. tests and retests were administered to 303 in an illuminated room, the remaining 69 subjects were tested in a dark room. On the basis of the analysis of results for each of the foregoing conditions it was concluded that a) to enjoy the maximum test-retest reliability, the N.L. test must be employed under the conditions for which it was designed; b) under these conditions the N.L. test's selectivity is poor when judged by strict statistical standards; c) the most favorable passing criterion for the N.L. test appears to be one of 3 errors (inclusive) and d) with the alteration of the passing criterion it becomes apparent that the circumstances will allow for a substantial improvement of the N.L. test. On the basis of the improvement possible, it may be concluded that the additional experimentation necessary to achieve this gain would be justified. Several possibilities for improvement of the N.L. test are also considered.

3257
Peters, R.N. THE EFFECT OF LOW-PASS FILTERING OF SIDE-TONE UPON SPEAKER INTELLIGIBILITY. 060 Res. Foundation Contract W6NR 22525, Proj. NR 145 993 & USN School of Aviation Medicine, BuMedSurg. Proj. NR 001 104 500.47, Joint Proj. Rep. 49, April 1956, 8pp. USN School of Aviation Medicine, Naval Air Station, Fla.

3257
To study speaker intelligibility as a function of low-pass filtering of side-tone, 24 speakers read intelligibility testing materials under four side-tone conditions, two filtering and two nonfiltering conditions. Frequencies above 600 cycles per second in side-tone signal were attenuated for filtered conditions with compensation made for level due to filtering versus nonfiltering. Criterion measures of speakers' intelligibility were obtained from panels of listeners (12 per panel). The data were analyzed by variance techniques for differences among the four conditions.

STUDY OF A NEW SYSTEM FOR AIR TRAFFIC CONTROL
EMULATING THE CURRENT COORDINATED DISPLAY.
Contract DA 36-039-sc-64567, June 1955, 82pp.
Bell Telephone Labs., Whippany, N.J.

3262
To compare dynamic visual acuity tested with a rotary
prism and with a rotating mirror apparatus, threshold
measurements were obtained from 150 naval cadets. Two
groups (50 each) were tested with both devices (angular
velocities of 20 and 110 degrees per second for mirror;
50 and 77 for prism of 15 prism diopters). Rotating ob-
jects (three groups) were tested only with prism (4, 8,
and 16 prism diopters) for angular velocities found to
produce a similar range of visual acuity loss (25/20 to
20/200). Frequency distributions of threshold data, com-
parisons of results from the two tests, and analyses of
effects upon visual acuity of circular movement were made.
Suggestions are given concerning use of rotary prism as a
test of dynamic visual acuity.
G. T. I. R 7

3257
This report presents a broad plan for a new system of
air traffic control based on the use of radar as a pri-
mary source of traffic control information. This infor-
mation can be integrated with other supplemental flight
control data so as to present a fully coordinated pic-
ture of the air traffic control situation in a control-
ler's area. The display is presented by means of a
cursor-coordinated three-dimensional display. The require-
ments of the new system are given in detail, preliminary
circuit design considerations are presented, and the need
for simulation of the system in order to demonstrate fur-
ther its operational feasibility is discussed.

McCroskey, R.L., Jr. SOME EFFECTS OF ANESTHE-
TIZING THE ARTICULATORS UNDER CONDITIONS OF
NORMAL AND DELAYED SIDE-TONE. Contract N60NR
22525, ONR Proj. Designation NR 145-935, Bullard
& Surgery Proj. NM 001 104 500, Joint Proj.
Rep. 65, July 1956, 12pp. U.S. Naval School
of Aviation Medicine, Naval Air Station, Pen-
sacola, Fla.

3265
To determine the relative effects of tactile cues
from the articulators and auditory side-tone upon speech,
six speakers recorded three forms of multiple-choice
intelligibility tests under four conditions: (1) normal
side-tone, (2) delayed (0.13 second) airborne side-tone,
(3) disrupted tactile feedback (articulators anesthetized),
and (4) delayed side-tone plus loss of tactile feedback.
The stimuli were presented to 900 listeners in quiet and
in noise (4 signal-to-noise ratio). Criterion measures
of duration, correctly articulated words, and correct
word perception were studied by analysis of variance
techniques. The findings are discussed in relation to
factors affecting speech accuracy.

Hardy, L.H. POLYCHROMATIC PLATES FOR TESTING COLOR VISION. FINAL REPORT. Contract N60NR
70200, Oct. 1950, 15pp. Office of Naval Research, Washington, D.C. (Columbia University,
New York, N.Y.).

The H-R-R Polychromatic Plates is a device for screening color-defective Ss, classify-
ing red-green and blue-yellow defectives, and estimating extent of defect in terms of mild,
medium, and strong. The test yields no clues for memorization or coaching; and the symbols
(simple geometric designs) are familiar to all types of Ss. It was evaluated as a screening
device with 110 normal and 57 defective Ss; results show it agrees with the American Op-
tical approved test. The evaluation of its classification of the 57 defectives shows re-
sults in agreement with the Nagel Anomaloscope. The rating of extent of defect for the
57 Ss was also compared with several standard color vision tests. (REIAS)

Vobator, J.C., Hirots, H.W. & Lichtenstein, N. SAN DIEGO COUNTY FAIR HEARING SURVEY. J. Acoust. Soc. Amer., July 1950, 22(4), 473-483. (USN Electronics Lab., San Diego, Calif.).
(USNLT Rep. 210).

A phonographically recorded test of the ability to hear pure tones was given to 3666
people at the San Diego County Fair in the summer of 1948. Absolute thresholds were de-
termined at 5 frequencies and masked thresholds at 2 frequencies. The results were analyzed
according to the age, sex, musical training, and past noise environment of the listeners.
and according to their statements as to whether or not they had difficulty in hearing. As
expected, auditory sensitivity was found to decline with age; women were found to be more
sensitive than men for the higher frequencies; and men who worked in noise showed greater
than normal losses at high frequencies. The data indicated, in addition, that musically
trained men and women possess greater hearing sensitivity than do men and women without
musical training, and that the 20-29 year old males tested at San Diego in 1948 appeared
to have a greater loss at the high frequencies than did most males of the same age group
who were tested in surveys before the war.

3270 Hellibrandt, F.A. & Moutz, Sara Jane. ERGONOMAPHIC STUDY OF HAND DOMINANCE. Amer. J. Phys. Anthropol., June 1950, 3(2), 225-236. (Baruch Center of Physical Medicine & Rehabilitation, Medical College of Virginia, Charlottesville, Va.).

The influence of variations in stress on hand dominance was studied on 65 normal adult subjects. Differences in functional capacity were elicited from 144 ergographic work experiments. Observations were confined to wrist extension. Both unilateral and bilateral exercise was administered. The evidence supports the following conclusions: a) the laterality distribution curve is unimodal and essentially normal in form; b) the mean degree of functional superiority is moderate and falls to the dextral side of ambilaterality; c) bilateral exercise tends to equalize functional performance; d) both hands perform equally well under moderate stress and differences in handedness cannot be evaluated; e) fatigue suggests asymmetry in functional capacity; f) hand dominance is subject to wide physiological variation; g) it is postulated that the relative difference in performance at that point in the curve of work where optimal functional capacity is demonstrated, may be a sound and definable criterion of laterality.

3273 Kozsa, V., Briggs, R.W. and others. HIGH ALTITUDE BASECUTS. Memo Rep. NREMO-635-66K. Sept. 1950. 30p. USAF Air Materiel Command, Engineering Division.

3272 This memorandum reports the results of 14 human tests of high altitude bailouts which investigate their feasibility from a physiological standpoint, their practicability of automatic equipment for ejection seat and free bailout methods of escape. Descriptions of apparatus and methods as well as subjective reports of the parachutists are given.

3275 Mann, C.W., & Canella, C.J. AN EXAMINATION OF THE TECHNIQUE OF COPULOMETRY. Contract NMR-475-05, ONR Proj. Designation NR 142-456, BuMed and Surgery Proj. NM 001 110 500, Rep. 42, Joint Proj. Rep. 42, May 1956, 21pp. U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Fla.

3271 Haber, H. & Fleck, H. A COLOR SATURATION THRESHOLD METER. J. opt. Soc. Amer., 1950, 40, 450-451. Special Project. USAF, School of Aviation Medicine, Randolph Field.

3271 This report describes a meter designed to measure the threshold of color saturation and desaturation in which a gradually changeable mixture of white and colored light can be produced. A change in ratio of luminance of two lights can be measured between zero and infinity. Details of design are presented with a functional sketch of the meter. Two additional improvements are suggested. G.I.R.

3275 To examine copulometry as a psychophysical tool in the analysis of the vestibular apparatus, a total of 22 subjects was studied: nine normal, eight seasick, three aviators, and two pathological cases. Each subject was rotated, in darkness, at velocities of 9, 17, 32, and 60 degrees per second. Immediately after rotation, two types of copulograms were obtained: (1) sensation (reports of duration of sensation of rotation after chair was stopped), and (2) oculogyral, OGI (reports of duration of first post-rotational effects). Copulograms were analyzed with respect to linearity, slope, intercept, correlation of sensation, and OGI copulograms, and variability of after effects. All data were studied for differences between the seasick and non-seasick. T. G. I. R 15

3272 Mann, C.W., & Ray, J. ABSOLUTE THRESHOLDS OF PERCEPTION OF DIRECTION OF ANGULAR ACCELERATION. Contract NMR-475-05, ONR Proj. Designation NR 142-456, BuMed and Surgery Proj. NM 001 110 500, Rep. 41, Joint Proj. Rep. 41, May 1956, 15pp. U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Fla.

3277 Mann, C.W. FINAL TECHNICAL REPORT. Contract NMR-475-05, ONR Proj. Designation NR 142-456, BuMed & Surgery Proj. NM 001 110 500, Rep. 43, Joint Proj. Rep. 43, June 1956, 7pp. U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Fla.

3272 To test the organismic sensitivity of the human to accelerated horizontal rotation, threshold measurements were made by applying a given degree of angular acceleration to the subject and varying the time for reporting direction of movement yielded 75 percent correct responses. The range of angular accelerations was from 0.027 to 0.133 degrees per second squared. Testing was done in the dark with head in a fixed position. The time thresholds are analyzed as a function of angular acceleration. The importance of the time factor in threshold determinations is discussed. T. G. R 8

3277 This is a final report of a joint project between Tulane University and the United States Naval School of Aviation Medicine, Pensacola, Florida. The primary concern of research was with the visual, proprioceptive, and other sensory mechanisms influencing disorientation of pilots. A brief outline of the development of the project, a listing of technical reports, and a general progress report are presented. Areas are suggested in which further research is indicated. R 43

3278
Chubb, L.W. LOW TEMPERATURE FACE PROTECTIVE DEVICE. Contracts DAM 109 qm 224 & W44 109 qm 2011, Dec. 1950, 20pp. Rayfield Corporation, Cambridge, Mass.

A low-temperature head-protective device has been developed which meets the design requirements from the trial of torque, respirator EX 43-2. The major changes include interior design of AF A-13 of mask has been copied to improve universality of fit, angle of vision has been greatly enlarged through use of larger poggie lenses brought closer to the contour of the face, ease of donning and doffing has been improved by using 1 adjustable but permanently fastened elastic headstrap, half of the models have been equipped with a speech diaphragm to improve speech transmission. Rifle aiming interference has been reduced by poggie radiation and intake valant have been located in recesses to insure against accidental dislocation. (NICAS)

3279
French, R.S., & Martin, L.B. A FLIGHT-LINE TROUBLESHOOTING TRAINER FOR A COMPLEX ELECTRONIC SYSTEM: THE MAC-2 TRAINER. Proj. 7709, Rep. AFFTC-EX-57-106, July 1957, 11pp. Maintenance Lab., AFFTC, ARDC, Lowry AFB, Colo.

3279
This report describes the basic features of a flight-line troubleshooting trainer (MAC-2) for the MA-7A Bomb Navigational System. The trainer was designed to represent system data flow and operation in the simplest possible terms while retaining characteristics of a miniature system. The relationships of control and indicators, including the potential for a variety of malfunctions, were built into the device by means of circuitry resembling that of the actual system. Basic operation of the MA-7A System data-flow tracing and circuit analysis, the use of schematics, and the selection and use of appropriate test equipment can be learned and practiced as a supplement to practical training.

3258
Strong, H.L. ALASKAN WET-COLD FIELD TEST OF EXPERIMENTAL PERSONAL AND SURVIVAL EQUIPMENT. Memo. Rep. no. WCHXD-670-21R. Sept. 1950. 32pp. USAP, Air Materiel Command, Engineering Division.

3288
This memorandum report describes an Alaskan wet-cold field test conducted to assess the protective value of experimental personal and survival equipment. Eleven articles, including an igloo-type shelter, pneumatic fabric, modified Yukon store, tools, boots, etc. are individually described, evaluated for efficiency and protection, and recommendations are made for future use.

3295
Whittingham, D.G.W., Davidson, I.L. & others. AN INVESTIGATION OF SOME OF THE EFFECTS OF MARCHING IN FLYING BOOTS. EXERCISE OSTHOPOD I. AFRC 729. Dec. 1949. 56pp. Great Britain, Flying Personnel Research Committee, RAP Institute of Aviation Medicine.

3299
This report describes an investigation of the practicability and efficiency of the Paraborough flying boot and its effects on the human foot during a 60-mile simulated survival march in hot weather. Effects are assessed by radiographic, podographic and thermal measures on the wearer's foot; location and number of lesions (blisters) and wear on the boot itself are determined. A separate investigation is conducted under laboratory conditions to observe any relationship between foot swelling and rise in environmental temperature.

3299
Page, H.E. & Lyon, V.W. PRELIMINARY REPORT ON PERFORMANCE IN THE SWS CYCLOHAKIC LINK AND ITS RELATIONSHIP TO SUBSEQUENT PERFORMANCE IN STAGE A OF FLIGHT TRAINING. Proj. NX 001 058.09.01, Research Rep. Nov. 1950. 24pp. Naval School of Aviation Medicine, Pensacola.

3299
To test the effectiveness of preflight training in the SWS Link Trainer (a flight simulator), 100 Naval aviator students were given five hours of link instruction. Achievement was measured with four turning maneuvers in a link that yielded performance scores, and the instructors assigned subjective grades. These measures are intercorrelated and correlated with subjective grades on performance of 65 of the students in Stage A of flight training. Results are discussed regarding needs for further research.

3300
Kaizer, H. A QUANTIFICATION OF TEXTURES ON AERIAL PHOTOGRAPHS. Tech. Note 121, June 1955, 33pp. Optical Research Laboratory, Boston University.

3300
The purpose of this experiment was to obtain the basic data necessary for the development of ordered categories for the description of aerial photographs. Seven aerial photographs of natural terrain were studied. Texture was measured physically by determining the (1/e) th parameter of the autocorrelation function for density. Twenty subjects arranged the same photographs in order of coarseness of texture. The subjects viewed the photographs under reflected light for one set of judgments, and by transmitted light for another. A correlation is reported between the orders generated by the subjects, and those by the autocorrelator, and the utility of this relation for the classification of aerial photographs is discussed.

MORANT, G.H. SURVEYS OF THE HEIGHTS AND WEIGHTS OF ROYAL AIR FORCE PERSONNEL. IV. AVERAGE WEIGHTS AS A CRITERION OF THE PHYSICAL CONDITION OF GROUPS OF MALE SERVICE PERSONNEL. FRAC 711(c). Oct. 1950. 11pp. Livingston Research Committee, London, England. (RAF Institute of Aviation Medicine, Farnborough, Hants, England).

a) This report presents provisional average weight standards for groups of British male Service personnel. b) The 4 grades of weight distinguish between 'probably excessive', 'good', 'satisfactory', and 'poor'—refer to average weights reduced to a constant height (67.5 in.). and the method used in doing this is described (section 4.3). The standards are not intended to indicate the significance of weights of individuals. c) 2 systems are presented, one far untrained, and the other for trained personnel. They refer to British conditions and may be inappropriate for the corresponding communities in any other country. d) The limits of the grades of mean weights were chosen after comparison of the records for 19 series relating to a total of 1,400,000 adolescents and men. An American investigator using American data might conclude that the 'probably excessive' zones of the proposed British standards should be labelled satisfactory and that any below them should be labelled 'poor'.

STUNT, S.C. PREMODULATION SPEECH CLIPPING AND FILTERING: A CONSIDERATION OF THEIR EFFECTS ON THE INTELLIGIBILITY OF SPEECH. Proj. W4 003 041.21.04. MNL Rep. 155, Vol. 9, Aug. 1950. 6pp. USN Medical Research Lab., New London, Conn.

Speech clipping and filtering circuits in voice communication systems so distort the transmitted speech as to raise a question of their effect on intelligibility. Results of several experiments indicate that speech clipping alone improves intelligibility when signals are partially masked by electrical noise entering the system between transmitter and receiver. Signals which are not so masked are similarly affected to almost the same degree. Intelligibility improves as clipping increases up to at least 24 db. Under extreme noise masking, very heavy clipping (100 db or more) improves intelligibility, but reduces noise masking. or signals not so masked. Other experiments show that intelligibility is not likely to suffer when voice frequencies below 500 cycles are sharply attenuated, with the possible exception that when masking white noise is very intense, restoring low frequencies causes a slight increase of intelligibility. Attenuating frequencies above 3500 cycles has no significant effect on intelligibility. However, reducing the low-pass cut-off point to 2500 cycles does lower intelligibility considerably. It is suggested that band-pass filtering limits be 600 to 4000 cycles.

3306
Strughold, R. THE HUMAN TIME FACTOR IN FLIGHT. II. CHAINS OF LATENCIES IN VISION. Nov. 1950. 9pp. USAF, School of Aviation Medicine, Randolph Field.

3303
This report reviews the general nature of a contract program on social perception and group effectiveness. The method of measuring interpersonal perception is described. Investigations summarized here, deal with relatively simple structured work units and with formally organized crews and the subgroups within them. These latter have included B-29 Combat Crews, Tank Crews, and Open Hearth Shops. Two studies in progress are designed to explore intergroup relations and productivity of the whole organization. Methodological studies completed are listed along with technical reports and journal publications by members of the research team.

R 15

3306
To analyze the time consumption of the various processes which lead to distinct visual perception, data from pertinent literature is analyzed in terms of conjugate and disjunctive eye movements, accommodation and pupillary reaction. This complex of processes is designated as "chains of sensory latencies of lower order" as opposed to "chains of sensory latencies of the higher order" formed by recognition, comprehension, etc. The importance of these complexes for safety in ground and air traffic is pointed out.

Bell Telephone Labs. SYSTEMS ENGINEERING RELATING TO COMMUNICATIONS FACILITIES FOR THE COMMON SYSTEM OF AIR TRAFFIC CONTROL. PART I. HARTFORD SECTION - TRAFFIC STUDY OF COMMUNICATIONS AND RELATED OPERATIONS. Contract DA 36-039-sc-64567, June 1955, 273pp. Bell Telephone Labs., Whippany, N.J.

3304
This interim report on air traffic control represents a study of the application of an air-ground data link. Preliminary consideration is given to (1) system planning, (2) specific technical problems associated with an air-borne data link, and (3) general performance requirements for the data link. Three equipments (an ATC Signalling System, a data transfer and display, and an ATC plotting display) are considered and their utilization in the Traffic Control System analyzed. An integrated system of communications and displays, semi-automatic in nature, is proposed for operational simulation studies. Technical problems of derivation, storage and display of traffic control information are studied and general conclusions stated.

I.

3307
This is a final report on one sector of a study of the communications traffic in air traffic control. In an effort to understand the system, especially the manner in which communications was interwoven with the control system, statistical studies were made of voice communications (duration of calls, incoming vs. outgoing, and predictability), message classifications, rates of communication activity, calling rates and holding times, communication delays, and age of information. These data were studied in relation to aircraft delays and clearances. Analyses were directed towards prediction of effect of making changes in the present systems. Recommendations are made. Individual memoranda covering the statistical studies in detail and a collection of tables and charts are appended.

3308
Low, P.M. EFFECT OF TRAINING ON ACUITY OF PERIPHERAL VISION. Rep. 66, Sept. 1946, 94pp. Division of Research CAG. (School of Medicine, University of North Carolina).

3308
To study the effects of systematic training of peripheral vision, 13 subjects completed a three-month course (twice-weekly laboratory periods). Test objects (Landolt Broken Circles, Airplane Silhouettes, and Isolated Forms) were used with a hand-operated perimeter under carefully controlled exposure conditions. An initial acuity test was given with a check test every fourth period and the airplane silhouettes were used for training. Special tests included: Isolated Circles, Night Visual Acuity, Rapid Recognition, and transfer tests of Isolated Forms, acuity at 90° from line of vision, and Non-Formalistic Recognition. Three types of scores were derived (acuity, millimeter variability, and percentage standard error) and analyzed for changes during the course of training. Manual for testing procedure is appended.

Davis, H., Silverman, S.R., & McLaughlin, D.R. PITCH AND FREQUENCY. Contract N60nr 272, 950, 9pp. Office of Naval Research, Washington, D.C. (Central Institute for the Deaf, St. Louis, Mo.).
"Tone-pips" were produced by delivering brief rectangular electrical pulses through 2 sound-effects filters in cascade with both high and low cut-offs set at 2000 cps. Nearly all of the acoustic energy of the final signal was found to be concentrated in a band about an octave wide and centered at 2000 cps. The pulsing frequency was varied independently between 50 and 150 pips per second. Listeners describe the resulting sound as a "metallic buzz". Listeners vary greatly in their ability to identify the 2 "pitches" present in this sound and in the accuracy with which they match with a pure tone either the pulsing frequency (about 130 per sec.) or the band-pass frequency (2000 cps in the present series). Errors of exactly 1 octave are particularly common. In the theoretical discussion we argue that the "pitch" of a pure tone is a double attribute compounded of "buzz" (correlated with frequency of volleys of nerve impulses) and "body" (correlated with position of maximum stimulation on the basilar membrane).

Keist, B.P., Shaeley, W.P., Byers, J.M., Jr., & Chinn, H.I. RELATIVE EFFECTS OF HEAD IMMOBILIZATION AND MEDICATION ON THE INCIDENCE OF AIRSICKNESS. Rep. 55-78, Oct. 1955, 3pp. USAF School of Aviation Medicine, Randolph APB, Tex.

3311
To investigate the relative effects of head immobilization and medication on the incidence of air sickness, 102 paratroopers on simulated combat jumps were randomly distributed aboard C-119 aircraft. They were divided evenly into four groups receiving C.65 milligrams of hyoscine hydrobromide with and without head support and placebo with and without head support. On four two-hour flights (jumps on three) each man had served as subject in each group. The incidence of airsickness (vomiting) was analyzed for differences due to medication and head rest. Further study was made of differential effects on individuals exhibiting motion susceptibility.

Smith, E.E. EFFECTS OF THREAT INDUCED BY AMBIGUOUS ROLE EXPECTATIONS ON DEFENSIVENESS AND PRODUCTIVITY IN SMALL GROUPS. Contract N60nr-1147(63), NR 170 226, Tech. Rep. 1, Aug. 1956, 62pp. Group Process Laboratory University of Colorado, Boulder, Colo.

3312
To investigate the effect of threat induced by ambiguous role expectations upon group performance, 146 subjects were placed into five-person problem-solving groups in four conditions (one control condition contained three person groups). The task was a variation of the "twenty-question" parlor game, with work productivity measured during the second ten-minute period. Role ambiguity was induced by means of two trained silent plants into experimental groups and was reduced by pre-task clarification of roles of silent plants in control groups. Measures were made of task efficiency, group defensiveness, group satisfaction, group cohesiveness, inter-member attractiveness, and intra-group hostility. The results are analyzed for changes due to changed role expectations.

Gibbs, P.A., & Huber, F. STUDIES ON EFFECTS OF WINDSHIELDS AND/OR AIR OF DIFFERENT DENSITIES ON STEREOSCOPIC VISION. I. MATHEMATICAL PRINCIPLES CONCERNING DISPLACEMENT EFFECTS ON BIODIRECTIONAL PERCEPTION OF DIRECTION, SIZE, AND DISTANCE, AND TRIDIMENSIONAL PERCEPTION OF DEPTH. Rep. 1, Nov. 1950, 21pp. USAF School of Aviation Medicine, Randolph Field, Tex.

In the present paper, the mathematical principles were derived for the effect of transparent plane-parallel panels on displacement (i.e., perception of direction), apparent enlargement, apparent change in shape, and apparent change in distance of an observed object. Furthermore, the change in the angle of parallax at which two objects at different distances are seen was computed when a panel or windshield with plane-parallel surfaces is interposed. All calculations pertain to resurfaced, laminated, bulletproof, heat-treated, windshield panels with 38.1 mm. thickness and a refractive index of 1.515. It was shown that with the great distances encountered in aviation all effects of interposed panels were negligible with exception of the change in the angle of parallax and thus the apparent change in distance. Depending on the angle of incidence of the panels, the change in the angle of parallax may amount to $\pm 30\%$. If the distance was below 10 m (indoor experiments) all the effects were significant. Numerical calculations show that the deviation of light rays through shock waves under practical conditions amounts to less than 1 min. of arc and thus presents a very small problem. It can therefore be omitted.

Edwards, D.A.W. SOME OBSERVATIONS ON THE EFFECTS ON HUMAN SUBJECTS OF AIR AND STRUCTURE BORNE VIBRATIONS OF VARIOUS FREQUENCIES. Sept. 1950, 121pp. FPRC, RAF Institute of Aviation Medicine, Farnborough, Hants, Eng.

3314
To investigate the effects of air and structure borne vibrations on human subjects, a series of studies were conducted. Personnel (ground engineers and test pilots) working with jet aircraft were questioned and examined. A detailed study of subjective impressions of exposure to high intensity structure and air borne vibrations was carried out by the author. Estimates of change in respiratory pattern and oxygen consumption were made. Principles of design and development of ear defenders were reviewed and an attempt made to improve existing patterns. The sources and spectral distribution of frequencies and intensities in reciprocating engine and jet propelled aircraft are described. A review of available literature is included.

Psychological Research Associates, Bureau of Ordnance. HUMAN ENGINEERING PRINCIPLES FOR MINE TEST SET DESIGN. Contract Word 15618, NAVORD Rep. 5339, May 1956, 95pp. Bureau of Ordnance, Department of the Navy.

3315

This manual presents some human engineering principles to assist the engineer in the design of Mine Test Sets for greater operator accuracy and efficiency. The first section is devoted to those considerations common to all mine test sets, such as labeling, coding, construction features and the arrangement, location, grouping and position of controls, indicators, cables, and other parts of the panel. Two sections are devoted to general types of Mine Test Set panel parts: controls and indicators. The final section is an illustration of the application of the principles to proposed panels for two Mine Test Sets, ME246 Mod 0 and ME246 Mod 0.

Human engineering check lists for overall design consideration are appended.

Bach, L.X.N., Sperry, C.J., Jr., & Ray, J.T. STUDIES ON THE EFFECTS OF FLICKERING LIGHT ON HUMAN SUBJECTS. Contract DA-44-009-eng 2448, Proj. 8-18-06-003, Final Rep., June 1956, 73pp. Department of Physiology, Tulane University Station, New Orleans 18, La.

3316

To investigate the effects of flickering light on human subjects with a view to the use of flickering light as a possible tactic in battlefield operations to cause interference with cognitive functions of the enemy, a series of studies were undertaken: (1) determination of intensity, frequency, time of exposure, and light-dark ratio, most likely to cause dizziness, sleep, or unconsciousness; and (2) determination of interference effects on such tasks as tapping in certain sequences, walking and rifle-firing. The results are discussed in terms of possibility of using this technique to achieve objective and effective interference with consciousness.

Jerger, J.P. THE EFFECT OF STIMULUS INTENSITY ON THE PATTERN OF RECOVERY FROM AUDITORY FATIGUE. Rep. 55-143, Jan. 1956, 6pp. USAF School of Aviation Medicine, Randolph AFB, Tex.

3318

To study the effect of stimulus intensity on the pattern of recovery from auditory fatigue, measurements were obtained from light subjects with a threshold tracing signal (4000 cycles per second) prior to and during recovery from a two-minute stimulating tone (3000 cycles per second). Intensity of stimulating tone varied (80, 85, 90, 95, 100, 105, and 110 decibels) in seven testing periods. Individual and mean recovery curves, threshold shifts at thirty seconds and magnitude of "bounce" at approximately two minutes are analyzed for each intensity level. Results are interpreted in terms of their significance for predicting susceptibility to permanent noise-induced hearing loss.

3325

Green, R.F., Morris, E.B., & Spragg, S.D.S. THE EFFECT ON PERFORMANCE OF VARYING THE DIRECTIONS AND PLANES OF MOVEMENT OF THE CONTROL CRANKS ON A COMPENSATORY TRACKING TASK. Prepared under Contract W600-241, T.O. 6, Proj. 20-M-1d, Tech. Rep. 241-8-18, Aug. 1955, 4pp. Special Devices Center, Fort Washington, N.Y. (University of Rochester).

3325

To determine whether certain display-control relations which had been found to be optimum for a following tracking task would also prove optimum for a compensatory tracking task, 32 subjects attempted to keep a target centered under cross-hairs of a three-inch aperture by using two hand controls rotating in the vertical plane parallel to the frontal body plane or by rotating left crank in the vertical plane parallel to the frontal body plane and the right crank in the vertical plane perpendicular to the frontal body plane. Four different combinations of directions of rotation were practiced during a 55-minute period. The scores (time on target) were analyzed for differences due to position of hand wheels and direction of rotation.

Jerger, J.P. LOUDNESS ADAPTATION FOLLOWING INTENSE ACOUSTIC STIMULATION. Rep. 56-9, Jan. 1956, 8pp. USAF School of Aviation Medicine, Randolph AFB, Tex. (Northwestern University).

3326

To study loudness adaptation following exposure to intense acoustic stimulation, twelve subjects adjusted the loudness of a control tone (right ear) to match a test tone (left ear) under three conditions: (1) continuous test tone (4000 cycles per second at 80 decibels), duration ten minutes, matching at one-minute intervals; (2) same procedure following a fatiguing tone (3000 cycles per second, 100 decibels, 100 seconds duration); (3) following the fatiguing tone, a discontinuous test tone with same matching procedures. The data were analyzed for differences between normal and post-fatigue adaptation. Comparisons were made with other measures of acoustic stress from a previous experiment. Results are interpreted in terms of their significance for isolating the noise-susceptible individual. G. R 5

Hattin, D.E. EFFECTS OF TILT ON A STANDARD MS 28024 TURN AND SLIP INDICATOR. Task 13681, Tech. Note WADC 55-630, Nov. 1955, 6pp. Directorate of Flight and All-Weather Testing, WADC, Wright-Patterson AFB, Ohio.

3330

To determine the effects of tilt on a standard MS28024 turn and slip indicator, five pilots made six flights with the indicator mounted with its face set (1) parallel, (2) five degrees face up, (3) fifteen degrees face up, and (4) fifteen degrees face down with respect to a plane perpendicular to the longitudinal axis of the aircraft. Four standard maneuvers were performed and photographic records made of instrument behavior. Pilots filled out questionnaire on their observations. Results were evaluated in terms of the advisability of using a tilted turn and slip indicator as a primary flight instrument in event of altitude indicator failure.

Austin, G.M., Lee, A.S.J. & Grant, F.C. A NEW TYPE OF LOCALLY-APPLIED STEREOTAXIC INSTRUMENT. *J. Amer. Med. Assoc.*, May 1956, 161, 147-148. (Neurosurgery Dept., University of Pennsylvania, Philadelphia, Penn.).

A new lightweight stereotaxic instrument (weighing 1.5 lb.) for use in the brain of human beings is constructed mainly of anodized aluminum with a sterilizable plastic electrode holder. The instrument may be attached any place on the skull by means of three screws in the external table of the skull. The position of the electrode holder, referable to the basal and sagittal planes, is fixed by an arm filled with Wood's metal and chain. The reference planes of measurement include: a) an angular adjustment along the sagittal plane of the skull by means of a vernier; b) a coronal plane of angular adjustment up to 15°; c) a translation movement, lateral from the midline; and d) a vertical measurement along the electrode track.

3335

Spalding, C.K. RADIATION-EXPOSURE SURVEY OF X-RAY AND ISOTOPE PERSONNEL. ANALYSIS OF A TOTAL OF 7678 FILMS WORN BY PERSONNEL IN THESE TWO FIELDS SHOWS CLEARLY THAT THE X-RAY WORKER RECEIVED CONSIDERABLY MORE RADIATION EXPOSURE THAN THE ISOTOPE WORKER. *Nucleonics*, Dec. 1949, 5(6), 63-66. (Radiology Dept., New England Deaconess Hospital & Pathology Lab., Harvard Cancer Commission, Boston, Mass.).

Analysis of a total of 7678 films worn by X-ray and isotope personnel shows clearly that the X-ray worker received considerably more radiation exposure than the isotope worker. The latter personnel rarely ever approach the permissible-dose level, while several X-ray workers received greater than the permissible dose. (HEIAS)

Contract AF 33(616)-32, Proj. 7155, WADC Tech. Note 55-522, June 1955, 41pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio. (University of California).

3336

To investigate the evaporation of water from the human body as a function of temperature, humidity, pressure and wind velocity, tests were conducted on two subjects. In one series of fifty tests, five levels of temperature, water vapor pressure, altitude pressure, wind velocity, and time were used and weight loss measured every five minutes. In addition, skin and rectal temperature, heart rate and estimated water accumulation on the body were measured. Additional series of tests at constant temperature (50° F mean value) were made. Oxygen was given for altitudes above 8000 feet. Data were analyzed as functions of the environmental variables over the specified ranges.

Miller, R.B. HUMAN ENGINEERING DESIGN SCHEDULE FOR TRAINING EQUIPMENT. Contract AF 33(038) 22638, WADC TR 53 138, June 1953, 34pp. USAF Aerospace Medical Lab., Wright-Patterson AFB, Ohio. (American Institute for Research, Pittsburgh, Penn.).

3338

This report is an organization of several hundred considerations which, from the human engineering standpoint, are important to the relevance and efficiency of training equipment. These considerations are applicable to a training device during initial planning, specification, prototype, or production model stages of trainer development. The items of the Design Schedule are grouped as follows: 1) designing a trainer to use as a demonstrator of principles, 2) controls, 3) displays, 4) control-display interaction, 5) programs, 6) scoring and error analysis, 7) motivation of the student, 8) conditions of practice and learning, 9) facilities for the instructor, and 10) research data on the task.

3340 Reynolds, J.B. & Blodreau, Ina McB. AN EVALUATION OF SOME MANIPULATION TESTS FOR A BASIC SCALE OF MOTOR ABILITIES. Res. Note P & MS 52 5, March 1952, 6pp. USAF Air Training Command, Human Resources Research Center, San Antonio, Tex.

The present study is concerned with the evaluation of a group of manipulation tests with a view toward their later inclusion as items in a general scale of motor abilities. They are suitable scale material in terms of simplicity and durability of apparatus and ease of administration. Of 10 manual tests, 8 form a general cluster with respect to intercorrelation, and correlation with the Airman Classification Battery AC-1A. The 2 Finger Control items have little in common with the other manipulation or Airman Classification Battery variables. The other manual tests involve manipulation of small objects, while Finger Control is manipulation of the fingers only, and involves no testing materials. The 8 clustering manipulation tests meet the preliminary criteria for inclusion as items in a basic scale of motor abilities. They are fairly complex, in terms of moderate correlation profiles. Retaining them as possible items and yet they tend to have individual correlation profiles. Retaining them as possible items in a manipulation test for further evaluation seems warranted.

Duncan, C.P., & Underwood, B.J. SPATIAL ERROR GRADIENTS IN MOTOR LEARNING AND TRANSFER. Contract AF 33(038)-11396, RDO 694-44, Tech. Rep. 53-65, April 1953, 11pp. WADC, ARDC, Wright-Patterson AFB, Ohio. (Northwestern University).

3342

To study the effects of task similarity on transfer of training, three groups of 26 male college students practiced moving a lever into the appropriate one of six radial slots in response to one of six signal lights. After 60 trials with one slot-light relationship, 30 trials were performed with a different relationship, the degree of similarity between the two tasks varying among the three groups. Errors and error gradients are analyzed in detail and discussed regarding implications for training and equipment design.

Massachusetts Institute of Technology. INTELLIGIBILITY OF PROCESSED SPEECH. SUPPLEMENTARY REPORT. Contract W 19 122 ac 14, Tech. Rep. 11, Sept. 1949, 62pp. Acoustics Lab., Massachusetts Institute of Technology, Cambridge, Mass.

The work accomplished from July 1948 to July 1949 on the study of the intelligibility of processed speech is outlined. The over-all program includes 2 major phases: factors affecting intelligibility and bandwidth time compression of speech. Under the first phase, the effects of certain types of distortion on articulation and the determination of the threshold of flutter for a frequency-modulated tone are discussed. For the second phase, the work done on the speech-compression problem, the experimental work on amplitude and time quantization of speech waves, and proposals for future work are summarized. The instrumentation to be used for psychoacoustic experiments such as intelligibility tests and threshold determinations is briefly described.

Prakash, A. BAYES, AND MINIMUM PROCESSES IN SAMPLING FROM FINITE POPULATIONS. Contract N6003 251, Task III (NR 042 993), Tech. Rep. 15, Feb. 1953, 10pp. Department of Statistics, Stanford University, Stanford, Calif.

3345

The primary aim of this paper is to investigate the assumptions in modern decision theory needed to yield the classical results in estimation and design in sampling from finite populations. The finite population is regarded as the outcome of a fixed sample size experiment performed by nature or some conscious being, using some probability distribution unknown to the statistician. The loss function, however, does not depend upon the form of the probability distribution but only upon the outcome of this large experiment. Use has been made of the fact that optimum strategy is to choose a sample of fixed size by the method of simple random sampling. The Bayes and minimum estimates and sampling procedures are obtained for various populations.

Husson, G.S. & Reis, A.B. PHYSIOLOGICAL ADAPTATION TO CHRONIC HYPOXIA: A. RESTING OXYGEN CONSUMPTION. Rep. 55-14, Sept. 1955, 7pp. USAF School of Aviation Medicine, Randolph AFB, Tex. (Johns Hopkins University School of Medicine).

3351

To investigate the possibility of physiological adaptation to a state of chronic hypoxia, the resting oxygen consumption of 42 individuals with cyanotic congenital heart disease and that of 45 individuals with noncyanotic congenital heart disease (age range--six to forty years) were measured. The data (oxygen consumption in milliliters per minute per square meter of body surface and basal metabolic rate) are compared for differences due to chronic hypoxia.

Bishop, D.E. OCTAVE BAND ANALYSIS OF NOISE MEASUREMENTS OF SHIPBOARD LIVING QUARTERS. Contract N0001 54669, Tech. Rep. 3, Proj. A 024 9 (Formerly 90 1099A), March 1953, 52pp. Armour Research Foundation, Illinois Institute of Technology, Chicago, Ill.

This report presents the octave band analysis of noise measurements taken in 100 compartments of 8 vessels of Task Force 86, and 30 compartments of the USS Midway (CVB 41). The data are presented in terms of the median overall and octave band sound pressure levels for each compartment. The median levels for each compartment are determined from the set of noise measurements taken at different times in each compartment. Comparison of the collected noise spectra of compartments of different type vessels showed no significant differences in the shape of the median spectrum for destroyer-type vessels compared to the median battleship and heavy cruiser spectrum. The median levels for the battleship and heavy cruiser spectrum are approximately 3 db greater than the median levels of the destroyer-type vessels. Comparison of the variation of spectra levels with time showed that the median range of variation for 50% of the measurements in each compartment was approximately 4 db in each octave band. For design purposes, the spectra of many of the compartments can be approximated by a spectrum having a constant, decreasing slope of 4 db per octave, with the speech interference level 20 db below the overall sound level. From the limited data available, the median ventilation system spectrum has an increased proportion of energy in the low frequencies, with a decrease of sound levels in the higher octave bands approximating 6 db per octave.

3353
Miller, J.G. THE DEVELOPMENT OF EXPERIMENTAL STRESS-SENSITIVE TESTS FOR PREDICTING PERFORMANCE IN MILITARY TASKS. Contract DA 49 083 OSA 611 B 8 154, Proj. 29562000, PRS Tech. Res. Rep. 1079, Oct. 1953, 57pp. Psychological Research Associates, Washington, D.C.

3353
To find out if certain available tests were able to distinguish a man's reactions under stress conditions as opposed to his reactions in a normal situation, a number of potentially stress-sensitive tests were selected on the basis of a review of the literature and pretested on 48 paratroopers making their first jump from the 34-ft. mock tower. Four tests (critical flicker-fusion at dim intensity, the trembleometer, cancellation of C's, and the Primary Mental Abilities Word Fluency) were then administered to 500 pre-inductees under ordinary testing conditions and under stress induced by a continuous 8000-cycle, 90 db noise. The findings were interpreted in terms of a general theory of stress.

McGill, W.J. MULTIVARIATE TRANSMISSION OF INFORMATION AND ITS RELATION TO ANALYSIS OF VARIANCE. Contract AF 18(600) 322, HROAL Rep. 32, ca. 1952, 19pp. USAF Human Factors Operations Research Labs., Bolling AFB, Washington, D.C. (Research Laboratory of Electronics, Massachusetts Institute of Technology, Cambridge, Mass.).

The simple model of information transmission with one input variable and one output variable is inadequate in most psychological applications. More desirable is a model that permits us to study input-output correlations with several variables at the input, or at the output, or both. This paper shows that the definition of transmitted information may be generalized to include the effects of multiple sources of information. Multivariate transmission analysis resembles analysis of variance in many ways, but there are also fundamental differences between the methods. A "components of response information" model is developed in which response information is analyzed into several parts. One of the components is an error term; the others measure correlations between the transmitting variables and the responses. Statistical tests of the significance of the transmitting variables are possible.

Tolson, J., & Corkindale, K.G. COMPARATIVE PHYSIOLOGICAL TRIAL OF ROCKET-FUEL-RESISTANT CLOTHING. Rep. 49, July 1955, 16pp. Clothing and Equipment Physiological Research Establishment, Directorate of Physiological and Biological Research, Ministry of Supply, London, England.

3365
To compare two types of rocket-fuel-resistant clothing, a test was carried out in a hot climatic chamber at a temperature of 77° F., relative humidity being approximately 64 percent. Eight men wore each suit twice during four test days for periods of work and inactivity. The heat stress was assessed by measuring internal body temperature, pulse rate, and total weight lost. Sweat retained in clothing was measured to compare the ventilation afforded. Subjective opinions and user preferences studied by analysis of variance techniques for differences attributable to suit design. User preferences and critical comments are presented. Design recommendations are included.

Grings, W.M. (Princ. Investigator). SHIPBOARD OBSERVATION OF ELECTRONICS PERSONNEL: GENERAL CONCLUSIONS AND RECOMMENDATIONS FOR FURTHER RESEARCH. Contract NONR 228(02), Proj. NR 153 093, Tech. Rep. 7, July 1953, 30pp. Dept. of Psychology, University of Southern California, Los Angeles, Calif.

3367
This report is the last of a series of technical reports based on shipboard observations of electronics personnel on destroyer-type ships. Objectives of the research are re-examined and degrees of their attainment are evaluated. General conclusions derived from the research, suggestions for improvement in the electronics maintenance situation, and recommendations for future research within the electronics area are included.

3368
Hambacher, W.G. HUMAN ENGINEERING INVESTIGATIONS OF THE INTERIOR LIGHTING OF NAVAL AIRCRAFT: INVESTIGATIONS INTO THE OPTIMAL CHARACTERISTICS OF VISUAL WARNING AND CAUTION SYSTEMS. THE EFFECTS OF VARIATION IN TEMPORAL CHARACTERISTICS OF WARNING LIGHTS ON THEIR ATTENTION-GETTING AND -HOLDING VALUE UNDER DAY AND NIGHT CONDITIONS. NAMC-ACEL-299, TED NAMC-EL-52004, Part 7, Aug. 1956, 13pp. Air Crew Equipment Laboratory, Naval Air Experimental Station, NAMC, Philadelphia, Penn.

3368
This investigation was undertaken to develop an empirical basis for the design of warning lights in aircraft. Reaction times were measured on 12 subjects while they were continuously engaged in a tracking task. Four different delay periods were interspersed randomly between a "ready" signal and the stimulus. All of the subjects performed the task during the day and during the night. The results are factor-analyzed to determine whether any of these variables have a significant effect on reaction time.

Grings, M.K. (Princ. Investigator). SHIPBOARD OBSERVATION OF ELECTRONIC PERSONNEL: A DESCRIPTION OF THE RESEARCH. Tech. Rep. 1, Jan. 1953, 11pp. Dept. of Psychology, University of Southern California, Los Angeles, Calif.

3371

A nontechnical account is presented of a research program designed to investigate personnel problems associated with electronic maintenance and operation. The procedures used to obtain objective descriptions aboard ships operating in the Pacific area are given along with a description of the groups observed. The rationale underlying the development of a battery of observational techniques is discussed with each technique described in general terms. The treatment of data is discussed briefly and the methods used are evaluated. The paper concludes with some general evaluative comments on the use of a multi-method approach.

Morgan, R.L. & Eckstrand, G.A. EFFECTS OF A CHANGED ENVIRONMENTAL CONTEXT UPON PERFORMANCE OF A TRACKING TASK. Contract AF 18(603) 78, NADC TR 53 235, Oct. 1953, 20pp. USAF Aerospace Medical Lab., Wright-Patterson AFB, Ohio.

3373

To study the effect of environmental context on transfer of training, two groups of 20 male Ss kept movable cross-hairs centered on a spot with a control stick in a simulated cockpit. One group practiced in a complex situation (enclosed cockpit, red panel lights, helmet, engine noise, vibration, etc.), the other in a simpler situation (open cockpit, ambient illumination, no helmet, no noise, no vibration). A week later, both groups practiced in the complex situation. Tracking accuracy under final conditions is interpreted regarding degree of realism required in training simulators.

McGuigan, F.J. & Deneberg, J.H. ACCURACY OF M1 RIFLE SCORES OBTAINED ON THE KNOWN-DISTANCE RANGE. Res. Memo. 4, Jan. 1954, 10pp. Human Resources Research Office, George Washington University, Washington, D.C.

3374

This study compares the accuracy of "line" scoring (where coach or firer records position of a marker held over the hit) and "pit" scoring (where crew in pit score from a close-up study of the target) in evaluating marksmanship with the M1 rifle. Scores obtained both ways were compared for six companies of trainees ("pit" scores alone were obtained for four other companies). Some Ss were told of the "pit" scoring; others were not. Results are interpreted regarding relative accuracy of scoring methods and effectiveness of current training, and recommendations are made for future research.

Flanagan, J.L. A SPEECH ANALYZER FOR A FORMANT-CODING COMPRESSION SYSTEM. Contract AF 19(604)-626, Sol. Rep. 4, AFRC-TN-55-793, May 1955, 114pp. Acoustics Laboratory, MIT.

3375

This paper describes a system for reducing the bandwidth necessary for the transmission of intelligible speech. It consists of an automatic encoder which translates the following features of speech into narrow-band control signals: (1) the frequencies of the first three formants; (2) the amplitude of voicing excitation; (3) the amplitude of turbulent excitation; and (4) the fundamental voice frequency. These control signals actuate a synthesizer which is, in effect, an electronic analogue of the human vocal mechanism. The precision necessary in such a system is deduced from psychophysical data in the literature, and the performance of a preliminary model with a bandwidth of 30 cps is evaluated.

3377 Judd, D.B., Plaz, L. & Farnsworth, D. TRITANOPIA WITH ABNORMALLY HEAVY OCULAR PIGMENTATION. J. Opt. Soc. Amer., Dec. 1950, 40(12), 833-841. (National Bureau of Standards, Washington, D. C.).

The chromaticity confusions characteristic of tritanopia may be represented on the (x, y)-chromaticity diagram by a family of straight lines intersecting at a copunctal point near the shortwave extreme of the spectrum locus. A case of congenital tritanopia is reported that departs from typical tritanopia, first by having a junctionity function abnormally curtailed on the shortwave end, second by having chromaticity confusions among object colors describable by straight lines on the (x, y)-plot intersecting in an area surrounding the spectrum locus at 460 mμ instead of near the shortwave extreme, and third by confusing incandescent lamp light at a color temperature of 2900°K with the spectrum at 566 mμ instead of the typical tritanopic value of 579 mμ. It has been found that all three of these disagreements with typical tritanopia are to be expected from a tritanope possessing normal macular pigmentation combined with an ocular pigment five times normal. We believe, therefore, that this case of atypical tritanopia departs from typical tritanopia because of abnormally heavy ocular pigmentation.

Greer, F.L. SMALL GROUP EFFECTIVENESS. Contract NMR 1274(00), Series 1900 - Institute Rep. 6, 1956, 29pp. Institute for Research in Human Relations, Philadelphia, Penn. (Rand Corporation, Santa Monica, Calif.).

3386

To study relationships between personality and effectiveness in small groups, a large number of natural Army groups performing a field task were used. The measure of group effectiveness was based on observer ratings of 120 nine-man infantry rifle squads during a six-hour, black firing simulated combat problem. Each subject answered a questionnaire which measured eight personality and seven demographic variables. A ten-item sociometric questionnaire was given and members of the 13 most and least effective squads were interviewed. The findings are discussed in relation to leadership and group cohesiveness.

Hadley, M.E. & Cooper, M.L. (Prof. Div.). COMMUNICATION IN HIGH-LEVEL AMBIENT NOISE FIELDS. PART I. NOISE ANALYSIS AND EQUIPMENT PERFORMANCE. FINAL REPORT. Contract DA 36 039 SD 6449, Proj. 12B, Proj. 84B, May 1956, 146pp. The Signal Corps Communication Lab., Fort Monmouth, N.J. (Radio Corporation of America, Camden, N.J.).

3388

To provide design information relevant to Signal Corps voice communications systems used in and between high-level noise environments, the noise spectra in three helicopters and seven armored vehicles were determined and analyzed. Articulation tests were conducted using the interphone portion of Radio Set AF/RC-7 (representative of present Signal Corps equipment) under conditions of high-level sound in both laboratory and field. Using the noise spectra obtained, calculations were made of the articulation performance of a system composed of elements which are now available and the system was tested. The characteristics of the recommended system are specified. Interim measures for improvement in intelligibility of the present system are given.

Grater, T.V. COMMUNICATION WITH CLIPPED SPEECH SIGNALS. Contract DA 36 039 SD 15375. Quarterly Rep. 7, 1 Feb.-30 April 1953, 99pp. Communications Circularity Lab., Northwestern University, Evanston, Ill.

In this study of communication with clipped speech signals the viewpoint is taken that intelligibility may be associated with the correlation functions of speech spectra and individual sounds. The effect of infinite clipping on the correlation functions of clipped speech sounds is determined using methods which have been developed for noise theory. Since the behavior with whispered speech has been found experimentally to be similar to the behavior with voiced speech, this leads to criteria for the design of the linear filter to produce the infinite clipper. The statistical properties of the rectangular waves resulting from infinite clipping are derived. Using these, the improvement in signal-to-noise ratio which may be achieved by the use of infinitely clipped speech is investigated. It is shown that further improvement may be obtained through the use of the correlation detector, but that this improvement is not restricted to the use of clipped speech. A measure of the loss of intelligibility resulting from mixture with noise is obtained by the use of the concept of the cross-correlation function. The effect of time quantizing on the intelligibility of the infinitely-clipped wave is investigated; conclusions drawn from the study of the correlation function of the time-quantized wave agree with published experimental results. Possible applications of infinite clipping are suggested.

Eckstrand, G.A. & Morgan, R.L. A STUDY OF VERBAL MEDIATION AS A FACTOR IN TRANSFER OF TRAINING. WADC TR 53 34, Feb. 1953, 28pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3404

To determine whether the same verbal responses to a set of color stimuli and a set of response forms will result in these stimuli becoming functionally similar, 62 Ss divided into three groups learned three tasks using a modified Hull-type memory drum. Task 1 consisted of learning to push one of six switches for each of six colors presented on the drum. Task 2 differed for each group: 1) learned to associate one of the six colors with each of the six forms used; 2) learned to associate written names of the colors with the forms; and 3) learned to associate names of house parts with the forms (control group). Task 3 consisted of learning to push one of the six switches for each form. Errors on trial 1, errors to one perfect trial, and average number of correct responses per trial were analyzed for task 3 performance. T. R 14

Drachler, A.J., Bratt, R.M. & Yankov, D.M. SENSITIVITY AND DEFICIENCIES OF PRECOMBAT TRAINING AS REFLECTED BY IMPROVEMENT IN KOREA. PMS Rep. 954, Jan. 1952, 25pp. The Personnel Research Branch, Adjutant General's Office, Washington, D.C.

3407

To evaluate the effectiveness of infantry training for actual combat, 57 infantrymen were interviewed on the main line of resistance during hostilities in Korea. They were questioned as to the strong and weak aspects of their training in the light of their combat experience. Results (percent responses) are analyzed for implications for improvement of infantry training. Verbatim responses are appended. T. 2 for

Fraser, D.C. A STUDY OF FATIGUE IN AIRCRAFT INTERIM REPORT. 1. VALIDATION OF TECHNIQUES. AFM 185/52, Dec. 1952, 13pp. Psychological Lab., Applied Psychology Research Unit, M.C., Cambridge, England.

3409

This paper reports the results of giving a laboratory vigilance task to groups of navigators at different altitudes. The main feature of the task is that the operator has to detect the significant stimuli (large holes) that are interspersed randomly throughout a long series of neutral stimuli (smaller holes) as they move across a horizontal display he then has to photograph the significant stimulus when it is exactly half-way through its travel by pressing a camera button. The score is the variance of the subject's estimates about his own mean estimates. Results are given comparing navigator and naval ratings performance for performance after short and long sorties and for performance under stress conditions. T. G. 2 8

Stump, R.E. TOGGLE SWITCHES - ACTIVATION TIME AS A FUNCTION OF THE PLANE OF ORIENTATION AND THE DIRECTION OF MOVEMENT. WADC TR 52 51, Sept. 1952, 10pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3410

To determine, in various combinations of plane and direction of movement, the time required to throw a conventional toggle switch to the on position and then off, 12 Ss were required to perform this operation in each of six directions of throw variously assigned to three planes of motion (frontal, parallel, and flat). A spring-loaded toggle switch was used and the times required to perform the on-off throw were recorded. Practical implications of the data for operation of an indicator such as a Yeeder-type counter were discussed. T. G. 1.

Neely, K.K. A STUDY OF MAYDAY AND S.O.S. AS RADIO-TELEPHONE DISTRESS SIGNALS. DRML Proj. 118, DRML Rep. 118 5, POC D77 94 40 07, May 1955, 6pp. Defence Research Medical Labs., Toronto, Ontario, Canada.

3412

To determine the relative merits of MAYDAY and S.O.S. as radiotelephony distress signals, the detectability values (audibility thresholds) were compared in the presence of speech and noise. Twelve speakers of varied dialects made three-minute recordings of each term with an overall noise level of 55 decibels. Ten listeners, in a white noise environment of 103 decibels, responded to a multiple choice intelligibility test and the test words as they were fed into the earphones simultaneously. Detectability thresholds of each listener/speaker combination (120) were tabulated for each test word - the lower threshold being considered the more efficient index for a distress signal. T. R 7

Lutz, G.C., Bancroft, R.M. & Carter, E.T. RAPID DECOMPRESSION WITH PRESSURE-DEMAND OXYGEN EQUIPMENT. *Proj. 21 1221 0008*, Rep. 2, April 1953, 5pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

3415
To measure pressures imposed upon the lungs and other organs of the chest in the event of sudden loss of cabin pressure at high altitudes while using pressure-demand oxygen equipment, 35 rapid decompressions were made from a simulated cabin altitude of 20,000 to 25,000 ft. to a simulated flight altitude of 47,000 to 50,000 ft. in 0.3 to 0.5 seconds during normal respiratory activity with the pressure-demand oxygen equipment. Barometric and gas pressures were recorded directly and intra-thoracic pressures indirectly. Changes in blood oxygen saturation were recorded on a number of Ss. Subjective impressions were obtained after testing. A control test without positive mask pressure was run.

Klemmer, E.T. & Muller, P.F., Jr. THE RATE OF HANDLING INFORMATION: (KEY PRESSING RESPONSES TO LIGHT PATTERNS). *HFORL Mono Rep. 34*, March 1943, 11pp. USAF Human Factors Operations Research Laboratories, WADC, Bolling AFB, Washington, D.C.

Several tests were given to determine the rate of transmission of information through the human channel when the information was encoded for presentation in flashing lights and the operator's output was the pressing of corresponding keys. The independent variables were the rate at which the lights were flashed (2 to 5 per sec.), and the number of bulbs which might be lighted in the stimulus (1 through 5). All possible stimulus bulbs were equally probable and any number could be lighted simultaneously. In addition to these forced rate tests, the 5 bulb test was given as a self-pacing test. The main results were: a) Increasing the stimulus presentation speed increases the information transmission rate only up to a point where the S is making a few errors. Further increases in presentation speed result in large decreases in informational transmission; b) Increasing the number of possible light bulbs in the stimulus from 1 through 5 more than tripled the maximum informational transmission rate; c) In the range of speeds from 2 to 5 per sec. the reaction time is not a function of stimulus presentation rate; d) The reaction time increases with the number of possible light bulbs in the stimulus but is not a linear function of the information presented in the range from 2 to 5 stimuli per sec.; e) The stimulus presentation speed at which maximum transmission occurs is very close numerically to the reciprocal of the reaction time for that test; f) The self-pacing test results in as high information transmission as the maximum reached in the forced rate tests; g) The Ss would put out information with the key pressing response at a rate double that of their ability to transmit information from the flashing lights.

Doelling, K., Merton, D.A., et al. A CORRELATION OF TURBOJET NOISE DATA. *Contract AF 33(616)-2151*, Proj. 7210, WADC TR-51-401, July 1956, 126pp. Aero Medical Lab., WADC, AFPC, Wright-Patterson AFB, Ohio.

3418
Turbojet noise data have been compiled from measurements in engine test facilities and under static open field conditions and are presented in this report. About 100 measurements on 20 types of turbojets (no jet stream modifiers such as teeth or corrugations) are given. Total acoustic power and distribution of power in octave bands of frequency have been calculated and tabulated. For open field data, directivity information is presented in plots of sound pressure level as a function of angle. Each acoustic measurement is accompanied by the engine operating conditions. A history of each test includes source of data, type of measurements and method used to calculate acoustic power. No critical evaluation of the data is given.

Adley, J.V. DIRECTION-OF-PLANE-TURN STEREO-TYPES. Contract AF 18(600) 55, Proj. 7152, Task 7. 575, WADC Tech. Rep. 57 308, July 1957. 11pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

Right-handed subjects were asked to grasp a knob and turn it so as to effect a specified change in the intensity of a light mounted just above it. Equal numbers of subjects were asked to increase and to decrease the brightness of the light, the request being phrased in a variety of ways. Two significant tendencies were found. First, 73.3% of the subjects turned the knob clockwise to increase or counterclockwise to decrease the brightness of the light. This tendency was strongest when an increase was required and when the function to be controlled was phrased in positive terms (i.e., as "brightness" rather than "dimness"). It was not significantly dependent upon the use of the words "increase" or "decrease" or upon the sex of the operator. Second, 62.5% of all subjects turned the knob clockwise. This general turn-clockwise tendency was found to persist among an additional set of right-handed subjects when the light was covered up and the subject was asked simply to turn the knob; among left-handed subjects (used only in this condition) the tendency to turn clockwise was not statistically significant.

Merin, R.E. & Grant, D.A. SPATIAL STIMULUS-RESPONSE CORRESPONDENCE. PERFORMANCE ON A KEY-PRESSING TASK AS A FUNCTION OF THE DEGREE OF SPATIAL STIMULUS-RESPONSE CORRESPONDENCE. Contract AF 18(600) 54, WADC TR 53 252, Oct. 1953, 27pp. USAF Aerospace Medical Lab., Wright-Patterson AFB, Ohio. (University of Wisconsin, Madison, Wisc.).

This report describes an experiment to determine the effects upon speed and accuracy resulting from systematic variations in indicator-control arrangements. The indicators (stimuli) were 8 red lights arranged in a row on a display panel. The subjects operated a finger keyboard of 8 controls (response keys), likewise arranged in a row. Any light could be made the stimulus for any response key, and in yet through this mechanism that spatial stimulus-response correspondence was varied. Kendall's tau, a measure of rank correlation, was used to measure the degree of correspondence. Performance with direct correspondence between the stimulus lights and response keys was found to be very much superior to all other conditions studied. Change from direct correspondence multiplied the average time per unit of work by a factor of 2 to 4 and increased errors by a factor of 4 to 15. Performance with direct correspondence was also found to be relatively independent of a supplementary source of visual information feedback and relatively free from interference training.

Gordon, M.B. (Proj. Engineer). HUMAN ENGINEERING STUDY OF NAVAL AIR RESERVE TRAINING. PHASE I: SURVEY OF PROBLEMS. Contract NMR 895(00), SDC Rep. 895 001, March 1953, 44pp. USM Special Devices Center, Fort Washington, N.Y. (International Public Opinion Research Corp., New York, N.Y.).

This study was undertaken to: a) identify and define the problem areas in Naval Air Reserve training; b) order the problem areas in terms of the importance to Naval Air Reserve Training objectives; c) recommend practical steps which will improve the reserve training program. 1) problem areas were defined in operational items and in relation to other problems. Each area is followed by action recommendations specified in terms of goals, steps for implementation and anticipated end results. It was recommended that: a) the function of the Naval Air Reserve within national defense policy be reviewed in order to clarify the goals and objectives of the NAR training program; b) attention be devoted to the selection and training of instructors; c) training syllabi be standardized; d) there be improved implementation of the system for establishing the requirements for and the utilization of training devices.

Daniels, R.E. & Konhauser, J.D.E. A PROCEDURE FOR RATING COMMUNICATION SYSTEM STRUCTURES. Contract DA 49 025 SC 150, DA Proj. DA 3 99 01 001, SC Proj. 102 E, SC Tech. Requirements SCEL 2101 E, Haller, Raymond & Brown, Inc., Proj. 57, Jan 1956, 78pp. Haller, Raymond and Brown, Inc., State College, Penn.

A procedure is presented for rating various net structures or connectivity patterns encountered in a communication system. It is gross enough to allow application when traffic load and other more detailed information about the using organization is not available, but it has sufficient flexibility to allow use of such information when it is available. An over-all rating is defined in terms of four sub-ratings which, in turn, are intended to score a net structure with respect to directness of paths of communication, invulnerability of the net to failure of individual paths, cost--in a generalized sense--of installation and maintenance of the net, and the message handling capacity of the net. An example illustrating the procedure and its flexibility is included. In addition the procedure is applied to a portion of an infantry Division of the New Army of the Field and to a Rifle Company.

Brown, F.R. A STUDY OF THE REQUIREMENTS FOR LETTERS, NUMBERS, AND MARKINGS TO BE USED ON TRANS-ILLUMINATED AIRCRAFT CONTROL PANELS. PART 4. LEGIBILITY OF UNIFORM STROKE CAPITAL LETTERS AS INFLUENCED BY SIZE AND HEIGHT TO WIDTH RATIO AND AS COMPARED TO GERMANIC STYLES. REPORTED NOV 11 1953, 28pp. US Army Medical Research and Development Command, Philadelphia, Penn.

3453

To determine the effect of variations in size and in height-to-width ratio upon the legibility of capital block letters as they would be used on aircraft cockpit plastic lighting plates, a series of experiments was performed. In addition, a font of Germanic style capital letters characterized by variable height-to-width ratios, serifs, and monospaced stroke-widths was used. Tests with letters differing in these four characteristics were conducted using two exposure durations and five levels of red trans-illumination which simulated the conditions of night viewing of the plastic lighting plates. Daylight illumination and one exposure duration were used for the same letter variables. Recommendations were made on the basis of the results for letters to be used on plastic lighting plates. T. G. McCormick, E.J. et al. A STUDY OF JOB INTER-RELATIONSHIPS. Air Force Res. and Developm. Proj. 200-003-0010, Aug. 1954, 29pp. Occupational Research Center, Psychology Department, Purdue University.

3456

This report represents a summary of a series of studies on the development of check lists of work and knowledge components of jobs, the assessment of their utility in defining job interrelationships, and the employment of suitable check lists to determine patterns of job interrelationships among some 4,000 jobs. The check lists are briefly described along with the statistical analysis of job variables. The results of an analysis of clerical and metal-working jobs are presented in terms of the relative consistency among different checklists. The results of the analysis of 44 variables in 4,000 jobs are presented and discussed with regard to their pattern of distribution and significance as job requirement factors. T. R 23

3458

USAF. Northeastern University. VISUAL MESSAGE PRESENTATION. Contract AF 19(122) 7, Quort. Progress Rep. 15, Feb. 1953, 48pp. USAF. Northeastern University, Boston, Mass.

Included herein are reports of progress made in the various topics under active study during the period from October 15, 1952 to January 15, 1953. General consideration is given to certain methods for obtaining speech compression. One approach considered involves the coding of certain phonemes and the reduction of waveform redundancy for the rest. Treated specifically are: a) the segmentation of phonemes, b) the extraction of the pitch period, c) the use of discriminatory analysis in vowel identification, d) the linguistic assessment of the phoneme-identification approach, and e) the portrayal of the joint distribution of original speech and its delayed version. Also given are descriptions of certain apparatuses for use in speech analysis. These include: a) equipment for observing speech waveforms, b) a variable-delay speech recording and playback system, and c) R.C. tilting and delay networks. R 21

Carroll, J.E. & Schohan, B. CONSTRUCTION OF COMPREHENSIVE ACHIEVEMENT EXAMINATIONS FOR NAVY OFFICER CANDIDATE PROGRAMS. Proj. NR 154 138, Nov. 1953, 129pp. American Institute for Research, Pittsburgh, Penn.

3459

The purpose of the project reported here was to construct a new series of examination materials for measuring end-of-course achievement of students in naval officer candidate programs. Rather than mere factual information, test items were to measure "integrated knowledge" (problem-solving and decision-making ability). The examinations were administered as year-end tests to NROTC students in May 1953 and to various classes of officer candidates at the U.S. Naval School (Officer Candidate), Newport, Rhode Island. Statistical analyses, designed to evaluate the examinations given to the latter group are presented and discussed in detail. T. G.

3445

Kinkle, G.A. & Wolff, J.F. "RESPONSE GUIDANCE" AS A FACTOR IN THE VALUE OF ACTIVE PARTICIPATION IN TRAINING FILM INSTRUCTION. Contract AF 33(038) 13678, HUMAN MEMO. 36, March 1953, 18pp. USAF Human Factors Operations Research Lab., Bolling AFB, Washington, D.C. (Yale University, New Haven, Conn.).

3445

In this experiment, two alternative "participation" procedures were tested as adjuncts to film instruction. In one procedure, the "participation" (practice) materials included hints or guidance clues to assist trainees in obtaining the correct answer. The other procedure was identical except for the absence of these clues. Approximately 660 men were shown a film on the use of the slide-rule—half used the guided practice and half the unguided practice method. A test of 25 items was given to all men immediately following the film. Test data were analyzed for effect of the two practice procedures. The effect of difficulty of material and level of intelligence on the results was also studied.

Coonan, T.J., & Klemmer, E.T. READING LINEAR SCALES: THE CONTRIBUTION OF EYE MOVEMENTS TO ACCURACY. AFRCR-TN-56-8, Oct. 1956, 19pp. Operational Applications Laboratory, AFRCR, Bolling AFB, Washington, D.C.

3450

To study the relation of eye movements to accuracy in reading scales, four practiced subjects were tested in two scale reading tasks. One task allowed only a single eye fixation; the second allowed two or more fixations. Exposure duration was varied from 0.10 to 1.00 second in both tasks. A photographic record of eye-movements during the task was taken and scale-reading errors recorded. The film records were analyzed in terms of whether or not an eye movement occurred, time of occurrence, and scale position fixated. Percent error scores were analyzed as a function of exposure time for both eye movement and single fixation tests.

Goodman, S.L. WHAT MAKES FOR READABLE WRITING AND READING SUCCESS. Contract AF 18(600) 335, Res. Memo. 10, July 1953, 35pp. USAF Human Resources Research Institute, Maxwell AFB, Ala. (Division of Communications, University of Illinois, Urbana, Ill.).

3446

This report is concerned with two questions: what printed material best succeeds in carrying knowledge to man? and, what abilities, traits, etc., does man need to succeed in reading various materials? Research evidence is presented on one facet of these two problems: how readable writing relates to reading success. The various sections, each accompanied by a bibliography, are: 1) How can we measure reading success? 2) What do we know about reading success in adults? 3) What makes for readable writing? 4) How does readable writing relate to reading success? and 5) How can writing be evaluated so as to improve reading success?

Webb, Wilse S., & Nolan, C.Y. A STUDY OF THE ACTIVITIES OF AVIATION MACHINIST'S MATES IN FLEET ACTIVITIES. Contract Nonr-816(02). Tech. Rep. 1. 1953. 94pp. ONR, Washington Univ., St. Louis, Mo.

3463
This study attempts to develop a method of describing the actual job activities of Aviation Machinist Mates in the fleet in order that the Aviation Machinist Mates curriculum may be evaluated in terms of these activities. A questionnaire designed to analyze activities was constructed and administered to 216 Aviation Machinist Mate Trainees and to trainees in other schools. The results are discussed in terms of frequency of certain activities, the population's attitude toward the activities, and a correlation between trainees and experienced Machinist Mates with regard to description of job activities.

Yoder, P.R., Jr. AIMING POST REFLECTORS T1 AND T2; INSTRUMENT LIGHT PROJECTOR T16; DESCRIPTION OF MATERIEL AND ANALYSIS OF FACTORS AFFECTING FIELD USE THEREOF. Ordnance Proj. TR1-1055C, DA Proj. 513-01-006, Rep. M55-1-1, Jan. 1955, 8pp. Fire Control Instrument Center, Frankford Arsenal, Philadelphia, Penn.

3464
This report presents a detailed description of the following equipments designed for use in an aiming system for night firing with field artillery weapons: the Aiming Post Reflectors T 1 (no tint) and T 2 (red tint), and the Instrument Light Projector T 16. Each of these items is discussed in terms of the factors affecting their field utilization, their optimal efficiency, and their potential modification to increase efficiency. Abundant illustrations and diagrams are presented.

Mentzer, E.G. TESTS BY THE ANALYSIS OF VARIANCE. WADC Tech. Rep. 53 23, Jan. 1953, 48pp. WADC, Flight Research Lab., Wright-Patterson AFB, Ohio.

The Analysis of Variance procedure is described, and its possible applications and usefulness are discussed. The various statistical models and the tests by Analysis of Variance are explained. Test schemes and alternate test schemes are given (in Section VI) for all possible models of the two-factor, three-factor, and four-factor cases.

3467
Bolt, R.H., Beranek, L.L. & Newman, R.B. HANDBOOK OF ACOUSTIC NOISE CONTROL. VOLUME I. PHYSICAL ACOUSTICS. Contract AF 33(038) 20572, Phase II, Suppl. Agree. 1, CO 2, WADC TR-52 204, Dec. 1952, 397pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Bolt Beranek and Newman, Inc., Cambridge, Mass.).

3467
This handbook, comprising two volumes, is intended to provide an overall view of the noise control problem. Noise is here taken to mean only acoustic noise. This first volume is concerned with noise stimuli, their generation and control. The introductory chapter is concerned with general aspects of noise control, terminology, and measurements. Major sections are devoted to 1) noise source characteristics--specification of, aircraft engine noise, fluid flow devices, industrial machine noise, and miscellaneous environmental noise; and 2) methods of noise control.

Hertman, A.E., Randall, W.C. & Peiss, C.N. THE EFFECTS OF AMBIENT TEMPERATURE AND AIR HUMIDITY ON THE REGIONAL RATES OF SWEATING. THE ELEVENTH OF A SERIES OF REPORTS ON STUDIES ON CHANGING HEAT LOSSES. Contract AF 18(600) 96, Tech. Rep. 6680, Part II, Jan. 1953, 69pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (St. Louis University, St. Louis, Mo.).

3468
To determine the effects of ambient temperature and air humidity (Pa) on sweating responses, evaporation from skin surface and thermal balance, four resting, nude, male Ss were exposed to the following environmental conditions: 1) "varied stress" in which operative temperature (Ta) rose at a rate of 0.1 degree C per minute from an initial level of 26-33 degrees C to 41 degrees C and Pa rose to high or moderate levels; and 2) "constant stress" in which Ta (39-42 degrees C) and Pa (high or low) were pre-set to cause heavy sweating. During experimental periods of 2 to 3 hours, Ss rested in a chamber on-screen nets allowing free circulation of air and evaporation. Regional sweating rates were obtained from 20 body surface areas and total sweat output was estimated. Recommendations for future research were made. T. G. I. R 13

3470
Morse, P.M. MIT PROJECT ON FUNDAMENTAL INVESTIGATIONS IN METHODS OF OPERATIONS RESEARCH. Contract DA-19-020-ORD-2684, DA Proj. 599-01-004, Ordnance R & D Proj. TB-0001, OCH Proj. 968, MIT Proj. DIC 7125, Interim Tech. Rep. 2, April 1, 1954 through Nov. 30, 1954, 37pp. MIT.

3470
This is an interim report of the MIT project on fundamental investigations in methods of operations research. The research program is described in terms of the active and completed projects. Included are the following: equipment failure and maintenance, development of waiting line theory and computational techniques, water use in a hydroelectric system, etc. A list of operations research seminar topics is presented.

Ades, H.W., Graybiel, A., Morrill, S.W., Tolhurst, G.C., & Niven, J.I. NYSTAGMUS ELICITED BY HIGH INTENSITY SOUND. ONR Proj. Designation NONR-1553, Joint Proj. NM 13 01 99, Subtask 2, Rep. 6, Feb. 1957, 21pp. US Naval School of Aviation Medicine, Naval Air Station, Pensacola, Fla.

3471
In order to study some of the extra-auditory effects of loud noise deaf subjects are stimulated by high intensity sound, both pure tone of several frequencies (100-3000 cps) and wide band noise. In those showing positive response to vestibular stimulation in one or more standard tests, nystagmus was a regular consequence when the noise was of a sufficiently high intensity. Distinct and apparent movement in the visual field were in some cases regular concomitants of nystagmus, in others, less consistent.

Kidd, J.S., & Alluisi, E.A. RESEARCH ON HUMAN ENGINEERING ASPECTS OF AIR TRAFFIC CONTROL. Contract AF 33(616)-3612, Proj. 7132, R.F. Proj. 690, Rep. 4, April 1957, 52pp. Research Foundation, Ohio State University.

3480

Bray, C.W. (Dir.). RESEARCH PLANNING CONFERENCE ON FLEXIBLE GUNNERY TRAINING, 30 NOVEMBER - 2 DECEMBER 1950, LOWRY AIR FORCE BASE, DENVER, COLORADO. Conference Rep. 51 1, 57pp. ~~USAF Human Engineering Research Center, Lackland AFB, Tex~~

3473

This is a report of research conducted at the Wright Air Development Center on the human engineering aspects of air traffic control (ATC). Included are descriptions of operational studies of various existing ATC systems, the results of systems research on simulated ATC operations, studies on the role of such factors as lighting, visibility, etc., theoretical formulations concerning research methods, statistics, mathematical models, etc., and a description of equipment used in the study and simulation of ATC systems. R 509

3490

This is the report of a conference having the following purposes: 1) to answer four questions raised by Headquarters USAF on flexible gunnery training, 2) to familiarize HRC personnel with the current flexible gunnery training program, and 3) to review psychological research on the flexible gunner. Some details are given of research on synthetic trainers, in airborne training, and on selection of flexible gunners. Appendices include course outlines and training programs. T.

3474

Lambert, E.H., Wood, E.H., & Baltes, E.J. MAN'S ABILITY TO WITHSTAND TRANSVERSE ACCELERATION WHEN IN THE SITTING POSITION. N601 199, Rep. No. 418, Mar. 1945, 3pp. National Research Council, Committee on Medical Research, Office of Scientific Research and Development. (Acceleration Lab., Mayo Aero Medical Unit, Rochester, Minn.)

5 subjects in the sitting position have been exposed to transverse acceleration in the dorsal-ventral direction of up to and including 10 g for 3 to 10 secs. No residual harmful effects were observed in any of the subjects. During the period of exposure the pulse rate decreased and the blood content of the ear increased in all subjects in whom the head was not supported at a level appreciably above that of the trunk. Premature systoles occurred during part of the exposures in 2 subjects. All subjects noted some feeling of dyspnea at accelerations above 8 g. Distracting epigastric pain occurred in 2 subjects. This pain was decreased by supporting the hips and shoulders above the level of the cockpit floor. Recommendations are listed which should be considered if it is proposed to expose pilots in the sitting position to high transverse accelerations.

3475

Miles, W.R. A MICRO-RECORDER FOR MEASURING SKIN TEMPERATURE AND SWEATING IN AIRPLANE PILOTS. Nov. 1943, 43pp. Div. of Research, US Civil Aeronautics Administration, Washington, D.C. (Yale University School of Medicine, New Haven, Conn.).

The details for the construction of the C.A.A.-N.R.C. Micro-Recorder, its calibration and the technique of reading the records are described and discussed in this report. This instrument is designed to measure emotional responses (temperature and humidity) on exposed areas of the skin. A small watch movement is employed to drive a recording disc capable of taking records over a period of twelve hours. A temperature unit and a humidity unit with small writing levers are mounted on the inside of the instrument at a position as close as possible to the front. By means of appropriate openings in the front plate of the watch case, the sensitive elements are directly exposed to the temperature and humidity 1 cm. from the skin, while the entire unit is mounted on a ring of porous rubber sponge material. Voss, H.A. & Wickens, D.D. MEMORANDUM ON A COMPARISON OF FREE AND STADIAMETRIC ESTIMATION OF OPENING RANGE. Contract OENSR 700, Proj. N 105, Memo. 29, OSD Rep. 6114, Oct. 1945, 26pp. US Office of Scientific Research & Development, Washington, D.C. (University of Pennsylvania, Philadelphia, Penn.).

3481

Birmingham, H.P., Householder, A.S., Kappauf, W.E. & Taylor, F.V. CHECK SIGHT SCORING METHODS. Contract CENSR 815, Proj. N 111, Rep. 1, OSD Rep. 4525, Jan. 1945, 12pp. US Office of Scientific Research & Development, Washington, D.C. (Brown University, Providence, R.I.)

3479

To compare ability of the 20 millimeter gunner to estimate opening range using the reticle of the Gun Sight Mark 14 with that of the range setter using unaided vision, 183 enlisted men were divided into two groups (gunners and range setters) and given training in range estimation on the firing line over a period of three days. They were then trained and tested in estimating the opening range of 1700 yards on both torpedo and medium altitude bombing runs. Differences in range estimations between the two groups were analyzed for the various conditions of the experiment. T. G.

3481

An analysis is made of the reliability and accuracy of two procedures for check sight scoring in a situation where one man tracks in both train and elevation. Both procedures involve measuring the percent of time that the tracker keeps the target within a defined scoring circle; one is a continuous scoring based on stop-clock scoring, the other is a sampling procedure based on spaced observations and a count. Comparative tests with four laboratory people acting as scorers and a larger scale test with 45 enlisted men as scorers were made. An outline for a recommended check sight scoring procedure is given. T. G. R 2

3482

Adams, J.A. STUDY OF FACTORS DETERMINING INDIVIDUAL DIFFERENCES IN SUSCEPTIBILITY TO NEGATIVE TRANSFER EFFECTS. Proj. 21 09 002, March 1955, 3pp. State University of Iowa, Iowa City, Iowa.

3452

This is a short note stating the objectives and describing the methods of Lewis' studies of transfer in motor learning. Included are short descriptions of the Complex Coordination Test (Machburn Apparatus), the Two-Hand Coordination Test, and two versions of the Turret Pursuit Apparatus.

3483

Deese, J., Lazarus, R. & Strange, J. STUDY OF THE EFFECTS OF STRESS UPON THE LEARNING AND PERFORMANCE OF PERCEPTUAL-MOTOR TASKS (21 09 004). Co. 1955, 5pp. Johns Hopkins University, Baltimore, Md.

3483

This paper describes the background, the experimental design, and the treatment of an investigation of the effects of stress upon the learning and performance of a psychomotor task in different individuals. Fifty trials on a simple perceptual-motor task (Rotary Pursuit Test with divided attention) were administered to 280 Air Force basic trainees under five different conditions of failure stress. The performance scores are to be studied in relation to findings from the Morshach test as well as to learning.

3485

Sidorsky, R.C. & Newton, J.M. SHIP CONTROL V. THE EFFECTS OF MOTION AND NUMBER OF SURFACES ON DEPTH CONTROL WITH A CONTACT ANALOG DISPLAY. Contract NMR 2512(00), Proj. SUSIC, Electric Boat TR SPD 59 010, P59 012, Feb. 1959, 9pp. Electric Boat Div., General Dynamics Corporation, Groton, Conn.

3485

To investigate two design characteristics (the use of one versus two surfaces and effect of displaying forward motion) of the Contact Analog (CA) display in submarines, five officers controlled a simulator which incorporated a CA display and a single joystick. They were required to make 200-foot depth changes under the four different display conditions. Three performance measures (depth error at 180 seconds, greatest depth error after 60 seconds, and time within plus or minus 30 feet of the ordered depth) were studied by variance analysis for effect of displays, motion, direction of depth change, range and subjects.

3486

Gagne, R.W. EXPERIMENT ON TRANSFER OF TRAINING BETWEEN TASKS DIFFERING IN PRECISION OF MOVEMENT. March 1955, 3pp. USAF Perceptual & Motor Skills Research Lab., Lackland AFB, Tex.

3486

This is a brief description of two experiments (using 240 and 144 basic airmen as Ss) in transfer of training between tasks requiring different degrees of precision of movement. The task was a modified rudder control apparatus, and precision was varied by varying target width. Numerical results are not reported.

3488

Nunex, R.V., & Seidel, R.J. PSYCHOLOGICAL AND PHYSIOLOGICAL EFFECTS OF GUN BLAST WITH SPECIAL REFERENCE TO RECOILLESS RIFLES. Proj. DA 5502-09-010, Rep. R-1403, HE Rep. 18, Aug. 1957, 26pp. Pitman-Dunn Labs., Frankford Arsenal, Philadelphia, Penn.

3488

This report reviews the literature on general effects of gun blast which supplements a previous review (1955). Particular emphasis is given to recoilless rifles, although the information presented would pertain to all high explosive weapons engendering similar blast pressures at operator positions. Mean peak pressure, physiological effects, immediate cause of death, and lethal limits are discussed. Effects of blast on psychomotor efficiency and blast protection for the body and the ear are considered. Recommendations for further inquiries are included.

Reynolds, J.B. EXPLORATORY STUDIES WITH VARIOUS FORMS OF PSYCHOMOTOR TASKS. Proj. 21-09-004, March 1955, 3pp. HRRQ, Perceptual and Motor Skills Research Laboratory.

3490

This paper reports briefly on a method for studying the components of motor skills by examining certain psychomotor apparatus tests that have been shown to have validity for selection of Air Force specialists. Preliminary results from studies of two-hand coordination tasks are discussed along with modifications of, or new pieces of, apparatus for testing the components. The practicability of the method is discussed.

3491

Reynolds, J.B. THE NATURE OF DIFFERENCES IN PERFORMANCE BETWEEN GROUPS TRAINED WITH DIFFERENT DEGREES OF SPACING BETWEEN TRIALS. Proj. 21 09 003, March 1955, 2pp. USAF Perceptual & Motor Skills Research Lab., Lackland AFB, Tex.

3491

This is a brief description of some experiments on the effects of different degrees of spacing between trials on the acquisition of complex motor skills. No quantitative data are reported.

3492

Vanderplas, J.M. A COMPARISON OF FOUR METHODS OF MEASUREMENT OF SHAPE DISCRIMINATION. Proj. 21 09 001, March 1955, 4pp. USAF Human Resources Research Center, Lackland AFB, Tex.

3492

To determine what differences, if any, appear in the results of three methods of measuring shape discrimination, a standard set of stimuli were prepared (one standard and five comparison shapes of varying degrees of similarity). The methods were varied in manner of stimulus presentation and response data collection. Response data are analyzed and compared for the various methods. Discussion is in terms of development of a criterion method for such studies.

3495

Kappauf, W.E. NOTES ON THE DESIRED CHARACTERISTICS OF TRAINERS. Proj. N 111, Memo. 7, Jan. 1945, 8pp. Applied Psychology Panel, NDRC, Washington, D.C.

3495

This is a discussion of desired characteristics of trainers from the point of view of "... what the man is to learn," and "... the training conditions which foster most efficient learning." Discussion includes the following topics: nature and types of trainers, transfer, validity, avoidance of "secondary cues," practice, knowledge of results, guidance, motivation, and design recommendations.

3496

Kappauf, W.E. NOTES ON THE DESIGN OF PHOTOTUBE SCORING DEVICES FOR TRACKING TRAINERS. Contract OEMSR 815, Proj. N 111, Memo. 9, May 1945, 6pp. Applied Psychology Panel, NDRC, Washington, D.C.

3496

This is a discussion of the feasibility and requirements for the design of phototube scoring devices for tracking trainers. Equations for computing optimum tube aperture and target radii are formulated, and the effects of loss of sensitivity through cell degeneration are computed.
T.

3497

Kappauf, W.E. STUDIES OF THE RELIABILITY OF THE SCORING SYSTEM OF THE GUNNERY TRAINER MARK 5. Contract OEMSR 815, Proj. N 111, Memo. 12, Aug. 1945, 14pp. Applied Psychology Panel, NDRC, Washington, D.C.

3497

This report describes some studies of the reliability of the scoring system of the Gunnery Trainer Mark 5 and proposes corrections for the defects. Sample data on three-five Ss are reported, (percent hits per run). A proposed set of instructions for use of the trainer is appended.

3498

Fry, C. A., Bridgman, C. S., & Allen, M. J. THE PERFORMANCE OF CYCLOPEDIA ON EYE AND HEAD POSITIONS. March-1959. Aug. 1963. 3499. ONI, Report to the National Defense Research Committee.

3498

To study the dependence of cyclophoria on various positions of the eyes in the orbits, with respect to each other, and on positioning of the head, a series of measurements were made for a variety of conditions of stimulation of the motor mechanism of the eye, including right and left versions, convergence and divergence, elevation and depression, and accommodation. The results are presented as averages of four or five separate settings. A synoptometer, haploscope, and head position instrument were used. An examination of the data is made in terms of Listing's law and applications made to design and use of height finder and range finding. G.I.

3499

Kappert, M.E. SUMMARY OF RESEARCH ON PSYCHOLOGICAL FACTORS IN THE OPERATION OF ANTIAIRCRAFT LEAD COMPUTING DEVICES AND DIRECTORS. FINAL REPORT. Contract ONR 615, Proj. N 111, Rep. 5, OSD Rep. 5425, Sept. 1945, 12pp. Scientific Preliminary Paper, NRC, Washington, D.C.

3499

This is a summary of the work accomplished under a project on psychological problems in operation of anti-aircraft lead computing sights and directors. In addition to an historical review of the project, a brief description is given of various activities including: preparation of operating procedures for director systems, operator-oriented analysis of directors, investigation of the reliability of trainers, research on tracking training, and research on the accuracy of unaided aerial target range estimation. H 25

3500

Kohl, Jessie M. REPORT OF SOUND CONFERENCE. 14-15 JUNE 1945. 146pp. NSA Medical Research Lab., New London Submarine Base, Conn.

3500

This is a report of a conference on sound which discussed such general topics as: selection of underwater sonar operators, methods of testing auditory acuity and standardization of military pure-tone audiometry. The results of relevant research studies are presented in detail. T. G. I. R 5

3502

Lambert, E.H. COMPARISON OF THE PROTECTIVE VALUE OF AN ANTI-BLACKOUT SUIT ON SUBJECTS IN AN A-24 AIRPLANE AND ON THE MAYO CENTRIFUGE. Contract W(33-033) ac 9166, Rep. 487, Oct., 1945, 9 pp. National Research Council, Office of Scientific Research and Development, Committee on Medical Research, Committee on Aviation Medicine.

3502

This study assesses the protective value of the G-4 (Z-1) anti-blackout suit against the effects of acceleration on passengers in an A-24 airplane and on the Mayo centrifuge. Thirteen subjects provided measures of g-tolerance under various g-line patterns determined by visual decrement, blood content of the ear, and pulse rates. Results are statistically analyzed, and recommendations are made as to the protective value of the suits. F.T.

3503

Valentine, G.A. PRELIMINARY DESIGN STUDY - UPWARD EJECTION SEAT - SHORT RANGE AIRCRAFT. Contract AF 33(600)-30072, Sept. 1956, 438pp. Wright Air Development Center, AROC, Wright-Patterson AFB, Ohio. (Stanley Aviation Corp., Denver, Colo.).

3503

A study is made to define some of the problems involved in high-speed upward ejection of pilot from aircraft and to determine and evaluate as many feasible solutions to these problems as possible. Seven aspects of seat design are considered: automatic escape sequences, seat adjustment devices, restraint harness configurations, limb retention devices, thrust devices, guide rail configurations, and crash acceleration absorbers. Recommendations are made as to features to be incorporated in an emergency escape system for an 800-knot short-range aircraft. T. G. I. R 6

Berry, R.M., Brown, A.H., Head, L.C., Hafe, J.P., et al. A SYSTEM OF AUTOMATIC DEVICES FOR THE DETECTION AND RECORDING OF ERRORS IN A 105 MM HOWITZER BATTERY. Contract ONR 615, Proj. SRS 11, OSD Rep. 5313, July 1945, 14pp. Office of Scientific Research and Development, Washington, D.C. (Tufts University, Medford, Mass.).

The devices described here were designed and constructed for use in connection with a general investigation of psychological factors in the operation and design of field artillery sighting equipment. The system consists of a set of sound scribers by means of which the verbal commands are recorded on wax discs, and a set of remote (indicating) devices for scale settings on the range quadrant, scale settings on the panoramic telescope, and actual directions and elevations of the howitzer tubes. The sound recording apparatus and remote indicator dials were mounted on benches in an Ordnance Maintenance Truck and connected with various parts of the system through electric cables. (HEIAS)

3504

Silvestro, A.W., Kelly, J.B. & Courtney, D. HUMAN FACTORS CONSIDERATIONS IN THE DESIGN OF AIRPORT TRAFFIC CONTROL QUARTERS. FINAL REPORT. Contract FAA/BRD 89, Proj. P, Rep. 28, Aug. 1959, 85pp. Courtney and Company, Philadelphia, Penn.

3505

This is the third and final report of a project devoted to bringing human factors considerations to the design of airport traffic control quarters. The recommendations in all three reports represent a best approximation of the task requirements and needs of human controllers as both human beings and control specialists, and the applicable knowledge from prior human factors research. This report sets out in some detail certain elements of the over-all task: 1) console design, 2) the sit-stand chair, 3) panel layout, 4) floor covering, 5) acoustical treatment, 6) lighting, 7) color, 8) air conditioning, and 9) radiation safety and living facilities. Recommendations are supplemented with the necessary drawings.

3506

Searle, I.W. & Murry, K.L. THE RADAR NAVIGATION TRAINER. Proj. 506 006 0002, Ser. Note AC 52 5, May 1952, 15pp. Naval Research Establishment, Rockland AFB, Tex.

3506

This research note describes the details of design and construction of a radar navigation trainer for use in an experimental ground course to teach basic phases of radar navigation in preparation for training on more advanced types of radar. Radar motion pictures are the essential component of the trainer. Instructions for operation--range measurement, alignment, and steering--are given.

Senders, J.W. & Cruzen, Marianne. TRACKING PERFORMANCE ON COMBINED COMPENSATORY AND PURSUIT TASKS. Contract W 33 038 AC 19816, RDO 694 17, WADC TR 52 39, Feb. 1952, 14pp. USAF Aero Medical Lab., Wright Patterson AFB, Ohio. (USAF Aero Medical Lab. & Antioch College).

3509

To investigate the functional relationship between performance and the nature of the tracking task, various combinations of pursuit and compensatory tracking were introduced into a one-dimensional visual tracking task. Each of five subjects performed 25 trials on each of five conditions: zero, 25, 50, 75, and 100 per cent pursuit components in the task. Accuracy of performance was scored as time-on-target and analyzed as a function of per cent of pursuit component. The data were also studied by analysis of variance techniques.

This is a selected list of references from the large literature pertaining to scientific method. The references are annotated and are divided into 4 main divisions: introductory materials, historical sources, material on the philosophy of science, and, finally, works on scientific method per se. (HEIAS)

R 190(approx.)

3513 McFarland, R.A. & Moxley, A.L. HUMAN FACTORS IN HIGHWAY TRANSPORT SAFETY. ca. 1954, 295pp. Harvard School of Public Health, Boston, Mass.

Reports on 258 collision accidents incurred during the operations of a large trucking company in one year were analyzed to ascertain the relative importance of, and interrelationships between, environmental factors, vehicle condition, and factors pertaining to the drivers in causing these accidents. This analysis was undertaken in order to make specific recommendations for accident prevention, based directly on the determined causes. Type of vehicle contact, i.e., rear end, sideswipe, right angle, backing, and fixed object collisions, are analyzed separately. It is clear from the analysis that factors pertaining to the driver were predominant in causing most of the accidents. Findings are summarized in the form of specific recommendations for driver procedure and driver supervision, and for preventive measures through vehicle design and environmental control. (HEIAS)

Vaughan, J.A., MacLeod, A.R., & Iampietro, P.P. SOME PHYSIOLOGICAL RESPONSES OF MEN WEARING BODY ARMOR IN THE DESERT. Proj. 7-83-01-0040, Tech. Rep. EP-44, March 1957, 19pp. USA Quartermaster Research and Development Center, Natick, Mass.

3514

To compare the use of various models of body armor under summer desert conditions (Yuma, Arizona) and their effect on the heat stress of the active soldier, measurements of heart rate, sweat rate, and body temperature were made on 15 heat acclimatized men during moderate exercise. Three body coverage areas were compared with a control condition (standard uniform). Effective temperature (E. T.) was used as an index of environmental stress. The data were studied by analysis of variance techniques for differences due to amount of coverage and for tolerance levels.

Berkowitz, L., & Levy, B.I. PRIDE IN GROUP PERFORMANCE AND GROUP-TASK MOTIVATION. J. ~~Person.~~ Soc. Psychol., 1956, 53(3), 300-306. (ARDC Proj. 7713, Res. Rep. AFPTC-TR-57-43, April 1957. Crew Research Lab., AFPTC, ARDC, Lackland AFB, Tex.).

3515

To test the relation between pride in group performance and task motivation, 25 groups (3 subjects each) were distributed among five conditions: four representing a factorial design in which sets of either favorable or unfavorable performance evaluations were directed to the group as a whole or to individual members; the fifth was a control with no evaluations. At the end of the first work period (on a simulated Air Defense task) the subject completed a "pride in group performance" attitude scale, then had a 15-minute break. An index of concern with the group task (or task motivation) was constructed from the frequency of observed task-oriented discussion during the "break". These data were analyzed for differences due to type of evaluation received.

Slade, I.M. PROTECTION AGAINST RADIANT HEAT. Paper SM/A/2/52, Jan. 1952, 6pp. The British Iron & Steel Research Association, London, England.

3525

This paper discusses the problem of protecting steelworkers against intense radiant heat. Various types of protective clothing are reviewed and a preliminary investigation in the use of heat reflection from the outer surface of the clothing. Six samples of aluminum coated fabrics were tested for performance in reflecting heat rays and for the amount of heat transmitted. The most promising sample was further compared with asbestos and ordinary white overall material. A loose overall and apron were made from the experimental material and are undergoing tests in a steelworks. (See 4004)

Coakley, J.D., Muchmore, S.C., & Dunlap, J.W., Jr. HUMAN ENGINEERING STUDY OF OPERATING TIMES FOR COLLECTION AND REDUCTION OF METEOROLOGICAL DATA. Contract DA-36-039-SC-64647, Proj. 3-99-01-022, Final Rep., April 1957, 33pp. USA Signal Corps Engineering Labs., Fort Monmouth, N.J. (Dunlap and Associates, Inc., Stamford, Conn.).

3526

This is a human engineering evaluation of a system in which meteorological data are reduced to ballistic information. The primary evaluative criterion employed is that of time, i.e., the total time required in the performance of the various functions essential to the basic task. Operator-tasks, sub-tasks, and sub-task elements were analyzed and given time evaluations. The results are presented and discussed in terms of their relative implications for work sequences, manpower-time relations, the effects of sequencing, etc. Possibilities for further system development are carefully outlined and discussed.

Finsinger, J.E. (Dir.). THE EFFECT OF ANOXIA ON THE CRITICAL FLICKER FREQUENCY IN PSYCHO-NEUROTIC PATIENTS AND NORMAL CONTROL SUBJECTS. Contract NSORI 76, Proj. XIV 05 684, Tech. Rep. 13, May 1950, 7pp. ONR. (Psychiatry Dept., University of Maryland Medical School, College Park, N.J.).

In a series of 5 psychoneurotic patients and 5 control Ss the threshold for flicker and for fusion was measured while breathing air and while breathing a mixture of 14% oxygen and 13% oxygen. The critical fusion frequency of the control Ss was consistently higher than that of the patients in each condition of testing. Patients showed a greater decline in the mean critical frequency in cycles per sec. while breathing 13% oxygen than did the control Ss. The tentative conclusion is that patients are more severely affected by the reduction in oxygen than the control Ss.

Shands, H.C., Finesinger, J.E. PSYCHIATRIC ASPECTS OF FATIGUE. Contract NSori 76, Proj. XIV OS 664, Tech. Rep. 12, Nov. 1949, 14pp. ONR. (Harvard University Medical School, Dept. of Psychiatry and Mass. Gen. Hospital, Dept. of Psychiatry, Boston, Mass.)

This report covers an investigation of a series of well over 100 patients who complained of chronic fatigue in the absence of previous exertion or medical disease. It was found that these patients all had some type of neurosis, most prominently a neurosis associated with anxiety symptoms. The symptom of fatigue could be demonstrated to be related to acute or chronic emotional stress. The stressful situations included those commonly seen in psychiatric illness, specifically losses of important emotional relationships, pronounced changes in relationships (feelings of disappointment, rejection, guilt, etc.). The data support the hypothesis that a feeling of fatigue can be explained more satisfactorily as the conscious manifestation of a defensive inhibition of overt aggressive activity, rather than as the result of energy consumption in the past.

Finesinger, J.E. THE EFFECT OF BREATHING LOW OXYGEN MIXTURES ON A BATTERY OF PSYCHOLOGICAL PERFORMANCE TESTS IN PSYCHONEUROTIC PATIENTS AND NORMAL CONTROLS. Contract NSori 76, Proj. XIV OS 664, Tech. Rep. 11, March 1949, 16pp. ONR. (Harvard University, Medical School, Dept. of Psychiatry, and Mass. Gen. Hospital, Dept. of Psychiatry, Boston, Mass.)

A battery of psychomotor tests was administered to 31 normal control subjects and 30 psychoneurotic patients, first, while breathing 21% oxygen (sea level) and, then, while breathing 10% oxygen (18,000 ft.). The total exposure to the reduced oxygen tension was about 20 minutes, the tests being given during the latter 10 minutes of this period. The average performance in both patients and control groups dropped in almost every instance despite the counteracting effect of practice. The amount of decrement was significant at the 5% level of confidence in two instances with the patients (the Stylus Test and the Speed of Tapping Test); while with the controls, the decrement was not statistically significant in any instance. However, when the two groups were compared directly with one another in regard to the amount of change at the 10% level of oxygen, it was found that there was no significant difference between them. Both groups were also very much alike in regard to the type, frequency, and severity of physical symptoms reported.

Chase, W.P. DEVELOPMENT AND ANALYSIS OF A PROFICIENCY TEST FOR IDENTIFICATION OF ON-THE-JOB TRAINING NEEDS. Proj. 7709, Task 77156, Res. Rep. AFTRC-TN-57-28, March 1957, 40pp. Maintenance Lab., AFTRC, ARDC, Lowry AFB, Colo.

3532

To develop written proficiency tests for providing an objective means of identifying the specific training needs of individuals for K-System mechanics assigned to the Strategic Air Command, experienced mechanics and test technicians prepared an initial test outline in terms of division of knowledge into job areas. Tests were administered on trial basis to mechanics at several bases. Test results were analyzed and items reviewed with field engineers from the K-System manufacturer for items to be incorporated in an operational test. Scores from this form were studied in relation to other indices of mechanic proficiency. Another form was developed and organized into area tests. Results from both tests were analyzed to determine the best form for use.

Sulzman, J.H., Cook, E.B. & Bartlett, N.R. THE VALIDITY AND RELIABILITY OF HETEROPHORIA SCORES YIELDED BY THREE COMMERCIAL OPTICAL DEVICES. J. appl. Psychol. 1948, 32, 56-62. (USN Medical Research Lab., New London Submarine Base, Conn.)

Using 100 Ss, 3 tests for heterophoria, the Maddox rod, the Screen-Maddox rod, and the Screen and Parallax Tests, were compared. No clear-cut basis for preferring any one instrument to the other was found. No one of the 3 offered sufficient reliability to warrant the use of a fine scale for lateral or vertical phoria when the test was administered only once. Scores obtained with these 3 tests did not correlate to a satisfying degree with scores on one standard clinical test. However, reliabilities at least as great as some clinical tests now accepted and in use were found. (HEIAS)

Cook, E.B. & Wherry, R.J. A STATISTICAL EVALUATION OF PHYSICAL FITNESS TESTS. Res. Quart. Amer. Assoc. Hlth. phys. Educa., May 1950, 21, 94-111.

This study which was carried out at the Naval Submarine Base, New London, Connecticut, attempted to separate the similarities and dissimilarities underlying measurements derived from the following physical fitness tests: Behnke Step-up; Harvard Step-up; Schneider Index of Physical Fitness; and the hand dynamometer. Ss were 120 submarine enlisted candidates with an age range of 17-26 yrs; 2 groups of 6 Ss each were tested weekly during an intensive 3-day experimental period with strict regulation of their lives during this period. Statistical analysis of the data by correlational methods revealed a low correlation between the fitness tests (from -.284 to +.231). The data were further appraised by factor analysis with the following conclusions: a) There is a basic resting pulse rate which characterizes each individual and which tends to remain relatively constant during any given day with a low day-to-day stability. b) Pulse response to prolonged violent exercise is a basic physiological factor. c) Endurance time in seconds is a basic repeatable measure of individual differences. d) There is a basic resting blood pressure rate which characterizes each individual and influences his pulse reactions to exercise. e) The fitness tests varied widely in the choice of physiological functions which they actually measured, and also in the contribution of these items to final test scores. Recommendations are included. (HEIAS)

3535 Sulzman, J.H., Cook, E.B. & Bartlett, M.R. THE RELIABILITY OF VISUAL ACUITY SCORES YIELDED BY THREE COMMERCIAL DEVICES. J. appl. Psychol., June 1947, 31(3), 236-240. (Medical Research Dept., USN Submarine Base, New London, Conn.).

This note presents a summary of reliability data for the acuity scales of the Keystone "Telebinocular", the American Optical "Sight-Screener", and the Bausch and Lomb "Ortho-Rater". Also included is information on the correlation of these measures with acuity scores using standard Snellen-type letters. (HEIAS)

3536 Kreezer, G.L., Hill, J.H. & Manning, V. ATTENTION: A BIBLIOGRAPHY AND CLASSIFICATION OF THE PSYCHOLOGICAL LITERATURE. Contract AF 33(616) 135, R00 694 J1 & 694 47, WADC Tech. Rep. 54 455, Aug. 1954, 46pp. USAF Aero Medical Lab., Wright Air Development Center, Wright-Patterson AFB, Ohio. (Washington University, St. Louis, Mo.).

The following bibliography of 543 titles is based on a survey of the psychological literature on attention extending up to July 1954. The date of the earliest reference included is 1873. A classification of titles in relation to 37 subtopics in the area of attention follows the bibliography. This survey was undertaken as a basis for associated experimental studies of methods for measuring attention-demand value and experiments to determine the attention-demand value of a representative series of different kinds of stimuli.

Dorman, P.J., & Lawton, R.W. THE EFFECT OF PARTIAL SUPINATION COMBINED WITH THE ANTI-G SUIT ON G TOLERANCE IN NAVY PILOTS. A PRELIMINARY REPORT. WADC-NA-5436, W3 301 100 300, Rep. 4, TED ADC-AR-6300, May 1956, 12pp. U.S.N. Aviation Medical Acceleration Laboratory, NALC, Johnsville, Penn.

3541

To study the protection afforded by a position of partial supination (65 degrees) and the Navy 22 anti-blackout suit against positive accelerative forces, a total of 305 runs (human centrifuge) on nine trained centrifuge subjects and 24 Navy pilots was performed. The end point for terminating a run was grayout (peripheral light loss) and criterion of success was tolerance of a seven G stress for thirty seconds. All subjects were given runs in the upright position, those failing were given runs as follows until successfully meeting criterion: upright position with anti-blackout suit, partially supine position, and partially supine position with anti-blackout suit.

Gottfried, A., & Ikraht, K. EVALUATION OF INTERFERENCE EFFECTS ON SPEECH COMMUNICATIONS. SC Proj. 132A, DA Task 3-93-12-021, Tech. Memo. R-1748, March 1956, 7pp. Signal Corps Engineering Laboratories, Communications Dept., Fort Monmouth, N.J.

3542

An objective method (whistle-point) for determining the gain of a communication system under actual operating conditions is described. The method can be utilized for determining the desensitization of receiving equipment caused by radio frequency noise. The use of this method for obtaining true signal-to-noise ratio measurements at the output of a receiver is discussed. A standard speech test signal is suggested for intelligibility evaluation by means of the articulation index.

Varplanck, W.S., & Bishop, C.K. FIELD TEST OF OPTICAL INSTRUMENTS: FURTHER RESULTS. ONR N6ori-180, T.O., III, NR 143-292, June, 1950, 92 pp. ONR, (Indiana Univ., Dept. of Psychol.)

3544

To validate laboratory data on visibility of targets and nomographs based on the data (Tiffany Foundation), to determine the reliability of individual performers, and to relate the results to several evaluative tests for predicting visual efficiency, selected data from the research on Field Tests of Optical Equipment (performed at U.S. Submarine Base, New London, Conn., 1945) were analyzed statistically. A series of measures of the coefficient of atmospheric attenuation were derived with recommendations concerning the usefulness of the nomographs. The findings on individual differences are discussed with recommendations for further research to precede development of new visual efficiency tests.

Gebhard, J.W. ACCURACY OF ALIGNING THE MOVABLE RANGE MARKER WITH BLIPS ON THE PLAN-POSITION INDICATOR. Contract NSORI 166, Rep. 166 I 46, Aug. 1948, 53pp. USN Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Baltimore, Md.).

3546

To determine the accuracy of aligning the movable range marker on the rotating sweep of the Plan Position Indicator (PPI) with blips (targets) on a 20-mile sweep, four experiments were performed. Signals were displayed on the experimental PPIs (W 12-inch, TDT (Target Designation Transmitter) seven-inch, and BRI (Bearing and Range Indicator) five-inch displays), and a VF precision indicator used for making measurements. Errors (degree and direction of discrepancy between target and marker on the VF) are expressed in yards and analyzed in terms of the variables studied. Scope size, blip size, and type of equipment are discussed. T. G. I. R 9

3547

Gebhard, J.W. SOME EXPERIMENTS WITH THE VF AIDED TRACKING EQUIPMENT. Contract NSORI 166, Proj. NR 784 001, Rep. 166 I 53, Sept. 1948, 30pp. USN Special Devices Center, Port Washington, N.Y. (Psychological Lab., Institute for Cooperative Research, Johns Hopkins University, Baltimore, Md.).

3547

To compare tracking performance of radar operators using VF aided tracking equipment with manual tracking (centering the 2-scope presentation on a target by estimating course and speed and settling in an anticipated bearing and range displacement), three commonly occurring tasks were chosen. Experienced radarman were tested on each task using both methods. Error data were analyzed for differences due to tracking methods. T. I. R 4

3548

Gebhard, J.W. SPEED AND ACCURACY OF OPERATING THE TARGET DESIGNATION-TRANSMITTER MARK 11 MOD 1 AND THE BEARING AND RANGE INDICATOR MARK 3 MOD 2. Contract NS ORI 166, TO I, Proj. NR 784 001, Rep. 166 I 66, N.v. 1948, 37pp. USN Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Baltimore, Md.).

3548

To determine the speed and accuracy with which radar operators can designate bearing and range information with Target Designation Transmitters (TDT-11) and receive it with Bearing and Range Indicators (BRI-3), two sets of data were obtained from six operators: 1) speed and accuracy required to locate a randomly assigned target, to set controls and to contact a BRI; and 2) speed and accuracy required to match dial pointers by arranging controls, to locate and adjust on target, and to signal direction. The results were evaluated in terms of the proficiency of these equipments in acquiring high speed targets. T. I. R 3

3549

Gebhard, J.W. TARGET CODING BY MEANS OF VISUAL FLICKER. Contract NSORI 166, T.O.I., Proj. NR 784 001, SDC Rep. 166 I 68, Oct. 1948, 5pp. USN Special Devices Center, ONR, Port Washington, N.Y. (Psychological Lab., Institute for Cooperative Research, Johns Hopkins University, Baltimore Md.).

This memorandum deals with the technical aspects of flicker coding from the psycho-physical point of view together with an estimate of the labor required to carry out further necessary investigation. The chief variables that assume practical importance for coding by flicker are considered: intermittency of target, intensity of target, area of retina stimulated, light-dark ratio of cycle, and flicker patterning. (HEIAS)

3550
Garner, W.R. AUDITORY SIGNALS. Contract NS ori 166, T.O.I., Proj. Design. NR 784 001, SDC Rep. 100 I 71, Jan. 1949, 30pp. ONR, USN Special Devices Center, Port Washington, N.Y. (Systems Research, Institute for Cooperative Research & Psychology Lab., Johns Hopkins University, Baltimore Md.).

The problems and uses of auditory signals are surveyed. Auditory signals are a form of display, but are usually characterized by being discrete in time, and some action is assumed on receipt of the information. Whenever a communications situation is concerned with a limited kind of information, an auditory signal can be used to provide a fast indicator of what to do. They are also useful as a substitute for visual displays when the visual load on an operator becomes too great. A chief advantage of the auditory signal is that the transmission of information can be completely automatic. 2 systems, the radio range and the flybar, were used to illustrate the type of research done on these problems. Research on simple and complex discrimination, stimulus interactions, auditory localization, psychological scaling, and auditory illusions appears to be most profitable with respect to possible applications to the problems of auditory signalling. Coehard, J.V., Barber, J.L. & Halsey, R.Z. SIMULATED DISPLAY OF BEARING AND RANGE IN RECTANGULAR COORDINATES. Contract NSC 166, T.O. I, Proj. Design. NR 784 001, Tech. Rep. SDC 166 1 81, May 1949, 12pp. USN Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Institute for Cooperative Research, Psychology Lab., Baltimore, Md.).

Several experiments were conducted to determine the speed and accuracy with which target position can be read from an experimental display of radar bearing and range information in rectangular coordinates in which 360° of bearing were given on the x-axis and 40,000 yards of range were shown on the y-axis. A rectangular scope, produced by modifying a VD radar indicator, was first compared with a PPI with respect to accuracy of aligning a movable range marker with blips. The rectangular display was found to produce smaller alignment errors than the PPI, and to be free from the effect, present in PPIs, of greater error with longer ranges. The factor of target length had no effect on accuracy for the experimental display whereas on the PPI arc length interacts strongly with target range in determining alignment error. Several bearing grids were tested on a simulated rectangular display for the purpose of selecting the most suitable design. Bearing scales marked in intervals of 20° were found superior to those marked in intervals of 30° as measured by speed of reading and bearing error when visual estimations of target position were made. Size of display had no effect on either speed or accuracy, nor did different starting points of the bearing scale. It is concluded that a rectangular display is as efficient as, and in some respects superior to, a PPI for estimating target position. Its adaptability for displaying information for tactical evaluation is questionable due to the presence of distortion.

Chapanis, A. SOME ASPECTS OF OPERATOR PERFORMANCE ON THE VJ REMOTE RADAR INDICATOR. Contract NSC 166, T.O. I, Proj. Design. NR 784 001, Tech. Rep. SDC 166 1 91, June 1949, 50pp. USN Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Psychology Lab.)

2 experiments were performed to determine how well operators could extract bearing and range information from the VJ remote radar indicator when they used it in different ways. In general, speed is inversely related to accuracy. Those conditions which make for less speed are more accurate and vice versa. Also, an overwhelming amount of evidence is presented to show that the VJ and VF are inherently unstable from an electronic standpoint. (HEIAS)

Jerison, H.J., & Wallis, R.A. EXPERIMENTS ON VIGILANCE: ONE-CLOCK AND THREE-CLOCK MONITORING. Contract AF33(616)3404, Proj. 7193 71610, WADC Tech. Rep. 57 266, April 1957, 34pp. WADC, Wright-Patterson AFB, Ohio. (Aero Medical Laboratory; Antioch College, Yellow Springs, Ohio).

2 experiments on prolonged monitoring of Mackworth-type clocks are reported. In one experiment with 36 subjects a single clock was monitored. It was found that performance dropped from about 90% of the signals found to about 50% during the first half hour of work, and that the performance drop appeared to be continuous. In a second experiment, 11 subjects each monitored a panel of 3 clocks. Their performance curve appeared to be flat, but it seems likely that a rapid decrement from the 45% to the 27% level occurred during the first three minutes of work. These results are discussed in terms of the present state of knowledge about the human operator as a monitor and in terms of recommendations that have been made in the past concerning limitations of length of watches for monitors in order to maintain their efficiency.

R 10

3558 Gebhard, J.W. & Blodau, E.A. APPRAISAL OF AN EXPERIMENTAL PLAN POSITION INDICATOR PRESENTING SIMULATED BEARING, RANGE AND HEIGHT INFORMATION. Contract NS-ori-166, T.O. 1, SDC Rep. 166 I 37, Dec. 1947, 53pp. ONR, USN Special Devices Center, Port Washington, N.Y. (Systems Research Field Lab., Johns Hopkins University, Baltimore, Md.).

Two experiments were performed to appraise a conventional polar coordinate display modified to present bearing, range and height information. The display consisted of a PPI surrounded by an annulus. The first experiment measured the speed and accuracy with which operators could extract bearing, range, and height information from the display on 3 remote repeaters. The average time per target required on either a VJ with working error on the VC was 1.5 and on both VJ's, about 1.5. Average range error on a 40-mile scale was a 3 mile for all indicators. Average height error on a 40,000 ft. scale was a 500 ft. The second experiment measured speed and accuracy of target estimation for the display on a VJ, VJ, VJ, and VG. Average time per target was about 7 sec. Average range error on a 40-mile scale was about 1/2 mile, and the average height error on a 40,000 ft. scale was about 700 ft. (HEIAS)

3559 Lipschultz, H.L. & Sandberg, K.O.W. TARGET INDICATION AS A FUNCTION OF INSTRUCTION. Contract NSORI 166, Rep. 166 I 34, Nov. 1947, 22pp. USN Special Devices Center, Port Washington, N.Y. (Industrial Engineering Lab., New York University, New York, N.Y.).

3559 To determine the accuracy and speed with which a radar operator can indicate targets under three sets of instructions (for accuracy, for speed, and both accuracy and speed), five operators used two different methods to obtain readings on a search radar: 1) with continuous antenna rotation and the aid of a bearing cursor and movable electronic range ring on the PPI, and 2) by stopping antenna rotation on target and reading bearings from the relative bearing dial and ranges from the A-scope. Time and error data were analyzed with respect to both instructions and methods. Procedures to improve performance were discussed. T. G. I.

3560 Sandberg, K.O.W., & Lipschultz, H.L. A SURVEY OF THE IMPORTANCE AND USE OF CONTROLS AND DISPLAYS ON RADAR CONSOLE PANELS (A CONTRIBUTION TO PANEL LAYOUT). Contract NS-ori-166, T.O. 1, SDC Rep. 166 I-17, July 1947, 21pp. SDC, New York University, Industrial Engineering Laboratory.

3560 To determine, on the basis of importance and use, a sequence of priority considerations for the design and placement of controls and displays on the face of the radar console, four methods were considered and illustrated with an application to the SG-1b (Model 50) radar. These methods were: (1) an analysis of procedure under different operating conditions, (2) analysis of one operating condition which included times of elementary motion groups, (3) two group interviews (opinion) of thirty Navy personnel each, and (4) secret poll of six other personnel. The pooled results from these methods yielded a ranking of controls and displays on the basis of importance and use. T. I.

3561 Leyzorek, R. MOUNTING ANGLE OF A VJ REMOTE RADAR INDICATOR AND ITS EFFECT ON OPERATOR PERFORMANCE. Contract NSORI 166, Rep. 166 I 41, Feb. 1948, 13pp. Systems Research Lab., Johns Hopkins University, Jamestown, R.I.

3561 To investigate the effect of mounting angle of radar indicator on operator performance, seven experienced operators read bearing and range information from a VJ remote radar indicator mounted at seven angles (scope-face with respect to floor: 0, 15, 30, 45, 60, 75, and 90 degrees). Accuracy and speed scores were analyzed to discover whether there is an optimum mounting angle. A preference questionnaire was given to the operators and rank-order of the various angles was calculated on these results. Operator differences and practice effects were discussed. T. I. R 1

3562 Gebhard, J.W. DETECTION OF NEW TARGETS ON A CATHODE RAY TUBE (PPI-PRESENTATION) WITH AND WITHOUT AN ASSOCIATED AUDITORY SIGNAL. Contract NS-ori-166, T.O. 1, SDC Rep. 166 I 10, Feb. 1947, 9pp. ONR, Special Devices Center, Port Washington, N.Y. (Systems Research Field Lab., Jamestown, R.I.).

2 experiments were performed to determine whether the detection of a new target appearing on a radar plan position indicator (PPI) could be improved by synchronizing an auditory signal with the new blip. In the first experiment, 10 faint targets were presented on a PPI, and after one sweep of observation an eleventh one appeared. In the second, 10 saturated targets were presented among complex land and open sea returns, and after one sweep of observation an eleventh one appeared. The operators identified and reported the new targets upon discovery. The results of both experiments showed that detection of new targets accompanied by an auditory signal was accomplished without error, whereas targets searched for by visual means alone were found only half the time. No practical use can be made of the results of this experiment at the present time. It would in fact, not be possible for engineering reasons, to employ the experimental procedures in an operational situation. The experiment was done, however, as a preliminary test of a principle which might lead to the conduct of other experiments from which practical results can be expected.

3563 Reed, J.D. & Bartlett, N.R. COMPARISON OF MANUAL AND STANDARD METHODS OF TARGET INDICATION. Contract NSORI 166, Memo. Rep. SDC 166 I 9, Feb. 1947, 10pp. USN Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Baltimore, Md.).

3563 To compare two methods of target indication from a radar presentation, four operators performed two tasks on a simulated search radar: 1) estimated range and bearing of target with the aid of a bearing cursor and range marks were reported verbally, and 2) indicated target position by use of a pointing device attached to a pantograph. Targets were presented in varying numbers (five to thirty) on three sizes of scope (7, 10, and 20 inches). The results were given in terms of accuracy and speed scores for both methods. An error analysis was made. Effects of scope size and number of targets was discussed.

Williams, S.B. & King, E. THE EFFECT OF CRT BIAS ON VISIBILITY OF TARGETS ON A REMOTE PPI. Contract N5 ori 166, T.O. 1, Memo Rep. 166 I 6, Dec. 1946, 12pp. ONR, Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Psychological Lab. & Electrical Engineering Lab., Baltimore, Md.).

The cathode ray tube of a VD remote PPI indicator has an optimal bias level with respect to target visibility. Every experiment in which CRT bias was varied yielded a curve of visibility with a maximum lying somewhere between the lowest and highest intensity (CRT bias) settings. In all cases maximum visibility was obtained with a moderately bright, light-yellow background, that is, with a comparatively low bias, and not with the dark or high bias background frequently employed by trained operators. The exact specification of this optimal level in volts or in units of illumination is not yet possible with existing measuring instruments. However, it can be fairly well defined visually. The experiments illustrate the difficulties of measurement and the methods employed.

Chapanis, A. ACCURACY OF ORAL TRANSMISSION OF TARGET INFORMATION. Contract N5 ORI 166, Task Order 1, Memo. Rep. 165 I 5, Dec. 1946, 12pp. Systems Research Field Lab., Johns Hopkins University.

3566

To measure the speed and accuracy with which target (bearing and range) information can be transmitted orally over sound-powered telephones, teams of two men were employed in a total of 84 experiments. Target bearings and ranges were read at rates of four to 16 per minute and for various durations ranging from ten to 60 minutes. Tape recordings were analyzed for errors due to (1) talker versus recorder, (2) number of targets per minute, (3) successive work periods, and (4) subject differences.

Garner, W.R., Hanes, R.M. & Reed, J.D. CALCULATION OF BEARING AND RANGE ERRORS DUE TO DELAYS IN TRANSMISSION OF RADAR INFORMATION. Contract N5 ORI 166, Task Order 1, 166 I 11, Feb. 1947, 24pp. Psychological Lab., Johns Hopkins University.

3570

This report deals with the errors to be found in reported target position which can be attributed to delays in reporting range and bearing information from radar positions. In order to show the magnitude of these errors, and also to facilitate the calculation of maximum allowable delays, for any given set of conditions, mathematical formulae are derived for the calculation of errors in range and bearing due to time delays in transmission of information. Descriptive and summary graphs are presented showing the interactions of several conditions.

Chapanis, A. SPEED OF READING TARGET INFORMATION FROM A DIRECT-READING, COUNTER-TYPE INDICATOR VERSUS CONVENTIONAL RADAR BEARING-AND-RANGE DIALS. Contract N5 ori 166, T.O. 1, Memo Rep. 166 I 3, Nov. 1946, 12pp. ONR, Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Systems Research Field Lab., Jamestown, R.I.).

This experiment measured the time required by operators to read bearing and range information from 4 types of standard Navy radar equipment (the SG and SR radars and VF and VJ remotes), and from a direct-reading, counter-type bearing and range indicator of experimental design. The results show that the experimental indicator enables operators to read bearing and range information in about one-half the time required for similar readings from the 4 standard units. The data also show that the fewest number of errors occurred in target information read from the experimental indicator. Most of the errors made in reading target settings from the radars occurred in the bearing information.

Garner, W.R. SOME PERCEPTUAL PROBLEMS IN THE USE OF THE VG REMOTE PPI. Contract N5 ORI 166, Task Order 1, 166 I 2, Sept. 1946, 34pp. Systems Research Field Lab. & Psychological Lab., Johns Hopkins University.

3568

This report is one of a series concerned with a study of the VG, a radar remote indicator of the plan position type which uses a two-mirror system of reflection and projection to obtain a presentation 25 inches in diameter. An analysis was made of the perceptual problems involved in the use of the radar. Two experiments, using six Navy radar operators, were run (1) to compare the efficiency of plotting directly on the VG with that of a plotting table and (2) to test the use of the VG for obtaining range and bearing information about targets for the purpose of locating directors on targets.

Garner, W.R. A STUDY OF FACTORS AFFECTING OPERATION OF THE BG REMOTE PPI. Contract N5 ori 166, T.O. 1, SDC Rep. 166 I 1, Aug. 1946, 33pp. USN Special Devices Center, ONR, Port Washington, N.Y. (Psychological & Systems Research Field Labs., Johns Hopkins University, Baltimore, Md.).

This study determined the effects of various electronic and optical factors on the operation of the VG. Among these factors were: video gain, CRT bias, the limiting of PPI adapters, use of a higher accelerating voltage on the CRT, the type of viewing screen, and the intensity of the reflected light. An analysis of the operation of the VG was made in terms of detectability (ability of the targets to be seen), variability of detectability scores, and discriminability (ability of targets to be distinguished from each other). Each of these factors was studied separately and in relation to the other factors. 6 radar operators served as Ss. Detectability was measured by having S search continuously on a clear field while target intensity was increased 1 db/antenna sweep. Discriminability was measured by having S indicate when 2 concentric lines appeared to be separate as they moved around the scope. (HEIAS)

3571 Bartlett, H.R. & Sweet, A.L. THE AGREEMENT IN RANGE AND BEARING REPORTS FROM TWO VF RADAR REPEATERS TRACKING THE SAME TARGET SIMULTANEOUSLY WITH THE B-SCOPE. Contract NS or 166, Memo. Rep. 166 1.12, Feb. 1947, 11pp. ONR, Special Devices Center, Port Washington, N.Y. (John Hopkins University, Baltimore, Md.).

The error indices for stationary targets deviated from the Preliminary Instruction Book. 56% of the bearing reports from 2 VF repeaters were in exact agreement for a stationary target, and in no case was the disagreement greater than one degree. With respect to range reports, 19% were in exact agreement, 56% agreed within 20 yards, and all reports agreed within 100 yards. When contacts are moving, however, these data are not appropriate. For example, for targets with a relative speed of 80 knots, only 39% of the bearing reports were in exact agreement, and only 41% of the range readings agreed within 100 yards. The agreement between two VF reports decrease markedly as the speed of a target is increased. Therefore, the reliability of a single report of the position of a contact depends upon the relative motion of that contact with respect to the position of the radar.

3575 Gaito, J. HUMAN ENGINEERING INVESTIGATIONS OF AIRCRAFT COCKPIT VISUAL DISPLAYS: THE CHOICE OF SUBJECTS IN DIAL LEGIBILITY EXPERIMENTS--A METHODOLOGICAL STUDY. Proj. TEP NAM AE-7047, Part IV, Rep. NAMC-ACEL-316, Feb. 1957, 12pp. Air Crew Equipment Laboratory, Naval Air Experimental Station, NAMC.

3575 To investigate the validity of extrapolating results of an experiment based on one population to other populations, a paper and pencil test on aircraft clock designs was administered to 127 experienced naval pilots, to 60 naval non-pilot aircrewmen, and to 55 naval non-aircrewmen. Using mean number of errors and mean time per reading as criteria of legibility, differences among the three samples were analyzed by various non-parametric statistical techniques. Differences studied were speed, accuracy, and relative effectiveness of the various clock designs. Implications of the findings for experimental research are discussed.

3578 Bisom, J., & Keith, Lela. INJURY RATES IN NEW YORK STATE INDUSTRIES, 1955. Publ. B-94, Nov. 1956, 23pp. Division of Research and Statistics, Department of Labor, State of New York.

3578 This is a summary of the results of the fourth annual survey of injury rates by the Division of Research and Statistics of the State Department of Labor in cooperation with the United States Bureau of Labor Statistics. Requests for work injury information were sent to approximately 53,000 factory establishments. Replies were received from 33,000 representing over 3/4 of all manufacturing employees in the state. Injury-frequency rates (number of disabling injuries per million employee-hours worked) and injury-severity rates (number of days lost per million employee-hours worked) were computed. These rates are given for type and size of establishments and comparisons made with previous records.

Rowland, W.M. A STUDY OF METHODS OF GUN SIGHTING AT EXTREMELY LOW LEVELS OF ILLUMINATION. Contract N6ori 199, Sept. 1942, 4 pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The possibility of accurate gun sighting at illuminations below the foveal threshold was investigated. 27 experienced Ss were used. It was found that by proper use of the paracentral retina it is possible for trained observers to sight a gun at a dark object seen against a background the brightness of which is considerably below the foveal threshold, and to shoot with a moderate degree of accuracy. Illuminated sights are not as satisfactory at very low levels of illumination as ordinary sights. (HEIAS)

3585

Brown, J.L., Kuhns, Margaret P., & Adler, H.E. RELATION OF THRESHOLD CRITERION TO THE FUNCTIONAL RECEPTORS OF THE EYE. J. opt. Soc. Amer., 1957, 47(3), 198-204. (Contract AP 33 (038)-22616. Aero Medical Lab., WADC ARDC, Wright-Patterson AFB, Ohio. Columbia University).

3585

This study was designed to assess the effect of increasingly higher order luminance thresholds upon the transition from rod to cone function as reflected in performance of a series of visual tasks. Utilizing the Hecht-Schlaer adaptometer, luminance threshold measures were made in the dark adapted eyes of two subjects with eight color and some neutral tint filters. Seven gratings requiring visual acuities from 0.042 to 0.625 were employed. The results are presented and discussed in terms of the threshold luminance as a function of change in visual acuity requirements. The character of the visual function is described and the implications of the research related to situations in which the dark-adapted individual must read visual displays at higher levels of illumination. 3586

Lipschultz, H.L. & Sandberg, K.O.W. A STUDY OF ALIGNMENT ERRORS BETWEEN THE BEARING CURSOR AND ANTENNA TRACE ON THE PPI OF THE SG-1b (MOD.50) RADAR. Contract N5-ori 166, Memo Rep. 166 I 20, July 1947, 5pp. ONR, Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Systems Research Field Lab., Jamestown, R.I.).

The bearing cursor and the antenna trace of the PPI on the SG-1b (Mod. 50) radar are often found to be non-coincident. This report summarizes the results of a study on the alignment of the cursor and of the antenna trace under various conditions. No change in alignment between the antenna trace and bearing cursor was observed after the equipment was in the "on" position for a 6-hour period. Slight changes in alignment were observed after the equipment had been in "stand-by" condition overnight. Larger changes in alignment were observed as a result of movement of the chassis in and out of the console. Computations from these data show the maximum bearing errors resulting from misalignment.

3587

Gebhard, J. & Newton, K.V. BRIGHTNESS OF CREASE PENCIL MARKS ON A VERTICAL PLOTTING BOARD. Contract N5 ori 166, Memo Rep. 166 I 23, July 1947, 11pp. ONR, Special Devices Center, Port Washington, N.Y. (Johns Hopkins University, Systems Research Field Lab., Jamestown, R.I.).

The brightness of marked and unmarked positions on 2 vertical edge-lit plotting boards was measured with a Macbeth Illuminometer. 1 board was a Square Knock-down type at the Field Laboratory, the other was a Mark 4 Mod. 1 modified by the removal of the rear sheet of plastic. The upper seven-eighths of the boards was quite evenly illuminated. Near the base, about 8 in. from the lights, there was a sharp rise in brightness. Marks placed at the bottom of the board were about 5 or 6 times brighter than those near the top. On the Square Knock-down board the marks were about 5 times as bright as those on the modified Mark 4 board examined. China-marking pencils in white and yellow produced marks about 50-60 times as bright as the unmarked board. Other colors were relatively very dim. More light was reflected upward from a mark than in any other direction. If both sheets received the same amount of light from the lamps, marks placed on the front and rear of the board were about equally bright. The brightness of the lines etched into the plastic was about the same as a yellow grease pencil mark. A heavily marked up board contributed little to general room illumination. Over the range of 100 to 120VAC a change of 1 volt across the lamps produced a change in the brightness of a mark of about 0.5 apparent foot candles.

3588 Bartlett, N.R. TARGET INDICATION FROM THE PPI OF THE SG-1b (MOD 50) RADAR. Contract NSORI 166, SDC 166 I 24, Sept. 1947, 50pp. ONR, USN Special Devices Center, Port Washington, N.Y. (Systems Research Field Lab. & Psychological Lab., Johns Hopkins University, Baltimore Md.).

4 radarsmen served as operators in an experiment measuring the effectiveness of target indication from PPI. Measures were made with respect to the number of simultaneous raids, antenna rotation speed, and the use of reading aids such as the bearing cursor and range trace. A 10 min. "battle problem" was conducted with each SG. The following conclusions were reached: a) in general, higher rotation speeds are to be preferred to lower speeds, for they do little harm and may do some good. 10 rpm is about maximal for advantages of the higher speed. b) The limitation of the maximum frequency of reports than can be obtained in the traffic-handling capacity of the operator. All other factors are minor. c) There is little merit or disadvantage to the use of the bearing cursor. When used with the range trace, the bearing cursor increases slightly the frequency of reports; when used alone, it decreases them slightly. d) Most of the facts were definitely in favor of the range trace, and only one--the cost in time to use it--is against it definitely. (HEIAS)

3591 Chapin, A. THE RELATIVE EFFICIENCY OF A BEARING COUNTER AND BEARING DIAL FOR USE WITH PPI PRESENTATIONS. Contract NS ORI 166, Memo. Rep. 166 I 26, Aug. 1947, 15pp. ONR, Special Devices Center, Port Washington, N.Y. (Systems Research Field Lab., Johns Hopkins University, Jamestown, R.I.).

In a continuation of earlier work on this problem, a direct-reading bearing counter was constructed and mounted on a VJ remote radar indicator so that this method of exhibiting the bearing of targets could be compared with that of the bearing dial normally used for the purpose. An experimental placement of the range counters, above the PPI and directly to the right of the bearing counter, was also tested. The first experiment measured the speed and accuracy with which radar operators can locate a target appearing on the PPI, adjust the bearing cursor and movable range rings to the position of the target, and read the bearing and range rings to the position of the target, and read the bearing and range of the target from each of 4 different combinations of the bearing counter, bearing dial, and 2 range counters. The results show that, on the average, an operator can perform this sequence of operations 1.7 sec. (13.3%) faster per target when he reads bearings from the counter rather than from the dial. There were fewer serious bearing errors in readings from the counter than in those from the dial. Further analysis of the data shows that the increased speed in performance with the bearing counter was not obtained at the expense of accuracy in operating the equipment. The second experiment compared the bearing counter and dial in terms of the speed with which settings could be reproduced on the 2 types of indicators. The bearing dial proved to be superior to the counter for this type of operation. Taken in conjunction with the data of the earlier study on this problem, these experiments indicate that a direct-reading counter is more efficient than an annular scale for presenting bearing information which must be read from an instrument. The counter-type indicator, however, is less efficient if settings must be reproduced on set into the equipment. R 8

3589 Reed, J.D. & Bartlett, N.R. THE ACCURACY OF RANGE ESTIMATION ON A PPI WITH RESPECT TO THE DISTANCE OF THE TARGET FROM RANGE RINGS. Contract NS ORI, Memo Rep. 166 I 29, Nov. 1947, 9pp. Johns Hopkins University, Baltimore, Md.

3589 To investigate the relation between accuracy of range estimation of radar targets and the proximity of targets to the range ring, four radar operators estimated the location of targets on simulated Plan Projection Indicators. Factors varied were scope size (7-, 10-, and 20-inch diameters), target size (6 and 20 degrees), and target number per trial (5, 10, and 20). Errors of estimation (accuracy) were analyzed with respect to distance from nearest range ring, distance beyond the next smaller range ring, frequency with which certain criteria of accuracy can be expected, and scope size.

3590 Williams, S.B. THE SEARCH FACTOR IN DETECTING WEAK RADAR TARGETS. Contract NSORI 166, Memo. Rep. 166 I 28, July 1947, 11pp. Johns Hopkins University, Baltimore, Md.

3590 To study the relation between size of search area and speed of target detection on radar scopes, a series of detectability (first appearance of weak signal of gradually increasing intensity) measurements were made. The variables were area of search (entire scope to an area 3/4 by 3/16 inches), scope size (5, 7, and 25 inches in diameter), signal size (20 and 10 degrees lobe width), and noise or noise-free background. Detectability scores (db of signal voltage) were analyzed as a function of search area, target size, and noise background. Implications for radar practice were discussed.

3592 Sweet, A.L. & Morgan, C.I. COMPARISON OF THE CENTER-VERSUS-LEADING EDGE OF THE TARGET PIP IN RANGE DETERMINATION BY THE VF REMOTE RADAR INDICATOR. Contract NS ORI 166, Memo. Rep. 166 I 25, July 1947, 11pp. Johns Hopkins University, Baltimore, Md.

3592 To compare two methods of range determination on a radar scope, two experiments were performed. In both the stationary targets signals were sent through the SG radar to two VF indicators 1) where it was detected simultaneously by operators using each equipment either by using the leading edge or center of pip method and 2) where range measurements were made with one VF calibrated to the center of the pip and the other to the leading edge. The data were analyzed by computing the discrepancy between actual range and reports from the VF's. Differences in accuracy for the two methods were analyzed.

3593 Cookley, J.D. (Proj. Dirac.). THE EFFECT OF HEAT UPON THE PERFORMANCE OF MEN IN HIGH SPEED AIRCRAFT: A CRITICAL REVIEW. Proj. 20 H 16, Rep. 151 1 17, June 1948 107pp. USN Special Devices Center, Port Washington, N.Y. (Psychology Corporation, Division of Bio-Mechanics, N.Y.).

The effect of high temperature upon human performance is examined by means of a review of the relevant literature. The problems provided by high temperature for airplanes that fly at high speed are outlined. The thermal zone in which men feel comfortable is described, as well as thermal zones which cause deterioration in performance. Very high temperatures, combined with other adverse conditions, affect various aspects of human behavior. "Normal" performances on moderately complex tasks may be observed at effective temperatures up to about 85°F. As measured by the willingness of subjects to expose themselves to heat, 120°F is tolerable for an hr., 107°F for 2 hrs., and 95°F for 4 hrs. with severe humidity. (MC1A5) R 105

3594 Gebhard, J.W., DeGroot, S.G., & Glickman, R.W. THE INTERPRETABILITY OF PLOTTED INFORMATION ON POLAR-COORDINATE DISPLAYS. Contract N55R1 166, Proj. Des. NR 507 470, Rep. 166 1 152, July 1952, 7pp. Johns Hopkins University, Baltimore, Md.

3594 To investigate the intelligibility of plotted information; information on friendly and enemy targets was plotted in a simple code (shape) on 24-inch polar-coordinate displays, photographed, made into slides, and presented to five trained observers. The time taken to answer oral test questions was measured and analyzed for influence of (1) number of tracks in a sector (4 to 20), (2) length of past history in the tracks (three and ten minutes with and three minutes without time notations), (3) position on display (east, south, and west sectors), and (4) observers. The need for further study using dynamic displays is discussed. T. G. I.

3595 Hollander, E.P. CONDITIONS AFFECTING THE MILITARY UTILIZATION OF PEER RATINGS: THE NEWPORT STUDY I. RELIABILITY. Contract NMR 760(06), Tech. Rep. 1 56, Jan. 1956, 21pp. Psychological Labs., Carnegie Institute of Technology, Pittsburgh, Penn.

3595 To determine the reliability of peer ratings under various instructional sets and time exposures, 23 trainee sections at the Naval Officer Candidate School (OCS) in Newport were studied over a 16-week period. Four basic sociometric forms of the peer nomination variety were used. All sections were given a primary form calling for "success as a future Naval officer"; also, each section received one of three secondary forms--"leadership qualities," "interest and enthusiasm in Naval service," and "probability of success in OCS." Approximately half of the sections were given a "for research purposes" set the other half "for administrative purposes." Peer ratings were made at the end of 3, 6, and 13 weeks. Both internal consistency of scores and relationship over time were analyzed. T. R 15

3597 McCleary, R.A., & Morgan, C.T. GEAR-RATIOS FOR CURSORS OF PPI'S. Tech. Rep. SDC 166 1 96, June 1949, 5pp. ONR, Special Devices Center, Port Washington, N.Y. (Psychology Laboratory, Johns Hopkins University, Baltimore, Md.).

An experiment was designed in which different distances of cursor movement and different gear-ratios were run in random order. There were 7 different operators. The details of the experimental design were so arranged that a complete analysis of variance could be carried out on the results. Both the time taken to make a setting and the number of errors made in settings were used as measures of the operator's performance. There is an optimum gear-ratio for operating a remote PPI. This optimum, however, depends upon a number of factors--the most important of which is the angular distance through which the cursor must be moved to get it on the p.p.i. If the distance is very short, say, 15 degrees, the optimum is high--in the neighborhood of 20 revolutions of the crank for one revolution of the cursor. If the distance is longer, say, 165 degrees, the optimum is much smaller--about 5:1. If one averages all distances likely to be encountered in normal operation of PPI's, the optimum is still about 5:1. This, therefore, is the recommended ratio for typical radar operation.

3598 Gebhard, J.W., & Howbray, G.H. EFFECT OF THE REFLECTION PLOTTER ON THE VISIBILITY OF SIGNALS ON PPI SCREENS. Contract N5 orf 166, Tech. Rep. SDC 166 1 119, Dec. 1950, 7pp. USN Special Devices Center, Port Washington, N.Y. (Psychology Lab., Johns Hopkins University, Baltimore, Md.).

Measurements were made to determine the effect of the Reflection Plotter on the visibility of simulated radar signals on PPI screens. Three sizes of target were viewed at 12 inches on a CRT with a P-7 phosphor. These were: small (1 μ sec X 1"), medium (3 μ sec X 10") and large (10 μ sec X 30"). The data were obtained by the method of attenuating an 8 volt signal until a just visible signal was discerned. This measure was expressed in decibels, attenuation and was found at screen luminances corresponding to 2, 5, 8, and 10 volts of CRT bias beyond visual cut-off for the tube. No noise was used in the tests. In conditions of visibility were investigated: a) No Reflection Plotter; b) Clean Reflection Plotter without edge lighting; c) Clean Reflection Plotter with faint edge lighting; d) Dirty Reflection Plotter with bright edge lighting. The results show that the clean Reflection Plotter (condition 2) produced about 3 db of loss in signal visibility over the condition where no Plotter was used. A brightly lighted Plotter whose surface has been used and wiped to smear the residue of old grease pencil marks (condition 4) produced a 7 db loss over the condition where no Plotter was used. It is recommended that the Reflection Plotter should not be used on equipment whose primary purpose is the detection of weak radar signals. R 6

Cohn, J.E., Carroll, D.G., Armstrong, B.W., Shepard, R.H., et al. STUDIES ON GAS EXCHANGE APPLICABLE TO FLYING PERSONNEL. THE MAXIMAL DIFFUSING CAPACITY OF THE LUNG IN NORMAL MALE SUBJECTS OF DIFFERENT AGES. Contract AF 18(600) 435, Proj. 21 1201 0014, Rep. 4, Sept. 1954, 8pp. USAF School of Aviation Medicine, Randolph AFB, Tex. (Environmental Medicine Dept., Johns Hopkins University and Hospital, Baltimore, Md.).

The maximal diffusing capacity of the lung for oxygen was determined in 21 normal subjects ranging in age from 17 to 76 years. There is a significant decrease in maximal diffusing capacity with age, the relationship being best described by the regression equation $D_{O_2} = 0.2 \text{ age} - 40.9$. The findings are of interest in relation to the nature of the aging process. It is not unlikely that the changes in the capillary bed of the lung in relation to age are similar to those occurring in other organs. The data presented and the regression equation derived therefrom provide normal standards with which to compare findings in patients with pulmonary disease.

Contract AF 18(600) 435, Proj. 21 1201 0014, Rep. 3, Sept. 1954, 15pp. USAF School of Aviation Medicine, Randolph AFB, Tex. (Environmental Medicine and Medicine Depts., Johns Hopkins University and Hospital, Baltimore, Md.).

Multiple determinations of diffusing capacity have been performed during treadmill exercise on 3 normal subjects, using the low oxygen method of Lillenthal et al. (2). The severity of exercise and the severity of hypoxia were both varied over a wide range. In the 2 younger subjects, the diffusing capacity rose sharply at levels of oxygen consumption between 500 and 1,200 ml. per minute. There was no further rise when the oxygen consumption was increased to more than 2,200 ml. per minute. In the older subject, the diffusing capacity rose at values of oxygen consumption between 500 and 900 ml. per minute and there was no further rise at approximately 1,200 ml. per minute. The findings suggest that maximal values for diffusing capacity were achieved, and that the maximal diffusing capacity was lower in the older subject. The data also suggest that the maximal diffusing capacity can be reached either by hard physical work or by moderate work in association with severe hypoxia. From the technical point of view, both exercise and severe hypoxia facilitate the determination of diffusing capacity by the method which was employed. Various physiologic mechanisms affecting the behavior of the pulmonary capillary bed during exercise and hypoxia are discussed. The maximal diffusing capacity is thought to provide a quantitative estimate of the diffusion characteristics of the entire diffusing surface of the lungs.

Moser, H.M., Dreher, J.J., & Adler, S. A COMPARISON OF HYPONASALITY, HYPERNASALITY, AND NORMAL VOICE QUALITY ON THE INTELLIGIBILITY OF TWO-DIGIT NUMBERS. Contract AF18(600)316, RF Proj. 519, Tech. Rep. 25, APCRC TN 55-60, July 1955, 5pp. Ohio State University Research Foundation.

3607

This study was designed to evaluate the effects of hypernasal and hyponasal as compared to normal nasal delivery upon the intelligibility of two-digit numbers. Six speakers reflecting Eastern and General American dialects recorded a list of two-digit numbers under conditions of simulated hyper- and hyponasality and normal delivery. The recorded lists were then presented to 11 subjects at two signal-to-noise ratios, and the number of errors were assessed. Triple analysis of variance was employed to determine the effects of methods, noise, speakers, and their combinations upon intelligibility. The dynamics of the two nasal conditions are discussed in terms of their negative influence upon effective communication.

Moser, H.M., Dreher, J.J., & Adler, S. THE EFFECTS OF CONTROLLED BOUNCE BLOCK AND PROLONGED BLOCK ON THE INTELLIGIBILITY OF OPERATIONAL WORDS. Contract AF18(600)316, AFRCRN-55-61, RF Proj. 519, Tech. Rep. 26, June 1955, 6pp. The Ohio State University Research Foundation.

3608

This study was designed to investigate the effects of normal, bounce block, and prolonged block methods of voice transmission on the intelligibility of operational words. Fifty PB words of high frequency in air operations were recorded by the same speaker utilizing each of the three methods and presented to three groups of listeners (34 normal, 54 bounce block, and 48 prolonged block). An analysis of the relative intelligibility of the words under each of the methods of presentation leads to a discussion of the potential factors operant in each of the three methods and certain specific recommendations concerning further research.

Moser, H.M., Dreher, J.J., & Adler, S. THE EFFECTS OF CONTROLLED AFFECTIVE TONE ON INTELLIGIBILITY. Contract AF 18(600)-316, AFPC TH 55-59, HW Proj. 519, Tech. Rep. 24, June 1955, 6pp. Ohio State University Research Foundation.

3610

This study was designed to determine the effect of conveying two-digit numbers with different emotions (by controlled intensity) upon their relative intelligibility. Four professional actors recorded a series of two-digit numbers while conveying four emotions: Joy, anger, sadness, and unemotionality. Thirty-nine subjects were then presented with the recorded lists and their responses were recorded with regard to number correct for each method of transmission. Analysis of variance was employed to assess the relative contribution of each method to intelligibility. Conclusions are drawn concerning the role of emotion in intelligibility. T. G. R 3

Green, R.F., Zialles, H.L. & Spragg, S.D.S. THE EFFECTS OF VARYING DEGREES OF KNOWLEDGE OF RESULTS ON KNOB SETTING PERFORMANCE. Contract N60NR 241, SMLDEVEN Proj. 20 M 1D, Task 6, Tech. Rep. SPECDEVEN 241 6 20, Aug. 1955, 5pp. USN Special Devices Center, Port Washington, N.Y. (University of Rochester, Rochester, N.Y.).

3619

To investigate the effect of giving different kinds, or degrees of specificity, of knowledge of results on accuracy of knob setting, three groups of 30 subjects each were given the task of bisecting an angular extent (blindfolded) by turning a knob through the entire extent of travel twice and then setting the knob at the midpoint of the angle. Three degrees of knowledge were used, one for each group: 1) no objective knowledge given by experimenter of previous trial result; 2) limited knowledge given in terms of "correct," "too far," or "not far enough"; and 3) exact knowledge given in terms of degrees of error. Mean settings (in terms of constant errors) and variability scores were analyzed for the effect of the three conditions. Implications for training are discussed. T. G.

Williams, J.A.C. COMPENSATING REST ALLOWANCES. A PRELIMINARY SURVEY OF VALUES APPLIED IN BRITISH INDUSTRY. CA/PE/2, April 1955, 6pp. College of Aeronautics, Aircraft Economics and Production Dept., Cranfield, England.

A survey was made of Compensating Rest (CR) Allowances applied in time study in British industry. This note summarizes and comments briefly upon these allowances now in use and presents 4 tables of allowances. A CR is "applied to an element of work so that the worker can recover from the physical and/or mental effort necessary to perform the work element," in a manner reported previously (3613). It should enable a normal worker, trained in the task, to work at a standard rate throughout the day without undue fatigue. The values appearing in the tables are for the following factors: energy output or effort, posture, attention, special clothing, external environment, eye strain, and general (personal hygienic needs, uncongenial surroundings, and monotony). (HEIAS)

Williams, J.A.C. INDUSTRIAL TIME STUDY PROCEDURE. AN EXPLANATORY NOTE OF ITS PURPOSE AND A STANDARD METHOD. CA/PE/1, ca Apr. 1955. College of Aeronautics, Aircraft Economics and Production Dept., Cranfield, England.

This report presents the method used in the Work Measurement technique of Time Study in Great Britain. Time Study is defined as the determination of the proper time to allow for the effective performance of a specified task and is applied to repetitive work whose work content may be measured directly or derived synthetically. Following observation and recording of element times, a numerical rating is derived. (Observed rate of accomplishment of an element relative to concept of a standard rate and expressed on a suitable numerical scale is the Rating.) A Compensating Rest allowance is then applied to each element time value to compensate for physical and mental effort, posture, etc. This figure is then used to calculate a standard day's work. The appendix gives an example of the procedure. (HEIAS)

Hajewski, T.R. FACTORS AFFECTING PUNCHING SPEEDS OF HOLLERITH OPERATORS. MECHANICAL FACTORS OUTSIDE THE CONTROL OF THE OPERATORS. Gofa Note 6, June 1954, 11pp. The College of Aeronautics, Cranfield, England.

On the basis of a number of tests using a standard keyboard under normal operating conditions and employing motion-study techniques, the following conclusions are reached respecting the influence on punching speeds of the various factors. The stroke of the key has very little influence on punching speeds; the spacing of the keys has an appreciable effect on punching speeds; the so-called "stiffness" of the punch is often not stiffness in the mechanical sense, but is a physiological reaction in the operator to different key-top pads; a certain amount of variability of pressure is always inherent in the machine, and operators are, within certain pressure ranges, extremely sensitive to such variability.

Appley, D.G. & Appley, M.H. (Formerly Applezweig, D.G. & Applezweig, M.H.). STRESS AND BEHAVIOR: I. THE BEHAVIOR INTERPRETATION INVENTORY. Proj. NR 172 228, Contract N60R 396 (02), Aug. 1954, 15pp. ORR, Connecticut College, New London, Conn.

The prediction of behavior under stress may be made more meaningful within the framework of a motivational theory. Psychological stress is produced by a conflict of motives. An eclectic system of motivation was evolved, out of which a motivational measure was constructed. 31 behavior modes are listed; these represent varieties of responses which may be given to situational stimuli. The behavior interpretation inventory is a multiphasic motivational measure designed to yield a motivational profile. It consists of 124 items, 4 for each of the 31 behavior modes, each item containing a short description of a situation involving a mode of behavior, and 4 alternative responses describing reasons for the behavior described. The S chooses the most likely reason. 4 different forms have been constructed for the inventory. Analysis of data on all 4 forms is in progress. (HEIAS)

Fry, G.A. & Alpern, M. EFFECT OF FLASHES OF LIGHT ON NIGHT VISUAL ACUITY. PART I. Jan. 1953, 26pp. Vision Committee Secretariat, Armed-Forces-National Research Council, University of Michigan, Ann Arbor, Mich. (Ohio State University Research Foundation, Columbus, Ohio).

3629

To investigate the ability of the eye to see a dark object against a sky background at night after exposure to a brief flash of light, threshold measurements were made (three Ss) of the appearance of a vertical black bar on a background of constant luminance (0.0107 mL) following exposure to flashes of light varying in brightness, duration, number, area, and position in relation to test object. Data were given as time (seconds) required for return of visual acuity following flash exposure. Theoretical considerations were discussed.

Allen, M.J., Fitts, P.M. & Slivinske, A.J. A MOVING TARGET OPTICAL PROJECTOR FOR USE IN AIR TRAFFIC CONTROL RESEARCH. Contract AF 33(616) 43, RDO 694 43, WADC Tech. Rep. 53 417, Jan. 1954, 8pp. WADC, USAF Aero Medical Lab., Dayton, Ohio.

The specifications and design of a moving target optical projector are described. This projector was specifically designed to meet the requirements of a versatile research apparatus in human engineering studies of air traffic control systems based upon ground displays of radar derived information. Although a few other optical simulators for air traffic control have been developed, none of these appears to offer all the advantages of the present one. The most important features of the simulator unit herein described are a) the linearity and precision of target movement which can be obtained without distortion or loss of focus of the image, b) the flexibility of coding provided for the target image and the area immediately surrounding each image, and c) flexibility in providing a simulated one-man display or a large projection screen which can be used by several controllers. The projector can be used singly or a large number can be used together. It can provide a static display, or when connected with a suitable course generator, it can produce a moving target display. The projector also has potential future use in an actual traffic control center.

Ammons, R.B., Ammons, Carol H. & Morgan, R.L. TRANSFER OF TRAINING IN A SIMPLE MOTOR SKILL ALONG THE SPEED DIMENSION. Contract AF 33(038) 10 196, WADC TR 53 498, March 1954, 22pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (University of Louisville, Louisville, Ky.).

3631

This study was conducted to obtain information on the general problem of the influence of the speed of a training task upon the performance of a following task. The task used was rotary pursuit at four different speeds. The speeds were assigned to the training and transfer periods in a way that resulted in all 16 possible combinations of speeds in the two periods and were presented under three different conditions of distribution of practice. A total of 48 subgroups were used forming a total of 193 Ss. The performance data were analyzed for transfer effects between tasks of different speed requirements.

Ammons, R.B., Ammons, Carol H. & Morgan, R.L. MOVEMENT ANALYSIS OF THE PERFORMANCE OF A SIMPLE PERCEPTUAL-MOTOR TASK UNDER VARIOUS CONDITIONS. RDO No. 694-17, Tech. Rep. 54-36, April 1954, 19pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio.

3633

To determine the value of motion pictures as a technique for recording, analyzing, and classifying movements made during the performance of a continuous perceptual motor task, a study was made of changes in rotary pursuit performance (64 subjects) due to duration of practice, introduction of rest periods, increased accuracy and rate of requirements. Motion picture recordings were made of the first and last twenty minutes of practice, and all movements were first classified into categories of types and then scored for each subject. Scoring reliability was estimated by correlating results from two scorers and by comparing performance scores for similar groups. The results were compared with those from other studies and validity of method determined. Implications for training are discussed. G. I. R 12

Brown, K.T. FACTORS AFFECTING RATE OF APPARENT CHANGE IN A DYNAMIC AMBIGUOUS FIGURE AS A FUNCTION OF OBSERVATION TIME. WADC TR 53 482, Dec. 1953, 32pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3635

To investigate the rate of apparent change of an ambiguous figure (RAC) as a measure of certain physiological processes which contribute to visual fatigue, a method of determining curves showing RAC as a function of observation time was developed. A series of experiments were conducted to determine: 1) the general shape of the curve, 2) the relation between curves for right and left eyes of a given subject, 3) subject differences, 4) reliability of method, 5) differences in binocular and monocular curves, and 6) interocular transfer of increase in RAC.

3636 Brown, K.T. FACTORS AFFECTING DIFFERENCES IN APPARENT SIZE BETWEEN OPPOSITE HALVES OF A VISUAL MERIDIAN. J. Opt. Soc. June 1953, 43(6), 464-472. (USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.). (WADC Tech. Rep. 53-253.).

A difference in apparent size between opposite halves of the same visual meridian may be called a half-meridian difference (HMD). The HMD's have been measured in 6 subjects for both the horizontal and vertical meridians, using the right eye, left eye, and both eyes. All 6 kinds of measurements were made on each subject for periods of from 2 to 9 weeks. Significant differences were found between the HMD's of the left and right eyes in both meridians. Thus an ocular factor contributes to HMD's. This factor appears to be different visual angles for corresponding retinal points. Trends were sometimes found with respect to time, so there is also an unstable factor in the visual system which contributes to HMD's. This factor varies independently along the horizontal and vertical meridians. With a given meridian, however, the HMD's of the left and right eyes vary concomitantly. Thus the unstable factor is common to the two eyes and is probably located in the visual cortex. Since trends were found with respect to time, this means that for a given locus of retinal stimulation the subjective directional value relative to a foveal stimulus varies in a similar manner with respect to time. Thus topological transformations of subjective directional values have been found to occur. HMD's produced by the ocular factor appear relatively stable and usually small, whereas the HMD's of the left and right eyes are modulated concomitantly by the unstable factor, which sometimes causes large HMD's. These findings indicate that the relation between visual angles for a pair of corresponding retinal points is relatively stable, but the subjective directional values of both members of the pair with respect to a foveal stimulus sometimes vary markedly and concomitantly as a function of time.

3639 Gatti, Jennie. REPORTS OF RESEARCH IN THE FIELD OF ENGINEERING PSYCHOLOGY. Proj. 7180. WADC Tech. Rep. 54-220, Sept. 1954, 31pp. (USAF Aero Medical Lab., Wright-Patterson AFB, Ohio)

This bibliography lists by functional groupings the authors and titles of the reports published by the Psychology Branch, Aero Medical Laboratory, Directorate of Research, Wright Air Development Center, since its inception in 1945.

3637 Duncan, C.P. & Underwood, B.J. TRANSFER OF TRAINING AFTER TWO DAYS OF PRACTICE WITH ONE TASK OR WITH VARIED TASKS. Contract AF 33(616) 308, Proj. 7197, WADC TR 54 381, Sept. 1954, 14pp. (USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Northwestern University, Evanston, Ill.).

3637

To compare the effects of constant versus varied training on transfer of training, three groups of 45-46 college students practiced for two days pushing a lever into the slot appropriate to a visual stimulus. Stimuli were forms, nonsense syllables, and patches of color. One group practiced the same task (same stimuli) both days; another practiced five different tasks each day; the third had five different stimulus-response pairings each day. After training, all groups learned three additional tasks. Results (correct responses on final tasks) were analyzed for effects of variety of practice on transfer. Implications for the design of training equipment were discussed.

3638 Duncan, C.P. & Underwood, B.J. TRANSFER OF TRAINING AFTER 10 DAYS OF PRACTICE WITH ONE TASK OR WITH VARIED TASKS. Contract AF 33(616) 308, WADC TR 54 115, May 1954, 24pp. (USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Northwestern University, Evanston, Ill.).

3638

To study the effects of variety of practice on transfer of training, three groups of 36-37 college students practiced for ten days moving a lever appropriately in response to visual stimuli (forms, nonsense syllables, color patches). Conditions for the three groups were: 1) same task for ten days, 2) different task (stimuli) each day, and 3) same task but stimuli and responses reversed each day. Then all learned four final tasks in four days. Results (correct responses in final tasks) were analyzed for the effect of variety of practice on transfer, and implications for the design of training devices were discussed.

Jerison, H.J., & Wing, S. EFFECTS OF NOISE AND FATIGUE ON A COMPLEX VIGILANCE TASK. Contract AF 18(600)-50, Proj. 7193-71614, Tech. Rep. 57-14, Jan. 1957, 15pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio.

3642

To investigate the effect of noise stress on vigilance, nine subjects (college students) with normal hearing were required to monitor three clocks simultaneously and to respond when a clock hand made a double jump (about one minute for each clock). The experimental session consisted of 1/2 hour in quiet and 1 1/2 hours in noise (114 decibels); the control session was two hours in quiet (83 decibels); order of presentation was counterbalanced among subjects. Percent correct responses were analyzed as a function of time for both quiet and noise conditions. A further analysis of frequency of spontaneous responses was made. The findings are related to similar studies. T. G. I. R 5

3643

Morgan, H.L., Eckstrand, G.A., Rockway, M.R. & Newton, J.M. VERBALLY MEDIATED TRANSFER AS A FUNCTION OF ORDER OF TASKS. Contract AF 19(600) 78, WADC TR 54 41, Feb. 1954, 18pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3643

To investigate the effects of order of training tasks on transfer of training, eight groups of 35 college students were tested. Four experimental groups learned (in varying order) verbal and motor responses to the same stimuli (visually perceived forms), then the same verbal responses to new stimuli, while four control groups learned different verbal responses to the two sets of stimuli. Then all groups transferred the previously learned motor responses to the new stimuli. Performance on the final task was evaluated for transfer as a function of order-of-presentation and interpreted in terms of Hull's theory of "mediated stimulus equivalence." T. G. I. R 8

3644

Simon, C.W. EFFECTS OF STRESS ON PERFORMANCE IN A DOMINANT AND A NON-DOMINANT TASK. Contract W33 038 AC 19816, WADC TR 54 285, June 1954, 41pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Antioch College, Yellow Springs, Ohio).

3644

To study the relative effects of stress on dominant and nondominant tasks, 80 male college students practiced for varying amounts of time on a task requiring making settings by turning a knob to move a light. A clockwise turn of the knob caused the light to move clockwise (dominant task) for some Ss, counter-clockwise (nondominant task) for others. Then varying degrees of stress were introduced in the form of simultaneous tasks. Performance under stress was compared for the dominant and nondominant groups, and the results were discussed in terms of then-current learning theory. T. G. I. R 29

3645

Teichner, W.H., Kobrick, J.L. & Wehrkamp, R.F. EFFECTS OF TERRAIN AND OBSERVATION DISTANCE ON DEPTH DISCRIMINATION. Rep. 228, May 1954, 23pp. USA Quartermaster Research & Development Center, Natick, Mass.

3645

To determine the effects of observation distance, type of terrain, and time of day on monocular and binocular depth discrimination, an experimental study was conducted in the desert. Three types of terrain (sand, silt, and desert pavement) and a macadamized airstrip were the physical areas studied; distances of observation varied from 200 to 3000 ft.; and both mid morning and mid afternoon tests were made. Four Ss were used to obtain discriminations of the equality of spatial positioning of two homogeneous, smooth-textured, rectangular targets. The data were analyzed for the effect of these environmental factors on the precision of this visual function. T. G. I. R 31

3646

White, W.J. & Sauer, Shirley C. SCALE DESIGN FOR READING AT LOW BRIGHTNESS. Contract AF 18(600) 25, WADC TR 53-464, March 1954, 16pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3646

This study concerned the manner in which speed and accuracy of quantitative scale reading vary as a function of graduation mark width and interval size under three intensities of red illumination such as are encountered in cockpits at night. The data consisted of time and error scores obtained by 18 Ss, each serving under all conditions. Graduation mark width varied from 0.008 to 0.063 inch; graduation intervals varied from 0.05 to 0.25 inch; and illumination levels were 0.002, 0.01, and 0.10 ft.-L. Conclusions were drawn concerning dimensions of scales for visual presentation of quantitative information in aircraft cockpits. T. G. I. R 13

3647

Mackie, R.R., Morehouse, L., & Clegg, D.A. MEASUREMENT OF FORCES AFFECTING HUMAN BODIES IN AIRCRAFT ACCIDENTS: A STUDY OF THE CRASHES DURING LANDING OF TWO INSTRUMENTED P6F DRONE AIRCRAFT. Contract Monr 1527(00), Proj. NR 118-381, Tech. Rep. 2, Feb. 1956, 36pp. Human Factors Research, Inc., Los Angeles, Calif.

3647

To determine whether instrumentation might provide crash load data which would be useful to those confronted with the task of designing for crash survival, accelerometers were placed in drone aircraft used for missile evaluation. The accelerometers, which were actuated upon being stimulated by a force of 8g or more and would continue for eight seconds, were mounted on the seat. Pictures were taken of a crash whenever possible. Findings (crash history, records of the magnitude and pattern of g forces with respect to time for duration of crash) from two airplane crashes were obtained and studied. Recommendations for future research are made. G. I

3649
Lundervold, A.J.S. ELECTROMYOGRAPHIC INVESTIGATIONS OF POSITION AND MANNER OF WORKING IN TYPEWRITING. Acta Physiol. Scand., 1951, 24: Suppl. 84. (Neurological Clinic and Pharmacological Institute, University of Oslo, Oslo, Norway & Human Anatomy Dept., University Museum, Oxford, England).

18 women and 29 men, belonging to different age-groups and having varying degrees of practice in typing, were subjected to electromyographic examination while typing on the machine. The combined force of muscle contractions increased when: writing speed increased, the writer was tired or chilled, in cases of loud noise, bad lighting and under psychic influences. Unpracticed writers and those in whom insertion activity had been recorded employed more muscle power than the others. Examination of individual motor units in patients with peripheral paresis showed that the same motor units were active in slow typing as in typing with maximum rapidity. In 51 out of 63 persons with occupation myalgia examined electromyographically insertion activity was recorded. All those used greater muscle power when writing on the machine than did the healthy Ss, and there were frequently recorded continuous action potentials during typing. (HEIAS)

Bradley, J.V. DESIRABLE CONTROL-DISPLAY RELATIONSHIPS FOR MOVING-SCALE INSTRUMENTS. Proj. 7182 71514, WADC TR 54 423, Sept. 1954, 20pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3651
This report summarizes a series of experiments designed 1) to investigate the effects of certain control-display relationships on making settings with moving-scale instruments, and 2) to attempt to find the optimum control to moving-scale display relationship. In each experiment several display-control assemblies were used which required the subject to make settings on the moving-scale dial by a knob control which was located below or above the dial. In one case a moving-pointer was used. The relationships of control and display were varied as to direction of scale increase and knob turn, and direction of scale rotation in relation to knob turn. Errors in setting were recorded and analyzed. Recommendations are included.

Baker, C.W. FORMATION LIGHTS FOR FIGHTER AIRCRAFT. Proj. 7180, 170C Tech. Rep. 55 124, March 1955, 15pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

An important consideration in the design of formation reference lighting on fighter aircraft is that the wing pilot should be provided with unambiguous information about the attitude and distance of the lead aircraft. The present formation lighting system used on fighter aircraft is inadequate in this respect, and, at least partially as a result of this, pilots frequently experience disorientation and confusion during night formation flight. The past research on formation lighting is reviewed and recommendations are made for modifications of the present formation lighting systems. These recommended modifications include: a) redesign of the wing-tip navigation lights so that they provide suitable reference lighting for wing aircraft, b) installation of a linear light on the fuselage near the wing root, and c) the use of a single rotary detent control knob which provides control for 3 brightnesses of formation lights, navigation lighting for cruise and join-up, and an off position.

Loucks, R.B. LEGIBILITY OF AIRCRAFT INSTRUMENT DIALS: THE RELATIVE LEGIBILITY OF VARIOUS CLIMB INDICATOR DIALS AND POINTERS. Proj. 286, Nov. 1944, 5pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Various modifications of the AC Type C-2 climb indicator were compared as to the accuracy with which they can be read during brief exposures. Removal of all mid-division lines beyond the 500-foot point as well as the words "up" and "down" results in a dial which is more legible than the standard indicator. It is clear from the reports of subjects being tested that mid-division lines which change in value from one part of a scale to another prove confusing and give rise to errors. Although a majority of subjects being tested prefer the dial with numbers at each of the scale divisions, the numerals at the 3,000 feet and 5,000 feet points of the simplified dial referred to above can be omitted without decreasing its legibility. Under the specific conditions of this experiment, numbers and division lines 1/32 inch in thickness are as legible as heavier lines and numbers, and are superior to lines and numbers 1/64 inch in thickness. A pointer which has only a luminous tip is inferior in legibility to the standard dial hand, but a pointer with a strip of luminous paint only 1/32 inch in width, throughout its length, is as satisfactory as the standard hand.

3654
Loucks, R.B. LEGIBILITY OF AIRCRAFT INSTRUMENT DIALS: THE RELATIVE LEGIBILITY OF MANIFOLD PRESSURE INDICATOR DIALS. Proj. 325, Dec. 1944, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Objective data are reported for providing specifications for optimum legibility of aircraft manifold pressure dials. With ultraviolet light the standard manifold pressure indicator dial (AC Type D-10) exhibits an improved legibility when the small numbers at the mid-division marks are obscured. A manifold pressure dial with 1/4 in. numbers is superior to a dial with 3/16 in. figures. It appears desirable to compress the width of the numerals in relation to their height in order that the association between a particular number and its appropriate division mark is of optimal clarity. It has been demonstrated that the starting point of a scale can be shifted considerably without affecting the dial's legibility. Within certain limits, the legibility of a dial appears to be closely associated with the angular spacing of the division marks. Two scales which have a difference in the angular spacing of the division marks that is only about one and a half degrees exhibit a statistically significant difference.

3655 Loucks, R.B. EVALUATION OF AIRCRAFT ALTITUDE INDICATORS ON THE BASIS OF LINK INSTRUMENT GROUND TRAINER PERFORMANCE. Proj. 341, Rep. 1, June 1945, 17pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Four different types of artificial horizon indicator have been compared with the standard AAF type of horizon indicator in terms of the objectively scored Link trainer performance as the subject attempts to maintain the fuselage in level and horizontal flight under conditions of rough air. All of the modified horizon indicators tend to show a slight superiority to the conventional instrument as contrasted with the differences between two similar instruments, and in the case of one category of measurement with the British type of horizon there is some degree of statistical significance to such differences. The indicator in which the moving pointer and horizon bar rotate in an opposite direction to that of the conventional type of AAF flight indicator is the one instrument that shows a superiority which has a questionable statistical significance. The reversed rotation indicator is also the one instrument which is most consistently preferred by the subjects. From an analysis of the various factors which have been tested in the four comparisons of modified instruments vs. standard, it is concluded that the most easily interpreted horizon indicator is one in which the reference horizon line remains fixed and the miniature aircraft rotates clockwise and when the plane rolls to the left the miniature aircraft rotates counter-clockwise, that when the plane climbs, the tail of the miniature aircraft moves below the fixed horizon line that is nearest to the pilot.

3656 Saul, E.V., Raben, Margaret W. & Jaffe, J. THE EFFECTS OF RIFLE RECOIL ON MARKSMANSHIP PERFORMANCE: A REVIEW OF THE LITERATURE AND THE DESIGNATION OF RESEARCHABLE HYPOTHESES. Contract DA 19-029-ORD 3461, Proj. TB 1-1000, Proj. Rep. 1, May 1955, 16pp. Institute for Applied Experimental Psychology, Univ. of Massachusetts, Medford, Mass.

3656 This paper presents the results of a concise survey of the literature relating the effects of rifle recoil to shooter behavior. A series of problems, amenable to experimental investigation, are suggested. These problems pertain to: 1) motor performance characteristics of the shooter and 2) design characteristics of the weapon. T. R. 21

3657 Harter, G.A., & Fitts, P.M. THE FUNCTIONAL SIMULATION OF COMPLEX SYSTEMS BY MEANS OF AN ANALOG COMPUTER, WITH THE F-86D, E-4 SYSTEM AS A SPECIFIC EXAMPLE. PART I. Contract AF 18(600)-1201, Proj. 7716, Tasks 77292 & 57050, Res. Rep. AFPTRC-TN-56-133, Part I, Dec. 1956, 12pp. Interceptor Pilot Research Laboratory, AFPTRC, Tyndall AFB, Fla.

3657 This report deals with the problem of simulation of complex systems, such as aircraft and radar, for training and research. A technique is described for analyzing certain types of physical systems for the purpose of determining how the system can be described mathematically and represented by an appropriate set of equations in an electronic computer. Such problems as degree of fidelity of simulation required and design of general purpose equipment that could be readily modified to represent new or novel systems are considered. Advantages and limitations of such a simulator are discussed. G. I. R 10

3661 Scales, Edythe M. & Chapanis, A. THE EFFECT ON PERFORMANCE OF TILTING THE TOLL-OPERATOR'S KEYSSET. J. Appl. Psychol., Dec. 1954, 38(6), 452-456. (Bell Telephone Laboratories, Inc., Murray Hill, N.J. & Johns Hopkins University, Baltimore, Md.).

3661 To investigate two measures of keying performance, accuracy and time, as a function of inclination of the keyset, 16 subjects were tested. The keyset was inclined at eight angles (0, 5, 10, 15, 20, 25, 30, and 40 degrees) relative to the horizontal working surface. Both practice and test sessions were included in the study, each extending over eight days. The subject's task was to key lists of ten-place number and letter combinations. Eight-by-eight Latin squares were used, the principle variables being subjects, days, and inclinations of the keyset. Time and error scores were analyzed for the effect of the variables with the results presented in a series of graphs. G. I. R 2

3662 Field, Sally M., & Davis, S.W. FATIGUE AND STRESS SYMPOSIUM, 24-26 JANUARY, 1952. Proj. Doughboy, Tech. Memo ORO-T-185, Sept. 1952, 139pp. Operations Research Office, Johns Hopkins University, Maryland.

3662 This symposium was aimed at providing background knowledge and experience in the areas of fatigue and stress. Each of nine researchers presented a summary of the pertinent information in his field and recommended possible measurement techniques for use under combat conditions and in future research. T. G.

3663 Bahrick, H.P., Noble, M. & Fitts, P.M. EXTRA-TASK PERFORMANCE AS A MEASURE OF LEARNING A PRIMARY TASK. Contract AF 33(038) 10528, Res. Bull. AFPTRC TR 54 119, Dec. 1954, 5pp. USAF Personnel & Training Research Center, Lackland AFB, Tex. (Reprinted from: J. Exp. Psychol., Oct. 1954, 48(4), 298-302).

3663 This report describes a test of a technique for seeking information on the degree of learning of a task through performance on an extra task. After varying amounts of practice on a task requiring the pressing of a response key to a visual stimulus, 140 college students continued performing the primary task while also performing mental subtractions. For some Ss the visual stimuli were repetitive, for others, random. Performance on both tasks (during simultaneous performance) is analyzed regarding the additional information on learning and overlearning repetitive and random tasks contributed by the subtraction scores. T. I. R 6

3664 Gibson, Eleanor J. & Bergman, R. THE EFFECT OF TRAINING ON ABSOLUTE ESTIMATION OF DISTANCE OVER THE GROUND. Contract AF 33(038) 22373, Proj. 7706, Task 77116, AFPTRC TR 54 95, Dec. 1954, 29pp. USAF Skill Components Research Lab., Lackland AFB, Tex.

3664 To determine the effect of training on absolute judgment of distance over the ground, 21 targets (18 by 24 inches, designated by a three-plate, three-color system) were arranged on a level mown grass field at distances varying from 43 to 435 yards as viewed from six different station points. A pretest and posttest were given to two groups (122 Ss). Interpolated activity differed: Group I received training (knowledge of results), Group II performed a paper-pencil test. Scores (estimates in yards) for the two groups on pre- and posttests were analyzed for effect of training. The course of learning was further analyzed. T. G. I. R 17

Pickrel, E.W. PREDICTION OF THE TRAINABILITY OF "SLOW LEARNERS" FROM TESTS WITH A SYMBOLIC AND NONSYMBOLIC CONTENT. Proj. 7703, Task 77078, Res. Bull. AFPTRC TR 54-82, Dec. 1954, 12pp. USAF Personnel Research Lab., Lackland AFB, Tex.

3666

To study the efficacy of symbolic tests in evaluating men of marginal ability, two experiments were performed. In the first, two symbolic (words) and two nonsymbolic (pictures of concrete objects) tests and a reading test were administered to 274 airmen of marginal ability. In the second, symbolic and nonsymbolic tests were administered to 213 marginal airmen who were also trained on simple verbal and mechanical tasks. Correlational analyses of test results were interpreted regarding the nature of abilities measured with symbolic and nonsymbolic tests and the tests' comparative predictability of success in verbal and mechanical tasks.

Lesli, W. TRANSFER IN BURST CONTROL HABITS. Proj. 7708, Task 77141, Res. Bull. AFPTRC TR 54-81, Dec. 1954, 14pp. USAF Armament Systems Personnel Research Lab., Lowry AFB, Colo.

3667

This is a study of the effects of inverting the ratio of time triggering a burst in aerial gunnery to time resting between bursts on learning a desired burst-rest ratio. Eighty-four gunnery trainees were given special practice on maintaining a 1.5:0.5 ratio, then were given one or two tests with gun-cameras with a ratio of 1.5:4.0 required. A control group (68 Ss) was tested without prior practice. Results (errors in maintaining the required burst-rest ratio) were interpreted regarding the effects of such ratio inversion in training.

Volers, W.D. A COMPARISON OF THE COMPONENTS OF SIMULATED RADAR BOMBING ERROR IN TERMS OF RELIABILITY AND SENSITIVITY TO PRACTICE. Proj. 7713, Task 77219, Res. Bull. AFPTRC TR 54-74, Dec. 1954, 14pp. USAF Crew Research Lab., Randolph AFB, Tex.

3668

This study pertains to the problem of the effects of practice on the components of visual bombing error, and the consequences for proficiency evaluation. Simulated radar bombing was carried out by B-29 crew members during their combat training. The data were analyzed to discover the differences between range and deflection measures in terms of constant (mean) error, reliability, and sensitivity to practice. Circular error was also included in certain comparisons. The influence of the following factors was treated: targets, axes, crews, using a particular target, and within-crew variability.

Lawrence, D.H. & Goodwin, W.R. TRANSFER IN TRACKING BEHAVIOR BETWEEN TWO LEVELS OF SPEED. Contract AF 33(038) 14350, Proj. 509 C20 0009, AFPTRC TR 54-70, Dec. 1954, 11pp. USAF Personnel & Training Research Center, Lackland AFB, Tex. (Stanford University, Stanford, Calif.).

3669

To investigate the transfer effects on changing between tracking tasks of different speeds, 54 college students practiced tracking with a joystick for 22 trials. Targets had two speeds (approximately 75 and 100 targets per min.). Groups practiced varying amounts (0-18 trials) at the slow speed, then shifted to the fast speed. Hits on high speed trials were analyzed as a function of amount of practice at slow speed and with regard to whether the S shifted to high speed when told to or when he felt ready to.

3670. Gibson, J.J. THE VISUAL PERCEPTION OF OBJECTIVE MOTION AND SUBJECTIVE MOVEMENT. Psychol. Rev., Sept. 1954, 61(5), 304-314. (Cornell University, Ithaca, N.Y.)

3 problems are first considered: how we see the motion of an object, how we see the stability of the environment, and how we perceive ourselves as moving in a stable environment. The experimental evidence on the perception of motion and movement is surveyed and the implications are stated as hypotheses for consideration and research. Some preliminary assumptions toward a psychophysics of kinetic impressions are set forth; these include the classification of relevant motions into 6 types: translation, rotation, size transformation, perspective transformation, deformation, multiple movements. The physical events producing these geometrical types of motion are described. (HEIAS)

3672. Bennett, V.F., Fitts, P.M. & Noble, M. THE LEARNING OF SEQUENTIAL DEPENDENCIES. J. exp. Psychol., Oct. 1954, 48(4), 303-312. (Ohio State University, Columbus, Ohio).

The 4 experiments reported here are concerned with: a) the relative difficulty of learning digram versus trigram probabilities, and b) the effect in such situations of sequential guessing habits. Exp. I was designed to determine sequential guessing habits in a situation where it was possible to make only a chance number of successes. 20 Ss predicted which of 5 events would occur, with knowledge of results provided after each response. By using a restricted random procedure, all possible engrams, digrams, and trigrams appeared equally often. The pattern of correct responses thus had maximum uncertainty. In Exp. II, 2 groups of 20 Ss each were given patterns which had equal engram but unequal digram (and trigram) probabilities. For one group the digrams conformed to the digram guessing habits obtained in Exp. I (Concordant group); the digrams for the other group were those used infrequently in Exp. I (Discordant group). A total of 10 digrams was used for both groups; practice continued for a total of 250 responses (25 repetitions of each digram). Exps. III and IV were similar to Exp. II except that trigram instead of digram patterns were used. All possible engrams and digrams appeared equally often in the pattern of correct responses; an appropriate prediction had to be based on the 2 preceding events. A total of 50 trigrams was used for both groups in each of these experiments. In Exp. III a total of 500 responses (10 repetitions of each trigram) was given. In Exp. IV the principle by which such patterns are generated was explained, and a total of 1000 responses (20 repetitions of each trigram) was given. It was found that the digram patterns of Exp. II were learned, but that little or no learning occurred with the trigram patterns of Exp. III and IV. It also was found that the influence of guessing habits persisted for an appreciable number of responses, especially when there was little learning.

Shaw, M.E. SOME EFFECTS OF UNEQUAL DISTRIBUTION OF INFORMATION UPON GROUP PERFORMANCE IN VARIOUS COMMUNICATION NETS. *J. abnorm. soc. Psychol.*, Oct. 1954, 49(4), 547-553, Res. Bull. AFPTRC TR 54 115. (University of Wisconsin, Madison, Wisc.).

3677

To examine the effects of unequal distribution of problem-related information in different group structures, 15 four-man groups were randomly assigned to six experimental conditions (combinations of two types of information distribution - equal and unequal, and three communication nets - wheel, slash and circle). Each group solved three eight-item problems; each subject completed a questionnaire from which indices of morale and leadership were derived. Time, number of message units, and errors were recorded for individual positions and structures. The data were analyzed for effect of variables upon leadership, morale, and problem-solving efficiency. The centrality index was examined in light of these results.

Bilodeau, E.A. RATE RECOVERY IN A REPETITIVE MOTOR TASK AS A FUNCTION OF SUCCESSIVE REST PERIODS. *J. exp. Psychol.*, Sept. 1954, 48(3), 197-203. USAF Personnel & Training Research Center, Lackland AFB, Texas. (Skill Components Research Lab., Lackland AFB, Texas.) (IR 54 113)

5 groups of 5s practiced cranking as fast as possible for 10, 30, 90, or 180 sec. trials. Practice trials were distributed by interpolating either 0, 10, 30, 90, or 180 sec. of rest between trials. In general, rate of cranking decreased as a function of practice time or of number of previous practice trials. At all points each rest group was appropriately ranked from that with longest interpolated rest to that with least interpolated rest. Examination of recovery revealed the typical rest recovery function; that is, the rest recovery associated with rest 1 was an increasing and negatively accelerated function of rest duration. With successive rest periods, however, the amount of recovery increased progressively for the shorter interpolated rest periods, but decreased progressively for the longer resting period. This trend continued until two of the rest groups had exchanged their relative ranks. An extrapolation beyond the last rest period suggested a point at which recovery might be independent of all four rest durations. The independence after additional rests was verified for groups with 10 and 90 sec. of rest by replicating these groups, but using twice the number of rests. A comparison of the differences between the various resting conditions and the no-rest control group showed the greatest difference between groups to take place early in practice, but the most marked adjustment in difference between groups during the initial period of practice. This analysis, together with others, suggested that during the successive additional periods there is a rapid adjustment in rate of cranking and that with successive additional periods of practice and rest there is but a slight further adjustment in the pacing effect.

Anderson, G.V., Fruchter, B., Manuel, H.T. & Vorchel, P. SURVEY OF RESEARCH ON SPATIAL FACTORS. Contract AF 33(038) 11046, Proj. 503 002 0001, Res. Bull. AFPTRC TR 54 84, Dec. 1954, 59pp. USAF Personnel and Training Research Center, Personnel Research Lab., Lackland AFB, Tex. (University of Texas, Austin, Tex.).

This survey outlines the progress of research which has attempted to describe the spatial abilities by factor analytic techniques. It deals with discussions of the nature of space as shown in correlational and factorial studies of ability and with the present status of research on spatial factors. The treatment is from two points of view, the historical development of factor description and the comparison of factors found in research utilizing various types of spatial tests. The original research descriptions of these factors are presented and new interpretations which lead to some new hypotheses are developed. (HEIMS)

Parks, R.B. VERBAL FEEDBACK IN PEDESTAL SIGHT MANIPULATION. Proj. 7708, Task 77141, Res. Bull. AFPTRC TR 54 91, Dec. 1954, 8pp. USAF Armament Systems Personnel Research Lab., Lowry AFB, Colo.

3686

To study the effects on gunnery performance of being informed verbally of results, 133 student airmen practiced (16 trials per day for five days) tracking and framing with a pedestal sight. Knowledge of results differed for different groups, including none (control), general knowledge of errors for individuals and for groups, and precise knowledge of errors for individuals. Improvement in time-in-error scores in range, azimuth and elevation is evaluated for the effects of amount and kind of verbal feedback.

Muckler, F.A. & Matheny, W.G. TRANSFER OF TRAINING IN TRACKING AS A FUNCTION OF CONTROL FRICTION. Contract AF 33(038) 25726, Proj. 7706, Task 77122, Res. Bull. AFPTRC TR 54 122, Dec. 1954, 14pp. USAF Skill Components Research Lab., Lackland AFB, Tex. (Reprinted from: *J. appl. Psychol.*, 1954, 35(5), 364-367).

3688

The transfer of training in a manual pursuit tracking task was studied as a function of changes in control friction. A subject body of 105 Air ROTC students was divided into seven groups—a control group (no friction change), three groups with different increases in control friction, and three groups with different decreases in control friction. Results were expressed as mean number of trials to reach criterion of initial control friction, and their implications were discussed.

Ludvig, E., & Miller, J.W. AN ANALYSIS OF DYNAMIC VISUAL ACUITY IN A POPULATION OF 200 NAVAL AVIATION CADETS. Contract Nonr-586(00), ONR Proj. NR-142-023, BuMed Proj. NM 001-075.01.07, Joint Proj. Rep. 7. Dec. 1954. 18pp. U.S. Naval School of Aviation Medicine, N.A.S., Pensacola, Fla.

3711

To analyze dynamic visual acuity, the ability of 200 Naval Aviation cadets to see moving targets (Landolt Ring) was tested. The results are presented and some aspects of the data are analyzed. The chief variables considered are the thresholds determined at an angular velocity of 200/sec. and 1100/sec. and the a and b parameters of the empirical equation $y = a + bx$ relating visual acuity to angular velocity of the test object. The frequency distribution of each of these variables is presented and tested for normality. Correlations between the variables are also analyzed and discussed.

3713

Duestsch, J.J., & Herbert, M.J. THE DEVELOPMENT OF A STATIC TARGET APPARATUS AND TASKS FOR THE STUDY OF CONTROL AND RETICLE CHARACTERISTICS. Proj. 6-95-20-001, Rep. 187, May 1955, 16pp. AMRL, Fort Knox, Ky.

3713

A target-alignment apparatus is described which use rate controls and a cathode-ray tube display to permit study of control and reticle configurations. To compare two methods of hand-control manipulation, two preliminary experiments were performed. In one study, all movement was restricted to the right hand; in the other, each hand controlled a separate plane. Three measures of performance were obtained: total time to align target with reticle initial error (a first movement which moved target away from reticle and final error (target not in alignment at moment of triggering). Scores were studied for differences due to type of control and for usefulness in further research on the apparatus.

Gerjuoy, H. & Bechtoldt, H.P. GENERALIZATION EFFECTS IN SUCCESSIVE DISCRIMINATION LEARNING AS MEASURED BY RESPONSE SIMILARITY. FINAL REPORT. Contract NONR 1261 (00), Proj. NR 154 154, March 1955, 99pp. Dept. of Psychology, State University of Iowa, Iowa City, Iowa.

3721

This is a report of a series of studies (involving 261 college students) on discrimination learning with complex stimuli. Ss were required to learn appropriate motor or verbal responses to the position of a stimulus that included (in addition to position) such irrelevant cues as colors and auditory cues. Major variables were: number of discriminations to be learned concurrently, nature of various cues, and relative frequency of stimuli presentation. Results are discussed with regard to the interaction of generalization effects.

Stevens, S.S. PITCH DISCRIMINATION, MELS, AND KOCK'S CONTINUITY. J. Acoust. Soc. Amer., Nov. 1954, 26, 1075-1077. Contract NSori-76, Proj. Order 1, ONR. (Harvard University, Psycho-Acoustic Lab.)

Recent data on pitch discrimination are shown to agree reasonably well with the values that would be predicted on the assumption that Jnd's for pitch are subjectively equal when measured in mels. The facts relating to-diplacsis and the estimation of musical intervals suggest that the difference limen may be expected to vary irregularly with frequency. A further argument is made that Kock's theoretical explanation of pitch discrimination is invalid.

Havron, M.D., Lybrand, V.A. & Cohen, E. THE ASSESSMENT AND PREDICTION OF RIFLE SQUAD EFFECTIVENESS. Contract DA 49 083 OSA 658 D 13 253 20, Proj. 29564000, PRB Tech. Res. Note 31, Nov. 1954, 80pp. USA Adjutant General's Office, Personnel Research & Procedures Div., Washington, D.C.

In the present study, a daylight live firing field problem and a night blank firing field problem were developed to complete a comprehensive set of criterion field problems for use in assessing combat readiness and for research purposes in validating selection and assignment procedures. These field problems were developed by the combined efforts of military and technical experts. The problems were field tested with 112 9-man rifle squads. Criterion scores on each problem were derived for the squad leaders, the squad members, and for the total squad. The agreement among the umpires scoring each problem was found to be very high. Though the daylight blank firing problem and the night blank firing problem were more related to each other than either was to the daylight live firing problem, each field problem made a reasonably independent contribution to the composite score on unit effectiveness. The field problems can be used as criteria for validating potential squad selectors and as operational measures of squad effectiveness. Measures of 58 variables were also administered to the 112 squads. Significant validity coefficients were found for selection measures of general mental ability, specific aptitudes, and noncognitive personality characteristics similar to those already in use in the Army's selection and classification system. The successful predictors were usually measures of the squad leader. Interpersonal measures found to be indicative of group effectiveness were group measures of ability to anticipate the behavior of other squad members, the degree to which the squad leader fulfills the role expected of him by his squad members, the number of members nominated by the squad for an ideal rifle squad, and agreement between own preference and perceived preference of the squad.

Zeldner, J., Goldstein, L.G., & Johnson, C. D. FACTOR ANALYSIS OF VISUAL ACUITY TESTS DURING DARK ADAPTATION. Proj. 29562000, PRB Tech. Res. Note 40, Nov. 1954, 41pp. Adjutant General's Office, Personnel Research Branch, Personnel Research and Procedures Div.

3696
The objective of this study was to determine the factorial structure of visual acuity tests administered during dark adaptation to various low brightness levels. 100 subjects were first adapted to a photopic level of illumination and then tested at intervals while adapting to scotopic, mesopic, or low photopic brightness levels. The test targets were the modified Landolt ring (a measure of retinal resolution) and the Chevron Contrast (a measure of brightness-contrast sensitivity). A principle-axis factor technique was used to factor the 35-variable intercorrelation matrix. After 19 rotations of the factor matrix, an orthogonal simple structure was found. Eight factors were isolated, identified, and are discussed.

McKelvey, R.K. & Cohen, J.D. THE BEHAVIOR OF INDIVIDUALS AND PERSONNEL SYSTEMS IN THE SURVEILLANCE FUNCTIONS OF AN AIR DEFENSE DIRECTION CENTER: 1. EXPERIMENTAL METHOD. PROJ. 7712, Task 77207, Tech. Rep. AFPTTC TR 54 98, Dec. 1954, 29pp. USAF Personnel and Training Research Center, Lackland AFB, San Antonio, Tex. (USAF Research and Development Command, Mather AFB, Calif.).

In order to collect and process data applicable to a multi-purpose program of research on the performance characteristics of Aircraft Control and Warning operators and teams in the surveillance functions of an Air Defense Direction Center (ADDC), a combination of time sampling and continuous behavior observation techniques of activity analysis has been developed. A method of schematizing operating procedures in stimulus-response terms and devising from it an optimal arrangement of observers and recording devices and a system of data reduction is described. Research objectives are briefly outlined. Developments in recording devices, aids for observers, and apparatus to facilitate data processing are presented. Methods of training observers and phasing observational techniques into the operational situation without significantly influencing ADDC standard operating conditions are described. Plans for analyzing the data and evaluating the data collection and processing procedures for their operational applications are indicated.

Hollis, J.R. HUMAN ENGINEERING EVALUATION OF TRUCK, 1/4 TON, 4x4, UTILITY, M38A1. Proj. T81 1000 5, Tech. Memo 12, Mar. 1955, 11pp. Human Engineering Lab., USA Ordnance Corps, Aberdeen Proving Ground, Md.

The 1/4 ton, 4x4, Utility Truck, M38A1, was evaluated from the human engineering standpoint. Fixed working limits on future vehicles should be no smaller than those on present vehicles. The distance between the floor of the cab and the bottom of the dashboard should be at least 20 inches. There should be a minimum of 10 inches vertical distance between front edge of seat and lower edge of steering wheel rim. Forward arm reach requirements should not exceed 34 to 35 inches. At least 28 inches between lower rim of steering wheel and the base of the back of the driver's seat is required. There should be 4 inches of horizontal adjustment in the driver's seat.

Pollack, I. MASKING OF SPEECH BY REPEATED BURSTS OF NOISE. *J. acoust. Soc. Amer.*, Nov. 1955, 26, 1053-1055, Contract NSori 75, Proj. Order 11, ONR. (Harvard University, Psycho-Acoustic Lab.)

The masking of speech by a periodically interrupted white noise was examined over a wide range of noise levels, rates of interruption, and noise-time fractions. To a first approximation, the masking produced by an interrupted noise is a constant fraction of that produced by a continuous uninterrupted noise. The masking produced by an interrupted noise is primarily a function of the interval between successive noise bursts and is relatively independent of the noise-time fraction and the rate of interruption of the noise, except insofar as these determine the interval between noise bursts. The effect of interrupted noise on the loudness of speech was also examined.

Hughes, J.R. AUDITORY SENSITIZATION. *J. acoust. Soc. Amer.*, Nov. 1955, 26, 1054-1070, Contract NSori 75, Proj. Order 11, ONR. (Harvard University, Psycho-Acoustic Lab.)

This experiment studied the lowering of the absolute auditory threshold that follows low-tone stimulation. Monaural thresholds were determined continuously with a recording audiometer before and after the ear was exposed to a pure tone. The frequency, intensity, and duration of both the exposure tones and the test tones were varied. Auditory sensitization was found to be a general effect among seventeen subjects. The magnitude of the effect was investigated intensively with three subjects. Their results demonstrated that sensitization produced by a pure tone is nonspecific; a given tone can sensitize the auditory system to a relatively wide range of test frequencies. Conversely, a relatively wide range of exposure frequencies can sensitize the auditory system to a given test tone. This nonspecificity is consistent with what we know, through microelectrode studies, about the spread of energy on the basilar membrane and the spread of excitation in the auditory nervous system. Contralateral sensitization effects were found.

Zwislocki, J. FACTORS DETERMINING THE SOUND ATTENUATION PRODUCED BY EARPHONE SOCKETS. *J. acoust. Soc. Amer.*, Jan. 1955, 27, 146-154, Contract NSori 75, Proj. Order 11, ONR. (Harvard University, Psycho-Acoustic Laboratory)

The factors that determine the sound attenuation provided by earphone sockets are analyzed on the basis of experimental evidence, and an attempt is made to determine the practical limit of sound attenuation attained by earphone sockets, when comfort and sound transmission from the earphone to the ear are taken into consideration. For frequencies below 700 cps the attenuation is limited by the mass of the system and the impedance of the flesh under the earphone cushion. For frequencies above 700 cps bone conduction is the determining factor.

Proj. 6-60-11-020, Rep. 184, July 1956, 105pp. Medical Nutrition Laboratory (9937), Fitzsimons Army Hospital, Denver 8, Colo.

3726

This is a study of the dietary composition and adequacy of the food consumed by soldiers under an ad libitum regimen. A food intake evaluation of 98 soldiers was conducted for a period of approximately 30 days during which time the intakes of calories, protein, fat and carbohydrate were measured. The diet was controlled with regard to eliminating food substances which offer difficulty in obtaining uniform assessments. The results are presented and discussed in terms of the mean intakes and their relation to energy expenditure, change in body weight, requirements under varied temperatures, etc.

Zwislocki, J. DEVELOPMENT OF A SEMIPLASTIC EARPHONE SOCKET. *J. acoust. Soc. Amer.*, Jan. 1955, 27, 155-161, Contract NSori 75, Proj. Order 11, ONR. (Harvard University, Psycho-Acoustic Lab.)

The semiplastic earphone socket is characterized by high internal viscosity and low elasticity. It can be deformed easily, but in the absence of external forces comes back to its original shape. The high viscosity has a strong sound attenuating effect. The paper describes the developmental steps leading to the design of a circumaural semiplastic socket and the performance of the socket. Its most outstanding features are high noise attenuation and comfort.

Krueger, G.K. INFORMATION THEORY AND MAN-MACHINE SYSTEMS. J. operat. res. Soc. Amer., Aug. 1954, 2, 320-323. (Tufts College, Medford, Mass.)

Information theory has been used recently as the basis for some experimental studies of the abilities of humans as processors of information. One possible approach to the analysis of man-machine systems is to consider the implications of such experimental knowledge for the design of man-machine systems. The functions performed by human operators in these systems are primarily those of control of the energy resources of the system. Control functions involve, by their very nature, the availability of relevant information and the opportunity to transmit control decisions reached on the basis of this information. It is important not only that enough information be available to an operator in order to carry out his control responsibilities, but also that these tasks be not complicated unnecessarily by the provision of too much or irrelevant information. Moreover, in applying an informational analysis to control tasks, it is essential that consideration be given as to what sorts of categories are perceptually possible for operators since any analysis which does not take into account certain perceptual limitations of humans is likely to be invalid. Following this point of view it is suggested that intelligent design of man-machine systems involves compatibility between the control requirements of a system and the capabilities of the men in the system.

Gagne, R.M. AN ANALYSIS OF TWO PROBLEM-SOLVING ACTIVITIES. Proj. 7709, Task 77154, Res. Bull. AFTRC TR 54 77, Dec. 1954, 14pp. USAF Human Systems Personnel Research Lab., Lowry AFB, Colo.

3731

To study interacting effects of vestibular stimuli, six subjects were rotated (turntable) signalling subjective responses by key pressing. Stimulus conditions: positive angular velocity (28 degrees/second) for ten seconds after end of first subjective effect; velocity increased to 70 degrees/second; deceleration to 13.5 degrees/second at eight magnitudes (zero to 43.5 degrees/second²); maintained until subject signalled end of subjective effect. Records of responses, angular velocities and time were made. Intervals between termination of positive angular acceleration and termination of subjective reaction for actual direction and between termination of deceleration and termination of apparent rotation in the opposite direction were analyzed as a function of the magnitude of deceleration. Obtained results are compared to theoretical expectations. T.G.R 21

3735

This paper presents a description of two problem-solving activities illustrating types of commonly occurring human activities—diagnosing equipment malfunctions and interpreting aerial photographs—and an analysis of the behavioral characteristics which set them apart from routine, habitual acts. The analysis includes an attempt to "guess" at the nature of intervening variables which might then be subjected to experimental study.

Smith, O.W., & Smith, Patricia G. INTERACTION EFFECTS IN JUDGMENTS OF CURVATURE. Contract NOKR 401(14), Res. Rep., March 1957, 24pp. ONR, Cornell University.

3736

To investigate interaction effects of variables of stimulation in the field of view on judgments of curvature (criterion of perceived depth), subjects (132) viewed a semi-cylinder and made free observations as to surface, size, and curvature; following observation of scaled samples of curved surfaces (11 steps from concave to convex) judgments of curvature were made. The interaction of number of spots (9, 45, 126) upon the surface of the cylinder with the presence or absence of binocular disparity was studied at two distances of observation (near and far). Other cues (form transformation, linear perspective, brightness differences, etc.) were minimized. Free reports and scaled judgments were analyzed for interaction effects. An hypothesis is proposed to account for the findings. T. O. I. R 7

3740
To determine the range of fluctuation of vestibular sensations in normal persons, a series of observations was conducted. The subject, seated in a revolving chair, indicated the moment when he felt he had completed a 45° rotation; for angles smaller than 45° he attempted to keep his hand fixed relative to the room. The variation of threshold for rotary movement with time was recorded. Effects of repeated stimulations, weak and strong, were tested (five subjects) and the relation between stimulus and sensations for rotations in the horizontal plane were investigated. The implications of the findings for the design of a cupulometer and for the evaluation of measurements for diagnosis are indicated.

Miller, J.G. INTEGRATION OF BIOLOGICAL AND SOCIAL DETERMINANTS OF STRESS REACTIONS. Contract DA 49 007 575, Proj. Rep. 1, Sept. 1954 - Feb. 1955, 11pp. Committee on Behavioral Sciences, *University of Chicago*, Chicago, Ill.

Theoretical and bibliographical work concerning the characteristics of psychological and physiological stress has been carried out. Specific research designs have been developed and instruments collected, designed, or built to use in carrying out these experiments. Psychological test instruments include films, a road-map test, a coding test, a turntable test, a logical game, the myokinetic test, and a pendulum test. The physiological indices include measures of galvanic skin response, heart rate, blood pressure, and respiration. Each of the new instruments devised or built is described in this progress report. Pretests have been carried out on a few subjects under non-stress conditions to learn the characteristics of, and develop norms for, some of the instruments. Preliminary studies with the stress of alcohol in-lic game, coding test, and myokinetic test, administered under the stress of alcohol intake, suggest that they may be stress-sensitive. Future detailed studies with all three instruments under stress and non-stress conditions are planned for various sorts of stress. The data will be treated by factor or cluster analysis and other methods of process analysis to determine which psychological and physiological indices of stress covary.

Poulton, E.C. VERBAL EXTRAPOLATION AND INTERPOLATION. Apr 17/53, Oct. 1953, 12pp. *Medical Research Council*, Applied Psychology Research Unit, Cambridge, England.

A comparison was made between continuing sentences (extrapolation) and filling gaps of unstated size in sentences (interpolation), when both operations occurred at the same randomly selected places in a story. It was found that the operations did not necessarily give different answers, although interpolation was more difficult than extrapolation. However, by a suitable choice of postcontexts, changes could be produced in the meanings and first words of the answers. The addition of a postcontext could actually increase the range of answers given.

Shackel, B. THE HUMAN LINES IN CONTROL. 2. OPTIMUM CONTROL-DISPLAY RATIOS AT DIFFERENT DISPLAY DISTANCES. A.P.U. 215/54, April 1954, 7pp. Applied Psychology Research Unit, Medical Research Council, Cambridge, England.

3747

To test a proposed hypothesis relating optimum control and display linear movements to display distance, (optimum angular control movement/angular display movement equals a constant) twelve subjects performed on a one dimensional compensatory tracking task with a positional control and an instrument display. Taking the optimum ratio to be 3:1, at display distance of 500 millimeters, and forearm length of 300 millimeters, a value for the constant of five was obtained by the proposed formula. Two other distances (300 and 1500 millimeters) and six ratios from 3/4:1 to 5:1 were tested. Predicted optimum linear movements were calculated and compared with scores obtained from the tests. The implications for the problem of optimum tracking conditions are discussed. T. I. R 3

3748 Conrad, R. & Hille, Barbara A. COMPARISON OF PACED AND UNPACED PERFORMANCE AT A PACKING TASK. APU 219/54, July 1954, 17pp. Medical Research Council, Applied Psychology Research Unit, Cambridge, England.

An experiment to test the hypothesis that the output of industrial conveyor belt systems would be less than that expected from knowledge of the mean processing time, using 5 experienced operatives as Ss was carried out on the shop floor of a factory. 3 specific questions were examined: a) What is the nature of the distribution of cycle time when the work is unpaced?; b) If the same work is then paced at a rate based on the unpaced mean, is output adversely affected?; c) When operatives carry out a complete cycle; b) when the cycle is divided between two operatives. In the first condition, a machine delivers work to an operative at equal time intervals. In the second condition a machine delivers work at equal time intervals to one operative, who carries out part of the cycle, and then passes the work on to another operative who completes the cycle. The mean cycle time in the unpaced condition showed no significant change in length throughout the day, but the coefficient of variation (used as a measure of scatter) increased consistently and without exception, the change from the beginning to the end of the day being from 0.19 - 0.22, which is statistically significant at better than the .001 level. Under the paced condition with one operative completing the cycle, output was as good as in the unpaced condition. When the work was divided between two operatives output fell by about 12%. The partial failure of the original hypothesis is considered to depend, to some extent on certain unavoidable differences in the working conditions introduced when changing from unpaced to paced, but largely on the relationship between the cycle time distribution and the linear speed of the conveyor belt. Kerslake, D. McK., Waddell, J.L. & Brebner, D.F. THE DIFFUSION OF WATER VAPOUR THROUGH HUMAN SKIN. FPRC 902, Nov. 1954, 5pp. RAF Institute of Aviation Medicine, Flying Personnel Research Committee, London, England.

Past observations of total skin water loss from non-sweating subjects have failed to agree quantitatively with the hypothesis that such water loss is due to a passive diffusion of water vapour through the epidermis. The errors may be ascribed to the inclusion in the weight loss of the sweat produced by constantly sweating areas and to possible inaccuracies in the estimation of pulmonary weight loss. When these factors are controlled it is shown that the rate of water loss is a simple function of the vapour pressure gradient from saturation at approximately skin temperature to ambient water vapour pressure. Whiteside, T.C.D. VISION IN AN EMPTY VISUAL FIELD. THE RELATION OF THE EFFECTIVENESS OF A STIMULUS AT THE FAR POINT TO ITS ANGULAR DISTANCE FROM THE FOVEA. FPRC 898, Oct. 1954, 3pp. RAF Institute of Aviation Medicine, Flying Personnel Research Committee, London, England.

The presence in the field of view of a stimulus of detail which can be sharply focussed, prevents the involuntary focussing for near which takes place when the visual field is empty. The effectiveness of such a stimulus, however, depends on how near it is to the line of sight. When it is in the line of sight it is most effective and beyond 20 from the line of sight it rapidly becomes less effective in making the subject focus at infinity. It loses almost all its effect in making the subject focus at infinity by the time it is at 50 from the line of sight. The results show a striking similarity to the graph of visual acuity at various angular distances, from the fovea. This similarity is to be expected since the accommodation reflex is mediated through the stimulation of cones. R 2

Miller, H.G. INVESTIGATION OF ACCIDENTS FOR CAUSE AND REMEDY. NO. 3, Dec. 1954, 6pp. U.S. Department of Labor, Bureau of Labor Standards. (Prepared for the President's Conference on Occupational Safety).

The principal purpose of accident investigation is to obtain information that will be of help in the prevention of accidents. To fulfill this purpose, investigations must be objective, factual, and free of disciplinary implications. Accident investigation is of such prime importance to the accident-prevention program that the device must be preserved exclusively for obtaining information on accident causes. If it is ever used, or if there is a feeling that it will be used to establish guilt, it will lose some, and maybe most, of its usefulness as a method of obtaining the full and complete facts about an accident.

Salomon, Ann D. VISUAL FIELD FACTORS IN THE PERCEPTION OF DIRECTION. *Amer. J. Psychol.*, Jan. 1947, LX, 68-88. (Duke University, Durham, N.C.).
- 3764
To investigate some factors in the perception of direction, a basic reference pattern (tilted straight line varying in length from 0.5 to 22 inches) determined a direction which the observer (N=10) indicated by moving a dot (presented at 3, 2.5, and 0.25 ft. from proximal end of line) so as to locate it along the perceived extension of the line. Precision of repeated localizations was measured by calculating the standard deviation of the settings from the mean and analyzed as functions of length of reference line and distance of dot from end of line. Methods of localization and training are discussed.

Petherbridge, P., & Hopkinson, R.G. DISCOMFORT GLARE AND THE LIGHTING OF BUILDINGS. *Trans. Illum. Engng Soc., Lond.*, 1950, 15, 39-79. (Building Research Station, Garston, Watford, England.)
- 3765
To obtain more knowledge of the effects of glaring light sources on vision, a technique of subjective appraisal was used. The observer controlled a relevant physical variable to give, in turn, each of a series of precisely defined criteria of discomfort glare. Source intensity, shape and position, as well as contrast between source and surround were varied and the effects observed and evaluated. The effect of such factors as the displacement of a glare source from the general direction of view and the glare effect of a number of sources was also studied. The relation between the various physical factors is complex, but appreciation to problems of lighting design are made and discussed.

Hopkinson, R.G. THE MULTIPLE CRITERION TECHNIQUE OF SUBJECTIVE APPRAISAL. *Quart. J. exp. Psychol.*, 1950, 2, 124-131. (Building Research Station, D.S.I.R.)
- 3766
To make quantitative assessments of subjective aspects of perceptual responses to the physical aspects of a stimulus situation, an experimental technique (Multiple-Criterion) is described whereby the subject controls one of the significant variables and sets it to correspond with a limited number of defined criteria relating to a subjective variable. A functional relationship can then be estimated, for example, glare-discomfort. Precautions to be taken in design of experiments and the uses to which this technique has been put are discussed.

Hopkinson, R.G. & Petherbridge, P. TWO SUPPLEMENTARY STUDIES ON GLARE. *Trans. Illum. Engng Soc., Lond.*, 1954, 19, 220-224. (Building Research Station, Watford, Herts, Eng.)
- 3767
To study the validity of experimental procedures of assessment of glare discomfort and empirical formulae derived from model-scale studies, two experiments were performed: 1) full-scale and model-scale installations were compared; as the illuminance of the sources was increased the observer reported when each of four criteria of glare had been reached (just perceptible, just acceptable, just uncomfortable, and just intolerable); and 2) 70 Ss., representative of the general population, made glare judgments at three levels of source luminance; these readings were compared with those from an experienced team of observers.

Collins, J.B., & Hopkinson, R.G. FLICKER DISCOMFORT IN RELATION TO THE LIGHTING OF BUILDINGS. *Trans. Illum. Engng Soc., Lond.*, 1954, 19, 135-158. (Building Research Station, Watford, Eng.)
- 3768
To investigate discomfort due to flicker in lighting installations, a series of experiments was conducted on a full scale with the whole field of view undergoing fluctuation of illumination. Observers were asked to report on four criteria of flicker: just perceptible, just obvious, just uncomfortable, and just intolerable as frequency of fluctuation was varied. Variables investigated and analyzed by this procedure were: individual variability, luminance of field, wave-form of light-time characteristics of the source, including modulation and dark-time ratio. The results were related to fluorescent lighting practices and recommended procedures were included.

Hopkinson, R.G. INFLUENCE OF EXPERIENCE ON THE SENSITIVITY TO DISCOMFORT. *Nature*, Jan. 1952, 169, p40. (Building Research Station, Garston, Watford, England).

The sensitivity of a S to discomfort arising from his environment may be dependent in some degree on his familiarity with, or technical knowledge of the environment. This paper describes a study designed to test the existence of this sensitization using the apparatus of the 'control experiment' of a 'multiple criterion' study. 2 Ss also unfamiliar with lighting and glare technology were selected, along with other Ss who were familiar with the experiment and its technology. Under a series of conditions over a period of weeks, both groups were required to give assessments of personal discomfort due to glare. Although at first the assessments of the experienced Ss and the test Ss differed considerably, the test Ss being less sensitive to glare than the experienced Ss, as the test proceeded the test Ss developed a sensitivity which approached that of the experienced Ss. The experienced Ss held their criterion unchanged over the test period (in fact over a period of 2 years). (HEIAS)

Harris, J.D. ON LATENT DAMAGE TO THE EAR. *J. Acoust. Soc. Amer.*, 1955, 27, 177-179. (USN Medical Research Lab., New London, Conn.)

The purpose of this communication is to serve as a warning to the now numerous people seeking to prevent partial deafness in ears subjected to loud noise. If the results here can be extended to the case of permanent threshold shifts, they may indicate that work periods should be set not only to allow the ear to recover to normal by audiometric test, but to provide in addition a time interval sufficient for the effects of latent damage to be dissipated.

Pikier, A.G. & Harris, J.D. CHANNELS OF RECEPTION IN PITCH DISCRIMINATION. *J. Acoust. Soc. Amer.*, 1955, 27, 124-131. (USN Medical Research Lab., New London, Conn.)

Pitch discrimination was studied in 4 normal hearing subjects monaurally, binaurally, and in a variety of other channels of reception. No difference exists in sensitivity between the two normal ears of a subject, nor is there a difference between the sensitivity of the monaural channels and the binaural channel if all are matched for loudness. Also bone conduction was found to yield essentially equal pitch D's after loudness was matched. All channels, except successive interaural, are equivalent under matched conditions. Successive interaural channels (standard in the right, variable in the left, and vice versa) show some deterioration of sensitivity and some increase in variance which can be attributed to the monetary fluctuations of diplacusis. Similar fluctuations were found also with respect to a channel utilizing a monaural standard and a binaural variable stimulus, the two ears matched in loudness. Under these conditions, furthermore, a third pitch is sensed, a phenomenon we term "triplacusis." The authors suggest an interpretation of diplacusis and triplacusis as interaural interactions. In cases of perceptible hearing loss, however, the channels are not usually equivalent in pitch discrimination when matched for loudness. Evidently other principles must be sought for the pathological case.

3775 USN Special Devices Center. PSYCHOLOGICAL STUDIES OF ADVANCED NAVAL AIR TRAINING: EVALUATION OF OPERATIONAL FLIGHT TRAINERS. RESEARCH RESULT. Proj. NR 780 011, SDC Proj. 20 A 8, SDC TR 959 1 1, Sept. 1950, 4pp. USN Special Devices Center, Port Washington, N.Y. (The Psychological Corporation, New York, N.Y.).

This report presents the results of an experimental evaluation of Operational Flight Trainers (OFT) conducted at the Naval Advanced Training Command at Corpus Christi, Texas. Primary interest of the study was in training time savings and quality potential (improving efficiency) with secondary interest on trainer design improvement. In general, it was concluded that flight time cannot be saved in the FAA stage by use of OFT's but in the INST, basic and advanced, some savings can be made. OFT training does make a difference in proficiency of students with fewer serious errors and fewer total errors on most maneuvers. The Trainer can be used more effectively in Advanced Training as a superior type of briefing. With regard to trainer design it was noted that "air work" tasks were not simulated as closely as procedural tasks and a suggestion is made that the specific purpose of the trainer be defined. Further recommended for study is the potential value of trainers for operational and reserve flight training. (HFIAS)

3776 Olenski, Z., & Goodden, N.W. CLEARNESS OF VIEW FROM DAY-FIGHTER AIRCRAFT (PART OF "ABILITY TO SEE"). Rep. Aero 1862, Oct. 1943, 54pp. Royal Aircraft Establishment, Farnborough, England.

3776 To clarify the nature of "operational clearness of view" in fighter aircraft and the main hindrances to its improvement, a qualitative study was conducted. The importance and nature of seeing in combat were defined; hindrances to clearness of view were investigated by observation, analyses of photographs, and shadow photography; estimation of probable effects on fighting efficiency of such hindrances was based on personal experience, interviews, and survey of the literature; polishing and maintenance problems were investigated by tests and observations. Improvements necessary for clearness of view are discussed together with a number of detailed recommendations.

3777 Bullock, D.H., & Meyer, Susan R. PARAMETERS OF A VISUAL MONITORING TASK. Contract AP 30(602)-574; Scientific Rep. 1, RADG-TN-55-67. University of Buffalo.

3777 To investigate some factors influencing visual monitoring, 28 subjects were required to discriminate whether the second of two film-presented spatial-temporal patterns (successive appearances of a single dot in a square grid) was the same or different from the first. The variables were: (1) information loading (two to seven dots per pattern, 25 or 36 cells per grid); (2) rate of presentation (16 and 24 frames per second); (3) three dot sizes; (4) over-all task complexity (two to six or three to seven dots per pattern); and (5) position of change of dot. Two experiments were conducted. The data (mean and median percent discriminations) were studied by analysis of variance techniques for differences due to the experimental conditions.

3784 To investigate man's ability to stabilize and control in space a platform attached to his feet and supported by a jet thrust, five subjects made several experimental flights. The device was a small platform rigidly connected to a jet nozzle having its thrust axis perpendicular to the platform and its thrust opposed by the pull of gravity. Suitable cleats and tie-down straps were used to keep the feet from slipping. Additional weights and a source of moderate gyroscopic effect were tested. Other additions included rigid landing gear, a seat, and a control stick. The basic principles involved and possible military applications are discussed.

Duncan, C.P. & Underwood, B.J. TRANSFER OF TRAINING AFTER FIVE DAYS OF PRACTICE WITH ONE TASK OR WITH VARIOUS TASKS. Contract AF 33(616) 308, Proj. 7197, WADC TR 54 533, Dec. 1954, 15pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Northwestern University, Evanston, Ill.).

3793

To investigate the effects of variety of practice on transfer of training, three groups of 45-56 college students practiced five days making manual settings of a lever appropriate to visually perceived forms. Practice conditions were: 1) concentration on one task, 2) ten tasks (different stimuli), and 3) ten variations of task. All groups then practiced four days with forms, nonsense syllables, and color patches as stimuli. Intergroup differences in correct responses on the final tasks are interpreted in terms of the effectiveness of the variety of prior practice. Implications for the design of training devices are discussed.

Mason, H.M. A FURTHER STUDY OF EXPERIENCE-CENTERED AND REQUIREMENTS-CENTERED TESTS OF JOB KNOWLEDGE. J. appl. Psychol., 1956, 40, 14-16. APFTRC-TN-56-66, June 1956, APFTRC, San Antonio, Texas.

3790

To compare the validity of experience-centered and requirements-centered tests of job knowledge for use in placing men who enter the Air Force with previous experience or training that fits them for direct assignment to a job specialty, two tests based on actual job operations were developed and three tests were developed from items in formal statements of technical knowledge requirements. Test validities were determined by comparing test means for samples of mechanics (553) from three Air Force designated skill levels: apprentice, senior mechanic, and supervisor-technician. An analysis of variance design was used to determine the significance of relations between test means and criterion skills. Significant differences between pairs of tests in their relation to criterion levels were determined. T. R 3

McGuire, J.C. APPARATUS FOR PRESENTATION AND CONTINUOUS MEASUREMENT OF ERROR IN A TWO-DIMENSIONAL COMPENSATORY TRACKING TASK. Contract AF 33(616) 135, Proj. 7185, WADC Tech. Rep. 54 335, Dec. 1954, 25pp. WADC, Air Research and Development Command, Aero Medical Lab., Wright-Patterson AFB, Ohio. (Washington University).

An electronic compensatory-tracking apparatus which utilizes a two-dimensional target locus is described together with its computing and recording circuits. The apparatus was designed to provide a standard task of variable difficulty for use in the study of attention. The target path used approximates the equation $\theta = \cos 2\theta$. This is a four-leaved rose curve. The stimulus spot is displayed on the face of a cathode ray oscilloscope (CRO). Control is exercised by the subject through manipulation of a joystick of very low mass and friction. Subject error, represented by the displacement of the stimulus spot from the intersection of a pair of crosshairs on the CRO screen, corresponds to $\sqrt{x^2 + y^2}$ where x and y are the input voltages to the CRO. The quantity $\sqrt{x^2 + y^2}$ is computed continuously by the electronic analog computer and recorded both as a function of time and as an integrated error score. R 8

Rockway, M.R. THE EFFECT OF VARIATIONS IN CONTROL-DISPLAY RATIO AND EXPONENTIAL TIME DELAY ON TRACKING PERFORMANCE. Proj. 7197, Tech. Rep. 54-618, Dec. 1954, 20pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio.

3797

To demonstrate the interaction between control-display (C/D) ratio and exponential time delay on tracking performance, eight experienced operators performed a two-dimensional compensatory tracking task. Sixteen combinations of four C/D gear ratios (one degree of control movement produced either 3-, 6-, 15-, or 30-sixteenths inches of display movement) and four C/D exponential time delays (.3, .6, 1.5, and 3.0 seconds) were practiced by each subject on two different days. Mean percent time-on-target scores were studied by analysis of variance for differences due to ratios, delays, subjects and interactions. Graphic records of performance are presented for one typical subject.

Flyer, E.S., & Bigbee, L.R. THE LIGHT PLANE AS A PRE-PRIMARY SELECTION AND TRAINING DEVICE: III. ANALYSIS OF SELECTION DATA. Proj. 7701, Task 77023, Tech. Rep. AFTRC TR 54 125, Dec. 1954, 13pp. USAF Personnel and Training Research Center, Lackland AFB, Texas.

The present Technical Report deals with the possible use of the light plane as a selection device. This phase of the research sought to ascertain whether data on cadet performance in light plane training would add to the efficiency of existing selection procedures in the prediction of success in subsequent flying training. The light plane group (N=120) was given 25 hours of light plane flying during its six weeks of Pre-Flight Air Force Training prior to beginning Primary Pilot Training in the T-6 at Goodfellow Air Force Base. During light plane training numerous evaluative techniques were employed, and during subsequent training various performance criteria were collected. The major implication of this research is that evaluations of pilot proficiency made during light plane training are predictive of success in Primary and Basic Training and that the most effective prediction of performance during Primary and Basic is obtained when these measures are used in conjunction with the Pilot Stoline. It also is noteworthy that, the Pilot Stoline showed appreciable validity for the prediction of performance during light plane training.

- 3801 Haythorn, M.W. RELATIONSHIPS BETWEEN SOCIONETRIC MEASURES AND PERFORMANCE IN MEDIUM BOMBER CREWS IN COMBAT. Proj. 7713, Res. Bull. AFPTC TR 54 101, Dec. 1954, 20pp. AFTRC, Crew Research Laboratory, Randolph AFB, Tex.
- A battery of questionnaires including an attitude survey, a crew-description form, and a sociometric rating scale was administered to 102 medium bomber B-29 crews in combat over Korea. In this report the responses to the sociometric instrument were analyzed for their reliability and their relationships with the attitude scales, the crew-description form, and ratings of over-all crew effectiveness by superior officers (squadron and wing officers.) Significant correlations were found indicating that crew mean sociometric scores co-vary with crew mean attitude scores--particularly attitude scales related to pride in the crew--and with ratings of the crew by superior officers. The correlations between sociometric scores of individuals and the criterion measures were found to be to some degree a function of the formal crew position of the individual.

- 3802 Crowder, M.A. PROFICIENCY OF Q-24 RADAR MECHANICS: V. LEVEL OF TROUBLE-SHOOTING PERFORMANCE OBSERVED. Proj. 7709, Task 77151, Res. Bull. AFPTC TR 54 102, Dec. 1954, 37pp. AFTRC, Air Research and Development Command, Armament Systems Personnel Research Lab., Lowry AFB, Colo.
- A Performance Trouble-Shooting Test on an operating Q-24 system was administered to 126 working line mechanics. Of 979 individual problem trials, the malfunction was found without any false diagnoses in 497. It was found after one or more false diagnoses in 316, and 166 problem trials resulted in failures. A total of 906 false diagnoses were made in the 979 trials. On problems requiring interpretation of data flow the mechanics' performances were not as good as those obtained over all problems. For problems involving qualitative understanding of devices such as synchros and servomechanisms the performance shown was quite poor. The mechanics appeared to work to a great extent by trial and error; they used test equipment in only 242 of 623 problem trials where it was definitely required for a systematic solution to the problem; and they made a sufficient confirmatory check before replacing a subunit in only 203 of 600 problem trials where such a check was possible and necessary. It is believed that these results do not in themselves justify major investment in maintenance systems which relieve the line mechanic of the necessity of trouble shooting, even supporting such were possible. Some remedial factors which may account for the relatively poor performance are discussed. These include inadequate training and practice in systematic trouble shooting, situational factors on the job which might encourage trial-and-error behavior, and inadequacies in the mechanics' reference materials. Specific suggestions for improvement of trouble-shooting performance are a) specific training in systematic trouble shooting; b) continuing training on the job, monitored by periodic proficiency evaluation; and c) the provision of job-oriented maintenance handbooks.

- 3810 Parks, R.B. SOME ASPECTS OF PART AND WHOLE TASK PERFORMANCE IN FLEXIBLE GUNNERY PEDESTAL SIGHT MANIPULATION. Proj. 7708, Task 77141, Res. Bull. AFPTC TR 54 117, Dec. 1954, 8pp. USAF Armament Systems Personnel Research Lab., Lowry AFB, Colo.
- 3810 To evaluate consistency of student performance on the Flexible Gunnery Proficiency Evaluator, 120 student airmen were given four days of practice trials, and their performance (time-in-error) was intercorrelated for the four days. An additional 30 airmen were given tasks involving only one or two of the three basic task components--range, azimuth, and elevation. Correlations and performance curves are interpreted regarding interday reliability of S performance on the device, and performance on component tasks as contrasted with whole-task performance.

Tolhurst, G.C., & Peters, R.W. THE EFFECT OF ATTENUATING ONE CHANNEL OF A DICHOIC CIRCUIT UPON THE WORD RECEPTION OF VOICE MESSAGES. Contract N6onr 22525, Proj. NM 001 064.G1.36, Dec. 1954, 16pp. USN School of Aviation Medicine, Pensacola, Florida. (Ohio State)

Dichotic-listener reception of simultaneous messages was studied as a function of attenuation of the signal level of one of the messages. Listeners, serving in panels, received two messages simultaneously through dichotic headset circuits. The signal level of one message was attenuated in five steps of three decibels each relative to the level of the other message. The simultaneous messages were groupings from the multiple-choice intelligibility tests. Listeners heard the messages under conditions of quiet and noise. The noise was simulated aircraft noise.

Black, J.W. THE RELATIVE EFFECTIVENESS OF BRIEF INSTRUCTIONS TO ACHIEVE SLOW SPEED. Contract N6onr 22525, Proj. NM 001 064.G1, Rep. 37, Dec. 1954, 4pp. USN School of Aviation Medicine, Pensacola Air Station, Fla.

3812

To investigate the relative effect of various types of instruction upon eliciting changes in vocal sound pressure levels and voice intelligibility, 144 subjects received one of six types of instruction during an intelligibility test. The results are presented and discussed in terms of the most effective instruction in eliciting an increase in sound-pressure level without detriment to vocal intelligibility.

3813

Tolhurst, G.C. VARIABLES OF ENVIRONMENT AND PRINTED MATERIALS IN INTELLIGIBILITY TESTING. Contract N6onr 22525, Joint Proj. Rep. NM 001 064.G1.38, Dec. 1954, 10pp. USN School of Aviation Medicine, Pensacola, Florida. (Ohio State University)

Listeners and speakers in administrations of the multiple-choice intelligibility tests were exposed to comparison noises of two different spectra but of similar level. The noise recorded at the copilot's position in a twin-engine aircraft produced more masking of speaker intelligibility than the noise that simulated a single-engine spectrum. Recordings of two nine-member teams reading a form of the multiple-choice intelligibility tests in counter-balanced rotational order did not yield different intelligibility scores. Regular cross-out response forms for the multiple-choice intelligibility tests yielded higher scores than did forms prepared for IBM scoring. Listener variability was the same under both circumstances.

Tolhurst, G.C. SOME EFFECTS OF CHANGING TIME PATTERNS AND ARTICULATION UPON INTELLIGIBILITY AND WORD RECEPTION. Contract N6onr 22525, Joint Proj. Rep. NM 001 104 500.40, Jan. 1955, 15pp. USN School of Aviation Medicine, Pensacola, Florida. (Ohio State University)

Multiple-choice intelligibility items were read by one voice successively in a prolonged, a normal, and a staccato manner of delivery. The listener judgments indicated a preference for the normal and prolonged delivery over staccato; they also accorded different intelligibility values to the three conditions. When other speakers heard and repeated to listeners the words that they had heard recorded by one voice, the speakers' intelligibility scores varied in keeping with the precision of articulation of the original stimulus. Listener judgments of recorded, paired test items indicated that they could tell, with significantly better than chance frequency, differences between items that were precisely, normally, and slovenly articulated as the speakers repeated the items they heard.

Black, J.W. THE PERSISTENCE OF THE EFFECTS OF DELAYED SIDE-TONE. Contract N6onr 22525, Joint Proj. Rep. NM 001 104 500.39, Jan. 1955, 6pp. USN School of Aviation Medicine, Pensacola, Florida. (Ohio State University)

28 male experimental subjects read 10 lists of 5 5-syllable phrases, including one practice list. Lists 3 and 4 were read in the presence of 0.30-sec. delayed side-tone. A similar control group read with no delayed side-tone. Measurements were secured of reading rate and sound pressure level. The incremental effects of delayed side-tone upon sound pressure level was transitory; the retarding effect upon rate of reading persisted throughout the remaining reading time, 150 secs.

Peters, R.W. VOICE INTELLIGIBILITY AS A FUNCTION OF SPEAKERS' KNOWLEDGE CONCERNING THE CONDITIONS UNDER WHICH THEIR TRANSMISSIONS WILL BE RECEIVED BY LISTENERS. Contract N60nr 22525, Joint Proj. Rep. NH 001 104 500-41, Feb. 1955, 7pp. USN School of Aviation Medicine, Pensacola, Florida. (Ohio State University)

Speakers read multiple-choice intelligibility test words immediately after receiving voice transmissions under conditions of quiet or under various levels of noise. The speakers were informed that these transmissions represented conditions under which listeners would hear their voices. Among the speakers employed was a group of speakers not experienced in military voice communication procedure and a group experienced in these procedures. Of the speakers used, only those who were inexperienced in communication procedures became more intelligible in response to information that listeners would hear their voices under conditions of noise as opposed to conditions of quiet. In no instance did voice intelligibility vary consistently as a function of the amount of noise accompanying transmissions to the speaker.

Lloyd, V.V. A COMPARISON OF CRITICAL FUSION FREQUENCIES FOR DIFFERENT AREAS IN THE FOVEA AND PERIPHERY. *Amer. J. Psychol.*, 1952, 55, 346-357, Contract N60nr 271, Proj. NR 142 404, Task Order 9, 28p. (Columbia University)

An apparatus and procedure have been described for determining the critical fusion frequency as a function of intensity for the human eye. Areas with diameters of 1°, and 2° visual angle in the fovea and of 1°, 2°, 6°, and 14° visual angle centered 20° below the fovea have been investigated. The data for the foveal areas seem to indicate the functioning of a single receptor, i.e., cones. Those for the periphery fall into two parts which are probably due to rod and cone function, respectively, according to intensity-level. Both sets of data show that the critical fusion frequency increases with area of stimulation over a wide range of intensities. A comparison of results for the corresponding foveal and peripheral areas reveals that at low intensities the periphery is more sensitive to flicker than the fovea while for intermediate and moderately high brightness levels, the situation with comparable areas (1° and 2°) is reversed. The superiority of the periphery at low intensities is attributed to the greater sensitivity of the rods at these levels. At the very highest intensities the 1° and 2° foveal and peripheral areas show similar maximal critical fusion frequencies. Possible hypotheses to account for the higher maximal critical fusion frequency found with the 6° and 14° peripheral areas (as contrasted with the 1° and 2° foveal areas) are examined. It is concluded that either a) rods as well as cones contribute to flicker at high brightness levels, or b) peripheral cones have characteristics that differ from those of the foveal cones.

Diamond, A.L. FOVEAL SIMULTANEOUS BRIGHTNESS CONTRAST AS A FUNCTION OF INDUCING- AND TEST-FIELD LUMINANCES. *J. exp. Psychol.*, May 1953, 45, 304-316. (Columbia University)

Simultaneous brightness contrast is investigated in the fovea as a function of the inducing- and test-field luminances. The inducing and the test fields are adjacent squares, each subtending 33' on a slide, and presented to S's right eye. A match-field of equal size is presented to S's left eye. The S's task is to set the luminance of the match field so that its brightness appears equal to that of the test field. As the inducing field is varied in luminance from below to above that of the test field, the apparent brightness of the test field, and thus the contrast effect, is measured by the actual luminance of the match field. The results show the contrast function to be of the following nature. The test-field apparent brightness is depressed only slightly for inducing-field luminances less than that of the test field. For inducing-field luminances greater than that of the test field the depression of the test-field apparent brightness seems directly proportional to the luminance of the inducing field. Thus, a "bend" in the function occurs when the inducing-field luminance is approximately equal to that of the test field. This relation is consistent over a large range of test-field luminances. A theoretical formulation based upon the relation of the test-field apparent brightness to the activity in the visual field completely surrounding the test field leads to an equation satisfactorily fitting the data. The physiological nature of this surround activity is undetermined. The possibility of binocular contrast effects between the inducing and the match fields was considered and shown to be insignificant in a control experiment.

Lothridge, C.O. STEREOSCOPIC SETTINGS AS FUNCTIONS OF VERTICAL DISPARITY AND TARGET DECLINATION. *J. gen. Psychol.*, 1953, 49, 241-271. (Psychology Dept., Columbia University, New York, N.Y.). (ONR)

The purpose of the present experiment was to investigate the effect on stereoscopic settings of the introduction of vertical disparity and target declination. The dependent variable was measured in terms of the average and the variability of the settings made by the S. The independent variable, vertical disparity, is defined as a difference in the distance between the target and fiducial mark for the views presented to the right and left eyes. Target declination is defined as rotation of the target from the vertical position in the frontal plane. The stimuli, a vertical line (the target) and a circle (the fiducial mark), were stereoscopically presented to the S. 4 vertical disparities were introduced: 0, 3.8, 11.5, and 19.2 min., at each of the 4 target declinations: 0°, 30°, 60°, and 90°. The S adjusted the horizontal position of the right eye target until the fused target appeared in the same frontal plane as the fiducial circle. 4 experimental sessions were conducted for each of the 4 Ss. Conclusions were: Mean settings do not change systematically with vertical disparity. As the amount of vertical disparity increases, the precision of stereoscopic settings tends to decrease, as shown by an increase in variability. For a given vertical disparity, an increase in target declination up to 50° decreases the precision of stereoscopic settings, as shown by an increase in variability. For the horizontal target (90° target declination) a) variability decreases below that for the 30° and 60° declinations when 11.5 min. of vertical disparity is introduced; and b) at maximum disparity, 19.2 min., variability is between that found for the 30° and 60° declinations. The "unassociated tips" control experiment shows that values which are very close to those predicted by theory can be obtained under conditions where the tips are eliminated. When the distance factor (the distance between target and fiducial mark) was investigated with the vertical target, it was found that there was a decrease in precision when the distances between target and fiducial mark were used. Davy, E. THE INTENSITY-TIME RELATION FOR MULTIPLE FLASHES OF LIGHT IN THE PERIPHERAL RETINA. J. Opt. Soc. Amer., Dec. 1952, 42(12), 937-941. (Columbia University, New York, N.Y.).

This study investigates the effect upon threshold of multiple light pulses, 0.01 sec. in duration, that fall on the peripheral retina. In one series of experiments a train of 1 to 5 such pulses is presented, the interval between pulses being 0.01 sec. The maximum duration of such a train of pulses is shorter than the critical duration for a single flash of light, found by Long to be 0.10 sec., under conditions similar to those that hold in the present investigation. In another series of experiments, threshold determinations are made for two such pulses separated by 4 temporal intervals less than, and by 6 temporal intervals greater than, critical duration. The results indicate that the breaking up of a light stimulus into separate flashes has no effect upon threshold provided these flashes occur within a critical duration. When 2 flashes are separated by temporal intervals greater than critical duration, threshold energy rises and, at a temporal separation of 0.5 sec., is the same for each of two flashes as it is for one flash. Under the latter circumstances the subject reports the existence of two flashes.

Brown, J.L. EFFECT OF DIFFERENT PREADAPTING LUMINANCES ON THE RESOLUTION OF VISUAL DETAIL DURING DARK ADAPTATION. J. Opt. Soc. Amer., Jan., 1954, 44, 48-55. USAF Contract AF 33(038)-22616, Res. and Development Order 694-45, WADC, Psychology Branch of the Aero Medical Lab., Wright-Patterson AFB, Ohio. (Columbia Univ., Dept of Psychology, New York, N.Y.)

3822

Luminance thresholds for the resolution of various widths of grating line were determined during dark adaptation following light adaptation to luminances of 0.98, 100, 1290, and 11, 200 ml. for five minutes. Threshold curves were obtained for two observers for each of these preadaptation conditions using grating test objects which represented visual angles of 1.6, 4, and 24 minutes of arc as well as for light detection with no grating in the test field. The results are presented graphically for each subject and for each of the light-adapting luminances and are discussed in the text.

Leibowitz, H. SOME OBSERVATION AND THEORY ON THE VARIATION OF VISUAL ACUITY WITH THE ORIENTATION OF THE TEST OBJECT. J. Opt. Soc. Amer., Oct. 1953, 43, 932-905. Contract #60nr-271, Proj. NR 142-404, Task Order IX, U.S. Office of Naval Research. (Univ. of Wisconsin, Madison, Wisconsin.)

3823

To study the effect of pupil diameter and luminance level on the differences which result in visual acuity measures as a function of the angle of orientation of a grating test object, the data of 2 subjects from a previous experiment were analyzed to isolate the effect of orientation. The results are presented in a table as the threshold angle of resolution in seconds of arc for various orientations, luminances, and pupil diameters and in a figure as log visual acuity plotted against log pupil diameter. The results are then used to evaluate two of the explanations which have been offered for the phenomenon under consideration.

3824

Leibowitz, H. THE EFFECT OF PUPIL SIZE ON VISUAL ACUITY FOR PHOTOMETRICALLY EQUALIZED TEST FIELDS AT VARIOUS LEVELS OF LUMINANCE. J. Opt. Soc. Amer., June, 1952, 42, 416-422. Contract #60nr-271, Task Order IX, ONR. (Columbia Univ., Psychol. Lab., New York, N.Y.)

3824

Visual acuity for a grating test object was determined for 2 subjects as a function of artificial pupil diameter at 5 luminance levels. In order to eliminate the effect of variation of retinal illuminance with pupil size changes as a factor in acuity, the luminance of the acuity test field as viewed through each artificial pupil was previously adjusted to match a reference field of constant luminance viewed by the other eye through a fixed pupil at 5 luminance values of the reference field. Selection of maximum artificial pupil size was made on the basis of photos of the natural pupil taken under conditions similar to that of the experiment. The acuity data are plotted to show the effect of pupil size as a parameter of the acuity-reference luminance function.

Brown, J.L., Graham, C.H., Leibowitz, H. & Ranken, H.B. LUMINANCE THRESHOLDS FOR THE RESOLUTION OF VISUAL DETAIL DURING DARK ADAPTATION. J. Opt. Soc. Amer., March 1953, 43(3), 197-202. (Dept. of Psychology, Columbia University, New York, N.Y.).

3825

To study visual acuity during the course of dark adaptation, luminance thresholds for the visual resolution of five widths (visual acuity = 1.04, 0.62, 0.25, 0.083, and 0.042) of alternating light and dark lines were determined at various times during dark adaptation (two Ss). Threshold data for the different acuities were analyzed as function of time in the dark. Comparison was made with dark adaptation curves obtained with light detection thresholds.

3826

This article describes the development, design, and function of a device for simulating the visual displays of PPI scopes. The characteristics of the visual display as seen by the observer are discussed in detail along with specific aspects of target presentation such as the variability of luminance and contrast between target and background.

3827

Sleight, R.B., Bond, H.J. & Lerner, M.D. HUMAN ENGINEERING APPRAISAL OF MILITARY GENERAL PURPOSE WHEELED VEHICLES. FINAL REPORT. Contract DA 36 034 ORD 1597RD, DA Proj. 595 20 OG1, ORD Proj. T81 1000, Apr. 1955, 123pp. USAF Human Engineering Lab., Aberdeen Proving Ground, Md. (Applied Psychology Corporation, Washington, D.C.).

The purpose of this project was to make a broad analysis of truck cab design from the human engineering standpoint. Methods used were: a) interview and questionnaire, b) readability analysis, c) motion picture analysis, d) literature review, and e) application of known human engineering design principles. Modified designs of instruments, controls and their combination in the cab were suggested. The results indicated a need for simplifying the vocabulary and style of the technical manuals, relocating controls and instruments nearer the driver, adding and eliminating some controls, and improving visibility. Significant gaps in pertinent experimental literature were noted.

Vernon, M.D. THE USE AND VALUE OF GRAPHICAL MATERIAL WITH A WRITTEN TEXT. Occup. Psychol., April 1952, XXVI(2), 96-100.

3832

This is a report of 2 experiments exploring the value of using graphs to amplify a written text. In one experiment 15 adolescent girls read a text and saw 5 pictorial charts illustrating the text either before, during, or after reading; they were then asked questions on the contents of the text. In the other experiment, 22 adolescent girls made oral statements of what they remembered of the contents of texts read to them, some with, some without graphical illustrations. Results are discussed regarding the contributions of graphs toward learning facts and toward understanding the general argument of written texts.

3833

Vernon, M.D. THE USE AND VALUE OF GRAPHICAL METHODS OF PRESENTING QUANTITATIVE DATA. Occup. Psychol., Jan. 1952, XXVI(1), 22-34.

3833

This paper presents a summary report of the first part of a systematic inquiry into the remembering and understanding of information presented in graphic form. Data relating to vital statistics and manpower, production, and consumption during World War II were presented by graph, pictorial chart, and table. People of widely varying types were asked to study them and respond to questions relating both to facts and generalized conclusions which could be drawn from the data. Analysis relates the data to intellectual and educational level as well as to the differences among the three forms of presentation.

Adler, H.E., Brown, J.L., & Herrick, R.H. THE EFFECTS OF PUPIL SIZE AND FLASH DURATION ON ACUITY DURING DARK ADAPTATION. Contract AF 33(038)-22616, Proj. 7186, WADC Tech. Rep. 54-551, Nov. 1954, 11pp. WADC, Air Research and Development Command, Aero Medical Lab., Wright-Patterson AFB, Ohio. (Columbia University)

3843

To determine the effects of pupil size and flash duration on acuity measured during dark adaptation, the minimal luminances required for the resolution of each of three acuity gratings were obtained five seconds after the end of adaptation to each of four luminances and after thirty minutes of dark adaptation. The thresholds were found using either the natural pupil or a 3 mm artificial pupil in combination with a 0.016 or a 0.40 second test flash duration. Figures are presented showing log threshold luminances for three acuity levels 5 seconds and 30 minutes after light adaptation as a function of a) preadapting luminance and b) log visual acuity. Effects of pupil size and flash duration are analyzed.

VanderWeer, A.W. RELATIVE EFFECTIVENESS OF COLOR AND BLACK AND WHITE IN INSTRUCTIONAL FILMS. Contract N6 ONR 269, SDC TR 269 7 28, June 1952, 21pp. USN Special Devices Center, Port Washington, N.Y. (Pennsylvania State University, State College, Penn.).

3852

To compare the relative effectiveness of color and black and white instructional films, five films in both versions were shown to 500 high school students (half saw color and half saw black and white versions). Tests were given immediately and after a period of six weeks. Classes were equated in final analysis of data. Four of the films were shown to 199 students in alternate groups. Preference ratings were also secured. Test scores for immediate and delayed recall were analyzed for differences between the two versions in learning and remembering. Preferences and sex differences are discussed.

3853

Jackson, R. VISUAL PRINCIPLES FOR TRAINING BY TELEVISION. SDC TR 20 TV 2, June 1953, 26pp. USN Special Devices Center, Port Washington, N.Y.

3853

To uncover factors affecting the visibility of training aids when shown on television, 12 employees of the Special Devices Center viewed 105 training devices on a television screen and rated them for visibility on 14 5-point scales. Ratings are summarized in the form of 31 visual principles in the following areas: organization, figure to ground, contrast, materials, size, detail, depth, and color.

Ash, P. & Jaspens, M. OPTIMUM PHYSICAL VIEWING CONDITIONS FOR A REAR PROJECTION DAYLIGHT SCREEN. Contract N6ONR 269, SDC Proj. 20 E 4, SDC TR 269 7 37, Oct. 1953, 17pp. USN Special Devices Center, Port Washington, N.Y. (Pennsylvania State University, State College, Penn.).

3854

To study the effects of viewing conditions on learning with the aid of a cabinet type of projector, 721 naval trainees were shown a film on the assembly of the 40 mm. breech block and were then required to assemble breech blocks. The viewing conditions varied were angle of view (0°-60°), distance from screen (6-36 ft.), and room illumination (daylight and dark conditions). Mean speed scores from the assembly test are analyzed to determine optimum viewing conditions.

Ash, P. & Jaspens, M. THE EFFECTS AND INTERACTIONS OF RATE OF DEVELOPMENT, REPEITION, PARTICIPATION AND ROOM ILLUMINATION ON LEARNING FROM A REAR-PROJECTED FILM. Contract N6ONR 269, Proj. 20 E 4, SDC TR 269 7 39, Oct. 1953, 20pp. USN Special Devices Center, Port Washington, N.Y. (Pennsylvania State College, State College, Penn.).

3855

To study the effects of several factors on learning from a rear-projected film, approximately 1100 naval trainees saw one version of a training film on assembling a 40-mm breech block, then were tested on the actual assembling of one. Variables were: 1) rate of development of instructions in the film (fast or slow), 2) repetition of film (one, two, or three showings), 3) audience participation (concurrent practice or not), and 4) room illumination (daylight or dark). Results (speed scores and percent passing assembly test) were analyzed for the effects of the variables, and implications for the design and use of films are discussed.

Torkelson, G.M. THE COMPARATIVE EFFECTIVENESS OF A MOCKUP, CUTAWAY AND PROJECTED CHARTS IN TEACHING NOMENCLATURE AND FUNCTION OF THE 40MM ANTI-AIRCRAFT WEAPON AND THE MARK 13 TYPE TORPEDO. Contract N6 ONR 269, SDC Proj. 20 D 2, SDC TR 269 7 100, March 1954, 21pp. USN Special Devices Center, Port Washington, N.Y. (Pennsylvania State University, State College, Penn.).

3856

To study the comparative effectiveness of different types of training aids, 75 NROTC students and 148 naval recruits were given instructions on two pieces of naval ordnance followed by written tests over the material 1-2 days and 5-6 weeks later. Aids used in the instruction varied for different groups among mockups or cutaways, illustrations from manuals, and projected black and white and colored transparencies. Test scores for the groups are compared for evidence of differences in the effectiveness of the various aids, and recommendations are made for application of the results and for further research.

Bitterman, M.E. & Krauskopf, J. SOME DETERMINANTS OF THE THRESHOLD FOR VISUAL FORM. Contract AF 33(616) 63, WADC TR 55-331, Sept. 1953, 34pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3857

Five experiments concerning visual discrimination of geometric form are reported. Purpose of the experiments was to test a diffusion model for visual form perception derived from the Kohler-Mallach theory of figural after-effects. The experiments measured foveal form and brightness thresholds for luminous figures which were briefly exposed in a dark room. Measurements were in terms of intensity of illumination. Results were discussed as they related to other models (e.g., a physical diffusion model, and the Osgood-Meyer Model). Methodology of the present as well as of previous studies was scrutinized.

Morse, P.M. (Proj. Supervisor). M.I.T. PROJECT ON FUNDAMENTAL INVESTIGATIONS IN METHODS OF OPERATIONS RESEARCH, INTERIM TECHNICAL REPORT NO. 4 SEPTEMBER 1, 1955 THROUGH JUNE 30, 1956. Contract DA 19 020 ORD 2684, Proj. 599 01 004, Ordnance R & D Proj. TB 0001, OR Proj. 968 (rev), Proj. D.I.C. 7125, July 1956, 40pp. Massachusetts Institute of Technology, Cambridge, Mass.

3858

This report covers the third academic year of a project established to continue investigation of problems and techniques of Operations Research as applied to industrial and military problems. Active projects described are: waiting line handbook, a computer program for the transportation problem, an inventory and production control model, and the most economical number of work stations in a production line. Completed projects, given in full, are: a job-lot scheduling program, the revised simplex method, and modification of the Wilson formula when a sales forecast is available. Current publications and a list of seminar topics are included.

Doidge, W.T. & Holtzman, W.H. INFLUENCE OF COLOR ON FORM PERCEPTION. Presented at: 1953 Meeting of American Psychological Association, Cleveland, Ohio, 10pp. (University of Texas, Austin, Tex.).

3859-

To investigate the influence of color on the perception of form, 12 drawings from the Holtzman Form-Recognition Test (incomplete line-drawings of familiar living creatures) were used to which were applied four colors (red, yellow, green, blue) in four different patterns (solid, splotted, striped, speckled). A second series included an achromatic version. Recognition time for each stimulus was measured for 128 Ss. The data were studied by analysis of variance procedures and discussed in terms of effect of color, pattern, and form on perception.

3860

Twiford, L.C. FACTUAL ANALYSIS OF TRAINING. June 1955, 4pp. Pennsylvania State University, State College, Penn.

3860

As an aid to systematic analysis of training films, eight types of facts are presented and discussed as descriptive of film contents. The types of facts are: supporting or background, pertinent, learnable, important, retentive, motivational, quasi-motivational, and attractive. Learning profile analysis and listing of facts are discussed briefly as methods of factual analysis.

3861

Winick, D. & Tiffin, J. A COMPARISON OF TWO METHODS OF MEASURING THE ATTENTION-DRAWING POWER OF MAGAZINE ADVERTISEMENTS. June 1955, 6pp. Occupational Research Center, Purdue University, Lafayette, Ind.

3861

To compare methods for studying the eye appeal of advertisements, Ss were shown projected colored slides of pairs of magazine advertisements. In one presentation, 150 Ss indicated preferences for one advertisement in each of the possible pairings of ten viewed tachistoscopically. In a second presentation, eye movements of 36 Ss were recorded while viewing five pairs of advertisements. Results (preferences, first looks, and total viewing time) are compared to evaluate the tachistoscopic method relative to the method of recording eye movements.

3862

Kennedy, J.L. (Dir.). HANDBOOK OF HUMAN ENGINEERING DATA. SECOND EDITION. Contract N60RI 199 T.O. 1, Projs. NR 783.001 & HE 20 G 1, Rep. NAVEXOS P 643, Tech. Rep. SDC 199 1 2a, Nov. 1952, 300pp. USN Special Devices Center, Port Washington, N.Y. (Tufts University, Medford, Mass.).

This compilation of data is aimed primarily at providing the design engineer with quantitative measures of human capabilities and limitations and their application to machine design. The areas thus covered make up 9 main sections: the human machine - human engineering and experimental techniques; the human body - anthropometrics and functional use; vision - basic concepts and characteristics, factors influencing efficiency, and applications; audition - (same subdivisions as vision); skin sensitivity and proprioception - (same subdivisions as vision); motor performance - basic concepts, biological characteristics, task and job characteristics and efficient work arrangement; physiological conditions as determinants of efficiency - basic concepts and factors influencing; intelligence - summary; learning - basic concepts and processes, relevant characteristics, and training. A glossary of terms and author and subject indices complete the handbook. (HEIAS)

Eunt, D.P., & Craig, D.R. THE RELATIVE DISCRIMINABILITY OF THIRTY-ONE DIFFERENTLY SHAPED KNOBS. Proj. 7182, WADC Tech. Rep. 54-108, Dec., 1954, 16 pp. WADC, Air Research and Development Command, Aero Medical Lab., Wright-Patterson AFB, Ohio.

3866

To select tactually identifiable shapes that may be used to code control knobs, the subject (120) familiarized himself with 31 different knob shapes. With his right hand, he then made 13,560 paired comparisons between a knob shape which was felt and a three-quarter view picture of the knob. Each subject first made comparisons with the bare hand and then repeated comparisons while wearing a light-weight flying glove. Exposure was limited to 1.5 seconds; position of knob was varied systematically. Identification errors were tabulated for each knob and a number of identifiable shapes are presented and placed in one of three classes according to function. Suggestions are offered for application of these data.

Gardner, J.F. SPEED AND ACCURACY OF RESPONSE TO FIVE DIFFERENT ATTITUDE INDICATORS. Proj. 7189, WADC Tech. Rep. 54-236, Dec., 1954, 22 pp. WADC, Air Research and Development Command, Aero Medical Lab., Wright-Patterson AFB, Ohio.

3867
To determine the optimal attitude indicator design from a field of five designs, response time and accuracy of 100 subjects (fifty experienced pilots, fifty college students) were tested. Two of the attitude indicators were of the "earth reference" type (moving element was the horizon), two were "airplane reference" type (moving element was the airplane) and one simulated a "stabilized sphere" type of presentation. Condition one required a corrective manual response with simulated control stick to deviations as presented on the instruments; condition two called for a corrective verbal response. The data (reversal errors and response times) were examined by analysis of variance for differences due to type of indicator, method of response, and subject group.

Kerroll, J.E., & Parsons, H.M. STUDIES IN CIRCULAR TAG POSITIONING. 1. EFFECTS OF DISTANCE AND ANGLE OF MOVEMENT M-3/A-II. Contract AF 30(120)-430, 1 July, 1955, 24 pp. Columbia University Engineering Center, Electronics Research Laboratories, Dept. of Electrical Engineering, 632 West 125th Street, New York 27, N.Y.

3870
To determine the speed and accuracy with which an operator can place an electronically-painted circular tag over a similarly presented short line with x-axis and y-axis controls, five subjects made a total of 540 positionings in which they had to move the tag 0.1, 0.3, or 0.5 inches along twelve angles from the center of a cathode-ray tube (CRT) display. The angles were increments of thirty degrees from 360 and were grouped to require both knobs to rotate in the same and in opposite directions, the preponderant use of the x or y knob, the use of a single knob, and positioning in the four quadrants. Time and error scores were studied for effects of distance and angle of movement on speed and accuracy.

Nelson, W.H., & Webb, W.B. FACTORS INVOLVED IN CARRIER TRAINING ACCIDENTS IN THE NAVAL AIR BASIC TRAINING COMMAND. Special Rep. 56-8, March 1956, 8pp. U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Fla.

3871
To determine the major psychological factors present in accidents occurring in the carrier qualification phase of naval aviation training, approximately sixty students involved in an accident aboard a training carrier were interviewed. The interview was semi-structured with an effort made to gather information on specific aspects of the accident. The data were analyzed and classified as to major causes of carrier training accidents. Each classification is discussed and examples given. Recommendations for changes in manner and/or methods of instruction and training are made.

Saul, E.V., & Jaffe, J. EFFECTS OF CLOTHING ON GROSS MOTOR PERFORMANCE. Contract DA44-109-qm-1124, Project Ref. 7-95-20-003B, June 1955, 33pp. Quartermaster Research and Development Center, Environmental Protection Division, Natick, Mass. (Tufts College)

3872
This report describes the effects of three different types of military clothing ensembles on the efficiency of gross motor performance. Fifteen college men were tested in each of 28 motor performance tests, including extent and flexibility of movement, coordination, and steadiness tests. The statistically-evaluated results pertained to differences in efficiency of motor activity obtained by wearing the three different types of clothing.

Pattle, R.E. TOXIC EFFECTS WITH MIXTURES OF SULPHUR DIOXIDE AND SMOKE WITH AIR. Porton Tech Paper 525, Feb. 1956, 9pp. Chemical Defence Experimental Establishment, Directorate of Chemical Defence Research and Development, Ministry of Supply, London, England.

3876
To investigate the toxic effects of mixtures of sulphur dioxide and smoke with air, guinea pigs and/or mice were exposed under various conditions. The relative toxicities of sulphur dioxide-smoke mixtures and sulphur dioxide alone were determined; the effect of previous exposure to smoke before sulphur dioxide was assessed; and the effect of smoke which had been in contact with sulphur dioxide but the SO₂ had been removed from the gaseous environment was compared with ordinary smoke. The data were given in terms of "dosage up to death" and "dosage to 50 percent deaths". The findings are discussed in relation to lethality of atmospheric pollution.

3877
Biel, W.C. & Sweet, A.L. A FURTHER STUDY OF RADAR SCR 584 BURST SPOTTING ON TRIAL FIRE. Contract OEMsr 581, Proj. 505'6, OSD Rep. 5930, Rep. 16, Sept. 1945, 11pp. Office of Scientific Research and Development, Applied Psychology Panel, NDRC, Washington, D.C. (Tufts University, Medford, Mass.).
45 rounds of 90 mm gun trial fire were fired at each of 4 trial shot points, with a total of 180 rounds. The slant range of each burst was measured simultaneously by the following methods: a) photostereolites from 3 stations; b) visual observations using a B.C. Telescope at each of 2 flank stations and the spotting telescope on the antenna of a Radar SCR 584, thus providing range readings from 2 baselines 01-02, and 01-03; c) visual burst spotting from 2 radars - 9 operators in each set; d) photographic burst spotting with a light SCR 584; the fine range oscilloscope was photographed for each round and the films read later for range values. The operators doing the burst spotting, in general, were untrained in the method although they varied in previous burst spotting experience from none to a considerable amount. From the data it was concluded that: a) operator performance is an important variable in the accuracy of radar burst spotting of trial fire; b) radar measurement is of comparable accuracy to that of the B.C. Telescope technique if the operator is well trained, whereas with untrained operators, the radar method is less accurate.
R 3

3878 Gottsdanker, R. & Biel, W.C. A STUDY OF TRACKING ON DIRECTORS MSA2 AND MSA2E1. Contract OMSR 581, Proj. SOS 6, OSD Rep. 5929, Rep. 15, Sept. 1945, 23pp. USA Office of Scientific Research and Development, Washington, D.C. (Tufts University, Medford, Mass.).

On 24 airplane courses, photographic records were taken of tracking with 2 Directors, Director MSA2E1, with an aided tracking time constant of .143 sec., is slightly but reliably more effective in respect to tracking than Director MSA2, with an aided tracking time constant of .143 sec. A measure of tracking effectiveness adequate for comparing different instances of tracking on Director MSA2 or on Director MSA2E1 may be obtained by combining Tracking Variable Error and Rate of Change, giving each equal weight. For azimuth tracking with Director MSA2, rate of change of tracking error is more highly associated with prediction error than is amplitude of tracking error; for elevation tracking, the reverse is true for either director. For azimuth tracking with Director MSA2E1, the two factors are equally associated with prediction error. Amplitude of tracking error is lower for Director MSA2 in the case of azimuth tracking where rates are relatively high but lower for Director MSA2E1 in the case of elevation tracking where rates are relatively low.

3879 Rappaport, J.H., & Biel, W.C. A COMPARISON OF THREE SPEED RING METHODS AND THE COMPUTING SIGHT M7 IN ACCURACY OF FIRE CONTROL ON THE 40 MM GUN. Proj. SOS-6, Contract OMSR-581, OSD Rep. 5762, Rep. 14, Sept., 1945, 33 pp. OSD, NDRC, Applied Psychology Panel. (Tufts College, Medford, Mass.)

3879 To study the effectiveness of three methods (constant, discrete, and continuous) of aiming with the three speed ring sight for the 40 mm gun, and to compare this sight with the Computing Sight M7, 13 crews had varying degrees of training with various combinations of methods and sights over a six-week period. Firing accuracy is compared for the various conditions with regard to comparative accuracy of the methods and sights and also with regard to ease of teaching and learning.

3880 Biel, W.C., Brown, G.E., Jr. & Griffiths, W.J. STUDIES WITH THE VARIABLE DRIVE T-18, FOR 40 MM GUN CARRIAGE M2A1. Contract OMSR 581, Proj. SOS 6, Rep. 13, & OSD Rep. 5736, Sept. 1945, 22pp. Applied Psychology Panel, NDRC, Washington, D.C.

3880 This report describes two experiments conducted in an attempt to evaluate the Variable Drive T-18 (a mechanical-hydraulic device, adaptable to the 40 millimeter Gun Carriage M2A1, providing means for varying the handwheel-gun traverse speed ratio in infinitely small steps by foot-operated control) as a tracking mechanism, when used as the azimuth drive. 1) The gun, equipped with the T-18, was compared to a standard gun for ease and accuracy of tracking short-range fast moving targets. The adaptability of the gun pointers in learning to use the drive was also studied. 2) A further study was made to determine whether the mechanical-hydraulic drive itself contributed to superior tracking performance.

3882 Clark, R.E., Hoffman, A.C., Hudson, B.B., Mead, L.C., et al. THE EFFECTS OF SLEEP LOSS ON PERFORMANCE OF A COMPLEX TASK. Contract OMSR 581, OSD Rep. 5153, Memo 3, Sept. 1943, 9pp. Applied Psychology Panel, NDRC, Washington, D.C. (Tufts University, Medford, Mass.).

This memorandum presents the results of experiments in which Ss were required to go without sleep for 50 hrs. Because only 3 Ss could be tested at a time, the experiment was repeated 3 times. The experiment is regarded as a preliminary test of the hypothesis that observers would show signs of fatigue (decrement in efficiency of performance) when periodically tested in the performance of a psychologically complex task during a period of sleep deprivation. Graphical representation of the performance of the 9 Ss tested indicates a decrement in efficiency. Efficiency in performance of complex psychological tasks suffered a significant decline during the course of 50 hrs. wakefulness.

3883 Richards, W.J., Shuford, E.H. & Bickle, A.J. PART I - REACTION TIME; PART II - INTENSITY; PART III - VISUAL REACTION; PART IV - PROPOSED FUTURE WORK. Contract DA 23 072 ORD 472, TAI 59901 04, Tech. Rep. 22, 1951, 27pp. Ordark Research Project, University of Arkansas, Fayetteville, Ark.

3883 Three studies are reported. 1) The relationship between the intensity of white stimulus light and the reaction time of human Ss under two conditions of adaptation was determined. A total of 400 trials was given to each of four Ss, using ten intensities of the stimulus under conditions of both light and dark adaptation. 2) The relationship between the intensity of chromatic stimuli and reaction time was studied. A total of 1200 trials was given to each of four light-adapted Ss, using ten intensities of stimulus for each of five chromatic stimuli and one white stimulus. 3) The effect of variations in size of a white stimulus (diameter varied from 1 degree, 12 minutes to 45 degrees, 14 minutes) was studied.

3892
Haber, F. ESCAPE AND SURVIVAL AT HIGH ALTITUDE. Proj. 21 1209 0006, Sept. 1953, 11pp.
USAF School of Aviation Medicine, Randolph Field, Tex.

The purpose of this paper is to give a survey of the problems of escape at these altitudes which have not yet been attained by aircraft, and to show that the emphasis of the different problems during and after bailout will shift from escape to free fall. The speed of future aircraft will be limited by the temperatures caused by aerodynamic heating. Thermal considerations call for high altitudes if flying speed is increased. At the high altitudes required, windblast and dangers of escape proper will be reduced. The phase of free fall should last much longer after bailouts. High speeds attained in such falls create decelerations which could be dangerous.

3889

Ambler, Rosalie K. PRELIMINARY EVALUATION OF TWO FORMS OF THE SPATIAL APPERCEPTION TEST. Proj. NM 001.057.04.04, May 1953, 5pp. USN School of Aviation Medicine, Pensacola, Fla.

2 forms of the Spatial Apperception Test were administered to 565 Naval Aviation Cadets. Each test item required the identification of the correct airplane drawing of a group of 5 from which a given view of a shore line is visible. Each S took both forms. Half of them had Form I first and the other half had Form II first. Analysis of results revealed that Form II is significantly more difficult than Form I. Correlation between forms is .70. Significant practice effect is in operation. Certain aspects of its proposed use in the Flight Aptitude Rating battery are discussed.

3890

McCord, F. THE MEASUREMENT OF ADJUSTIVE EYE MOVEMENTS. Contract N7onr 434, T.O.1, Proj. NM 001 063.01.31, Joint Rep. 3, June 1953, 7pp. USN School of Aviation Medicine, ONR, Washington, D.C. & Psychology Dept., Tulane University, New Orleans, La.

Many methods have been used in the measurement of the adjustive eye-rolling reflex which occurs with body tilt. In the present paper, a method involving the use of after-images was studied. This method proved to be relatively simple. It yields results which are internally consistent and also in good agreement with results obtained by more complicated methods. Measures of the reflex were made with 6 normal adults at body tilts of 0°, 10° and 45°. It was found that magnitude of the adjustive eye-rolling reflex increased as tilt increased.

Ristenbatt, M.P. SURVEY OF TECHNIQUES FOR COLLECTION, REDUCTION AND ANALYSIS OF COMMUNICATIONS TRAFFIC ENGINEERING DATA. Contract DA 49-025-SC-150, DA Proj. DA-3-99-01-001, SC Proj. 102E, SC Tech. Requirements SCCL-2101 E, Haller, Raymond & Brown, Inc. Proj. 57, Feb. 1956, 90pp. Haller, Raymond and Brown, Inc., State College, Penn.

3891

This technical memorandum presents the results of a survey of communication data collection and reduction methods for voice radio and telephone systems. Two major systems are considered: a switching system and a party line system. Instrumentation for manual, semi-automatic, and automatic methods for data collection, reduction and analysis are developed for both major systems. The factors of frequency of use and amount of data to be collected are discussed in relation to an economic comparison of the proposed methods for achieving a desired objective. Appendices include a description of two systems developed for the Army to be used during Exercise Sagebrush.

3893 Atkinson, C.J. RATE AND SOUND PRESSURE LEVEL OF SPEAKING AS AFFECTED BY SPECTRUM CHANGES IN AMPLIFIED SIDETONE. Contract DA 36 039 sc 42562, Suppl. Rep. 1, July 1953, 14pp. Iowa State University, Iowa City, Iowa.

2 experiments, with 50 Ss in each, were performed in an attempt to assess the effect of the spectrum of sidetone on some of the aspects of speech. Sidetone, either filtered or not filtered, was returned to the ear of the talker. Rate was found to be affected slightly from one condition to another in 1 experiment and not in the other experiment. Sound pressure level was found to be changed by the sidetone conditions. It was lowest for the normal sidetone condition, higher for high-pass, and highest for low-pass conditions. Differences between the sound pressure level measures of speech during filtered and unfiltered sidetone were not numerically great, but the differences were statistically significant ($p < .01$). (HEIAS)
R 11

3894 Carhart, R. & Lightfoot, C. EFFICIENCY OF IMPAIRED EARS IN NOISE. B. THE DISCRIMINATION OF CHANGES IN INTENSITY. Contract AF 33(038) 22645, Proj. 21 1203 0001, Rep. 5, Sept. 1953, 9pp. USAF School of Aviation Medicine, Brooks AFB, Tex. (Northwestern University, Evanston, Ill.).

3894 The effect of noise on the ability to perceive changes in sound intensity was investigated as part of a general study of auditory efficiency in noise. Subjects were 31 normal listeners and 77 cases of hearing losses representing a range of etiologic types. Difference limens were measured for intensity change in quiet and in two levels of "white" noise for five different frequencies (250, 500, 1000, 2000, and 4000 cps). The over-all noise levels for normal and half of the hard-of-hearing Ss was 60 and 80 db; 80 and 95 db were used for the remaining Ss.

3895 Chinn, H.I., Strickland, B.A., Jr., Waltrip, O.H. & McGeary, I.D. EFFECTIVENESS OF VARIOUS DRUGS IN PREVENTION OF AIRSICKNESS. STUDIES DURING ROUTINE TRAINING FLIGHTS. Proj. 21 1208 0012, Rep. 1, Sept. 1953, 3pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

3895 To determine the effectiveness of various medications in preventing airsickness during training flights, two tests were conducted. In the first, navigation trainees were used as Ss during their regular training flights with the following preparations: placebo; Parsidol, 25 mg; Benadryl, 25 mg, with scopolamine, 35 mg; and the Benadryl-scopolamine mixture with dextrodine, 5.0 mg. Flights ranged from 2 to 12 hours duration. The second group, consisting of student officers and airmen flying as passengers on a one- to two-hour flight, were treated as above. Questionnaires were completed immediately after landing concerning nausea, vomiting, drowsiness, or fatigue. The significance of adding an analeptic drug to combat sedation effects was discussed.

3896 Chinn, H.I., Dugi, A.J. & Milch, L.J. EFFECTIVENESS OF VARIOUS DRUGS IN PREVENTION OF AIRSICKNESS. COMPARISON OF SCOPOLAMINE, POSTAFENE, AND PHENERGAN. Proj. 21 1208 0012, Rep. 2, Sept. 1953, 2pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

3896 To compare the effectiveness and side effects of certain promising air-sickness preventives (scopolamine, postafene, and phenergan) directly in the air, approximately 400 young airmen were studied. The procedure consisted of exposing 20 Ss simultaneously to an hour's flight of standardized turbulence. The medications (placebo and the three drugs) were randomly distributed on each flight. Each S received a capsule 24 hours before flight and a second, of identical appearance, one hour before. The incidence of vomiting was recorded by observers during flight, while all other side effects (dizziness, nervousness, sweating, dry mouth, excessive fatigue) were obtained through individual questionnaires.

3897 Gerathewohl, S.J. INVESTIGATION OF PERCEPTUAL FACTORS INVOLVED IN THE INTERPRETATION OF PPI-SCOPE PRESENTATIONS. FORM DISCRIMINATION UNDER CONDITIONS OF HEAVY VIDEO-NOISE. Proj. 21 1205 0004, Rep. 1, July 1953, 5pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

3897 To investigate the relative form discriminability of four regularly shaped targets (triangle, circle, square, cross) under conditions of impaired visibility (heavy background video-noise), each target was presented in a radar trainer at three simulated distances (10, 20, 50 miles) to 24 untrained observers. Differences in discriminability of the forms at each distance are analyzed and compared with discrimination judgments under normal conditions. Application is made to radar scope interpretation.

3898 O'Brien, B. A STUDY OF NIGHT MYOPIA. Contract W33(038) F18317, WADC TR 53 206, May 1953, 23pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (University of Rochester, Rochester, N.Y.).

3898 The literature on night myopia is reviewed in some detail and a critical evaluation of certain outstanding papers is presented. The effects of chromatic aberration, the Purkinje shift, spherical aberration, and involuntary accommodation in producing the myopia are considered. Two sets of experiments are described in which vision is restricted to cone vision thus eliminating the Purkinje shift. In one set both natural and ring aperture pupils distinguish between spherical aberration and involuntary accommodation. In the other, a ballistic flash technique prevents any accommodation after test target is displayed.

Reynolds, C.L. ANALYSIS OF 30-INCH DIRECT VIEW PLAN POSITION INDICATOR PPI-30-1 FOR AIR TRAFFIC CONTROL OPERATIONS. Proj. R-201-11. WADC TR 55-508, Sept. 1955, 25pp. Wright Air Development Center, ARDC, Wright-Patterson AFB, Ohio.

3912

To evaluate experimental techniques in the use of large-size radar displays for air traffic control, Radar Indicator PPI 30-1 was installed at Wright-Patterson Air Force Base and used as a supervisory monitor for a period of one year. No formal operational evaluation was made but observational data of the limitations and advantages of the Indicator were noted. A photographic evaluation was conducted in a light-proof tent and these data are given. Recommendations for further evaluational studies are made.

Bass, D.E., Kleeman, C.R., Quinn, M., Maliszewski, T.F., et al. MECHANISMS OF ACCLIMATIZATION TO HEAT IN MAN: THE EFFECT OF PROLONGED HEAT EXPOSURE ON BODY WATER DISTRIBUTION AND ELECTROLYTE AND NITROGEN METABOLISM. Rep. 214, June 1953, 72pp. USA Environmental Protection Research Div., QM Research & Engineering Center, Natick, Mass.

3916

Five healthy young soldiers were acclimatized to heat by living and working under controlled conditions for 14 consecutive days in a chamber maintained at 120 degrees F during 12 daytime hours and at 100 degrees F during the night. The following measurements were made: antipyrene, thiocyanate, and T-1824 spaces; sweat concentrations of Na, Cl, K, N, and creatinine; nitrogen and electrolyte balances; indices of adrenocortical activity (circulating eosinophils and urinary 17-ketosteroids); pulse rates and rectal temperatures during exercise. Progressive dehydration and salt deficiency were minimized by replacing salt and water losses with 0.2 percent saline. Major physiologic adaptations were discussed.

Fuch, F.L. INCIDENTS OF LEADERSHIP IN COMBAT. VOLUME V. ADMINISTRATION AND SUPERVISION OF DUTIES. Contract AF 18(600) 468, Res. Memo. 3, April 1953, 53pp. USAF Human Resources Research Institute, Maxwell AFB, Ala. (Psychological Services, Inc., Los Angeles, Calif.).

3919

A series of incidents demonstrating effective and ineffective leadership in the combat zone by Air Force officers was presented. These reports were obtained through personal interviews with officers on active duty in the Far Eastern Air Force. Fictitious names have been used but the ranks, types of units, and surrounding situational conditions were reported. All incidents represented some aspect of leadership behavior in the general area of administration and supervision of duties and were grouped under the following categories: 1) utilizing material and personnel, 2) delegating authority, 3) administering punishment or corrective action, and 4) employing verbal devices to affect harmony and motivation.

3920

Fuch, F.L. INCIDENTS OF LEADERSHIP IN COMBAT. VOLUME VI. EXECUTION OF DUTIES. Contract AF 18(600) 468, Res. Memo. 3, Feb. 1953, 51pp. USAF Human Resources Research Institute, Maxwell AFB, Ala. (Psychological Services, Inc., Los Angeles, Calif.).

3920

This report contained a series of incidents demonstrating effective and ineffective leadership in the combat zone by Air Force officers. These reports of actual situations were obtained through personal interviews with officers on active duty in the Far Eastern Air Force. In all cases names of individuals in the incidents remained anonymous to the interviewers; fictitious names have been added to the text. Ranks, types of units and surrounding situational conditions were reported. The incidents represented some aspect of Air Force leadership behavior in the general area of Execution of Duties.

Dolch, J.P. AN INVESTIGATION OF SOME PHASE AND INTENSITY RELATIONSHIPS IN THE INTERFERENCE OF BONE- AND AIR-CONDUCTED SOUND. SUPPLEMENTARY REPORT NO. 2. Contract DA 36 039 SC 42562, Aug. 1953, 65pp. State University of Iowa, Iowa City, Iowa.

3921

To investigate some of the phase and intensity relationships in the interference of pure tones simultaneously transmitted through air and bone conduction channels, an apparatus was constructed to provide three separate pure tone channels of exactly the same audio frequency with independent phase and amplitude controls in two of the channels. A method of phase shifting provided continuously variable phase shifts of 360 degrees with substantially no variation in the amplitude of the audio signal output. With the bone conduction receiver placed in the middle of the forehead, the subjects adjusted the phase and intensity of air conducted tones at each ear to the point where the bone-conducted tone was cancelled. Application of the findings to interphone communications were discussed.

3922 Robinson, E.J. & Coules, J. AN EXPERIMENTAL STUDY OF THE EFFECT OF PHOTOMETRIC BRIGHTNESS ON THE JUDGMENT OF DISTANCE AND SIZE. Contract AF 33(616)J2, Tech. Note 101, Sep. 1, 1953, 40pp. Opt'cal Research Lab., Ballston-Spa, N.Y.

The effect of brightness on judgments of size and distance under binocular and monocular conditions has been investigated. An apparatus was constructed which permitted the presentation of 2 homogeneous discs of light to a subject. Particular attention was paid to control of the stimuli likely to influence judgments, in the size experiments, psychophysical relationships were obtained between brightness and size and the percentage of "smaller" responses. The curves clearly indicated that brightness operated systematically to make the brighter object appear larger. This relationship was evident under binocular as well as monocular conditions. It was also indicated that as the absolute level of brightness increased, the effect of the brighter object in any particular brightness ratio decreased. In the distance experiments, the data indicated that a) brightness is a factor in judgments of distance under binocular and monocular conditions and b) under binocular conditions judgments of distance are a function of the actual distance of the object. It was also indicated that the effect of brightness on distance judgments is related to the psychophysical method used.

3923 Myers, M.D., McKee, R.R., Simmons, R.F. & Rodman, I.L. AN INDEX OF ACCIDENT EXPOSURE FOR FLYING IN USAF. REPT. Rep. 39, July 1953, 70pp. USAF Human Factors Operations Research Lab., Bolling AFB, Washington, D.C.

3923 A report is given on the initial phase of a research program designed to develop a method of evaluating flying experience which would reflect differences in exposure to accident hazard more accurately than does the simple summation of flying hours. The following operations were undertaken to develop the Index of Accident Exposure: 1) a unit of measurement combining hours and flights was developed to measure amount of experience, 2) measures of relative accident hazard for different kinds of flying experience were obtained, and 3) tentative weights for kinds of experience were developed and tested for accuracy of prediction from one sample to another. Pilot estimates of hazards were compared to estimates from accident data and pilot attitude was measured with regard to both methods of evaluating flying experience. T. G. I.

3924 Daniels, G.S., Meyers, H.C., Jr. & Morrill, Sheryl H. ANTHROPOMETRY OF USAF BASIC TRAINEES. Contract AF 18 (600) 30, WADC TR 53 12, July 1953, 103pp. USAF Army Medical Lab., Wright-Patterson AFB, Ohio.

3924 Body size data for 63 measurements of 852 Women's Air Force basic trainees are presented for use by the designers of Air Force equipment. The statistics reported for each measurement include the mean, standard deviation, coefficient of variation, standard errors of these statistics, range, and selected percentiles from the first to the 99th. In general, these statistics are reported in both the metric and the English values. A complete description of the anthropometric techniques used is presented. T. I.

3925 Morrison, F.A. & Hill, J.E. DISCREPANCY FACTOR PRESENTING OF STUDENT ACCIDENTS. Contract AF 18(600) 137, HPRC. Rep. 38, Aug. 1953, 10pp. USAF Human Factors Operations Research Lab., Bolling AFB, Washington, D.C. (Institute for Research in Human Relations, Philadelphia, Penn.).

3925 An exploratory study of a new approach to prediction of accidents attributable to pilot error is reported. A survey of 50 instrument pilots located at seven Air Training Command bases was made. They were interviewed to determine whether, in their experience, they had expected certain of their students to have accidents, and whether their expectations had actually been borne out by subsequent events. The percentage of student accidents thus "predicted" was calculated and the reasons or behaviors which led to these "predictions" were tabulated. A search of accidents in relation to those pilots brought before Flying Instruction Boards was made. Further research is recommended. T. R. 2

3926 Woodcock, A.R. WEI - OLD II: A THEORETICAL EXPERIMENTATION OF THE CAUSATION OF LUMP GOLF EXPERIENCED BY CLOTHED MAN. Rep. 199, Feb. 1953, 40pp. USAF Human Factors Operations Research Lab., Lawrence, Mass.

3926 A theoretical interpretation of why there is a sensation of coldness associated with high humidities near the freezing point is discussed. An earlier theory of heat transfer through wet insulation has been extended to include the theory of heat transfer through insulation when moisture is evaporated from the warmer boundary. This extension has been applied with varying external conditions of temperature and humidity, moisture permeability of the clothing, and solar or external radiation. Recommendations are made. T. G. R. 11

3927 Cohen, J. & Sanders, Virginia L. AN EXPERIMENT ON DIAL CODING. Contract AF 18(600) 50, WADC TR 52 709, Nov. 1953, 16pp. USAF Army Medical Lab., Wright-Patterson AFB, Ohio. (Antioch College, Yellow Springs, Ohio).

3927 To determine whether shape or color coding of dials would affect the speed and accuracy of locating particular dials in a display, three equated groups of Ss were tested over a five-day period on their ability to locate and check-read an instrument on a simulated instrument panel. On the sixth day, the locations of the instruments on the panel were changed, and the Ss were required to locate them. The three groups worked on different panels on which instruments were identified by: 1) labels only, 2) labels and color codes, and 3) labels and shape codes. The time to locate a given instrument and the accuracy of reading the direction of the pointer, as well as correct identification, were analyzed for effects of the coding. T. G. R. 4

3930 Tomodori, J., Brogan, F.A. & Washburn, D.D. AUDITORY DIFFERENCE LIMEN OF INTENSITY IN NORMAL-HEARING SUBJECTS. Rep. 55 31, Aug. 1955, 18pp. USAF School of Aviation Medicine, Randolph AFB, Tex.

3930 This paper is concerned with the validation of a method of regular modulation, used to obtain auditory difference limens of intensity, on normal hearing subjects. Several stimulus parameters were investigated: 1) ascending and descending mode of testing, 2) frequency and intensity of the carrier, 3) pattern and frequency of modulation. Averages and ranges of distribution were established. In addition, an attempt was made to correlate results from loudness-balance with those from difference limen measurements. T. G. I. R. 17

Buckley, Barbara B., Eaves, R.W. & Davis, J. SEARCH AREA AND TARGET VISIBILITY ON A TWO COGNITIVE-TASK TREE. Contract AF 33(622) 22640, WADC TR 52 303, April 1953, 14pp. USAF Human Factors Lab., Wright-Patterson AFB, Ohio. (Ohio State University, Columbus, OH.).
- 3934
This experiment tested the possibility that detectability (thresholds) for small targets on a radar scope could be improved by having observers search part of the scope rather than all of it. Possible ways of assigning two observers to watch the same incoming data were of particular concern. Three methods of assigning the search area were tested: whole, left-right halves, and outer-inner annulus. In three separate experiments, thresholds for 24 Ss were obtained under these conditions: 1) only the search area was visible, 2) the entire scope was visible, and 3) pairs of observers searched different parts of the scope. In the first two experiments, single observers were used.

Ellefsen, M.J. & Orr, F.D. CLINICAL EFFECTS OF PROLONGED INSULATED RUBBER BOOT WEAR. Proj. 6'64 12 C28, Subtask WEL S 8, Rep. 115, May 1953, 74pp. USA Medical Research Lab., Fort Knox, Ky.
- 3940
To determine the clinical effects of prolonged insulated rubber boot wear, a total of 36 men were studied while also undergoing a nutrition study at the Army White Forest, Fort Monmouth Military Reservation, New Jersey, from 5 January to 23 March 1953. The foot study was performed during a period when the Ss were exposed to cold and activity. Four groups were formed: 1) continuous wear of insulated boots for 12 hours, 2) same conditions for leather combat boots, 3) insulated rubber boots with normal foot hygiene, and 4) same conditions for leather combat boots. Two separate studies were performed: both subjective appraisal by the Ss and foot examinations conducted twice each day were made. Recommendations for fit, foot hygiene, and improvements to the boots were made.

Maguire, C. SEQUENTIAL DECISIONS INVOLVING THE CHOICE OF EXPERIMENTS. Contract N000121, Tech. Rep. 19, July 1963, 33pp. Department of Statistics, Stanford University, Stanford, California.

3346
The general problem of the sequential decision: a statistician must make in the choice of taking an action without experimenting or performing an experiment is described first in verbal terms and then is formulated mathematically. An iterative method for obtaining Bayes solutions is given. The optimum sequential decision procedure for the problem under consideration is shown to be characterized as follows: If, at any stage of experimentation, there is a continuation which has smaller risk than the optimum stopping risk for that stage, the first experiment is performed. If there is no such continuation, an optimal terminal action (no experiment) is taken.

Brown, J.L., Ehmke, Margaret P., & Adler, H.F. THE RELATION OF THRESHOLD CRITERION TO THE FUNCTIONAL RECEPTORS OF THE EYE. Contract AF 33(033)-22616, Proj. 7186, Task 71544, WADC TR 57-442, Aug. 1957, 22pp. Aero Medical Lab., WADC, AFSC, Wright-Patterson AFB, Ohio. (Columbia University).

3349
To investigate the relationship between visual acuity and luminance when the eye remains dark adapted, luminance thresholds were obtained for the resolution of a series of grating test patterns (visual acuity range from 0.042 to 0.625). Measurements were made for each of 8 selected color filters and with thirteen neutral tint filters. Threshold values (logarithms of luminance) were analyzed as function of visual acuity required for the resolution of the grating test objects for each spectral condition. The results are interpreted in relation to rod and cone receptors of the eye. Implications for practical situations wherein the observer is adapted to low luminance levels and must periodically rate acuity discriminations of visual displays are discussed.

Gregory, R.L. A PSYCHOLOGICAL STUDY OF GUN-TOWER ESCAPE FROM SUBMARINES. R.N.P. 53/744, O.R.S. 31, March 1963, 5pp. Medical Research Council, Naval Naval Personnel Research Committee, Applied Psychological Research Unit, Cambridge, England.
An experiment was undertaken to investigate psychological deterioration likely to prejudice gun tower escape in conditions of atmospheric deterioration to be expected in a submarine which is unable to surface. Simulated submarine conditions were used in which CO2 was elevated and O2 was lowered. Dummy escape gear was worked by 20 ss in pairs, with on 'escape' made every 15 min. over a 3-hr. period. Errors in the various steps of the operations were recorded. There was no sign of a systematic increase in error during the trials with CO2 of 3 and 4% and O2 of 17 to 16%. Some physiological changes were encountered and are to be reported elsewhere. (HEIAS)

3351
Loveless, M.E. MANUAL TRACKING ON HORIZONTAL AND VERTICAL LINEAR SCALES. FRAC 914, March 1955, 16pp. Flying Personnel Research Committee, London, England. (Nuffield Dept. of Industrial Health, University of Durham, King's College, Newcastle-upon-Tyne, England.)
In a compensatory tracking task, ss were required to control the pointer on a linear scale by means of a control knob placed vertically below it. With a horizontal scale, speed and accuracy were greater when a clockwise control movement caused the pointer to move to the right. With a vertical scale, speed and accuracy were greater when a clockwise control movement caused the pointer to move upwards. These direction-of-motion relationships are the same as those which have been shown to occur on the circular scale; they also correspond with the ss' preferences. Performance on the horizontal scale was superior to that on the vertical, and comparable to that obtained on the circular scale under optimal conditions (direct drive, target in top or left-hand quadrant). Performance on the horizontal scale is more consistent than on any other arrangement, and linear scales might be considered preferable to circular scales in circumstances where the ambiguous control-display relationships of the latter are undesirable.

Smith, R.J. A GRAPHICAL RECORDER FOR SYNCHRONOUS LINEAR REGISTRATION OF SEVERAL MECHANICAL MOVEMENTS. NACAC Proj. AC 94, Memo. 3, OSRD Contract CEMR 1171, Rep. 5337, Sept. 1945, 15pp. Applied Psychology Panel, OSRD, NRC, Washington, D.C. (University of Wisconsin, Madison, Wisc.).

This memorandum describes the specifications of construction, principles of operation, and directions for operating a graphical recorder of new design. Several special features of the instrument may be noted: a) it permits simultaneous linear registration of 4 different mechanical movements; b) each of the 4 records traverse the entire chart width; c) the 4 records are exactly superimposed in time on the chart; i.e., they have the same time-point reference on the recording paper; d) great flexibility is provided in the degree of expansion of the record with reference to the actuating movement; e) the recording is accomplished electrically. The recorder has been designed primarily to be used in conjunction with selsyn and servo follow-up systems to record simultaneously the various components of gunner performance in tracking, framing, and triggering flexible gun sights. In addition, the instrument may be employed for various other recording purposes. It is especially adapted to a) system analysis of electro-mechanical units with several moving output shafts, e.g., sighting systems or radar systems, b) remote recording of mechanical changes which may be indicated primarily by means of selsyns, c) graphical recording of instrument control, d) registration of error or the pattern of performance in the operation of training or test devices, and e) time scaled graphical recording of performance for experimental job analysis and job study.

3955

Berry, R.N., Brown, R.H., Mead, L.C., Nafe, J.F., et al. GROSS ERRORS IN READING SCALES OF PANORAMIC TELESCOPES. NRC Proj. SOS 11, Rep. 1, OSRD Contract CEMR 521, Rep. 4334, April 1945, 15pp. US Office of Scientific Research and Development, NRC, Applied Psychology Panel, Washington, D.C. (Tufts University, Medford, Mass.).

Compared with other instruments used in this study it was found that gross errors in reading the scales of the M-12 panoramic sight are excessive. Most of these errors can be accounted for either a) in the use of a coarse azimuth scale or b) in the design and manufacture of the coarse azimuth scale and other parts of the instrument. That the use of a scale for coarse azimuth readings is the primary factor in the occurrence of 100 μ m errors is demonstrated by the few such errors made with the use of the A.M.R.L. modified M-12 sight in which a scale is not used for coarse azimuth readings. The 5s who made 105 100 μ m errors in reading the scales of their own M-12 sight, after 4 practice trials made only 8 such errors on the A.M.R.L. modified M-12 sight, and after 10 practice trials made no gross errors at all. The effects of good design and manufacture may be seen in the results with the German sight. Other large errors, although not specifically remedied in the A.M.R.L. and German sights, tend to disappear with their use. This indicates that, with instruments easier to use, these errors will occur less often.

Berry, R.N., Brown, R.H., Mead, L.C., Nafe, J.P., et al. ERRORS IN READING SCALES AND CHANGING DEFLECTIONS OF PANORAMIC TELESCOPES. OSRD Contract CEMR 521, NRC Proj. SOS 11, Repts. 4 & 5070, May 1945, 15pp. Applied Psychology Panel, OSRD, NRC, Washington, D.C. (Tufts University, Medford, Mass.).

This report includes all errors of 5 μ m or greater made in 5500 tests in reading the scales and setting deflection shifts on panoramic sights. 25 gunners were used and the sights, mounted on 105 mm. howitzers, were: a) a standard M-12; b) an M-12 with modified coarse azimuth scale; and c) an M-5. There were 654 errors observed. Of these roughly two thirds are errors in reading and one third are errors in setting. About half as many errors were made on the M-5 as on the M-12 sight. Specific factors in instruments and procedures which make for errors were sought. The nature of the errors made in reading the scales of these sights indicate that the use of dual scales, and the design and construction of the scales, are the important factors in the occurrence of errors. The design of the sight also makes deflection shifts so complex a problem that errors must be expected. The number of errors that occur may be increased or decreased by altering certain features of the sights used and by altering the procedures essential to their use. Suggestions are made as to the elimination of excessive errors.

Hoff, E.C. & Greenbaum, L.J., Jr. A BIBLIOGRAPHICAL SOURCEBOOK OF COMPRESSED AIR, DIVING AND SUBMARINE MEDICINE. VOL. II. NAMED P 5033, Nov. 1954, 368pp. Office of Naval Research, Bureau of Medicine & Surgery, Navy Dept., Washington, D.C.

This is a source book of references to the literature in medical problems of diving, compressed-air work, and submarine operations. Citations comprise unclassified reports and documents as well as books, monographs and papers appearing between 1 January 1946 and 31 December 1951. Some references not available for Volume I (1946) are included. The contents are classified as to general studies of submarine medical problems, technical procedures and research apparatus, special anatomy, physiology, and biochemistry, biology of very high hydrostatic pressures, diseases and accidents in personnel, protection and preservation of personnel, selection and training of personnel, special psychological and psychiatric problems and special problems of swim-diving. Indices of authors, sources for unpublished reports, and of subjects are included.

USN Electronics Lab. HUMAN ENGINEERING: A BIBLIOGRAPHY. April 1955, 464pp. USN Electronics Lab., Bureau of Ships, San Diego, Calif.

An unannotated bibliography of human engineering literature, released in April 1955, is presented. This bibliography is topically organized around 4 main topic headings: a) human engineering practices; b) human operating characteristics; c) factors affecting the efficiency of the human operator; and d) body measurements. Subtopics are used to organize the articles under these main topic headings. (HEIAS)

Erikson, C.W. PARTITIONING AND SATURATION OF THE PERCEPTUAL FIELD AND EFFICIENCY OF VISUAL SEARCH. Contract AF 33(038) 22642, WADC TR 54 161, April 1954, 11pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3959

This report described a series of experiments on the effects of various conditions of display upon visual search. The time required to locate a constant number of signals in a square display was determined 1) where the number of irrelevant signals was varied from 10 to 70 and 2) when the number of partitions of the display was varied by the use of grid lines. Grid lines were used to partition the display into a 9x9, a 13x13, and a 16x16 matrix. Search times obtained under the various conditions were analyzed for effects of saturation, partitions, display size, and subjects.

Mohr, M.V. & Erikson, C.W. EFFECT OF THE NUMBER OF PERMISSIBLE RESPONSE CATEGORIES ON THE LEARNING OF A CONSTANT NUMBER OF VISUAL STIMULI. Contract AF33(038) 22642, Tech. Rep. 54 163, April 1954, 26pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Johns Hopkins University, Baltimore, Md.).

90 Ss were required to learn to apply either 2, 4 or 8 irrelevant labels to a set of 16 similar and previously unfamiliar complex visual patterns. Immediately following practice in this task, Ss were required to learn to identify the patterns again using a different set of irrelevant verbal labels which were either 2, 4 or 8 in number. The relative performance of Ss in the second phase was found to be significantly affected by the number of labels used in that phase but not by the number of labels which had been used in the initial phase. The amount of positive transfer effect found in the second phase was independent of the specificity of the labeling activity experienced in the first phase. The extent to which each S correctly labeled each pattern in the first phase was not indicative to any important degree of his relative success in labeling each pattern in the second phase. The performance of each S during the first phase, relative to the other Ss in each group, was indicative of relative performance within each group during the second phase. It was suggested that these results, which minimize the importance of the label-pattern associations formed during labeling practice, may be expected only in the case where relatively meaningless or indistinctive labels are employed. A definition of the distinctiveness of verbal labels was suggested in terms of the extensional meanings of the labels acquired in practice in identifying objects.

Long, E.R. & Lee, M.A. THE INFLUENCE OF SPECIFIC STIMULUS CUEING ON LOCATION RESPONSES. THE THIRD OF A SERIES OF REPORTS ON "SET" AS A DETERMINER OF PERCEPTUAL RESPONSES. Contract N33(038) AC 21269, WADC TR 53 314, Dec. 1953, 14pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (University of Virginia, Charlottesville, Va.).

3964

This study is the third in a series of laboratory investigations designed to explore the concept of set and its applicability to the perception of stimuli against background "clutter." The present experiment sought to learn whether and under what conditions stimulus location would be benefitted by providing the observer with setting cues relative to the shape or contour of the critical stimulus figure to be detected, without any spatial location cuing. The following variables were studied: amount of areal clutter (number of confusion figures), degree of figural restriction (figural contour cuing), and temporal position of figural cuing with respect to stimulus presentation.

Christensen, J.M. QUANTITATIVE INSTRUMENT READING AS A FUNCTION OF DIAL DESIGN, EXPOSURE TIME, PREPARATORY FIXATION, AND PRACTICE. WADC 694 15, Tech. Rep. 52 116, Sept. 1952, 51pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

The present experiment is the first of a series undertaken in an effort to determine the nature and significance of certain variables involved in the reading of dials. The Ss were required to read various types of dials at selected exposure times without knowledge of which one of the various dials used in the experiment would be exposed next. 6 variables were considered in this experiment, viz., Ss, Exposure time, Practice, Moving Pointer vs Moving Scale Clockwise vs Counterclockwise Rotation, and Point of Fixation. All effects were significant singly and/or in combination with other effects. Ss interacted with all other variables, either singly or in combination. Exposure time was shown to be an exceedingly powerful and important factor. Relationships discovered at one exposure time became insignificant or even reversed at other exposure times. This interaction between dial type and exposure time casts serious doubt on the practice of inducing errors in dial reading experiments by the expedient of reducing exposure time. Some of the interactions changed with practice, showing the importance of level of training in experiments of this nature. Moving pointer dials were better than moving scale dials at exposure times of the same order as those used by pilots in actual flying situations. Dials with clockwise scales were generally superior to dials with counterclockwise scales.

3967

Long, E.R. & Lee, M.A. THE ROLE OF SPATIAL CUEING AS A RESPONSE-LOCATOR FOR LOCATION RESPONSES. THE SECOND OF A SERIES OF REPORTS ON "SET" AS A DETERMINER OF PERCEPTUAL RESPONSES. Contract N33(038) AC 21269, WADC TR 53 312, Dec. 1953, 17pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (University of Virginia, Charlottesville, Va.).

3967

This is the second in a series of investigations into the nature of perceptual set and its possible application to the process of data assimilation. Subjects were required to locate a single geometrical figure added to a 64-cell square matrix already containing 16 or 32 geometrical figures as confusion figures or clutter. In aid of location, the space in which the figure appeared was heavily outlined; this areal cuing was varied by enclosing different amounts of the matrix. Subjects were allowed to observe the outlined area 1) both before and after or 2) only after stimulus presentation. Frequencies of correct locations were analyzed to determine if perceptual error existed and if areal cuing increased location accuracy.

Long, E.R., Bendeman, P.R. & Reid, L.S. THEORETICAL CONSIDERATIONS AND EMPIRICAL INVESTIGATION OF "SET" AS RESPONSE RESTRICTION. Contract N33(038) AC 21269, WADC TR 53 311, Dec. 1953, 24pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (University of Virginia, Charlottesville, Va.).

3968

This report is the first of a series relating to laboratory experiments designed to examine the nature of perceptual "set" and its application to human operator efficiency in the communication process. An analysis of message reception in the communication process lead to statements of the assumptions for a theoretical model of set and predictions derived from the model. An initial exploratory experiment was described which entailed the manipulation of three variables in a complex perceptual task requiring the Ss to locate and identify single distorted geometrical figures that had been added to a 64-cell square matrix already containing 16 other figures as "clutter." The variables were: 1) type of setting limitation, 2) degree of setting, and 3) type of response.

Erikson, C.W. MULTIDIMENSIONAL STIMULUS DIFFERENCES AND ACCURACY OF DISCRIMINATION. Contract AF 33(033) 22542, Tech. Rep. 54 165, June 1954, 11pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Johns Hopkins University, Baltimore, Md.).

The present report is concerned with the effect of stimulus variation in several dimensions simultaneously upon the accuracy of discrimination in absolute judgment. The dimensions were size, hue and brightness. The discrimination measures for these dimensions were obtained separately and were compared with discrimination measures obtained by compounding these dimensions in various ways. Discriminability was better for the multidimensional series of stimuli than for any of the compounded dimensions used alone. It was further shown that the discrimination accuracy for a compounded or multidimensional series can be predicted if the discrimination accuracy of the separate dimensions is known. This prediction is based on the assumption that the accuracy of discrimination on the several dimensions is independent when simultaneously judged.

O'Brien, B. & Miller, Norma D. A STUDY OF THE MECHANISM OF VISUAL ADAPTATION IN THE CONE RETINA. Contract AF 33(033) 22542, Tech. Rep. 54 165, June 1954, 5pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3970

A series of investigations were reported on the physics and physiology of vision involving a resolution of fine detail. In each study a method was found that yielded results to clear cut that no statistical analysis of the data was required. Measurements of transverse sections of human retinas yielded precise cone spacing data from center to edge of fovea. Measurements with an electronic wave model confirmed the mechanism concentrating and isolating light by each cone. These histological data were correlated with measured ability to show effects of cone spacing. A new ballistic flash technique was used to measure cone thresholds, eye movements, and double star ability. Accuracy of fixation was demonstrated by a new technique. Resolving power of the retina was finally studied. T. G. I. R 19

Fry, G.A. & Alpern, M. EFFECT OF FLASHES OF LIGHT ON NIGHT VISUAL ACUITY. Contract AF33(038) 15630, E.O. 696 67, Tech. Rep. 52 10, Part 1, Nov. 1951, 44pp. USAF Wright Air Development Center, Air Research and Development Command, Wright-Patterson AFB, Ohio. (Ohio State University Research Foundation, Columbus, Ohio).

The purpose of the study was to determine the ability of the eye to see a dark object against a sky background at night after the eye has been exposed to a flash of light, or a series of flashes. The brightness of flashes and the S's visual acuity were measured. Results from the 3 Ss show that the following principles operate: a) the adaptation of any given part of the retina can be regarded as being independent of adaptation processes in other parts of the retina; b) reciprocity between time and intensity can be assumed to hold at least over a 3-sec. interval; c) the effect of a flash displaced from that part of the retina which is used in viewing an object can be accounted for in terms of stray light. The amount of stray light falling at any given part of the retina can be computed from the Stiles-Holladay equation. (HEIAS)

Fry, G.A. & Ihrig, N. EFFECT OF FLASHES OF LIGHT THROUGH THE CLOSED EYELID. II. USE OF DARK GREASE ON THE CLOSED EYELIDS AS A MEANS OF PRESERVING DARK ADAPTATION DURING A FLASH OF LIGHT. Contract AF33(038) 15630, RDO 696 67, Tech. Rep. 53 159, Part 2, Feb. 1953, 11pp. USAF Wright Air Development Center, Aero Medical Lab., Wright-Patterson AFB, Ohio. (Ohio State University Research Foundation, Columbus, Ohio).

This study was undertaken to determine the value of applying dark grease to the closed eyelids in preserving a state of dark adaptation during a flash of light. Max Factor's Dark Negro Grease Paint was the grease used and was applied to the upper and lower lids and the skin out beyond the margins of the orbit. The most important part to cover is the area of the lids directly in front of the pupil. An after-image technique has been used to determine the retinal illuminance produced by light falling on the closed eyelids. The results indicate that the grease reduces the light transmission through the eyelid to approximately 1/3 of the value obtained without the grease. This factor has been found to be approximately the same whether the lids are closed tightly or passively so that the advantage gained by using dark grease is added to that gained by tightly closing the eyelids. The security classification of the title of this report is UNCLASSIFIED.

3976 Brown, J.L., Diamond, A.L., & Miller, H.L. THE EFFECT OF DURATION OF LIGHT ADAPTATION ON TIME REQUIRED FOR DETECTION OF A TARGET ON A SIMULATED PPI SCOPE. Contract AF 33(030)22616, RDO 594-45, Tech. Rep. 52 259, Dec. 1952, 23pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Columbia University, New York, N.Y.).

Times required for the detection of a target on a simulated PPI scope were determined for various scope luminances after different durations of light adaptation to a luminance of 3100 millilamberts. Increased duration of light adaptation results in increased detection time up to a maximum value which varies with scope luminance. In general, detection time decreases with either an increase in target luminance or a decrease in background luminance for a given duration of light adaptation. Within the range of luminances investigated changes in target luminance result in a greater change in detection time than comparable changes in background luminance. The implication for radar scope viewing after adaptation to a high luminance is that optimum visibility will be obtained with maximum gain and as much negative bias as is possible without appreciable reduction of target luminance.

Herrick, R.M., Diamond, A.L. & Kubrs, Margaret P. LUMINANCE THRESHOLDS DURING DARK ADAPTATION FOLLOWING PREADAPTATION TO CATHODE RAY TUBE DISPLAYS. Contract AF 33(038) 22616, RDO 694 45, Tech. Rep. 52 260, Dec. 1952, 11pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Columbia University, New York, N.Y.).

With the identification of the position of a luminous dial pointer at the threshold criterion, luminance thresholds were determined at various times during dark adaptation following preadaptation to Cathode Ray Tube Displays. Each display consisted of a vertical trace line which traversed the Cathode Ray Tube screen at one of three rates. Dark adaptation curves, obtained for the 2 Ss after adaptation to the different displays are superimposed; initial thresholds are relatively low ($-2.0 \log$ millilamberts); and dark adaptation is essentially complete in 5 mins. The findings are interpreted to indicate that in certain Air Force applications, viewing such displays causes a definite temporary loss in the observer's ability to read instrument dials and to perceive objects external to the aircraft.

Erikson, C.W. & Maki, H.W. ABSOLUTE JUDGMENTS AS A FUNCTION OF THE STIMULUS RANGE AND THE NUMBER OF STIMULUS AND RESPONSE CATEGORIES. Contract AF 33(038) 22642, RDO 694 45, Tech. Rep. 54 162, April 1954, 15pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Johns Hopkins University, Baltimore, Md.).

In the psychophysical method of absolute judgment, Ss are required to identify by a name, number or other value each member of a set of individually presented stimuli. Since the method does not provide any explicit standard for comparison, the S is required to base his judgments upon some subjective standard or reference point. This is essentially the condition under which we make many important judgments during our daily activities. The effects of 5 variables upon judgmental accuracy under the absolute method were studied. These were: the range on a stimulus dimension over which stimulus categories were selected for judgment, the number of stimulus categories presented for judgment, and the number of response categories available to the S for expressing his judgments. Doubling of the stimulus dimension produced some increase in judgmental accuracy, but the increase was slight. Judgmental accuracy remained constant as the number of stimulus and response categories was increased, with size of stimulus dimension held constant, provided that the number of response categories equaled or exceeded the number of stimulus categories. There was a loss in discrimination ability when the number of response categories was less than the number of stimuli to be judged. It was suggested that both of these results could be attributed to the end or anchor effects which appear to characterize the absolute method.

Brown, J.L. THE EFFECT OF DIFFERENT PREADAPTING LUMINANCES ON THE RESOLUTION OF VISUAL DETAIL DURING DARK ADAPTATION. Contract AF 33(038) 22616, RDO 694 45, Tech. Rep. 52 14, July 1952, 27pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Columbia University, New York, N.Y.).

Luminance thresholds for the resolution of various widths of grating line were determined during dark adaptation following light adaptation to luminances of 0.50, 100, 1290, and 11,200 millilamberts. The dark adaptation curves for the finest gratings, representing high visual acuity, start at a high initial luminance and drop to a final steady level after 5 to 10 minutes in the dark, as is characteristic of cone function. Curves for coarser gratings may display both cone and rod portions, or after light adaptation to low luminances may represent rod function only. The higher the degree of resolution required, the higher the position of the dark-adaptation curve on the log threshold luminance axis. Increasing the level of light adaptation results in higher initial threshold luminances and a more gradual decline to a final steady value. The final steady value of threshold luminance for a given grating size is little influenced by the level of light adaptation.

R 16

3981

Diamond, A.L. & Gillinsky, Alberta S. LUMINANCE THRESHOLDS FOR THE RESOLUTION OF VISUAL DETAIL DURING DARK ADAPTATION FOLLOWING DIFFERENT DURATIONS OF LIGHT ADAPTATION. Contract AF 33(038) 22616, RDO 694 45, Tech. Rep. 52 257, April 1952, 21pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Columbia University, New York, N.Y.).

Dark adaptation curves representing 3 levels of visual acuity have been determined for 2 Ss following preadaptation for from 1 second to 10 minutes to a constant luminance of 1000 ml. a) At all acuity levels, the initial thresholds rise, and the speed of dark adaptation decreases as duration of preadapting light increases from 1 second to approximately 5 minutes. These effects are less pronounced at the highest acuity investigated, 0.62. A threshold response at this level represents cone adaptation exclusively. b) At lower acuities, 0.083 and 0.042, an additional effect occurs as a function of duration. The shorter the period of light adaptation, the less prominent is the primary cone dark adaptation, and the sooner does the rod dark adaptation appear. c) Duration of light adaptation has a marked effect upon the level of threshold luminance early in the course of dark adaptation. The effect becomes progressively reduced as time in the dark increases. d) As the level of acuity increases, the threshold luminance also increases, depending upon the amount of change in acuity and the pre-adapting duration.

Sivinski, A.J. THE FACTORS OF TASK COMPLEXITY AND PREVIOUS PRACTICE ON A PATTERNED COMPONENT. Contract W3J(038) AC 21269, ADD 694 37, Tech. Rep. 53 313, Dec. 1953, 21pp. USAF Wright Air Development Center, Aero Medical Lab., Wright-Patterson AFB, Ohio. (University of Virginia, Charlottesville, Va.).

The present report covers a laboratory experiment attempting to relate independently the following variables to proficiency of performance in a complex task situation: a) previous practice on a patterned component of the total task; b) task complexity (defined as the number of discrimination-response units composing the task); and c) intercomponent stimulus similarity. The results indicated that previous practice on the patterned component and task complexity were significantly and independently related to total task proficiency, the former tending to increase proficiency, the latter tending to reduce it. Stimulus similarity approached significance as a factor contributing to overall task proficiency.

3983
Spragg, S.D.S. & Milfack, J.W. VISUAL PERFORMANCE AS A FUNCTION OF THE BRIGHTNESS OF AN IMMEDIATELY PRECEDING VISUAL TASK. Contract W3S(038) AC 18317, WADC TR 52 265, Dec. 1953, 16pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (University of Rochester, Rochester, N.Y.).

3983
To investigate the effect on visual performance at low photopic brightness levels of the brightness of an immediately preceding visual task, a group of Ss performed two successive tasks: 1) reading banks of instrument dials (photographic reproductions) at 27 inches with brightness levels of 2.9, 0.083, 0.005 ft.-L and 2) reading banks of Landolt rings with periscope viewing at 18 ft. and 6.0, 0.076, 0.01, 0.007, and 0.0035 ft.-L. A second group performed in reverse order. The analysis of data was primarily in terms of time scores. Implications for instrument dial brightness for night flying and other night visual tasks requiring vision of details were discussed.

3984
Jenkins, W.L. & Karr, A.C. THE USE OF A JOY STICK IN MAKING SETTINGS ON A SIMULATED SCOPE FACE. Contract AF 18(600) 24, WADC TR 53 430, March 1954, 7pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Lehigh University, Bethlehem, Penn.).

3984
To determine the significance of certain variables in the use of a joystick to make settings in two dimensions on a simulated scope face, a series of experiments were conducted using apparatus where the movement of the joystick was translated directly into displacement of the cursor in approximately a linear fashion. Variables were: 1) length of joystick (12, 18, 24, and 30 inches); 2) ratio between joystick tip and movement of cursor (2, 2.5, and 3); 3) reversed operation (cursor moving down when stick is pushed away from operator); and 4) position of S's switch (in hand not operating joystick, pushbutton in top of switch, and foot pedal). Setting time, variability of settings, and missettings were analyzed for effect of variables on accuracy of settings.

3985
Ehles, F.H., Jr. REMINISCENCE IN MOTOR LEARNING. Ph.D. Dissertation, June 1956, 26pp. University of Texas, Austin, Tex.

3985
To determine simultaneously the effect of the type of pre-rest practice, initial level of mastery, and test-retest interval on reminiscence in motor learning, 270 subjects were tested. Under pre-rest practice conditions three inter-trial rests of 10, 35, and 60 seconds were used; pre-rest practice was discontinued when subjects reached either the 5, 25, or 45 percent mastery-levels; and subjects were given either an immediate retest or were tested for recall after a delay of 30 or 60 minutes. Ten subjects were assigned randomly to each of the 27 experimental conditions and administered the SAM Rotary Pursuit Task. The data were analyzed by several methods for differences that could be attributed to the experimental conditions.

3986
Cole, E.L., Milton, J.L. & McIntosh, B.B. ROUTINE MANEUVERS UNDER DAY AND NIGHT CONDITIONS, USING AN EXPERIMENTAL PANEL ARRANGEMENT. THE NINTH OF A SERIES OF REPORTS ON EYE FIXATIONS OF AIRCRAFT PILOTS. WADC TR 53 220, March 1954, 50pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3986
This is the ninth report in a series of investigations of eye movements of pilots during instrument flight. The frequency, duration, and sequences of eye movements made by 15 pilots when flying day and night maneuvers with a new panel arrangement were summarized and compared. Also, for comparison of standard and experimental panel arrangements, data previously obtained using the standard air force panel during routine maneuvers under day conditions were included. The data were analyzed in terms of the most frequently used instruments, differences between day and night flights, and differences between panels. Efficient panel arrangement was discussed.

3987
Gardner, J.F. & Lacey, R.J. AN EXPERIMENTAL COMPARISON OF FIVE DIFFERENT ATTITUDE INDICATORS. WADC TR 54 32, May 1954, 20pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3987
To compare two principles of aircraft attitude indication (earth reference with moving element representing horizon and airplane reference with moving element representing the aircraft), simulated indicators were "flown" in a Link Trainer by experienced pilots and by college students with no flight experience. Four indicators were used representing the two principles defined above and a fifth one provided a "stabilized sphere" type of presentation. Records of pilot performance for a variety of flight maneuvers, control reversals following rough air-gusts, and pilot preferences were recorded and analyzed.

3988
Hunt, D.P. THE CODING OF AIRCRAFT CONTROLS. ADD 694 17, Tech. Rep. 53 221, Aug. 1953, 26pp. USAF Wright Air Development Center, Aero Medical Laboratory, Wright-Patterson AFB, Ohio.

3988
This report summarizes the available information concerning several techniques of control coding which seem to be of value to the design engineers. Five methods of coding are discussed: shape, size, location, color, and mode-of-operation. Information is given concerning each technique so that the design engineer can apply these methods as the need arises. Many of the advantages and disadvantages are pointed out and the question when to code and the type of coding to use are discussed.

3989
Adler, H.E., Johns, Margaret P. & Brown, J.L. MASKING OF CATHODE RAY TUBE DISPLAYS BY AMBIENT ILLUMINATION. Contract AF 33(038) 22616, WADC TR 53 266, Nov. 1953, 24pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Columbia University, New York, N.Y.).

3989
To define the character of the relation between the luminance of a signal on a cathode ray scope and the approximate minimum ambient luminance which is effective in masking the signal, masking thresholds of ambient illumination were determined for a steady horizontal trace line displayed on a cathode ray oscilloscope. Ambient illumination was presented as a veiling luminance and also combined with three levels of direct illumination reflected from the tube face. Seven trace luminances were investigated at each of two trace widths, one and two mm. Implications for tolerable ambient illumination for radar operator workplaces are discussed.

Deese, J. & Ormond, Elizabeth. STUDIES OF DETECTABILITY DURING CONTINUOUS VISUAL SEARCH. Contract AF 33(038) 22642, WADC TR 53 8, Sept. 1953, 48pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

3990
This report describes a series of experiments concerned with the problem of fluctuations in the detectability of weak signals during prolonged visual search. The task was a search for isolated targets that appeared from time to time on a single sweep of a PPI-type CRT. These targets were brighter than the background noise, well above the differential threshold, and they were varied in time and location. Variables studied were rate of target appearance, intertarget time interval, spatial distribution, length of search period, and observer's knowledge of length of period.

Burke, C.J., Harasimban, R. & Benepe, O.J. SOME PROBLEMS IN THE SPECTRAL ANALYSIS OF HUMAN BEHAVIOR RECORDS. Contract AF 18(600) 16, R00 694 39, Tech. Rep. 53 27, July 1953, 6pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Indiana University, Bloomington, Ind.).

The theory of spectral analysis assumes an infinite length record. However, only finite records are ever available to the experimenter. In analyzing samples of human performance this limitation may be particularly acute since length records cannot be obtained without involving the risk of violating, due to fatigue and learning effects, the assumption of a stationary time series. The report describes, mathematically, the effects of finite length of record upon the spectral analysis of function with and without unsystematic components. The lack of an analytic mathematical basis for spectral analysis of human behavior is demonstrated, and the necessity of empirical investigation to establish its validity is pointed out.

Lofbrowitz, H.W. VISUAL FACTORS INFLUENCING THE PRECISION OF ADJUSTMENT OF RETICLE PATTERNS. Contract AF 18(600) 54, R00 694 49, Tech. Rep. 53 200, April 1953, 13pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (University of Wisconsin, Madison, Wisc.).

Vernier acuity refers to the ability to detect a discontinuity in a contour, or to line up straight edges so as to appear continuous. It is specified as the measure of variability of repeated attempts to make coincidence settings. The smaller the variability, the higher the acuity. The standard deviation for aligning dark bars on light, or light bars on dark background at one millilambert or greater illumination was 6 to 11 seconds of arc. As luminance is lowered below one millilambert, variability increases slowly at first, then more rapidly. At all luminance values, variability is increased about 20% if the components to be aligned are set obliquely. No improvement in acuity with practice was observed. Where precise vernier settings or readings are required, it is recommended that the stimulus components be aligned either vertically or horizontally and that a luminance of at least one millilambert be maintained. This minimum luminance will produce maximum vernier acuity, and preserve, as much as possible, the dark adaptation of the observer. (HIC/AS)

Fry, G.A. & Ihsig, W. EFFECT OF FLASHES OF LIGHT THROUGH THE CLOSED EYELID. PART I. PRESERVATION OF DARK ADAPTATION DURING A FLASH BY CLOSING THE EYELIDS. Contract AF 33(038) 15630, WADC TR 53 159, Part I, March 1953, 35pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Ohio State University Research Foundation, Columbus, Ohio).

3993
The major objective of this study was to investigate means of protecting one of the eyes during a short flash of light in order to preserve its dark adaptation. The second eye was used for critical seeing during the flash and the protected eye took over after the flash. The effect of a typical flash (125 ft.-c for a three-second period) upon dark adaptation of the passively closed eyes was measured by tracing the recovery of the ability to see. An afterimage method was devised for measuring retinal illuminance produced by light incident on the closed eyelid and was used to make a comparison of protection provided by closing the eyelid passively and tightly.

Massachusetts Institute of Technology. NOTES FROM MIT
SUMMER COURSE ON OPERATIONS RESEARCH. JUNE 16-JULY 3,
1953. 176pp. Massachusetts Institute of Technology,
Cambridge, Mass.

4003
This is a set of notes taken during lectures of the
Massachusetts Institute of Technology's summer course in
Operations Research in 1953. Operations research is de-
fined as an activity by which trained advice can be given
to management on quantitative matters that can be handled
scientifically. The various lectures include the follow-
ing topics: probability--fundamental concepts, distribu-
tions, ordered statistics, and mathematical models; time
series; waiting lines; Monte Carlo applications; linear
programming; operational experiments; transport, railroads
applications to stock market prediction--a business problem
and a bus problem; review, differential equation approach,
and game theory.

Slade, I.M. CLOTHING FOR PROTECTION AGAINST RADIANT
HEAT. Research, May 1955, 8, 178-182. INF/4/55.
(British Iron & Steel Research Association, London,
England).

4004
Clothing for protection against radiant heat, such
as in a steelworks, is discussed (see also 3525). The
method of heat reflection from the outer surface of the
garment is detailed. Various materials have been coated
with aluminum and tested for their protective values.
The particular situations in which each type might be
used are suggested along with the design of the clothing.
A thermofoil reflecting headgear is illustrated.

Comfort, Elizabeth & Gillespie, K.W. RESPIRATORY
RESPONSE TO OXYGEN BREATHING WITH A FULL-HEAD OXYGEN
MASK. WADC TR 53 130, April 1953, 13pp. USAF Aero Medi-
cal Lab., Wright-Patterson AFB, Ohio.

4005
An investigation was conducted to determine the ex-
tent to which dead space affects use and operation of
full-head oxygen masks. Quantitative measurements of gas
flow into the mask (k-1 helmet) during a single breathing
cycle at various levels of mask pressure were compared
with similar data recorded at a level of mask pressure
considered by the S to represent optimum breathing com-
fort. Probable concentration of carbon dioxide in in-
spired air during breathing was estimated by applying re-
sults of Haldane analyses of gas samples of mask air to
data resulting from analyses of oscillographic tracings
of breathing patterns. Ten Ss were studied. Physiological
and subjective acceptability of this type of mask
were discussed.

Barger, D.M. & Roush, R.G. A VELOCITY MODULATED RASTER
DISPLAY FOR BRIGHTNESS DISCRIMINATION STUDIES. Contract
AF 33(038) 22642, WADC TR 53 249, Aug. 1953, 6pp. USAF
Aero Medical Lab., Wright-Patterson AFB, Ohio. (Johns
Hopkins University, Baltimore, Md.).

4006
A research instrument for the study of human bright-
ness discrimination is described. Two standard and one
modified oscilloscopes are used to produce a rectangular
light field consisting of a raster of vertical sweep lines
on a cathode ray tube face. Independent control of the
brightness of each vertical sweep line in the raster per-
mits study of observer ability in detecting differences
in brightness in the light field as a function of bright-
ness differences between adjacent homogeneous fields, the
relative size of adjacent fields, and the brightness con-
tour or gradient which exists between two fields homogene-
ous in brightness. Block and schematic diagrams are in-
cluded.

Soloyants, G. & Corso, J.F. THE EFFECTS OF SOUND ON AUTO-
KINETIC MOVEMENT. Contract AF 33(038) 786, WADC TR 53
447, June 1953, 17pp. USAF Aero Medical Lab., Wright-
Patterson AFB, Ohio. (Pennsylvania State College, State
College, Penn.).

4007
To determine the effects of monaural and binaural
pure tone stimulation (1000 cps) on the total magnitude
and horizontal directional displacement of autokinetic
movement, 21 subjects were tested. Eight experimental
conditions (six of differential auditory stimulation, two
of equal binaural stimulation) and three control condi-
tions (pretest, within test, post test) were used with a
total of 4620 judgments made in all. The data were ana-
lyzed through rank order and analysis of variance tech-
niques for effects of auditory stimulation on the visual
illusion of apparent movement. In addition, the effects
of repeated light exposures (visual saturation) on mag-
nitude of apparent movement were determined.

Brown, R.H. & Baldwin, A.W. APPARATUS FOR RESEARCH ON
THE DISCRIMINATION OF VELOCITY. RDB Proj. NR 513 050,
NRL Rep. 4283, Dec. 1953, 6pp. USN Research Lab.,
Washington, D.C.

4008
This report describes an apparatus for research on
the discrimination of velocity. A target moving at con-
trolled velocity (direction and speed) is provided. It
is also possible to vary independently the brightness of
the test spot and the interval of time during which it is
seen. Experimental arrangements, the optical system,
control of exposure time and stimulus movement, and cali-
bration data are given. The above equipment was develop-
ed to be used in a program of basic research in tracking,
specifically in the study of the visual processes used by
the tracker in predicting the motion of a target.

Hast, G.M. RADAR TARGET FOLDER VIEWER. FINAL REPORT.
Contract AF 33(600) 15271, July 1953, 15pp. Hast
Development Company, Inc., Davenport, Iowa.

4009
A means for presenting to the navigator of a bomber
the data from the radar target folder (marked paper
prints of real or synthetic radar returns from the target
approach and target area) in close proximity to his radar
screen is described. The Radar Target Folder Viewer pre-
sents comparison radar target pictures from a 35 mm film
strip in a manner that provides for minimum visual re-
adaptation and permits convenient comparison of scope
returns.

Lightfoot, C., Carhart, R. & Gaeth, J.H. EFFICIENCY OF
IMPAIRED EARS IN NOISE. A. THRESHOLDS FOR PURE TONES
AND FOR SPEECH. Contract AF 33(038) 22645, Proj. 21 1203
0001, Rep. 4, Sept. 1953, 18pp. USAF School of Aviation
Medicine, Brooks AFB, Tex. (Northwestern University,
Evanston, Ill.).

4010
To determine the influence of noise on the auditory
efficiency of persons with impaired hearing, an audio-
metric study was made of the effects of thermal noise on
the monaural air-conduction thresholds of 31 subjects of
normal hearing and of 76 persons with various types and
degrees of hearing loss. Pure-tone thresholds and speech
(spondaic words) thresholds were obtained for quiet condi-
tions and for noise conditions. Over-all noise levels
for the controls and for 36 of the hard-of-hearing were
60 and 80 decibels, and for the remaining 40 subjects the
levels were 80 and 95 decibels. Results were analyzed
in terms of comparisons between the two groups and also
against the background of knowledge regarding masking in
the normal ear.

Pepler, R.D. THE EFFECT OF CLIMATIC FACTORS ON THE PERFORMANCE OF SKILLED TASKS BY YOUNG EUROPEAN MEN LIVING IN THE TROPICS. A REPORT ON THE FIRST TWO YEARS' PSYCHOLOGICAL EXPERIMENTS AT SINGAPORE. R.N.P. 53/765, C.E.S. 394, T.R.U. 22/51, Feb. 1953, 8pp. Climatic Efficiency Subcommittee, RNPCC, London, England. (Royal Naval Tropical Research Unit, University of Malaya, Singapore).

4012

The purpose of the work described here is primarily to validate, by experiment on men living in the tropics, the findings from a series of experiments carried out in England using a number of skilled tasks performed in warm and humid indoor climates. The subjects in England had been given short daily exposures to the hot climates for several weeks prior to the experiments. Two experiments on pointer alignment, one on Morse Code reception, and two on visual vigilance are described briefly together with the main findings. The extent to which they agree with findings from the experiments in England is discussed. The relative humidity of the climates, level of skill and of motivation of subjects, and task difficulty are identified as qualifying conditions.

Pepler, R.D. THE EFFECTS OF CLIMATIC FACTORS ON THE PERFORMANCE OF SKILLED TASKS BY YOUNG EUROPEAN MEN LIVING IN THE TROPICS. 4. A TASK OF PROLONGED VISUAL VIGILANCE. Rep. AFU 156/53, Mar. 1953; 24pp. Royal Naval Personnel Research Committee, Great Britain.

4013

To investigate the effect of living for extended periods in the tropics on performance of skilled tasks, vigilance during a prolonged visual task (24 naval ratings who had been living in the tropics for at least 12 months) was measured. The Cambridge Clock Test was used, the subject reporting small and infrequent changes in the display over a period of two hours; six different climatic conditions were tested. Physiological measurements of heat stress were taken (heart rate and rectal temperature). The experiment was repeated with some modifications by 18 subjects. Incidence of missed signals was analyzed for effect of the different climates. Physiological measures were studied in relation to performance. All results were compared to a similar experiment done in temperate zone. T. G. I. R 4

McMahan, C.A., Folger, J. & Feltis, S.W. GRADUATES OF THE AIR CORPS TACTICAL SCHOOL, 1921-1940. A DEMOGRAPHIC ANALYSIS OF THE POPULATION OF GRADUATES AND AN INQUIRY INTO THE RELATIONSHIP BETWEEN ACADEMIC PERFORMANCE AND CAREER DEVELOPMENT. Tech. Res. Rep. 15, April 1953, 57pp. USAF Human Resources Research Institute, Maxwell AFB, Ala.

4014

This is a study of the members of the classes which graduated annually from the Air Corps Tactical School throughout the 20-year period from 1921 to 1940. The data used were those readily obtainable from official military sources; the principal sources were the Official Army Register and the Official School Board Proceedings. It consists of a description and an analysis—a description of the population at time of graduation and as of December 1947 with respect to age, rank, educational background, rating, corps, and other characteristics; and an analysis of the factors relating to academic performance at the ATCS as well as the relationship between academic performance at the school and later career development. Strengths and weaknesses of the study are discussed. T. G.

Smith, A.A., & Boyes, G.E. RADAR TARGET DETECTABILITY AS A FUNCTION OF SEARCH AREA AND RANGE. DRML Proj. 163, Rep. 163-8, FCC D77-94-20-22, H.R. 128, June 1956, 5pp. Defence Research Board, Department of National Defence, Canada.

4015

To investigate some factors affecting target detectability on radar screens, threshold measurements were made by six subjects (target signal voltage increased until subject pointed to target). Using a twelve-inch cathode-ray tube display, three search areas (full-scope, half-scope, and quarter-scope), targets were presented at positions distributed equally in azimuth and ranging from 2/10 to 9/10 radius on a noise-free background. Visibility thresholds were also measured at ranges of 2/10, 4/10, 6/10 and 8/10 radius and azimuths of 45 and 225 degrees. The threshold data were analyzed as functions of search area and range and related to the practical problems of the radar operator.

King-Elisson, Patricia & Jenkins, J.J. THE ROLE OF LANGUAGE IN BEHAVIOR. VISUAL DURATION THRESHOLD AS A FUNCTION OF WORD FREQUENCY. A REPLICATION. Contract N80NR 66216, Tech. Rep. 6, ca. 1952, 7pp. University of Minnesota, Minneapolis, Minn.

4017

To examine the relationship between perception time and word frequency, ten experimental words (five-letter "paralogs") were selected. A pack of 100 cards, each bearing one word, was made up for each of 15-Ss. In each pack two of the words appeared 25 times; two appeared ten times; two appeared five times; two appeared twice; and two appeared once. Dummy cards (14) were added. Each S was told that the words were Turkish words and was required to spell and pronounce the words on each card in the deck. After 20 minutes of unrelated reading, the ten words were exposed tachistoscopically, beginning with 30 msec. and increasing with successive exposures, until correct identifications were made. Mean exposure time at recognition was analyzed in relation to frequency of appearance in the pack. T. G. R 9

Vanderplas, J.M. SOME PERCEPTUAL FACTORS INVOLVED IN THE DESIGN OF OBSTACLE WARNING DISPLAYS FOR AIRCRAFT. RDO 694-45, Tech. Note WCRD-TN-54-9, March 1954, 14pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio.

4018

This report constitutes a discussion of some perceptual problems involved in visually presenting information for spatial and geographic orientation of the pilot in flight and in the design of an aircraft display for obstacle warning. A summary is presented of general principles of visual perception of space, along with a discussion of how these principles may be applied in several representative designs of a pictorial or symbolic display for geographic orientation and obstacle warning. Several types of displays, both pictorial and symbolic, are discussed as examples of application of the principles, and suggestions are presented for their application to an obstacle warning display method.

Richards, D.L. & Sheeme, J.K. MEASUREMENT OF SPEECH LEVELS. SUMMARY OF RELATIONSHIPS BETWEEN MEASUREMENTS USING DIFFERENT METERS. Res. Rep. 12676, Nov. 1952, 6pp. Post Office Engineering Dept., Research Station, Collier Hill, London, England.

4023

The indication of a speech voltmeter is influenced by the mechanical and electrical characteristics of the meters; however, simple relations exist between the readings of most voltmeters. Data are assembled from five studies which enable the calculation of the relation between the readings of most speech voltmeters of known characteristics. In addition, the readings can be referred to a quantity independent of a particular meter--the percentage of time during which the instantaneous power of a speech signal does not exceed the meter reading. Some data on readings taken on logotons are included although the above relations do not hold in these cases.

Wing, J.F. OPTIMAL POSITIONS AND MOTIONS OF THE M46 RAY HANDWEELS FOR TWO-HANDED TRACKING. Proj. TNA 4470, Rep. 5 5258, Human Ergog. Rep. 17, Dec. 1956, 5pp. USA Frankford Arsenal, Picatinny Laboratories, Philadelphia, Penn.

4027

To determine optimal locations and motions of the azimuth and elevation handweels for two-handed tracking with the M46 millimeter Rifle, M46 RAY system, the equipment was examined for problems affecting two-handed tracking and pertinent literature reviewed to determine optimal parameters for handweel positions and motions. Problems of seat width, seat height, and hand clearance were also reviewed. The findings are presented and discussed for: 1) position of handweels due to lay of weapon, 2) assignment of tasks on gunner's hands, 3) planes and directions of movement of handweels, and 4) coordination of handweels during tracking. Deficiencies, requirements, and recommendations are given.

Daniels, F., Jr., Tannville, J.H. & Edwards, C.C. ENERGY COST OF CARRYING THREE LOAD DISTRIBUTIONS ON A TREADMILL. Rep. 203, March 1952, 24pp. USA Environmental Protection Research Div., ON Research & Engineering Center, Watlik, Mass.

4029

The energy cost of carrying loads of 27 to 78 lbs. on a horizontal, motor-driven treadmill at 3.5 mph (53.67 meters a minute) was determined for six test Ss. The loads were distributed in three positions: high on a packboard, low on a packboard, and around the waist as "saddle bags." Empirical formulae were developed from the data for predicting total energy output for carrying loads up to 80 lbs. in these three positions. The meaning of these formulae in terms of body mechanics is not known. Method of carrying loads was also evaluated in terms of subjective preference of the Ss. The rationale for basic studies in load carrying is discussed at some length.

Coxe, D.R. PROBLEM ANALYSIS OF A GENERAL PURPOSE EJECTABLE AIRCRAFT SEAT CAPSULE. Sept. 1952, 8pp. Goodyear Aircraft Corporation, Akron, Ohio.

The report represents a brief summary of some of the important aspects of a program conducted to investigate the feasibility of providing a safe means of personnel escape from aircraft flying at extreme altitude and speeds. The device was to be a versatile escape unit for a single occupant and to be used for multi-place and single-place aircraft. Due to problems greater emphasis was directed toward the multi-place installation. The dynamic, aerodynamic, and structural aspects of the escape problem were investigated. It was concluded that escape from high-speed aircraft at extreme altitudes by means of a general-purpose ejectable aircraft seat capsule appears to be feasible and practicable. (HEIAS)

4427

Landolt, E. & Miller, J.W. A STUDY OF DYNAMIC VISUAL ACUITY. Contract NMR 58600, Proj. Rep. 1 & NR 001 075.91.01, March 1953, 5pp. US School of Aviation Medicine, Pensacola, Fla. (Kresge Eye Institute, Detroit, Mich.).

Experiments were performed to ascertain the manner in which visual acuity deteriorates when the angular velocity of the test object moving in a horizontal plane is varied between 10°/sec. and 170°/sec. When visual acuity is tested with a moving object the acuity deteriorates markedly as the angular velocity of the test object relative to the eye is increased. The visual acuity of an individual may be evaluated in terms of 2 coefficients of which the first is a measure of the static value of visual acuity analogous to that determined by the classical methods. Static acuity is employed chiefly for such special purposes as reading and searching a static visual environment with the head motionless. The second coefficient is a measure of the visual acuity when the eyes are moving. This latter ability may be called dynamic visual acuity; it is employed for most normal functions of the eye. It is shown that individuals with substantially the same static acuity may differ markedly and significantly in their dynamic acuity.

Kentler, H.E. EXPERIMENTAL ANALYSIS OF PROBLEM-SOLVING BEHAVIOR. Contract NMR 18700, Proj. NR 150 044, Tech. Rep. 1, Nov. 1953, 38pp. Dept. of Psychology, University College of Arts & Sciences, New York University, New York, N.Y.

4431

To learn more about technician effectiveness, research was conducted to develop and study suitable performance test measures for use with electronic technicians. The administration of performance tests for electronic technicians was also investigated. A criterion measure of trouble-shooting was obtained through administration of individual trouble-shooting performance tests to 57 subjects using the 50-1b surface search radar. Each subject also was administered a battery of reference tests and a paper form of a trouble-shooting test, the "Tab Test." Data on inter-observer reliability, inter-scores reliability, internal consistency reliability, face validity, and test acceptability were reported.

T. 1. B 1

4432

A research program, explanatory in nature, dealing with factors influencing problem-solving behavior is described. Basic to all the experiments is an attempt to extend conditioning theory to problem-solving behavior. The results of the experiments are presented in five chapters, four of which report the studies of a particular problem area--tests of the extinction hypothesis, verbal learning in concept formation, the acquisition of flexibility in problem-solving situations, and frequency of reinforcement in concept formation behavior. The fifth chapter presents the general rationale of the research program.

Jenness, A.F. & Rouse, R.D. OPERATOR CAPACITY TO PREDICT TARGET POSITION. Contract AF 30 (582)566, Progress Rep. 2, Dec. 1953, 3pp. Williams College, Williamstown, Mass.

The quarter has been spent in redesigning and modifying apparatus. Numerous technical difficulties have been overcome, but further changes are necessary before routine experimentation can be begun. Preliminary data, gathered by the use of a transitional model of the apparatus, with the investigators as Ss, shows evidence of constant errors in the expected direction. After about 4 settings for the straight lines, average errors and variability show little change. Experience of the investigators, serving as Ss, suggests that after the main experiment is finished, emphasis should be directed to studying the effect of training on the improvement of judgments. Because of difficulty with the apparatus, no naive Ss have been employed as yet. 1

4434

Eckhardt, R.T. & Hedberg, R.D. CONTROLS AND DISPLAYS II: THE DETECTABILITY OF ERRORS IN CERTAIN GEOMETRICAL CONFIGURATIONS. Proj. TBI 1000 & TBI 15 C11, Memo Rep. NR 580, NE Rep. 2, Jan. 1954, 4pp. USA Frankford Arsenal, Pitman-Dun Labs., Philadelphia, Penn.

15 Ss were used to evaluate the ability of Ss to determine whether all or all but 1 of 9 lights were on. Ss were tested individually on each of the following 3 configurations: a) a square; b) a circle; and c) a straight line. The data indicated that it was easier to detect the malfunctioning light in a square configuration of lights than it is in a straight line or circular configuration. The circular pattern was read with more difficulty, than either the square or straight line presentation. Further, there was often a discrepancy between how S performed and how he thought he performed. (MEIAS)

4039
This study is reported on the role that carbon di-
oxide (CO₂) plays in human Se at altitude. 1) The rela-
tive influence of hypoxia and CO₂ stimuli upon pulmonary
ventilation in the postoperative hypoxic state was determined
using ten Se at simulated altitudes of 25,000 ft. 2) The
effect of adding CO₂ to inspired air on the duration of
useful consciousness at 33,000 and 35,000 ft. simulated
altitudes was studied on nine Se. 3) CO₂ and respiratory
regulation were studied on 14 Se at simulated altitude of
27,000 ft. breathing gas mixtures with varying concentra-
tions of CO₂. 4) The effect of adding CO₂ to inspired air
on the elimination of nitrogen was made on seven Se ex-
posed to simulated altitude of 20,000 ft.
T. G. 2 20

4040
A methodology was developed that provides a feasible
means of establishing visual requirements for battle
station assignments. The methodology consisted of deter-
mining the relationship between performance of Se on a
job-sample test and various levels of artificially in-
duced vision. To evaluate the method, a job-sample test
was constructed and the relationship between performance
and near visual acuity was determined by rather complex
statistical procedures and also by simple graphical pro-
cedures. The results were discussed in terms of the
manner in which the necessary data can be gathered and
analyzed in the practical situation.

Chambers, E.G. DESIGN AND USE OF SCALES,
DIALS, AND INDICATORS. A.P.U. 254/56, Oct.
1956, 39pp. Applied Psychology Research Unit,
Medical Research Council, Cambridge, England.

4040
This report summarizes the results of research on
the design and use of scales, dials, and indicators for
presenting visual displays of information, either quali-
tative or quantitative. The introduction deals briefly
with the functions and types of displays. Other topics
treated are: methods of investigation; scale design;
graduation and number systems; manuals; pointers;
scale reading errors; position of scale; color; illumi-
nation; viewing angle and distance; display-control
relationships; controls, setting, check controlling and
marking; multi-scale instruments; effects of environ-
ment on scale reading; vibration, noise, vigilance, and
fatigue; and warning devices. General conclusions
thought to be useful as guides for industry are given.

DeHaven, H., Tourin, B. C. Macri, S. AIRCRAFT SAFETY BELTS: THEIR INJURY EFFECT ON THE HUMAN
BODY. Contract N6001 26412, July 1953, 55pp. *Crash Injury Research, Cornell University,
Medical College, Ithaca, N.Y.*

A study of 1039 survivors of 117 plane crashes - ranging from moderate to extremely
severe in nature - has been made in order to factually evaluate the injury effects of 2 in.
lap-type safety belts with a loop-holding capacity from 1000 to 2000 pounds. The statistical
findings demonstrate that: a) the safety belt is not "dangerous"; b) the safety belt provides
protection for the body in crashes; and c) injuries which may seem related to safety belts
directly actually are determined by other factors such as safety belt installation failures
and vertically acting forces in accidents. The findings indicate that a significant decrease
in exposure to crash injuries in small planes can be achieved by: a) providing safety belt
installations (webbing, hardware, carry-through and anchorage points) which will hold oc-
cupants in place under conditions of crash force which leave cockpit and cabin structures
reasonably intact; b) wearing safety belts; c) using shoulder harness to prevent forcible
contact of the head and upper torso with structures of objects having dangerous injury poten-
tials; d) designing the landing gear, fuselage, floor and test structures to progressively
absorb vertically acting crash force.

Comfort, Elizabeth, AIRCRAFT EMERGENCY PRESSURE CELL. Tech. Note WARD 53 141, Dec. 1953, 8pp.
Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

Experimental long-term protection against incapacitating effects of decompression sick-
ness has been developed in the form of a pressurized one-piece capsule consisting of vinyl
coated nylon covered by an outer shell of inelastic urethane nylon. The equipment described
in this report represents a functional laboratory model capable of effectively lowering the
altitude around an occupant of a depressurized aircraft from 50,000 to 24,000 feet, or from
65,000 to 28,000 feet. It has the additional characteristics of being lightweight, stowable
and of minimal size.

4047 Harrison, J.M. & Phoenix, C. THE EFFECT OF VISUAL ANGLE AND DEGREE OF IMPERFECTION UPON THE RECOGNITION OF OBJECTS. Contract AF 33(616)432, Tech. Note 104, Sept. 1953, 9pp. Optical Research Lab., Boston University, Boston, Mass.

A study was conducted to measure the recognizability of imperfect images as a function of visual angle and the degree of imperfection. Test objects were artificial "photographs" of semicircles and isosceles triangles. The "grain" was a grid of squares upon which the semicircles and triangles were superimposed such that those squares more than half enclosed by the object were painted black and the rest left white. By using different size squares, varying object area-square area (O/S) ratios were obtained. Visual angle was altered by varying the distance between the S and the stimulus. The S was asked to judge whether each stimulus was a semicircle or a triangle. For visual angles in the range 25-155 minutes, the number of correct responses increased as the O/S ratio increased. At visual angles less than 25 minutes an increase in recognition was obtained for all O/S ratios that had not previously yielded 100% recognition.

Henry, F.M. THE EQUIVALENT "BENDS" ALTITUDE OF THE Y-1 PARTIAL PRESSURE UNIT. Contract AF 18(600)30, WADC Tech. Rep. 53-276, June 1953, 9pp. University of California, Berkeley, Calif.

The equivalent aviator's "bends" altitude of the Y-1 partial pressure suit has been determined by obtaining the critical altitude for appearance and disappearance of pre-established bends pains of various intensities. This was done by lowering and raising the decompression chamber altitude with the men wearing the unpressurized suit, and then by holding the chamber at a constant high altitude while the pain was relieved and caused to return by pressurizing and depressurizing the contents of the suit. The experiments were performed in the altitude chamber of the University of California (Berkeley). In 33 measurements on 17 men, the equivalent altitude of the suit averaged 1509 ft lower than the direct altitude chamber figure. A third of the cases showed no difference. The critical altitude for pre-established bends was 24,300 ft for mild and 31,400 ft for moderately severe pains. A table is presented to show the probability of relieving bends pain with the Y-1 suit. The average case of bends would be reduced to a tolerable intensity with 14 psi on the capstan at 46,000 ft cabin altitude. Wrist and ankle pains were relieved as effectively as shoulder, elbow and knee pains.

Reichman, M. THE INFLUENCE OF SIZE AND SHAPE ON THE VISUAL THRESHOLD OF THE DETECTABILITY OF TARGETS. Contract AF 33(616) 432, Tech. Note 109, Dec. 1953, 5pp. Optical Research Lab., Boston University, Boston, Mass.

4049

To test predictions made from a theory proposed by James, Hecht, Shlaer, and Smith that the constant (21%) required to detect a rectangular target was a positive function of the area within 1.5 minutes from the edge (defined as the useful area) of the target, 200 experiments were conducted. Differential thresholds of detectability were obtained for a series of 24 rectangles which varied in area, useful area, and perimeter. The second study also obtained differential thresholds of detectability for a series of seven stimuli composed of pairs of rectangles. Threshold data were analyzed as functions of area, perimeter, useful area, and separation distance between rectangles.

Courtney, D. (Proj. DIF.). PSYCHOLOGY AND GROUND SAFETY. Contract AF 18(600) 301, HFCRL Rep. 43, Aug. 1953, 146pp. USAF Human Factors Operations Research Lab., Bolling AFB, Washington, D.C. (Institute for Research in Human Relations, Philadelphia, Penn.).

4050

This report presents an analysis of the Ground Safety Director's job together with pertinent psychological literature. Based upon library research and field visits to representative Air Force bases, the functions and areas of knowledge important in the work of the Ground Safety Director are outlined. These areas are then reorganized into six topics for intensive treatment (the results of which are presented in this report): psychological factors in accident causation, safety promotion procedures, principles of driver training, principles and procedures of driver evaluation, practical principles of effective interviewing, and human relations and safety.

Crook, H.N. & Baxter, Frances S. THE DESIGN OF DIGITS. Contract W33 038 ac 14552, ADD 694 51, WADC Tech. Rep. 54-262, June 1954, 65pp. USAF Aero Medical Lab., Wright Air Development Center, Wright-Patterson AFB, Ohio.

This report presents the results of a series of experiments on the design of dial type numerals and reviews a number of related studies by other investigators. Design characteristics of transilluminated numerals in the Air Force-Navy Aeronautical style at very low brightness were investigated. The experimental results indicate narrow stroke widths and close spacing were unfavorable. With area held constant, the effect of height/width ratio varied from digit to digit. Configurational characteristics could not readily be improved, but a round-tipped "3" in an open style was found to be superior to the standard flat-topped design. Data on confusions among both intact digits and digits with small stroke defects showed reasonable degrees of consistency. A number of special observations for which the test situation was well suited threw light on problems of experimental technique. From an analysis of the literature it was concluded that most of the contradictions on digits by different investigators can be resolved and the data fitted into a coherent pattern. The principles given can be used as guide lines for charts and checklist designs to give better readability.

Memmenan, R.H. & Long, E.R. A COMPARISON OF THE VISUAL AND AUDITORY SENSES AS CHANNELS FOR DATA PRESENTATION. Contract W33(038) ac 21259, Proj. 7152, Tech. Rep. 54-253, Aug. 1954, 38pp. USAF Wright Air Development Center, Aero Medical Lab., Wright-Patterson AFB, Ohio.

It is the contention of the present report that the choice between the eyes and the ears as sense channels for the presentation of information to the human operator rests upon the specific demands of various operational data, some of which have implications for visual or auditory presentation. These 3 sets of demands are: a) demands imposed by response variables (e.g., orientation in space, fine quantitative comparison, rapid referability); b) demands imposed by operator variables (e.g., previous habits, fatigue, motivation); c) demands imposed by special environmental conditions favoring one or the other sense channel (e.g., ambient noise, sudden changes of illumination, excessive vibration). The stimulus properties of light and sound differ; the receptor characteristics of vision and audition also differ. It is possible, by matching these distinguishing sense characteristics with specific demands of particular situations, to suggest some "division of labor" between the 2 sense channels for purposes of data presentation. 4 principal categories of demands for informational input have been proposed as follows: a) typical demands for visual presentation; b) typical demands for auditory presentation; c) typical demands served by either sense alone; d) typical demands for dual audio-visual presentation.

Cohen, J. & Webb, Ilse B. AN EXPERIMENT ON THE CODING OF NUMERALS FOR TAPE PRESENTATION. Contract AF 18(600) 50, ADD 694 31, WADC Tech. Rep. 54-86, Dec. 1953, 14pp. USAF Aero Medical Lab., Wright Air Development Center, Wright-Patterson AFB, Ohio. (Antioch College, Yellow Springs, Ohio).

One way of transmitting information to aircraft crews would be to automatically punch or print numerical information on tape in the airplane in response to radio or radar signals. The tape may be scanned by a device to take control action and also be monitored by people. A compromise system of marking the tape has to be worked out which is efficient for both mechanical and human scanning. 24 Ss were tested to determine the speed and accuracy with which they could read Arabic numerals and 5 systems of coded numerals. The experiment provides preliminary information about the applicability of certain principles of coding in the selection of numeral representations for the punch or printed tape method of presenting information to airborne personnel. All Ss were fastest and most accurate with the Arabic numerals and all but 3 were slowest with the code based on the position of a single dot on a grid. The fastest and most accurately read numeral system, excepting the Arabic, was the symbolic Arabic code which resembles the Arabic, but the numerals are printed with 6 straight line elements. The 3 codes based on the number of dots or lines were intermediate in terms of reading speed.

Conrad, R. SOME EFFECTS ON PERFORMANCE OF CHANGES IN PERCEPTUAL LOAD. A.P.U. 210/54, June 1954, 18pp. Medical Research Council, Applied Psychology Research Unit, London, England.

The perceptual load was systematically varied for each of 12 practiced Ss. From an analysis of performance records it was found that: a) Errors occurred when signals requiring action were bunched. It was pointed out that with load changes the errors arising from this source would change in certain skills, but not in all. b) Errors occurred when Ss failed to determine the correct signal order. These errors only occurred when the interval between successive signals was short. Increasing the load had the effect of increasing the frequency of such errors, and of increasing the maximum interval between 2 signals likely to result in such error. A subsidiary experiment showed an association between the incidence of this type of error and a general shortage of time. c) With load increases, errors were more likely to arise in event-sequences of identical temporal structure, even when an essential element of the sequence was an event which occurred after the error. d) Recovery from error took longer with greater loads. e) Even under the condition of greatest stress, attention was apparently distributed strictly according to display demands rather than in accord with either a spatial or a signal-frequency pattern.

Leonard, J.A. THE EFFECT OF PARTIAL ADVANCE INFORMATION. A.P.U. 217/54, June 1954, 23pp. Medical Research Council, Applied Psychology Research Unit, London, England.

An experiment was carried out to study the effects of partial advance information. In successive tests spread over 8 months it was found that a) it was possible to produce reaction times or rates of gain under the experimental conditions which were comparable with those obtained under the 3 choice condition. b) it was possible to produce reaction times or rates of gain under the experimental condition which were better than those obtained under the 3 choice condition. c) The main effect of the forewarning in reducing the reaction time to the specific signal in the experimental condition was obtained with forewarning lasting .10 secs. although considerably more time had to be allowed to obtain the maximum effect. d) There is some evidence that the full effect of the warning signal was retarded when the duration of forewarning was .20 secs. e) It seems just possible that performance under the experimental condition with a forewarning lasting .04 secs. is at least as good as performance under the 6 choice condition, provided one adds the .04 sec. to the reaction time obtained under the experimental condition. f) A difference between performance under the 6 choice and the 3 choice condition was maintained although that difference was not as large as had been expected.

Siddall, G.J. VARIATIONS IN MOVEMENT TIME IN AN INDUSTRIAL REPETITIVE TASK. A.P.U. 216/54, Aug. 1954, 13pp. Medical Research Council, Applied Psychology Research Unit, London, England.

An industrial repetitive task was filmed under conditions of normal production. From by frame analysis was carried out to determine what variations in the times of the component elements might exist a) between cycles of different duration b) within cycles of constant duration. It was found that as the duration of the cycle increased, the manipulative movement contributed proportionately more and more, and the travel movements proportionately less and less to the total cycle time. A movement which combined both manipulative and travel characteristics provided an approximately constant proportion of the cycle time. 2 possible explanations of these relative differences are briefly discussed. Variations in the component element values of cycles of constant duration were found which were considered to relate to variations in the moment to moment demands of the skill sequence in achieving the aims of the skill.

Sanders, Virginia L. & Cohen, J. THE EFFECTS OF ABSOLUTE AND CONDITIONAL PROBABILITY DISTRIBUTIONS OF INSTRUMENT SETTINGS ON A SCALE READING: REPEATED EXPOSURES OF THE SAME SETTING. Contract AF 18(600) 50, RDR 694 31, WADC Tech. Rep. 54 253, Oct. 1954, 45pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

The first of a series of experiments designed to investigate the effect on scale reading of the sequence of pointer settings, and responses to them, is reported. This paper analyzes response sequences in the limiting case in which repeated successive exposures of the same stimulus are administered. Under these conditions information transmitted from scale settings to responses increases, with exposure number in a manner approximately described by a growth function. When the same stimuli are presented in random sequence, only a very slight, approximately linear increase in transmitted information is found. Increasing the exposure time or the number of graduations on the scale increases the amount of information transmitted, and increasing the exposure time also increases the rate of gain of information. Mean square error decreases with successive exposures, and the correlation between the logarithm of this measure and information transmitted is -.86. A research program to investigate the effects of different kinds of absolute and conditional probability distributions on instrument reading is proposed.

Merrick, R.M. FOCAL LUMINANCE DISCRIMINATION AS A FUNCTION OF THE DURATION OF THE DECREMENT OR INCREMENT IN LUMINANCE. Contract AF 33(038) 22616, Task 71544, Tech. Rep. 54 463, Oct. 1954, 16pp. Aero Medical Lab., USAF Wright Air Development Center, Dayton, Ohio.

The minimum observable change in brightness (luminance) as a function of a) the original adapting brightness and b) the duration of the change was investigated. The brightness of a centrally fixated adapting field was varied from .01 to 1000 millilamberts. The duration of the increment was varied from .0035 to 2.035 seconds. It was found that the longer the duration of the change in brightness, up to a critical point, the less the change in brightness required to be detected. Up to this critical point, the change in brightness (ΔI) multiplied by its duration (t) equaled a constant ($\Delta I \times t = K$). For longer durations the just-detectable change in brightness is constant ($\Delta I = K$). The critical duration varies inversely as a function of the adapting brightness—the higher the brightness the shorter the critical time over which the relationship $\Delta I \times t = K$ holds. These findings agree with the Bunsen-Roscoe law and indicate further that this law holds for a decrement as well as for an increment in brightness. These results are important in a great number of Air Force situations, especially those in which an observer must obtain information based on momentary increases or decreases in a field of light. For example, the results show that a very weak signal on a CRT screen may be detected if it persists long enough to allow the eye to integrate the energy emitted. The results also indicate that the integration time of the eye as well as the minimum luminance of the signal required for detection will depend upon the background luminance of the CRT screen. Analogous interpretations apply when the dark-trace CRT screen is employed as the detection device. Another example of the practical use of the data concerns blinker or beacon signal systems. The findings of the experiment permit one to estimate the minimum durations required between successive flashes of light for the detection of discrete flashes. R 19

4071

Simon, C.W. THE PRESENCE OF A DUEL PERCEPTUAL SET FOR CERTAIN PERCEPTUAL MOTOR TASKS. Contract W33 038 ac 19816, RPO 694 31, WADC Tech. Rep. 54 286, June 1954, 27pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Antioch College, Yellow Springs, Ohio.)

2 independent groups of 24 female college students acted as subjects in an experiment using a single, compensatory pursuit task. One group used a knob control; the other, a lever. In both studies, the zero position of the pointer and the motion relation between pointer and control were varied. Time-on-target performance scores were measured with the pointer in a 12 or 6 o'clock zero position and with the direction of movement of the pointer and control either agreeing or disagreeing. The pointer dial and the control were aligned vertically in the same plane; and arc of pointer movement was considerably less than 45 degrees on either side of the zero position. The major conclusions drawn were that a) performance is affected by an interaction between the pointer position and the pointer-control motion relation, b) subjects behave as if they perceive the rotary mechanical movements both linearly and curvilinearly, c) the motion agreement principle operates in both perceptual sets and performance is a result of the effects of both sets combined. Bradley, J.V. CONTROL-DISPLAY ASSOCIATION PREFERENCES FOR GANGED CONTROLS. Proj. 7182, WADC Tech. Rep. 54 379, Aug. 1954, 12pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

75 male college students and 25 human engineering psychologists were given a questionnaire presenting diagrams consisting of 3 concentrically ganged knobs and 3 dials which they were told the knobs operate. They were asked which dial they thought should be operated by each of the 3 knobs. Knob-dial associations were obtained with dials in horizontal and vertical arrays above, below, to the left of, and to the right of the knobs, and with dials differing in size, shape and distance from the knob axis. Knob-dial associations were found to be influenced by all of these factors except dial shape. Associations which were both strong and relatively unrivaled were found for dial position in a horizontal array (except when the array is to the left of the knobs), and for dial size. Subjects associated the spatial knob progression, front knob to back knob with the spatial dial progression, left dial to right dial and with the dial size progression, smallest dial to largest dial. Strong, but strongly rivaled, associations were found for dial position in a vertical array and for dial distance from the knob axis.

Thompson, M.E. STUDY OF RELIABILITIES OF SELECTED GROSS MUSCULAR COORDINATION TEST ITEMS. Contract AF 33(038) 22948, Proj. 509 020 0005, Res. Bull. 52 29, Oct. 1952, 11pp. Perceptual and Motor Skills Research Lab., USAF Human Resources Research Center, Lackland AFB, Tex. (University of Arkansas, Fayetteville, Ark.)

This study was concerned primarily with the development of a number of test items of gross muscular coordination which utilized simple apparatus and which could be scored on a pass-fail basis. Another aspect of the study involved the determination of test-retest reliability coefficients of each item which was administered to at least 100 college students. The reliability coefficients ranged from 0.16 to 0.95 with 56 per cent of the coefficients falling at 0.60, or above. Ninety-one per cent of the test items showed a practice effect in terms of a larger per cent of subjects passing the test on the second trial than the per cent passing on the first trial. Nine per cent of the test items showed the effects of fatigue as the per cent of subjects passing these items on the second trial was lower than the per cent passing on the first trial.

Holstetter, H.W. OPTOMETRIC CONTRIBUTIONS IN ACCOMMODATION AND CONVERGENCE STUDIES. J. Amer. Optom. Ass., March 1954, 25(8), 431-439. (Div. of Optometry, Indiana University, Bloomington, Ind.).

4075
As one of a series of studies conducted to determine how man discriminates velocity and acceleration, four observers discriminated velocity at eight speeds for each of eight exposure times. The observer presented with a spot, travelling at a controlled speed was required to give an unequivocal response to the visual movement—direction of travel. The minimal luminance required for the discrimination was determined for each condition. Threshold data were analyzed for sources of variation: duration of stimulus, rate of stimulus, and observer effects. The significance of the findings for understanding the visual processes of a tracker in predicting motion of a target was discussed.

Fry, G.A. & Ward, K.O. EFFECT OF CHROMATIC ADAPTATION UPON NORMAL COLOR VISION. FINAL REPORT. PHASE 2. Contract Monr 1066(00), Proj. NR 140 061, AF Proj. 537, March 1954, 22pp. Office of Naval Research, Washington, D.C. (Ohio State University Research Foundation, Columbus, Ohio).

The effect of adaptation to monochromatic stimuli of wavelengths 435, 490, 524, 573 and 741 mμ on the brightness and chromaticness of various monochromatic test stimuli has been investigated. In the course of this study, it has been discovered that at an intensity level of 27.1 c/m² with an artificial pupil having an area of 1.28 cm², the zone of the color mixture triangle bounded by lines between 436, 470 and 650 mμ is dichromatic. Isochromatic lines stretch across this zone. The importance of the knowledge of the existence of these isochromatic lines for chromatic-adaptation experiments has been discussed. Special attention has been paid to the role played by the Bezold-Brücke phenomenon in chromatic-adaptation experiments. The results indicate that adaptation to various monochromatic stimuli will reduce the brightness of various test stimuli and will also produce a measurable change in the form of the luminosity curve. Evidence from both the color-mixture data and the chromatic-adaptation data indicates that the straight-line portions of the spectrum locus represent legs of the polygon of fundamental colors.

Fry, G.A. EFFECT OF CHROMATIC ADAPTATION UPON NORMAL COLOR VISION. FINAL REPORT. PHASE 3. Contract Monr 1066(00), Proj. NR 140 061, AF Proj. 537, March 1954, 10pp. Office of Naval Research, Washington, D.C. (Ohio State University Research Foundation, Columbus, Ohio).

This report describes special adaptation experiments to determine the displacement of the red and green fundamental colors along the red-green leg of the polygon of fundamental colors and also to demonstrate whether stimuli at the red and violet ends of the spectrum lie on the red-green and violet-cyan legs of the polygon of fundamental colors. The fact that the green fundamental does not fall at the intersection of the violet-cyan and red-green legs of the polygon proves that the polygon has at least 4 sides. The theoretical implications of a 4-cornered polygon for color-mixture and chromatic-adaptation phenomena have been discussed.

Fry, G.A. EFFECT OF CHROMATIC ADAPTATION UPON NORMAL COLOR VISION. FINAL REPORT. PHASE 4. Contract Monr 1066(00), Proj. NR 140 061, AF Proj. 537, March 1954, 6pp. Office of Naval Research, Washington, D.C. (Ohio State University Research Foundation, Columbus, Ohio).

This report describes experiments related to the chromatism in the zone along the blue-red leg of the mixture diagram. The isochromatic lines in this zone appear to be extensions of the lines of constant hue that are found in the trichromatic region of the color-mixture diagram. The recognition of the existence of isochromatic lines in the dichromatic zone is important in connection with the interpretation color-mixture and chromatic-adaptation data.

Zeller, A.F., Harvey, E.S., Jr. & Burke, J.M. A STUDY OF UNDERSHOOT - OVERSHOOT NON-EMERGENCY ACCIDENTS, 1 JANUARY 1953 THROUGH 31 DECEMBER 1954. AFR 190 16, Aug. 1955, 49pp. USAF Directorate of Flight Safety Research, Norton AFB, Calif.

4098

During the calendar years of 1953 and 1954, the United States Air Force experienced 313 accidents in which the pilot undershot, and 135 accidents in which the pilot overshot the runway when he had the option of a normal landing with an aircraft in mechanically adequate condition. An analysis of factors that might be contributing causes of the accidents was made and recommendations for corrective action were made.

Loveless, N.E. MANUAL TRACKING IN THE FOUR QUADRANTS OF A CIRCULAR SCALE. II. UPPER AND LOWER QUADRANTS. FPRC 867, March 1954, 11pp. Flying Personnel Research Committee, London England; (Nuffield Dept. of Industrial Health, University of Durham, King's College, Newcastle-on-Tyne, England).

In a compensatory tracking task, Ss were required to control the pointer on a circular scale by means of a control knob. 2 targets, and 2 control-displays consisting of direct drive and reversed drive were used. Each S was tested under all 4 experimental conditions. Speed and accuracy were greatest with direct drive and with the target at the top of the scale. Direct drive with the target at the bottom of the scale ranked second, while performance was poorest under the 2 reversed drive conditions. Ss tend to respond to a deviation of the pointer with a control movement of the opposite sense. Ss respond primarily to angular displacements of the pointer. There is also a subsidiary tendency to respond to quasi-linear displacements of the pointer. These 2 tendencies may be present together, and will summate or conflict according to the choice of drive and target. (HEIAS)

Hurvich, L.M. & Jameson, Dorothea. SPECTRAL SENSITIVITY OF THE FOVEA. III. HETEROCHROMATIC BRIGHTNESS AND CHROMATIC ADAPTATION. J. opt. soc. Amer., March 1954, 44(3), 213-222. (Eastman Kodak Company, Rochester, N.Y.).

A series of experiments is reported that extends an earlier study of the foveal threshold luminosity function and its dependence on chromatic adaptation. Heterochromatic brightness matches were made by a large-step, equality-of-brightness method at 3 luminance levels: 10 mL, 20 mL, and 40 mL. Results are compared for chromatically neutral white, and blue, green, yellow and red adapting-surround fields at 3 levels of adapting luminance: 10 mL, 20 mL, and 40 mL. The results for suprathreshold photometric equations confirm the dependence of foveal luminosity on chromatic adaptation demonstrated earlier for threshold sensitivities. The foveal (1°) luminosity function is shown to undergo regular and consistent changes with changes in chromatic adaptation and to be further dependent on the ratio of surround/standard luminance. Implications of these results for the CIE system are touched upon.

Mouty, G.T. & Payne, R.B. EFFECTS OF WORK PROLONGATION UPON COMPONENTS OF A PERCEPTUAL-MOTOR TASK. Proj. 21 1601 0004, Rep. 6, Oct. 1954, 8pp. USAF School of Aviation Medicine, Randolph Field, Tex.

168 Ss, having received preliminary training on a compensatory pursuit task involving simulated aircraft instruments and controls, were randomly assigned for the 42 combinations of 7 pharmacological conditions, 3 systems of presenting information of performance adequacy, and 2 differing proximities of goal, and then required to perform the task for 7 hours. Measures of proficiency were taken. It was concluded that: a) The instruments marginally located on the instrument panel evidenced no more decrement in proficiency of control than did those instruments located centrally; b) In one comparison where the principal difference was occasioned by hand vs. feet operated controls, achieved proficiencies throughout the work period were not significantly different; c) Experimentally induced changes in the perceptual requirements of the task did not alter significantly the near equal rates of deterioration in the control of the central and marginal instruments. Lincoln, R.S. VISUAL TRACKING: III. THE INSTRUMENTAL DIMENSION OF MOTION IN RELATION TO TRACKING ACCURACY. J. Appl. Psychol., Dec. 1953, 37(6), 489-493. (Johns Hopkins University, Baltimore, Md.).

4104

To investigate the effect of spatial arrangements of and various speed rates of multiple-dial displays on performance, displays of six dials were prepared, half of which were spatially scattered and the other half arranged in a compact group. Pointer rotation was similar for all dials in series of trials and dissimilar in a replication. The task of the six subjects was to keep the pointer moving by operating a toggle switch at appropriate times. Performance data (total time pointers were stationary) were studied by analysis of variance for differences in the display properties.

4106

To study the transfer of skills as a function of the number of common instrumental relationships between tasks, three groups of 18 Ss practiced six days (ten trials per day) on either direct, velocity, or aided tracking. On the seventh day, six members of each group transferred to each of the two different tasks, the remaining six in each group continuing the original task. The course of learning each task is examined for the six training days, and amount of transfer is interpreted as a function of common instrumental relationships (translation, transformation, and integration) between tasks.

Brown, J.L. & Lechner, Marian. ACCELERATION AND HUMAN PERFORMANCE: A SURVEY OF RESEARCH. Proj. NH 001 111, Study NH 00 111, Task 300, WADC MA 5503, Rep. 1, March 1955, 39pp. USN Air Development Center, Aviation Medical Acceleration Lab., Johnsville, Pa.

This report summarizes the important research which has been conducted to date on the problem of human performance under acceleration. The material has been grouped according to 5 major headings: the senses, simple motor behavior, complex tasks, cognitive processes, and psychological effects. Research relevant to each of these classifications is reviewed, important questions which appear to remain unanswered are raised, and suggestions are made regarding desirable lines for future research. It appears that only a very limited amount of research has been conducted relating to actual performance sequences which may be required of pilots exposed to acceleration.

Conrad, R. MISSED SIGNALS IN A SENSORI-MOTOR SKILL. APU 187/53, Feb. 1953, 16pp. Applied Psychology Research Unit, Medical Research Council, Cambridge, England.

To explain why speed increases in the demanded rate of work in a sensori-motor skill led to a disproportionate deterioration in performance, specific association was sought between signals omitted and definable temporal relationships occurring as a result of continuous display changes. The distribution of the time intervals between the signals presented was such that some relationships occurred many times more often than others, the frequency being determined by the mean signal speed. A detailed examination of performance in these terms revealed that omissions occurred close to the nearest response more often than would be expected by chance, and they were as likely to occur just before the response as just after. Furthermore, the probability that a signal would be omitted when it occurred a constant time interval from a response increased linearly with mean speed. The effect of increasing the signal speed was twofold. Firstly, it increased the chances that a signal would occur close to a response, thus subjecting it to a hazardous temporal situation. Secondly, if a signal did occur close to a response it increased the chances that it would be omitted.

Koppard, W.L. & Smith, W.M. A PRELIMINARY EXPERIMENT ON THE EFFECT OF DIAL ORIENTATION AND DIAL SIZE ON THE SPEED AND ACCURACY OF DIAL READING. *Annals N.Y. Acad. Sci.*, Jan. 1951, 52, 1272-1277. (Psychology Dept., Princeton University, Princeton, N.J.).

Results of a preliminary experiment involving six Ss, 8 different dial designs, and 2 sizes of dials have been reported. Measures of reading time and error frequency were taken. The data obtained must be interpreted in the light of the fact that the subjects were graduate students reading at their own pace under instructions to be as accurate as possible. It was observed that frequency of dial reading error was primarily a function of the arc length in inches covered by one scale unit. For maximum reading accuracy, about 0.25 in. per scale unit seems to be required, although this distance may depend in part on whether the scale is graduated by 5s or by 10s. Regarding speed of reading, it was observed that speed depended most on the regular representation of each scale unit on the dial circumference. Reading speed was, therefore, relatively independent of dial size within the size limits studied, but varied markedly with the total number of units portrayed on the scale.

Spector, P. A SURVEY OF THE AIRWAYS AND AIR COMMUNICATION SERVICE ELECTRONICS MAINTENANCE SYSTEM. Contract AF 33(602) 24, RADC TN 55 388, June 1955, 22pp. American Institute for Research, Pittsburgh, Penn.

4124

A field survey of the Airways and Air Communications Service maintenance system was made. Particular emphasis was placed on the new periodic maintenance procedures. A sample of 11 AACS squadrons were visited. Maintenance of radio, radar, and teletype equipment was observed, with maintenance procedures being examined as they took place in the normal daily activity. Data were collected from direct observation and from interviews with officers and airmen. The findings are presented with a brief analysis where appropriate and a recommendation for alleviating difficulties found.

4125 USA Electronic Proving Ground. OPERATIONAL EVALUATION OF PILOT-ASSIST DEVICES: APPLICATION OF PILOT-ASSIST DEVICES TO ARMY AIRCRAFT. FINAL REPORT. Rep. AEPG 519 910 15. AEPG Task 6084, March 1956, 37pp. Aviation and Meteorological Dept., USA Electronic Proving Ground, Fort Huachuca, Ariz.

6 different types of commercial pilot-assist devices were procured and flight tested in the L-19 Army aircraft to determine which of the several techniques employed in these devices is most suitable for Army use. The devices were tested for course holding ability, speed of response during a stall, transient response, and roll-out characteristics. An analysis of the results of these tests revealed that the Lear AECOM Pilot-assist device performed the most satisfactorily. An L-19 Army aircraft in which the Lear AECOM was installed was flown to 3 other Army installations. Pilots from these installations flew the aircraft and completed questionnaires concerning desirability of the system, including their evaluation and comments on its performance. It was concluded from an analysis of pilot opinion questionnaires that a single-axis pilot-assist device is desirable in Army liaison type aircraft. A large majority of experienced Army aviators who evaluated the device expressed the opinion that such a device is desirable and necessary in this type aircraft. R 4

4126 McIntosh, E.B. THE INFORMATION-HANDLING CAPACITY OF THE HUMAN AS A FUNCTION OF CERTAIN CHARACTERISTICS OF THE STIMULUS SET. M.A. Thesis, 1953, 37pp. Ohio State University, Columbus, Ohio.

4126

To study the effects of patterns formed by stimulus lights and the probabilities of occurrence of various lights on the human's information handling capacity, seven stimulus sets were used which varied in 1) number of stimuli on panel, 2) spatial relations between these stimuli, and 3) frequency of occurrence of each stimulus within the set. The stimuli were presented randomly at a prescribed rate for each of the stimulus sets and the two Ss responded by pressing one of the matched response keys. The results were analyzed in terms of frequency and type of response to each of the stimuli, the number of no responses, and the amount of information transfer per second from each stimulus set. T. Bridgman, C.S. & Wade, E.A. SENSITIVITY TO CHANGES IN STIMULUS SIZE. REACTION TIME AS A FUNCTION OF RATE OF CHANGE. Contract AF 18(600) 54, WADC TR 53 199, April 1953, 10pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (University of Wisconsin, Madison, Wisc. & Tufts University, Medford, Mass.).

4127

To determine the relation between rate of stimulus size change and reaction time, ten subjects were required to respond to size changes in a circular target by pushing a lever forward when the target decreased and pulling it back when an increase was observed. The initial target size was 42 millimeters subtending an angle of one-half degree at observer's eye; rates of change in target diameter ranged from six to one millimeter-per second, corresponding to angular rates of 4.2, 3.5, 2.8, 2.1, 1.4, and 0.7 minutes of arc per second. Reaction times were analyzed as a function of rate of target size change. The results are discussed with reference to their use as a "third dimension" (range) on a visual indicator such as a radar scope. T. G. I. R 2

4128 Beckman, E.L.; Avance, T.D.; Ziegler, J.G. & Munter, M.N. HUMAN TOLERANCE TO HIGH POSITIVE G APPLIED AT A RATE OF 5 TO 10 G PER SECOND. PHASE IV. Proj. TED AEC AT 630, Rep. WADC MA 5302, BuMed Rep. WFO 060.10.03, June 1953, 15pp. USAF Development Center, Aviation Medical Acceleration Lab., Johnsville, Penn.

11 Ss were exposed to high positive G loads and the durations of the loads required to produce unconsciousness were measured. Measurements were made on 5 Ss at 15, 10, and 6G, and upon 7 Ss at 8G. Unconsciousness was determined by subjective experiences, and objectively by S's failure to respond to visual and auditory stimuli. The time during which Ss was exposed to the accelerative load until the onset of unconsciousness or confusion varied at different magnitudes of acceleration, and was longer at low levels of acceleration and shorter at high levels of acceleration. From this data it was concluded that, with respect to normal human adult males: a) Ss can be safely exposed to accelerative loads of 15 positive G for durations of 1 to 1.8 seconds if the load is applied at a maximum rate of 8 to 10 G per sec.; b) when Ss are exposed to accelerative loads of 15 G applied at a rate of 8 G per sec., unconsciousness may be produced if the duration of the maximum load is greater than 0.5 sec.; c) the visual symptoms of impending unconsciousness when the accelerative load is 8 positive G or more applied at a rate of 7 G per sec. or more; d) unconsciousness produced as a result of accelerative loads of 8 to 15 positive G applied at a rate of 7 to 8 G per sec. does not produce clinically demonstrable sequelae. Callup, H.F., Hambacher, W.O. & Dolby, J.R. HUMAN ENGINEERING INVESTIGATIONS OF THE INTERIOR LIGHTING OF NAVAL AIRCRAFT: INVESTIGATIONS INTO THE OPTIMAL CHARACTERISTICS OF VISUAL WARNING AND CAUTION SYSTEMS. THE ATTENTION-GETTING VALUE OF A STEADY LIGHT AS A FUNCTION OF BRIGHTNESS, WITH RESPECT TO RAPIDITY AND RELIABILITY. TED NAM EL 52004, Part 9, WADC ACEL 301, Oct. 1956, 15pp. USN Air Crew Equipment Lab., WADC, Philadelphia, Penn.

4132

To determine the brightness required of a steady light to make it an attention-getting as both alternating and flashing lights, one subject sat in a cockpit mock-up, outside of which was mounted a tracking task. The task was to perform the tracking task and press a response key as rapidly as possible when a stimulus light appeared. Both night and day illumination conditions were tested using ten brightness levels (randomly presented) for each. The onset of the light occurred outside the subject's visual field and was automatically moved into the visual field after a delay of five seconds. Reaction times and no responses were analyzed and compared for the three types of stimuli used: steady, flashing, alternating. T. G. I. R 3

Ferguson, E. INVESTIGATION OF THE ACCELERATION AND JOLT HISTORIES DURING ESCAPE FROM HIGH SPEED AIRCRAFT. WDC TR 52 278, Suppl. 1, Sept. 1953, 24pp. USAF Experimental Research Lab., Wright-Patterson AFB, Ohio.

4133

In an earlier report upper bound acceleration-time curves are exhibited showing upper bounds to the magnitudes of accelerations that may occur after a given time, t_0 , of escape from an aircraft. These curves depend only on escape speed and a minimum altitude for the first half sec. and only on escape speed thereafter. This report presents the results found by replacing the previously assumed constant drag coefficient by a uniform one-step drag coefficient to account for the sharp drag coefficient change expected as the escape unit passes through each speed cone. In this report the algebraic sign of the acceleration is not suppressed at the end and hence it will refer to lower bounds of negative accelerations rather than upper bounds.

Duerfeldt, C.H. EVALUATION OF "MOVING AIRPLANE" DISPLAY. Proj. TED PTR AE-7058.3, Rep. 1, Final Rep., Nov. 1956, 7pp. Naval Air Test Center, U.S. Naval Air Station, Patuxent River, Md.

4134

This document presents the results of an evaluation of a "moving airplane" attitude display, the model 1035 Flight Attitude Indicator (FAI). With the display installed in a T-2 airplane, a total of 14 pilots flew a series of practice, instruction, and performance check flights. These flights included the following aspects: instrument take-off, yoke pattern, half-cuban eight, maneuver, turn and reversals, etc. In addition to flight performance measures, each pilot completed a questionnaire which assessed his reactions to the display. The results are discussed in terms of the suitability of the display for all weather flight, its compatibility with required maneuvers, and finally, the training an experienced pilot would require for transition to this display.

Meehan, J.P., Stoll, Alice M. & Hardy, J.D. THE CUTANEOUS PAIN THRESHOLD IN THE NATIVE ALASKAN INDIAN AND ESKIMO. Proj. 22 1301 0002, Rep. 9, Dec. 1953, 14pp. USAF Arctic Aero-medical Lab., Alaskan Air Command, Ladd AFB, Alaska.

Cutaneous pain thresholds (thermal radiation method) were measured for 26 Alaskan Indians, 37 Eskimos, and 32 Whites. As no significant difference in pain threshold was found to exist between the Indian, Eskimo, and White subjects, it must be concluded that a) In these groups cultural differences are not such as to affect the pain threshold as determined by this method; and b) the ability of the Alaskan Indian and Eskimo to expose his skin to extreme cold without injury is not associated with an elevation of this threshold. It is possible, however, that exposure to cold stimulation might reveal a relative elevation of the "cold" pain threshold in the Alaskan Indian and Eskimo as compared to the populations of warmer climates. Information on this point is not available at this time. Also, the similarity of the pain thresholds in the three groups does not mean that reactions to situations in which pain is a prominent feature will be similar.

Dickel, L.R. A RATIONAL CURVE RELATING LENGTH OF REST PERIOD AND LENGTH OF SUBSEQUENT WORK PERIOD FOR AN ERGONOMIC EXPERIMENT. Contract N6008 270 20, Proj. NR 150 088, March 1954, 14pp. Princeton University, Princeton, N.J. & Educational Testing Service, Princeton, N.J.

4139

A rational function was developed relating the length of a rest period and length of subsequent work period in an ergographic experiment. Simple energy relations were postulated and used for a critical organ or neuromuscular structure whose performance failure would terminate the work period. Three subjects used a finger ergograph with a block limiting the excursion of the finger tip. The rate of finger contractions was one per second; failure to make a complete stroke ended each work period. Each of the selected rest periods was used once at each session. Mean length of work periods following each length of rest period was determined for each S.

Chinn, H.I. & Redmond, R.F. EFFECT OF DRUGS ON AIRBORNE PERSONNEL I. PRIMAQUINE AND HYPOXIA TOLERANCE. Proj. 21 1208 0009, Rep. 1, April 1954, 3pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

4145

To determine whether the dose of primaquine used in malaria therapy will affect hypoxia tolerance, the following experiment was performed. The time of useful consciousness (T.U.C.) for each S breathing an oxygen-nitrogen mixture was determined. When the S made gross errors on a standard writing test, counting backwards from 1000, he was asked to write his name; the clock was stopped when the writing became illegible. Blood samples were analyzed for hemoglobin and methoglobin. Then 14 Ss received 15 mg of primaquine daily for 14 days. Blood samples were again analyzed for hemoglobin and methoglobin and the T.U.C. was determined. The significance of the findings on aerial transportation of medicated passengers was discussed. T. Taylor, H.L., Henschel, A., Mickelsen, O. & Keys, A. SOME EFFECTS OF ACUTE STARVATION WITH HARD WORK ON BODY WEIGHT, BODY FLUIDS, AND METABOLISM. Contract AF 33(038) 21914, Proj. 21 32 004, Rep. 5, March 1954, 9pp. USAF School of Aviation Medicine, Brooks AFB, Tex. (University of Minnesota, Minneapolis, Minn.).

Data were reported on body weight and metabolism of healthy young men undergoing starvation with hard work. Experiments are reported in which men starved from 2.5 to 4.5 days while performing work on the motor-driven treadmill in amounts that resulted in a total daily caloric expenditure of 3500 to 4000 calories a day. The effects of acute starvation with and without work were compared by collecting data from the literature on men who had merely starved for five days. Cf. 4152. T. G. R 24

Hasty, G.T. THE EFFECTS OF DRUGS UPON THE COMPONENTS OF HAND STEADINESS. Proj. 21 1601 0004, Rep. 5, June 1954, 9pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

4147

To appraise possible differential effects of analeptic and sedative drugs upon coarse and fine manual tremor, 66 male, basic, airman volunteers were given practice on an apparatus designed to measure the two components of hand steadiness. The Ss were then assigned randomly to six groups receiving different dosages of analeptic and sedative drugs. An hour following drug administration, three successive measurements of hand steadiness were obtained at hour intervals. The data were treated by analysis of variance techniques to appraise differential effects of the drug treatments on fine tremor and coordinative activities. T. G. I. R 14

4148 Sherrick, C.E., Jr. VARIABLES AFFECTING SENSITIVITY OF THE HUMAN SKIN TO MECHANICAL VIBRATION. J. exp. Psychol., May 1953, 45(5), 273-282. (University of Virginia, Charlottesville, Va.).

An examination was made of the role of the skin as a mechanical system in producing the usual U-shaped sensitivity curve to vibration as a function of frequency. Conclusions: a) Both skin and bony tissue may have resonant points within the usual frequency range of vibrotactile investigation. b) The conductivity of skin is maximal at the frequency of greatest vibratory sensitivity, and bony tissue is more efficient in the propagation of disturbances. c) Mechanical impedance is minimal at the frequency of greatest sensitivity, and bony tissue shows a more sharply tuned resonance curve than relatively bone-free areas. The results of other investigators were discussed in the light of the present study, and it was concluded that more extensive research on sensitivity of pressure spots and on the physical characteristics of the skin may reveal the cause of the lack of agreement of results at present. Vernon, J.A. CUTANEOUS INTERACTION RESULTING FROM SIMULTANEOUS ELECTRICAL AND MECHANICAL VIBRATORY STIMULATION. J. exp. Psychol., May 1953, 45(5), 283-297. (University of Virginia, Charlottesville, Va.).

The simultaneous application of electrical and mechanical vibratory forces to a common locus on the fingertip was demonstrated to produce a cutaneous interaction. This interaction, as indicated by the detection of cutaneous beats, was best produced in the narrow frequency range of about 280- to 310-. The magnitude of the cutaneous interaction was measured by determining the effect of simultaneous subliminal electrical stimuli upon mechanical vibratory thresholds. When the 2 forces were presented in one phase relation (the absolute value was unknown), the mechanical vibratory thresholds were greatly lowered as compared with normal mechanical vibratory thresholds, but when the 2 forces were presented in a phase relation 180 degrees different from the first, there was little or no departure from normal thresholds. The evidence shows that electrical stimuli do not stimulate the skin by first producing mechanical movements in the skin. In that an interaction between electrical and mechanical vibratory stimuli has been demonstrated, even under limited conditions, it now appears fruitful to plan future work. The investigation is being extended by the use of continuous phase variation.

Training Analysis and Development Directorate, DCS/O Headquarters Technical Training Air Force. AN EVALUATION OF TRAINER-TESTERS. 1956, 45pp. Technical Training Air Force, Gulfport, Miss.

To evaluate the effectiveness of Trainer-Testers (a commercially developed paper and pencil troubleshooting simulator), tests were conducted at three Air Force Bases. Procedures included 1) a parallel groups controlled learning experiment for students in Basic Electronic Training with groups using the Trainers, actual equipment, both or neither; 2) the use of the Trainer-Testers in as many types of training situations as possible; 3) questionnaires to both students and instructors; and 4) various attempts to determine the usefulness of the Tester-Trainers as measuring devices. The findings are summarized in relation to effectiveness in teaching troubleshooting techniques, in testing student performance and as a partial substitute for real equipment; and in relation to its motivational value and as a teaching medium.

Javitz, A.E. HUMAN ENGINEERING IN CONTROL SYSTEMS. Elect. Mfg., March 1954, 100-111.

The perceptual and response mechanisms of the operator should be evaluated, stated, and designed into the end product concurrently with the design of the electrical, electronic and mechanical element. The human element also plays a part in systems performance and system maintenance. Human engineering extends in 3 directions with respect to equipment design: a) direct, e.g. medical equipment; b) indirect, e.g. machine tools, where human engineer controls are built into production machines; c) facility type controls built into aircraft control panels. Several examples are given on how control systems (e.g., airborne radar control) are designed bearing human engineering principles in mind. (HEIAS)

Henshel, A., Taylor, H.L. & Keys, A. PERFORMANCE CAPACITY IN ACUTE STARVATION WITH HARD WORK. Contract AF 33(038) 21914, Rep. 6, March 1954, 8pp. USAF School of Aviation Medicine, Brooks AFB, Tex. (University of Minnesota, Minneapolis, Minn.).

4152

The performance of healthy young men during starvation with hard work was studied under carefully controlled conditions in two experiments. Four men were Ss for a 2.5-day fast and 12 men for a five-day fast. The men walked at 3.5 mph on a ten percent grade (average expenditure of 550 calories per hour) for four hours each day in the shorter fast period and for three hours daily in the longer period. Recovery of performance was studied after four and after five days of refeeding.

Gregory, R.L. VARIATIONS IN BLINK RATE DURING NON-VISUAL TASKS. Quart. J. exp. Psychol., Nov. 1952, 4(Part 4), 165-169. (Medical Research Council Applied Psychology Unit, Cambridge, England).

4165

Blinking was recorded electrically, and related to various features of three non-visual tasks. A new type of suction electrode was developed for this purpose. Blink rate fell below the normal resting rate during the learning of a stylus maze, and during a special audio-tracking task. During pauses between each trial, blink rate was above the resting rate. There was a significant tendency for those subjects who showed the greatest difference in blink rate during the trials and the pauses between each trial to make the fewest errors per run of the stylus maze. In the audio-tracking task the Ss followed a changing note with a second oscillator. Blink rate was found to be inversely related to the rate of change of the course tone. R 4

White, C.E. MEMORANDUM ON NOISE MEASUREMENTS. Proj. MX 003 041-34, Memo. Rep. 53 11, July 1953, 11pp. Sound Branch, USN Medical Research Lab., Naval Submarine Base, Conn.

4166

This memorandum was written to answer some primary problems in the measurement of noise and in the interpretation of resultant data. The main areas dealt with were: 1) methods of measuring noise levels encountered in working areas and in audiometric testing spaces; 2) noise limits for these areas; 3) information on the frequency spectrum of noise; and 4) design and/or treatment of audiometric testing areas. A selected list of current publications which could be of assistance in studying and controlling noise conditions was appended. R 14

4167 Knowles, M.B., Garvey, M.D. & Newlin, E.P. THE EFFECT OF SPEED AND LOAD ON DISPLAY-CONTROL RELATIONSHIPS. J. exp. Psychol., Aug. 1953, 46(2), 65-75. (USN Research Lab., ONR, Washington, D.C.).

3 displays--light matrix, window, and auditory--and 3 push-button controls--matrix, row and column, and double column--were used in the experiment. There were significant interactions between the controls and displays. Altering the size of the combinations did not alter the display-control relationships appreciably. Under the forced-pacing conditions the error vs. speed trends for the various combinations were different; performance deteriorated less on the matrix-matrix combination. Presenting information at equivalent rates on the 2 forms of the matrix-matrix combination did not lead to equivalent error functions on the matrix-matrix and the window-row and column combinations. Performance in the self-pacing mode of operation was superior to performance in the forced-pacing mode. The results were discussed relative to compatibility, implications for design practice, and communication theory. R 5

Broadbent, D.E. MISCELLANEA: A NOTE ON BINAUDAL FUSION. Quart. J. exp. Psychol., 1955, 7(Part 1), 46-47. APN 25, 5/55. (Applied Psychology Unit, Medical Research Council, Cambridge, England).

4169

To investigate some conditions of binaural fusion, 18 subjects were presented with recorded speech through two headphones with a filter eliminating the low frequency components (500 cycles per second) on one ear and another eliminating high frequency components (2000 cycles per second) for the other. Subjects reported number of voices heard. A further series included: 1) metronome, 2) speech with a time lag of 0.25 seconds at one ear, 3) pure tones of 3000 and 500 cycles per second to the separate ears, and 4) a steady vowel sound (i). After reports were made subjects were informed of the nature of the stimuli and asked to distinguish which ear received the low-pitched stimulus. The relation of fusion to hearing theories is noted. 4171 Hembree, H.W. CRITERIA OF SOLDIER ACCEPTANCE. Rep. 229, May 1954, 31pp. USA Quartermaster Research and Development Center, Environmental Protection Div., Natick, Mass.

An attempt was made to develop a generalized method for attacking criterion problems. The theoretical approach taken was that the logical first step in the establishment of a predictive system is an analysis of the behavior the system is designed to predict. A general method was developed for isolating and defining dimensions or criteria of user acceptance and was applied to the problem of establishing a workable criterion system for predicting acceptance of Quartermaster equipment. 18 dimensions of criteria of soldiers acceptance were isolated and defined. It was concluded that: a) a general method of attacking criterion problems was developed and its usefulness demonstrated; b) that soldier acceptance is a complex multidimensional attitude which can be broken down into at least 18 components; c) that a pattern of components is required to evaluate the acceptance of any given item of clothing and equipment; and d) that soldier acceptance is subject to variations from individual differences among Ss, from variations attributable to the items being judged and to the different conditions under which items are used.  Browne, R.C. DISORIENTATION IN FLIGHT. FPRC 862, Jan. 1954, 2pp. Flying Personnel Research Committee, London, England. (King's College, The Medical School, Newcastle-on-Tyne, England).

Orientation becomes impaired when the head of the pilot is placed at an angle to the neck and body, or when vision is wholly or partially eliminated. Movements of the eye-ball are often interpreted as movements or oscillations of the object of regard. Any conflict arising from the input of the various balancing mechanisms produces disorientation. Suggestions are made for a solution to this problem. A simple could be made to demonstrate the difficulties of orientation and uncertainty of certain "feelings". Pilots should be taught to trust their instruments, not their feelings. Disorientation and its handling should be demonstrated to all pilots in a dual aircraft in cloud. Attitude indicators should be unmistakable, making use of attitude indicators which give a clear upside-down indication, and using a non-rolling gyroscope. Experiments are suggested in a centrifuge to study orientation when gravity is not active in the true vertical of the body. (NEIAS)

 Fepler, R.D. THE EFFECT OF CLIMATIC FACTORS ON THE PERFORMANCE OF SKILLED TASKS BY YOUNG EUROPEAN MEN LIVING IN THE TROPICS. 6. A TASK OF CONTINUOUS-POINTER ALIGNMENT AT TWO LEVELS OF INCENTIVE. TRU 28/52, CES 436, EXP 54/795, Nov. 1953, 17pp. Climatic Efficiency Subcommittee, RFRAC, London, England. (Royal Naval Tropical Research Unit, University of Malaya, Singapore).

4187
 To determine whether the effects of warm climates on the performance of a task requiring skilled movements would be similar at two levels of incentive, 16 fit young men who had been living in the tropics were tested in four indoor climates. Under high incentive, the men received information on their performance and verbal encouragement, while under low incentive no information nor encouragement were offered. The dry and wet bulb temperatures of the four climates were 85/75, 90/80, 95/85, and 100/90 degrees F. The task was to keep a pointer aligned with a moving pointer; two speeds of the moving pointer were used. Error scores were analyzed for changes in performance due to the experimental variables.

 Broadbent, D.E. THE TWENTY DIALS AND TWENTY LIGHTS TEST UNDER NOISE CONDITIONS. A.P.U. 160/51, Oct. 1951, 8pp. Applied Psychology Research Unit, Medical Research Council, Cambridge, England.
 The 20 Dials Test described in a previous report (Broadbent 1950) was given to 10 Ss each on 5 successive days according to the sequence quiet, quiet, noise, noise, quiet. Performance on the 'noise' days was worse than that on the quiet ones preceding and following, the degree of impairment amounting (on the score used) to about a third of the level of performance on quiet. The dials were then replaced by 20 small lamps, the S's task being to watch for the lighting of a lamp. 10 Ss received the routine used previously on the Dials, and 10 the sequence noise, noise, quiet, quiet. This task was much easier than the Dials, and did not show the practice effect usual on the other test. Nor did it show an overall effect of noise. Those individuals, however, who did show a practice effect also showed an effect of noise. The apparent absence of effect when all Ss are pooled on the 20 lights may be due to compensatory activity introduced by some Ss to overcome a felt impairment. This view is supported by the fact that the second run under noise conditions is worse compared to the preceding run than is the second run under quiet conditions; as would be expected if a compensatory effect could not be kept up. Further the second noise run is significantly worse than the second quiet run when scores are used which detect impairment in one part of the task.

Broadbent, D.E. PAVLOVIAN CONDITIONING AND VIGILANCE TASKS. A.P.U. 175/52, July 1952, 10pp. Applied Psychology Research Unit, Medical Research Council, Cambridge, England.

Evidence both from mathematical considerations and from experiment favours the view that only certain aspects of the total stimulus situation can initiate complex responses at one time; and stimuli possessing intensity, biological importance, and novelty are most likely to be selected at any time. These principles enable us to account for many phenomena of classical conditioning, including some which are usually neglected, and give an explanation of extinction (in terms of competing stimuli rather than competing responses) which has advantages over existing theories. They further provide a rational interpretation of certain experiments on human beings which are usually regarded as being of purely industrial importance: for example, the piling of factory work by the speed of the machine prevents occasional shifts in selection and so by the novelty principle increases apparent fatigue. They do not include an account of learning, as a permanent change in response to a particular stimulus, but are intended to remove certain confusing phenomena from the field to make way for future theories of learning. It is suggested that Pavlovian conditioning is of importance as making an account of these phenomena possible; and that further experiment on such matters as Pavlovian "induction" is highly desirable.

Baehrick, H.P., Fitts, P.M. & Rankin, R.E. EFFECT OF INCENTIVES UPON REACTIONS TO PERIPHERAL STIMULI. *J. exp. Psychol.*, Dec. 1952, 44, 400-406. (Ohio Wesleyan University, Delaware, Ohio & Ohio State University, Columbus, Ohio).

The experiment tested the hypothesis that an increase in incentive results in increased perceptual selectiveness favoring those parts of the stimulus field which are interpreted by the Ss as most relevant to the expected reward. A modified Buxton pursuit apparatus was used as a continuous central-tracking task. 3 kinds of intermittent peripheral stimuli, differing both in the amount of relevance to reward expectations and in the facility with which they could be detected in peripheral vision, were employed. 2 incentive conditions were used. The low-incentive condition was produced by telling Ss that the trials were practice trials. The high-incentive condition was produced by offering a sliding-scale bonus, which ranged from 5 cents to 3 dollars, for good performance. Results are in good agreement with the prediction that a condition of high incentive facilitates performance of a central task, but, in general, interferes with the performance of peripheral tasks. The detrimental results of the bonus upon responses to peripheral stimuli were greatest on the peripheral task in which expectation of reward can be assumed to have been the least.

Fitts, P.M. & Simon, C.W. SOME RELATIONS BETWEEN STIMULUS PATTERNS AND PERFORMANCE IN A CONTINUOUS DUAL PURSUIT TASK. *J. exp. Psychol.*, June 1952, 43, 428-436. (Ohio State University, Columbus, Ohio).

Various visual stimulus patterns formed by different arrangements of instruments and pointers were studied by means of a continuous, dual-pursuit task in which Ss adjusted 2 control knobs in order to keep 2 pointers within designated limits. 3 experiments indicate that Ss perform significantly better when instruments are a) close together, and b) aligned horizontally. With instrument alignment factors eliminated, pointer alignment in the 9 and 12 o'clock sectors gave significantly better performance than did alignment at 3 and 6 o'clock. With instrument alignment interacting with pointer alignment, performance was superior when pointers were aligned at 9 o'clock for horizontally-separated instruments, at 12 o'clock for vertically-separated instruments, or when the pointers were counterpoised. Hypotheses were proposed to account for a) the superiority of pointer alignment over non-alignment, and b) the superiority of performance when pointers are aligned in the left and upper sectors.

Forbes, T.W. CONTRIBUTIONS BY PSYCHOLOGISTS TO THE REDUCTION OF HIGHWAY TRAFFIC ACCIDENTS IN THE UNITED STATES OF AMERICA. A Paper presented at the Congress of the Association Internationale de Psychotechnique, Paris, France, July 1953, 17pp. National Academy of Sciences, NML, Committee on Highway Safety Research, Washington, D.C.

This paper represents an attempt to summarize contributions by psychologists during the last 15 yr. to the reduction of highway traffic accidents in the United States. Work has been classified as follows: development of criteria of safe driving, studies of selection and of supervisory factors in commercial fleets, of accident reports, of driver characteristics in relation to accidents, of driver characteristics in relation to engineering design, of offenders and law violators, and a discussion of theories of accident causation. The wide range of studies by many psychologists is briefly outlined with a few studies as illustrations. No claim is made for completeness, since undoubtedly many omitted studies are of importance equal to those included. (HEIAS)

Howland, D. & Noble, R.E. THE EFFECT OF PHYSICAL CONSTANTS OF A CONTROL ON TRACKING PERFORMANCE. *J. exp. Psychol.*, Nov. 1953, 46(5), 353-360. (Ohio State University, Columbus, Ohio).

The effects of various proprioceptive factors on learning and performance in a continuous compensatory tracking task were investigated by varying 8 combinations of 3 system constants, a spring of stiffness K, a damping element of viscosity B, and moment of inertia of value J. The Ss were required to apply a compensatory torque to a rotary control shaft so as to hold a cursor, which was describing simple harmonic motion, in alignment with a stationary target. The target and cursor were displayed as 2 vertical lines on the face of a 5-in. cathode ray tube. When they were in alignment they formed a single continuous line. In Part I, 8 experimental groups of 10 novice Ss each received 20 1-min. trials under a particular combination of system constants. In Part II, one practiced S was given 3 1-min. trials per day on each of the 8 conditions for 24 days. Time-on-target scores were taken for 3 different error tolerances. Different system constants in the control resulted in significant differences in mean time-on-target performance. In general, performance was best for the conditions containing the spring and poorest for those containing the moment of inertia. Variations in the control parameters influenced initial performance and these differences appeared to increase during the first 20 practice sessions in Part I. For the one S in Part II the effects appeared to decrease slightly as he became more skillful in the tracking task. Graphic recordings of hand-control position as a function of time were also taken. These records indicated distinctive movement patterns for the various conditions, particularly early in practice. These distinctive patterns tended to disappear with practice, so that the final records taken for the practiced S closely approximated the desired waveform regardless of the combination of parameters employed. Explanations of these results in terms of amount of physical work and augmentation of proprioceptive factors were considered.

4206

To increase the realism of leadership problems presented to students and to provide each student with maximum opportunity to participate in solving problems, a group film-discussion technique was developed and evaluated experimentally: ten films depicting military officer problems were produced. The problems were based on descriptions of leadership problem situations collected from junior officers, non-commissioned officers, and data from Korea. Small group discussions followed a film-showing with one representative from each group then participating in a panel discussion. Three officer classes were trained by this technique and evaluated in several ways to study the effect on leadership training.

Conrad, R. SETTING THE PACE. A.P.U. 235/55, March 1955, 8pp. Medical Research Council, AFPU, Cambridge, England.

NRL 147536

4210
The efficiency of a biomechanical process, or man-machine system, is dealt with theoretically and statistically in terms of one of its aspects - that of tempo or pace. Variations in "repetitive" work, a forced-pace system, a semi-forced-pace system with time margins, a system with queues (wherein work may be allowed to pile up), and an operative-to-operative system (wherein the output of one operative is dependent upon his precursor) are discussed.

Kelley, H.P. A FACTOR ANALYSIS OF MEMORY ABILITY. Contract N6ONR-270-20, Proj. NR 150 088, Reb. RB 54, 7, April 1954, 75pp. Princeton University, Princeton, N.J. & Educational Testing Service, Princeton, N.J.

4211
To investigate the factorial structure in the part of the area of memory involving relative immediate intentional retention, 24 tests of memory were constructed to include such types of memory as: rote, meaningful, span, and visual. These tests were administered to 100 pilot cadets. The results of the tests were intercorrelated and the resulting matrix factor-analyzed. The relation of 11 factors to immediate memory function is discussed in detail.

Brozek, J. & Taylor, H.L. TESTS OF MOTOR FUNCTIONS IN LABORATORY INVESTIGATIONS ON FITNESS. Contract AF 33 (338) 21914, Proj. 21 32 004, Rep. 4, May 1954, 20pp. School of Aviation Medicine, Randolph AFB, Tex. (Laboratory of Physiological Hygiene, University of Minnesota, Minneapolis, Minn.).

4213
A battery of tests of motor functions was used in the study of human fitness and of changes in fitness under a variety of biological stresses (hard work, heat and lack of sleep under conditions of acute and semistarvation). Employed were two tests of strength, three tests of speed, and one test of coordination. Examples are presented to show that the test battery, plus physiological indices of the ability to do hard physical work, measures deterioration in the presence of stress better than either approach alone and provides a more meaningful basis for analysis of fitness deterioration.

Meister, D. ECHO DETECTION AND DOPPLER RECOGNITION AS A FUNCTION OF TRAINING WITH STIMULI OF VARYING DIFFICULTY. Rep. 393, Aug. 1953, 9pp. USN Electronics Lab., San Diego, Calif.

4214
This report evaluates three methods of training student anti-submarine sonar operators in weak echo detection and doppler recognition. Each method consisted of a different level of stimulus difficulty obtained by varying the amounts of doppler and attenuation. Sixty-four male college students, selected on the basis of sonar operator standards, were trained by each method, and a test administered before, during, and after training. Results are expressed in terms of statistical comparison of the groups, systematic errors, learning rate, and reliability of tests. Recommendations for sonar training programs and future research are made.

McGuire, F.L. AN ANALYSIS OF AUTOMOBILE ACCIDENTS INVOLVING MILITARY PERSONNEL. Res. Proj. MM 005 052.33.01, June 1954, 49pp. USM Medical Field Research Lab., Camp Lejeune, N.C.

707 reports on automobile accidents involving Camp Lejeune personnel were gathered and analyzed, covering the complete calendar year of 1951. In addition, data were gathered concerning specific phases of these reports whenever the reported data were not adequate or a base-line or control group was needed. The factors analyzed and discussed were: a) Age and rank, b) Length of driving experience, c) Violations, d) What drivers were doing at time of accident, e) Physical condition of the driver (S), f) Use of alcohol, g) Vehicle defects, i) Light and weather conditions, j) Roadway character and visibility, k) Time (month of year, day of week, and hour of day). Implications of this analysis are discussed and suggestions for action are noted.

Moser, H.M., Dreher, J.J. & Adler, S. TWO-DIGIT NUMBER TRANSMISSION BY VOLUNTARY STUTTERING. Contract AF18(600)316, RF Proj. 519, AFRC, TN 54 82, Rep. 12, Sept. 1954, 7pp. USAF Air Research and Development Command, Andrews AFB, Washington, D.C. (Ohio State Research Foundation, Columbus, Ohio).

Information theory implies that redundancy should strengthen transmitted information which has low intelligibility values. Some evidence has been presented to show that this can be accomplished by phonetic repetition in monaural delay. The purpose of this study is to explore a method whereby partial repetition is effected at the beginning of a word by voluntary stuttering. Foreign and American listeners heard two-digit numbers transmitted in two different ways; (1) normal delivery (one-two), and (2) voluntary stuttering (wuh-one--tuh-two). The signals were presented at five different S/N ratios and the articulation scores were compared for differences (1) at noise levels and (2) between methods. In both methods American listeners achieved significantly higher articulation scores than foreign listeners at four of the noise levels. Voluntary stuttering gave both groups significantly better results, with score improvement relatively increased as the S/N ratio made listening more difficult.

Lawrence, D.H. & Coles, G.R. ACCURACY OF RECOGNITION WITH ALTERNATIVES BEFORE AND AFTER THE STIMULUS. J. exp. Psychol., March 1954, 47(3), 208-214. (Stanford University, Stanford, Calif.).

4223

To study the nature of the facilitative effect of presenting alternatives including the correct response on the rapid visual perception of objects, three groups of 20 college students were asked to identify 50 familiar objects presented tachistoscopically. Two groups were given lists of four alternatives for each object, one group before each exposure, the other immediately after; the control group had no alternatives. Alternatives varied between groups of four similar objects and groups of four perceptually discrete objects, and exposure times varied (.02 to .50 sec.). Results (percent correctly identified) were analyzed for the effects of the nature and time of presentation of alternatives.

Adams, R.E. & Taylor, D.W. FUNCTIONAL FIXEDNESS AS RELATED TO ELAPSED TIME AND TO SET. J. exp. Psychol., Feb. 1954, 47(2), 122-126. (Carleton College, Northfield, Minn. & Stanford University, Stanford, Calif.).

5 groups including a total of 67 Ss participated in Exp. 1 designed to test the hypothesis that functional fixedness decreases as a function of time. All Ss were first given the task of constructing an electric circuit. For half of the Ss in each group, the circuit employed a microswitch and for the other half a small relay. Following an interval of uncontrolled activity, all Ss were given Haier's 2-string problem. Among the objects available for possible use as a pendulum weight, the only 2 which would work were the microswitch and the relay. The purpose was to determine which of the 2 objects would be used in solving the problem. The length of the interval between the initial task and the 2-string problem varied, being 1 min., 1/2 hr., 1 hr., 1 day and 1 week for the 5 groups, respectively. Functional fixedness, as measured by the percentage of the Ss using as a pendulum weight the object not used in the initial task, did decrease as a function of time. The relation was significant at the .02 level. In Exp. II, concerned with the relation of functional fixedness to set, 45 Ss from the first 3 groups in Exp. I were given a Luchins series of water-jar problems. Problems 2 to 6 are all solved by the same indirect method. Performance on Problems 7 and 8, which can be solved either by this indirect method or by a more direct method, was used as the criterion of susceptibility to set. Performance on Problem 9, which can be solved only by a direct method, served as the criterion of inability to overcome set. Susceptibility to functional fixedness, as defined by the Haier 2-string problem, was found to have a significant relation to inability to overcome set, but no relation to susceptibility to set, as defined by the Luchins problem series.

Underwood, B.J. STUDIES OF DISTRIBUTED PRACTICE: XII. RETENTION FOLLOWING VARYING DEGREES OF ORIGINAL LEARNING. *J. exp. Psychol.*, 1954, 47(5), 294-300. (Northwestern University, Evanston, Ill.).

4226

To study the effects of degree of learning on retention, two 36-subject groups learned serial lists of 14 syllables; two 24-subject groups learned ten-pair lists of adjectives, one group for each list using massed practice (four-sec. intervals), the other using distributed (30-sec. intervals). Each group learned three lists to different degrees (one half list learned to seven trials overlearning). Retention was tested 24 hours after learning each list, half the Ss employing massed, half spaced practice. Mean trials for original learning and mean correct responses at recall are discussed regarding the effect of degree of original learning on recall under the various learning conditions.

Underwood, B.J. SPEED OF LEARNING AND AMOUNT RETAINED: A CONSIDERATION OF METHODOLOGY. *Psychol. Bull.*, May 1954, 51(3), 275-282. (Northwestern University, Evanston, Ill.).

4227

This is a theoretical discussion of the relationship between rate of learning and rate of forgetting. First demonstrating the inadequacies of previous techniques for comparing slow and fast learning groups, the author develops a method for equating the associative strength of learned material for fast and slow groups. Using data obtained from experiments reported elsewhere, the author obtains the empirical probability of a correct response as a function of number of previous reinforcements for each group, using these functions to determine equivalent base lines for plotting retention curves. Implications for theories of retention are discussed.

Crossman, E.R.F.W. ENTROPY AND CHOICE TIME: THE EFFECT OF FREQUENCY UNBALANCE ON CHOICE-RESPONSE. *Quart. J. exp. Psychol.*, June 1953, 5(Part 2), 41-51. (Medical Research Council Applied Psychology Unit, Cambridge, England).

A human subject making a sequence of choice-responses is considered as a channel transmitting information. Earlier work suggests that the rate of transmission is limited, and so that response time is proportional to the "entropy" of the source of signals. Entropy is reduced by unbalance in the relative frequency of the possible signals according to the formula, $\sum (p \log p)$. Unbalance should therefore reduce average response time. This prediction is tested in a card-sorting task. The Ss sorted playing-cards into classes in various ways; times taken were proportional to calculated entropy-per-card. Departures from the expected results occurred and were found to be due to differences in perceptual difficulty of discriminations. Some incidental results are mentioned.

Pollack, I. ASSIMILATION OF SEQUENTIALLY-ENCODED INFORMATION. IV. THE INFORMATIONAL CONTRIBUTION OF "WRONG" RESPONSES. Memo. 26, Sept. 1952, 9pp. USAF Human Resources Research Labs., Bolling AFB, Washington, D.C.

4233

To study the informational contribution of "wrong" responses in immediate recall, 25 Ss reproduced 280 messages read to them. Messages were composed of comments and numbers and varied in message length (4-24 units) and alternatives per message-unit (2-30). After each first reproduction, the S was told the location of his first error and required to guess (up to four times) among alternatives until the message-unit was correctly identified. This procedure was repeated for each error. After showing that correct responses were more frequent than would be predicted by chance, an analysis of the informational contribution of the "wrong" responses was made.

Pollock, I. THE ASSIMILATION OF SEQUENTIALLY ENCODED INFORMATION. II. EFFECT OF RATE OF INFORMATION PRESENTATION. NML Mon Rep. 25, Sept. 1952, 27pp. USAF Human Resources Research Lab., Bolling AFB, Washington, D.C.

The effect of three experimental variables upon immediate recall performance is considered. The three variables, which are suggested by the methodology of the theory of information, are: the rate of presentation of the recall materials; the length of the materials and the number of possible alternatives per unit of the materials. The recall materials employed were spoken messages with each unit of a given message selected independently from a defined class of possible alternatives. Two aspects of recall performance were selected for analysis: average proficiency of performance and the variability in performance among subjects. Systematic changes are obtained in both the proficiency and the variability measures as a function of the three variables. In terms of both measures, effects of rate of message presentation and of the informational content per message-unit (number of possible alternatives) are secondary to the effect upon recall performance of message-length (over the ranges considered). The findings are interpreted to indicate a defined "informational limit" for recall performance which is a function of the encoding procedures employed. It is suggested that the systematic changes in variability reflect changes in the range of encoding procedures employed by the experimental subjects.

Pollock, I. THE ASSIMILATION OF SEQUENTIALLY ENCODED INFORMATION. I. METHODOLOGY AND AN ILLUSTRATIVE EXPERIMENT. NML Mon Rep. 25, Sept. 1952, 27pp. USAF Human Resources Research Lab., Bolling AFB, Washington, D.C.

This paper presents a methodology for verbal learning based on the theory of information. The approach allows an objective quantification, in units not specified to the particular experimental operations considered, of: a) the learning materials employed (the informational input); b) the information lost (the error output); and c) the information gained (the difference between the informational input and information lost). The units are sufficiently general to allow for comparison of the results of a diversity of experiments. An illustrative experiment in short-time retention was designed to fulfill the requirements of the methodology. The major finding of the study is that the encoding of the learning materials for retention is an important determinant of the amount of information which can be retained. Specifically, for messages of a given length, the percentage of information gained or lost (relative to the information presented) is independent of the informational content per message-unit. For messages of a given informational input, however, the amount of information gained is greater for short messages with a high informational content per message-unit than for long messages with a low informational content per message-unit.

Anderson, J.V. A DETERMINATION OF THE STABILITY OF THE RELATIONSHIPS AMONG APTITUDE, SCHOOL, AND SHIPBOARD MEASURES OF ANTI-SUBMARINE SONARMAN PERFORMANCE. Proj. P5a 52, Rep. FR 4, April 1953, 22pp. USN Personnel Research Unit, San Diego, Calif.

This study is a replication and extension of the investigation reported in a previous study, "Relationships Among Aptitude, School, and Shipboard Measures for Sonarmen". Its primary purpose was to determine the stability of the findings of that study. A secondary purpose was to determine whether measures of auditory acuity for the poorer ear and better ear are comparable. Data from an additional 123 shipboard rating scales and matching student record cards were analyzed by correlational methods. The results were compared with those obtained in the previous study. In general, correlations obtained in the new study were not significantly different from those obtained previously. Within the range of hearing loss considered in the two studies, there appears to be no relationship between auditory acuity at high frequencies and anti-submarine sonarman performance. Attack Teacher grades seem to be consistent predictors of shipboard ratings. The negative relationships between the Mechanical Test scores and shipboard measures obtained in the previous study did not recur in the current study. High intercorrelations among items in the shipboard rating scale occurred in both studies and appear to be a characteristic of the type of rating scale employed. Auditory acuity scores for poorer and better ears do not differ to any appreciable extent in their relationships to other measures.

Johnson, Laverne, C. SPEED AND CONFIDENCE OF JUDGMENT AS PSYCHOLOGICAL VARIABLES. Contract Nonr 225(01), NR 150 087, Tech. Rep. 4, June 1954, 32pp. Office of Naval Research, Washington, D.C. (Psychology Dept., Stanford University, Stanford, Calif.).

The generality of speed and confidence was investigated by intercorrelating the decision times on 7 tasks and the confidence scores on 6 tasks. The results show that speed and confidence in one task are significantly associated with speed and confidence in another. The findings also suggest that confidence has a relatively greater degree of generality than speed. The second part of this study was an investigation relating a total score of decision speed and/or total score of confidence to certain personality measures: manifest anxiety, ego-control, authoritarianism, and achievement. No relationship was found between any of these personality measures and speed and/or confidence of judgment. A measure of behavioral confidence was also related to decision speed, to stated confidence, and to the four personality measures. The only measures significantly related to behavioral confidence were total decision time and the measure of achievement. Three additional problems were investigated. One, variability on decision tasks was studied in relation to the four personality measures. No relationship was significant here. The other two problems were the relationship of speed and of confidence of judgment to a measure of defensiveness and a categorization score in the object sorting task. The only relationship found was a positive one between total decision time and the number of categories.

Winder, C.L. & Mertz, K.R. SOME EFFECTS OF INDUCED SUCCESS AND FAILURE ON JUDGMENT BEHAVIOR. Contract NMR 225 (01), Proj. NR 150 067, Tech. Rep. 5, Aug. 1954, 24pp. Dept. of Psychology, Stanford University, Stanford, Calif.

4243

Judgment or decision-making was studied within the general framework of ego-psychology which focuses attention on this aspect of human behavior. The success-failure dimension of the psycho-social situation was manipulated by verbal confirmation of success or failure or by no evaluation being given. Two types of tasks were employed: 1) judgments based on S's experience with no stimulus material immediately present, and 2) judgments based on objective stimulus material. The effects of the variation in the psycho-social situation on judgment behavior was measured by speed, confidence, and stability of choice.

4244

Winder, C.L. & Mertz, K.R. A STUDY OF PERSONALITY CORRELATES OF JUDGMENT BEHAVIOR. Contract NMR 225(01), NR 150 067, Tech. Rep. 6, Aug. 1954, 20pp. Office of Naval Research, Washington, D.C. (Psychology Dept., Stanford University, Stanford, Calif.).

The goal of this study was to explore the proposition that aspects of decision behavior which have a satisfactory degree of generality from situation to situation and task to task are related to so-called personality characteristics. The dimensions of speed and confidence of judgment were selected for study since they have been shown to be stable intraindividual characteristics. The personality measures employed were the MMPI and the Adjective Check List. The sample of subjects was divided into a fast and a slow group on the basis of overall judgment speed. The fast group appears to be more impulsive and less conventional than the slow group. They seem to be overproductive in thought and action as compared with the slow group. The fast group checked more adjectives as being descriptive of themselves than did the slow group and the items which were checked differentially suggest that the fast group are more active and lazy, self-centered, and expensive in interpersonal relationships. The sample was also divided into high confidence, warranted confidence, and low confidence groups. The MMPI did not differentiate the high and warranted groups, but the low group was revealed as being rather anxious, introspective, and concerned with problems.

MEASUREMENT OF FORCES AFFECTING HUMAN BODIES
IN AIRCRAFT ACCIDENTS: A STUDY OF THE CRASHES
OF FOUR INSTRUMENTED PUP DRONE AIRCRAFT.
Contract Four 1527(00), Proj. ME 118-361,
Tech. Rep. 3, April 1956, 87pp. ONR,
Human Factors Research, Inc., Los Angeles,
Calif.

4257

To develop a method for recording accelerative
forces in airplane crashes, accelerometers were placed
in PUP drone aircraft used by the Navy for missile
testing. The instrument was mounted in the seat of the
aircraft prior to take-off. The design of the accelera-
tor was such that exposure to a force of 8 g or more
started the instrument and the pattern of forces was
recorded in two dimensions for 8 seconds. In event of
a crash, efforts were made to recover the instrument and
take pictures of the airplane; a crash history record
was made. Data on four crashes are presented with re-
commendations for future research.

Cronbach, L.J., A CONSIDERATION OF INFORMATION THEORY AND UTILITY THEORY AS TOOLS FOR PSYCHO-
METRIC PROBLEMS. Contract N60r1 07146, Tech. Rep. 1, Nov. 1953, 64pp. Office of Naval Re-
search, Washington, D.C. (College of Education, University of Illinois, Urbana, Ill.).

The present report presents 5 papers concerned with recent mathematical models applicable
to testing. Section I describes the communication model and shows that the test may be view-
ed as a communication system. This is a purely verbal presentation. Section II presents the
formulas for analyzing information according to Shannon's assumptions, and clarifies the
meaning of those formulas. Section III presents the formulas for analyzing information by
arithmetic averages. While these formulas will be replaced by a more adequate system eventu-
ally, they are somewhat closer in conception to utility theory than Shannon's. Section IV
discusses briefly the essential concepts of utility theory, together with the reasons for
preferring this schema to the formulations presented in II and III. Section V is a study by
means of utility theory of one particular test, intended for psychiatric screening of re-
cruits. (HEIAS)

Gibbs, C.B., THE CONTINUOUS REGULATION OF SKILLED RE-
SPONSE BY KINESTHETIC FEED-BACK, A.P.U. 190/53, March,
1953, 14pp. Applied Psychology Research Unit, Medical
Research Unit, The Psychol. Lab., Cambridge.

4269

The experiments reported were undertaken to eval-
uate the contribution of kinesthetic feedback in
skilled motor response by varying the response and
proprioceptive discharge in a visual-motor task.
Ninety-five normal subjects and one tabetic patient
used two types of joystick to control the output of
a velocity control servo-mechanism. One was a free-
moving lever; the other had strong spring centering
but could be deflected slightly by applying pressure.
Data reported are speed and accuracy of response,
learning curves, and transfer effects with the two
types of control.

Jeffrey, T.E. & Thurstone, L.L., A FACTORIAL ANALYSIS OF FOOT MEASUREMENTS. Contract DA
44 109 qn 1125, Tech. Rep. EP 10, July 1955, 26pp. USA Quartermaster Research and Develo-
ment Center, Natick, Mass.

This report gives the results of a methodological study carried out for the purpose of
investigating the nature of some of the critical factors determining the size of feet in
Army personnel. 29 measures taken from the anthropometric data collected in the Fort Knox
Foot Survey were factor analyzed. 10 factors were extracted accounting for the intercorre-
lations between these 29 measures with relatively small residuals. The absolute size of the
residual correlations after the extraction of the 10 factors was less than or equal to .06.
8 of the 10 rotated factors have been interpreted. This interpretation for each factor des-
cribes the nature of the underlying parameter responsible for the concomitant variation of
the measures with large projections on the factor. 2 factors were not interpreted. The
amount of the total variance for each measure accounted for by the 10 factors varied from
about 100 percent down to 11 percent. This indicates that at least one measure (100 per-
cent) shares all of its variance with one or more of the remaining 28 measures, and, conse-
quently, could be relatively unimportant in the determination of shoe lasts. On the other
hand, measures which share only 10 to 15 percent of their variance with other measures would
have to be considered specifically in the proper fitting of shoes.

Lukasik, S.J. & Nolle, A.W. (Eds.), HANDBOOK OF ACOUSTIC NOISE CONTROL, VOL. 1. PHYSICAL
ACOUSTICS: SUPPLEMENT. Contract AF 33 (600) 23901, RDO 695 63, WADC Tech. Rep. 52 204,
April 1955, 308pp. USAF Aero Medical Lab., Wright Air Development Center, Wright-Patterson,
AFB, Ohio. (Bolt Beranek and Newman, Inc., Cambridge, Mass.).

The Handbook of Acoustic Noise Control is intended to provide an overall view of the
problem of the control of acoustic noise. Since the publication of the first 2 volumes, the
need for their revision has become apparent. In some cases, material has been added to en-
large the coverage of original sections. In others, sections have been completely re-written
to present the latest experimental or theoretical information available. With ever-increas-
ing interest and activity in acoustic noise control, published procedures must, of necessity,
lag behind the newest thinking in the field. There are few areas of the noise control prob-
lem where the present answers are the "best." As the operational requirements for noise
control devices changes and as new or more powerful sound sources appear in our advancing
technology, better answers will have to be found. In presenting these revised sections,
an attempt is being made to keep up with our expanding knowledge. This supplement contains
additions and revisions to Volume I which treated the generation and control of various
types of noise sources. Similarly, Volume II, which analyzed the interaction between noise
and man, is being supplemented. These supplements, together with the unchanged sections of
Volume I and II, provide a unified view of noise control problems. cf. 3467

4276 Bitterman, M.E., Holtzman, W.H. & Barry, J.R. PSYCHIATRIC SCREENING OF FLYING PERSONNEL. CONDITIONING AND EXTINCTION OF THE GALVANIC SKIN RESPONSE AS A FUNCTION OF ADJUSTMENT TO COMBAT CREW TRAINING. Rep. 55 29, Feb. 1955, 9pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A group of 208 pilots assigned to Combat Crew Training were tested in a conditioning situation and their subsequent adjustment to training was independently evaluated. Conditioning variables were selected on the basis of factor analyses for correlation with the criterion evaluations of adjustment. No significant relation was found between the 2 sets of measures. Although an earlier study of 37 university men produced positive findings under laboratory conditions, the present research fails to support the laboratory findings with trained pilots entering Combat Crew Training.

Rhine, R.J. THE EFFECT ON PROBLEM SOLVING OF SUCCESS OR FAILURE AS A FUNCTION OF CUE SPECIFICITY. Contract HSOAR 25125, Proj. MR 150 149, Tech. Rep. 8, Feb. 1955, 57pp. Department of Psychology, Stanford University, Stanford, Calif.

4279

This report describes two experiments investigating the effects of success and failure (and their interactions with other variables) on problem-solving. In both experiments, five groups of 31-40 college students solved anagrams (in one case, alternated with number series) of varying degrees of difficulty under the expectation of getting half correct, with a final test of all groups on anagrams of moderate difficulty. Success on the final test was analyzed with regard to the effects of success or failure in completing half the experimental anagrams, similarity of experimental and test anagrams, sex differences, and need for achievement.

4280 Gottsdanker, R.M. PREDICTION-SPAN, SPEED OF RESPONSE, SMOOTHNESS, AND ACCURACY IN TRACKING. Lab. Note SCRL 55 6, April 1955, 22pp. USAF Skill Components Research Lab., Lackland AFB, Tex.

In a tracking task, a group of 7 Ss was given trials on a course which had a smooth path of motion and relatively few reversals of direction (low-frequency target), while a second group of 6 Ss used a course with few smooth portions and many unexpected changes (high-frequency target). Speed of response to error was independent of the course being tracked and thus did not have a relation of balance with prediction-span. It too did not appear to be influenced by practice on a given type of course. There were indications that reaction time may be used to predict differential proficiency in tracking on a high-frequency course. Further, the relation between reaction time and skill in tracking appears to diminish as the target motion becomes smoother.

Freedman, A., Kirkpatrick, C.M. & Huntington, E.C. FIRST PARTIAL REPORT ON SURVEY OF FOOT MEASUREMENTS AND THE PROPER FIT OF ARMY SHOES. SUBJECT: STUDY OF FACTORS BEARING ON THE ESTABLISHMENT OF SIZE TARIFFS, ON SIZE DESIGNATIONS AND ON SHOE FITTING. Proj. T 13, Dec. 1945, 4pp. USA Armored Medical Research Lab., Fort Knox, Ky.

This report represents a study of factors relevant to the establishment of shoe sizes and shoe fitting. It defines: a) the relationship of shoe size to the incidence of and type of foot casualties; b) the influence of marching and weight bearing on foot size; c) the role of socks in determining foot size; d) the importance of the wearer's judgment of fit on the selection of shoes. Conclusions reached pertain to the findings that the utility and casualty risk associated with the wearing of shoes too small in size is less than the utility and casualty risk associated with the wearing of shoes which are too large. Conclusions were also made concerning the tolerances and dimensional intervals between sizes. (HEIAS)

4278

Freedman, A. FOURTH PARTIAL REPORT ON ANALYSIS OF CHARACTERISTICS OF FOOTGEAR FOR ARMY FIELD USE. Proj. T 13, March 1946, 5pp. USA Armored Medical Research Lab., Fort Knox, Ky.

Recent studies have revealed the need for reconsideration of boot design for the Army. 4 general characteristics of or specifications for an all purpose, army combat boot are discussed: a) provide thermal protection; b) provide physical protection; c) provide maximal flotation and traction; and d) not prove a source of injury. These principles are incorporated in the design of field boots. An experimental boot design believed to possess the most suitable features for Army field use under a wide variety of terrain and climatic conditions is proposed. This proposed design is probably not suitable for garrison use. (HEIAS)

Krulow, G.K. & Weisz, A. STUDIES IN THE VISUAL DISCRIMINATION OF MULTIPLE UNIT DISPLAYS. Contract N ONR 494 (03), Proj. NR 145 088, Rep. 1954 494 03 23, Aug. 1954, 14pp. Tufts University, Medford, Mass.

4286
Four experiments were conducted on the determination of distance thresholds for one-, two-, and three-digit displays as a function of the number of alternative possibilities in each position of the display. In the first experiment, eight categories were defined in terms of one-, two-, and three-digit codes using different choices of elemental symbols to define three such sets of codes. In the second, thresholds were obtained for several binary choices used both as one- and three-digit displays. In the final two experiments, an alphabet of 32 symbols was used to investigate the relation of threshold magnitude to amount of information with single-position displays. T. R 3

4287
Christie, L.S. ORGANIZATION AND INFORMATION PROCESSING. Contract Nonr-494(03), Rep. 1954-494 03 25, 20pp. Office of Naval Research, Washington, D.C. (Tufts University, Medford, Mass.).

A theoretical analysis of systems organization as the management of information flow has been made. This analysis indicates that the action effectiveness of a system depends upon the efficiency of internal communication. Internal information handling necessitates decisions of 4 k.ods: routing, filtering, coding, and scheduling. The organization of these functions is affected by these factors: imposition of rules by outside authority, the rational pre-existing behavioral tendencies of the human components, learning, the exertion of control by authority within the group. Data from an experimental program designed to study the organization of routing, particularly with respect to the effect of rules for routing expressed as communication networks, was analyzed. This empirical analysis demonstrated the vital importance of so designing the system by the rules imposed that a basis for rational behavior is provided for the men in the system and so designing it that behavior optimized with respect to that basis will be optimum for total system performance. 4288 Shephard, R.J. THE PLACE OF THE PNEUMOTACHOGRAPH IN THE MEASUREMENT OF BREATHING CAPACITY. PRNC 916, May 1955, 15pp. Flying Personnel Research Committee, London, England. (RAF Institute of Aviation Medicine, Farnborough, England).

The physical characteristics of a pneumotachograph system suited to the investigation of breathing capacity are described. A trial of the apparatus in 8 normal Ss yielded M.B.C. values similar to those previously reported for low resistance systems. The sensitive recording system allowed further investigation of the theoretical background of the M.B.C. and "fast vital capacity" tests. There was wide personal variation in the optimum respiratory rate for the performance of the M.B.C. test, and most Ss showed some decline of maximum inspiratory velocity during the last few seconds of the test. The "fast vital capacity" tracings do not always conform to smooth exponential curves. Owing to the speed of delivery and volume delivered is less than the true vital capacity, particularly during inspiration. Although theoretical grounds suggest the prediction of the M.B.C. from a 30 sec fraction of the vital capacity tracing, in practice a better correlation is obtained from the entire fast inspiratory and expiratory vital capacity curves. This anomaly appears related to the considerable variations of peak gas velocity during the performance of fast vital capacity tests.

4292 USN Air Development Center. EFFECT OF REFLECTION PLOTTER ON SIGNAL DISCERNIBILITY ON AIRBORNE RADAR INDICATORS. TED Proj. ADC EL 8202, Rep. NADC EL 153 73, SDC TR 166 I 119, May 1953, 7pp. USN Air Development Center, Johnsville, Penn.

4292 To determine the effect on signal discernibility of the insertion of a reflection plotter between the crt of the radar and the operator, two pieces of equipment were set up for testing, one with a reflection plotter and one without. The Ss, who did not know which indicator was equipped with the plotter, were required to identify a series of targets on both indicators by calling out the bearing as soon as it was seen and to continue identification as long as possible as the signal level was reduced. Each S was given six rotations of the sweep on each azimuth setting and four azimuth settings for each signal level. The average number of missed targets was plotted against target attenuation and compared for the two conditions.

4293 Hendler, E. & Evans, R.G. TEST AND EVALUATION OF MODEL R3Y DITCHING SEAT. Proj. TED NAM AC 6302, May 1954, 15pp. USN Air Experimental Station, Aeronautical Medical Equipment Lab., Philadelphia, Penn.

11 shots were made using the HG 1 catapult and an anthropomorphic dummy to test and evaluate an aft-facing ditching seat for Model R3Y aircraft. In the catapult tests, the seat was mounted either along the direct line of catapult thrust (0 degrees) or at 20° to the left of this thrust line. The seat was designed to restrain personnel during a 0° (head-on) or a 20° ditching on water. The catapult car, on which the ditching seat was mounted, received an approximate square wave of acceleration, which was varied from an average acceleration of 5.8 G of 0.31 sec duration to 25.4 G of 0.154 sec. The ditching seat showed no major failures in any test. During the simulated 0° ditchings, there was no indication that physiologically dangerous forces were applied to the dummy. In the simulated 20° ditchings, the rotation of the unrestrained legs with respect to the relatively stationary torso did seem to apply dangerous forces to the dummy. This rotation could probably be prevented or minimized by securing the legs and modifying the lateral edges of the seat by the addition of material or straps.

4295 Crumley, L.H. & Atkinson, W. HUMAN ENGINEERING INVESTIGATION OF THE EXTERIOR LIGHTING OF NAVAL AIRCRAFT. PART I. A STUDY OF THE EFFECT OF FLASH RATE AND ON/OFF RATIO ON THE DETECTABILITY OF FLASHING LIGHTS. Rep. TED NAH EL 52003, Part I, Sept. 1954, 21pp. USN Air Test Center, Patuxent River Air Station, Patuxent River Medical Equipment Lab., Philadelphia, Penn.

The effect on detection time of flash rate, on/off ratio and subject differences was investigated in a factorially designed experiment involving 5 flash rates (40, 60, 80, 100 and 120 flashes per minute), 5 on/off ratios (1/2, 1/1, 2/1, 3/1, 4/1), 15 stimulus positions and 5 Ss. The experiment was conducted in an experimental situation which simulated red and green wing-tip lights as they would appear to a pilot about 2 miles removed from a plane which was approaching him head-on. Results of an analysis of variance performed on the averages of the 45 times each flash rate X on/off ratio combination appeared for 4 Ss (one S was dropped as atypical) indicated that flash rate was not a factor in the detection time but that there was significant subject X flash rate interaction; that subject was a significant factor and that on/off ratio was significant with ratios below 2/1 better than those above 2/1.

4298 House, H.A. COMPARISON OF TAXI LIGHT SYSTEMS FOR VP AND VR AIRCRAFT, FINAL REPORT. Proj. PTR EL 52018, Rep. 1, June 1954, 13pp. USN Air Test Center, Patuxent River Air Station, Md.

4298 To determine the taxi lighting system most suitable for VP and VR aircraft, five possible means of supplying lighting were compared: 1) a separate taxi light on the nose or nose wheel of the plane, 2) a controllable multi-purpose light, 3) intermittent use of regular landing lights, 4) landing lights having a second low wattage filament for taxiing, and 5) an oscillating taxi light. In addition, different wattage lamps and one versus two lamps were compared. Lights were installed in a test airplane and pilots were requested to operate and evaluate the lights while taxiing in unlighted areas at night.

4299 USN Air Test Center, INSTALLATION AND EVALUATION OF THE NAVY COMPOSITE APPROACH LIGHTING SYSTEM. Proj. TED PTR AE 10007.1, Serial ET311 161, Final Rep. 2, April 1954, 4pp. USN Air Test Center, Patuxent River, Md.

Test results indicate that the Composite Approach Lighting System is an improvement over the present Navy standard slopedline system and is satisfactory for use by all types of naval aircraft. The omission of any of the guidance features of the composite system, although these features are not necessary in all instances, is not considered advisable. Their need increases greatly with a decrease in visibility. Results indicate the need for full voltage (110 volts) or slight overvoltage (120 volts) at the red and green light fixtures to ensure brightness comparable to the white lights. Satisfactory flash-type runway lights are needed to accomplish the changeover from approach to runway light guidance. Such a light would eliminate the dark areas at runway and taxiway intersections. This is important especially on the instrument runway.

Schaefer, H.J. THEORY OF PROTECTION OF MAN IN THE REGION OF THE PRIMARY COSMIC RADIATION. Proj. NM 001 059.13.06, Aug. 1952, 17pp. USN School of Aviation Medicine, Pensacola Air Station, Fla.

4311

The potential hazards to humans from exposure to the primary cosmic radiation in flight at extreme altitudes centers upon the heavy nuclei component of the primary radiation. In two preceding reports the microspatial determination of the ionization dosage along a heavy nucleus track in tissue was derived in quantitative terms in its radial and longitudinal component. It was shown that in the terminal section of the tracks (the thin-down part) the dosage reaches excessively high values. In this report the actual number of the thin-down hits per hour in a "standard man" for all altitudes and all latitudes and for all components of a heavy spectrum is derived. Relationships between number of hits and thickness of shielding layers are graphically presented.

McLaughlin, S.C., Jr. THE EFFECT OF RED LIGHT ON THE ABSOLUTE VISUAL THRESHOLD. Proj. NM 001 059.28.02, Aug. 1953, 7pp. USN School of Aviation Medicine, Pensacola Air Station, Fla.

An hypothesis is advanced which may account for the appearance or non-appearance of red-light photosensitization in closely similar experimental situations in terms of the psychophysical method of threshold determination which is employed. This hypothesis, if valid, explains the appearance in the literature on vision of several sets of conflicting data during the past 10 years. Data are presented in support of this hypothesis, and these data appear to demonstrate, independently of the validity of the subject hypothesis, that the red-light photosensitization phenomenon previously reported from this laboratory should be regarded as nonexistent for purposes of operational application.

Guedry, F.E., Jr. THE RETENTION OF EFFECTS OF 'MASSSED' AND 'DISTRIBUTED' VESTIBULAR STIMULATION AS INDICATED BY THE DURATION OF THE OCULOGYRAL ILLUSION. Contract N7onr 434, Proj. NM 001 063.01.33, T.O. 1, Joint Rep. 33, July 1953, 20pp. USN School of Aviation Medicine, Pensacola Air Station, Fla. (Tulane University, New Orleans, La.).

An investigation was made of the effects of a 'masssed' and a 'distributed' rotation series on 2 aspects of habituation: a) the decrement in response duration within the habituation series, b) the retention of habituation. Following preliminary indoctrination, 2 groups of 10 Ss received 39 separate rotation trials in which the rotational and post-rotational durations of the oculogyral illusion were reported. This series of trials, which constituted the habituation series, was 'masssed' into a single period with 1 group, while with the other group, it was 'distributed' over 4 half-hr., daily sessions. Tests of retention were made 7 days after completion of the habituation series. Within the limits of this experiment, the response decrement produced by a 'masssed' series is at least as great as that yielded by a 'distributed' series. However if there is a systematic difference in the retention produced by these two series, it is the 'distributed' series which yields the greater retention.

Guedry, F.E., Jr. THE TRANSFER OF HABITUATION TO ROTATION WITH RESPECT TO THE MAGNITUDE OF THE VESTIBULAR STIMULUS. Contract N7onr 434, Proj. NM 001 063.01.34, Joint Rep. 34, July 1953, 19pp. USN School of Aviation Medicine, Pensacola Air Station, Fla. (Tulane University, New Orleans, La.).

This experiment is a study of the transfer of habituation with regard to the magnitude of the vestibular stimulus. Twenty human subjects received tests of the duration of the oculogyral illusion under two angular velocities before and after a series of 39 rotation trials in which an intermediate angular velocity was employed. The following inferences were made from the results: (1) Habituation is not specific to the 'practiced' angular velocity. (2) Habituation to a given intermediate stimulus will produce greater response reduction to stimuli of lesser magnitude and lesser response reduction to stimuli of greater magnitude than is obtained with the intermediate stimulus. This means that although the responses are reduced by the habituation series, the responses are indicative of a greater sensitivity to differences in vestibular stimuli after than before the habituation series. (3) Comparisons of the results prior to the habituation series have implications for theories of the vestibular end-organ which are discussed briefly. (4) Comparison of the rotational and postrotational results suggests that visual stimulation such as that produced by full room illumination has an habituatory effect which does not generalize to vestibular stimuli with opposite directional components.

Peters, R.W. THE EFFECT OF HIGH-PASS AND LOW-PASS FILTERING OF SIDE TONE UPON SPEAKER INTELLIGIBILITY. Joint Proj. Rep. 25, Aug. 1954, 9pp. USN School of Aviation Medicine, Pensacola Air Station, Fla. & Ohio State University Research Foundation, Columbus, Ohio.

Forty-eight speakers read multiple-choice intelligibility test lists under conditions of either low-pass or high-pass filtering of side-tone. The sound pressure level of the side-tone was kept constant for all band-pass conditions. The results indicate that speaker intelligibility improves significantly when the frequencies above 600 cps are attenuated in the side-tone circuit.

Sendroy, J., Jr. & Cecchini, L.P. THE DETERMINATION OF HUMAN BODY SURFACE AREA FROM HEIGHT AND WEIGHT. Res. Rep. 12:385 410, Oct. 1954, 24pp. USN Medical Research Institute, Bethesda, Md.

A simple, rapid, and accurate method of estimating human body surface area from height and weight has been developed. From the empirical relationships of height plus weight (in cm. and kg. respectively), and the "shape" factor of the ratio of weight to height, a chart has been constructed for the graphical estimation of surface area values in the range from 0.05 to 3.0 m. From this master chart a diagram has been constructed, whereby surface areas may be obtained with the same accuracy and more conveniently, from values of height and weight alone. A comparative evaluation and a statistical analysis of the method applied to 252 measurements of surface area have been made. The results indicate a margin of superiority in respect to accuracy, especially in the case of abnormal body types, for the present graphical method as compared with the well-known Du Bois height-weight formula. The self-adjusting power equation of Boyd has been found to give results generally comparable to those obtained by our diagram. According to these tests, the equation of Preitmann has been found to be biased and not sufficiently accurate to merit consideration for further use. All factors considered, the presently proposed graphical method would seem to be generally superior to other methods of obtaining a value for surface area from the simple physical measurements of height and weight.

USN Personnel Analysis Div. ANNUAL REPORT-FISCAL YEAR 1954, 46pp. USN Personnel Analysis Div., Bureau of Naval Personnel, Washington, D.C.

4322

This is an annual report of the Bureau of Naval Personnel, Personnel Analysis Division for the final year 1954. A summary of accomplishments and on-going studies within various problem areas is presented. Some of these areas are as follows: guided missiles, anti-submarine warfare, mine warfare, training for specific types of tasks and duties, and so forth.

4323

Kimble, G.A., & Wulff, J.J. THE EFFECT OF RESPONSE GUIDANCE ON THE VALUE OF AUDIENCE PARTICIPATION IN TRAINING FILM INSTRUCTION. Contract AF 33(038)134678, HFORL Rep. 34, April 1953, 8pp. Yale University, New Haven, Conn.

4323

This study was designed to test the effectiveness of "response guidance" in audience participation during training film instruction. Two groups of 330 Ss (basic trainees) underwent practice sessions interspersed between sections of a film on the reading of scales on a slide rule. For one group, the practice questions included hints or "guidance cues" to assist in obtaining the correct answer. The other group answered the same questions without the "guidance cues." Performances on a post-film test of proficiency, which included new as well as old problems, are compared.

Huggins, W.H. A THEORY OF HEARING. AFRC TR 53-14, May 1953, 124pp. USAF Electronics Research Directorate, AFRC, Bedford, Mass.

4330

A model of the inner ear has been developed which combines into a simple, plausible mechanism the mechanical, dynamical, anatomical, and neurological details of the cochlear structure. The mechanism adequately accounts for the results of a variety of physical and psychological experiments. It suggests a functional purpose for certain anatomical details of the cochlear partition and it unifies into a single consistent construct the experimental facts concerning hearing.

Fitzpatrick, R., Vasilas, J.W. & Peterson, R.O. PERSONNEL AND TRAINING FACTORS IN FIGHTER AIRCRAFT ACCIDENTS. Contract AF 33(038)13260, HFORL Rep. 37, April 1953, 36pp. American Institute for Research, Pittsburgh, Penn.

Data were collected for a large, relatively homogeneous sample of pilots, and this sample was subdivided into groups still more homogeneous with regard to assignment and experience. The relationships between accidents and scores on a number of tests were determined. The tests used were: Arithmetic Reasoning, Biographical Data (Pilot), Two Hand Coordination, Finger Dexterity, Dial and Table Reading, Speed of Identification and Discrimination Reaction Time. The results implied that it was not theoretically possible from a knowledge of certain of his test scores to predict the number of accidents a pilot may incur. There was a very slight indication that if a pilot obtains a low score on the printed classification test in Arithmetic Reasoning, he is more likely to have accidents of a judgment cause than a pilot who obtains a high score on the same test. No such relationships were obtained for any of the other tests or causes analyzed. (HEIAS)

4325

Berrien, F.K. & Sammons, H. A STUDY OF CHECK-OUT PROCEDURE IN JET AIRCRAFT. Contract AF 18(600) 137, HFORL Rep. 40, Aug. 1953, 43pp. USAF Human Factors Operations Research Lab., Bolling AFB, Washington, D.C. (Institute for Research in Human Relations, Philadelphia, Penn.).

4325

To investigate the relation between check-out procedures (an examination of a pilot to determine whether he is competent to fly a particular type of aircraft) and accident frequency, a rating procedure was developed through use of an interview and data blank. After pre-testing the data blank in the field, data collection from 14 operational jet squadrons was accomplished. Ratings of completeness of check-out procedures were studied in relation to pilot error accidents and accident frequency over a four-month period. Recommendations were made for improving the check-out procedures.

Torrance, E.P. SURVIVAL PSYCHOLOGY, SOME THINGS THE COMBAT AIRCREWMAN SHOULD KNOW ABOUT. THE PSYCHOLOGICAL ASPECTS OF SURVIVAL. HFORL Memo Rep. 42, Dec. 1953, 42pp. Human Factors Operations Research Lab., ARDC, Washington, D.C.

It may be some time before an adequate set of psychological principles for survival can be established. But meanwhile aircrewmembers are facing emergencies, surviving or not surviving. Some are not surviving because they are unable to use the equipment and technical training which they have been given. Some of those who do survive suffer needlessly for the same reason. The survival experiences of hundreds of Air Force personnel downed during World War II and the Korean combat have been studied to determine the mental and emotional problems arising under conditions of survival and the most practical steps to take in order to avoid or satisfactorily solve these problems. From this study came the principles listed in this booklet. Each is followed by typical examples quoted from actual survival reports, and under 'What To Do' you will find suggestions for applying the principles to training and actual survival situations.

Howard, R.A. SUN-SAND AND SURVIVAL. AN ANALYSIS OF SURVIVAL EXPERIENCES IN DESERT AREAS. ADTIC Pub. D 102, Jan. 1953, 42pp. Arctic, Desert, Tropic Information Center, USAF Air University, Maxwell AFB, Ala.

This study of desert survival episodes is not intended to be a statistical study of experiences or chances of survival. It is instead a report of the nature and range of experiences of military personnel isolated in desert areas during wartime. The analysis covers 382 individual successful survival episodes. Involved in this study are accounts of 142 additional men who were lost, strayed, or died en route. It is impossible to determine what percentage this might represent of the total number of men who went down. The stories were taken from the period of 1940 to 1943 and operations in North Africa. Only a few stories occurred after 1943. (HEIAS)

4332 Moser, H.M., Dreher, J.J. & Adler, S. THREE-DIGIT NUMBER TELLING AND REPETITION METHODS. Contract AF18(600) 316, AFRC TR 54 81, Rep. 11, Aug. 1954, 5pp. Ohio State University Research Foundation, Columbus, Ohio.

Three types of three-digit number telling were investigated: a) single digit (e.g., 3-1-4); b) group (e.g., 3-1-4); c) full word form (e.g., 314). The safest general rule to follow in telling three-digit numbers is to pronounce them as single units (a). Under favorable listening conditions and when Americans are on both ends of the communication link, either the form (b) or full word form (c) does as well, but only under these two conditions. As soon as a moderate amount of noise is present or when foreign speakers are involved, the single-digit telling method is required for maximum efficiency. Repeating a number does virtually no good if the repetition is in the same form (viz. 3-1-4, I say again, 3-1-4). Changing the form of the repeated number helps if the single-digit and group style is coupled in either sequence (AC or CA). In general telling method B is definitely to be avoided. In only one condition does it perform satisfactorily, namely, when it follows method C in a repeated message. (Method B alone, repeated, or in combination with any other form, results in poor listener reception.) The performance of international listeners on repeat methods is consistent regardless of the nationalities of listener or speaker.

4331 Moser, H.M., Dreher, J.J. & Patterson, R.E. SENTENCE ELEMENTS AND LISTENER RESPONSE. Contract AF18(600) 316, AFRC TR 54 80, Rep. 10, Aug. 1954, 18pp. Ohio State University Research Foundation, Columbus, Ohio.

The experiment investigated the intelligibility of various sentence elements in air language usage. The stimulus material consisted of 61 sentences using information that could be expected before and 52 sentences after a plane is airborne and was read by 6 speakers of various nationalities. 17 listeners of various nationalities heard the sentences at a 9 db S/N ratio, each sentence followed by a pause during which a verbatim repeat was attempted. The listener was simultaneously occupied with a minor manipulation task providing motor distraction. Accuracy of responses was calculated and analyzed as follows. No statistical superiority resulted from prefixing order with the word "please". A correlation of 0.95 exists between verbatim and paraphrase scores, making the more useful paraphrase a sufficient measure of listener reception of connected discourse. A list of paraphrase scores yielding superior response is given. No differences in articulation scores can be related to a word's root (Latin vs. Anglo-Saxon). The mode of utterance (command, question, or statement) does not affect its reception. Command words are as effective without tag words as with them. A low but significant correlation existed between sentence length and successful reception. (NEIAS)

4333 Lorge, I., Davitz, J., Fox, D. & Herrold, K. EVALUATION OF INSTRUCTION IN STAFF ACTION AND DECISION-MAKING. Contract AF 33(038) 28792, Tech. Res. Rep. 16, Dec. 1953, 70pp. USAF Human Resources Research Institute, Maxwell AFB, Ala. (Institute of Psychological Research, Columbia University, New York, N.Y.).

4333 The Quality Point Score (QPS) method for evaluating written decisions (see 4334) was employed to assess the effectiveness of instruction in staff action and decision-making at the Air Command and Staff School. The 55, 473 officer students, were required to submit solutions to problems and plans of action as individuals and as small ad hoc groups before and after receiving instruction. Scores on the written decision (pre- and post-course) are compared for individuals and groups. T.

4334 Lorge, I., Davitz, J., Fox, D., Herrold, K. et al. MANUAL FOR EVALUATING WRITTEN DECISIONS: THE QPS METHOD. Contract AF 33(038) 28792, Res. Memo. 20, Oct. 1953, 115pp. USAF Human Resources Research Institute, Maxwell AFB, Ala. (Columbia University, New York, N.Y.).

4334 A method for evaluating written decisions of Air Force students is described. A content analysis was performed on 300 written decisions on four problems in human relations. Discrete ideas were classified and were rated by four judges on a four-point scale for the amount of credit each deserved. Directions for scoring decisions and obtaining Quality Point Scores are given. Reliability of the method was measured by the correlation between independent scorings. Validity was measured by correlation between ranked judgments by advanced psychology students and Air Force officers of 60 statements. T.

4335 Findley, W.G., Frederikson, N.O. & Saunders, D.R. AN ANALYSIS OF THE OBJECTIVES OF AN EXECUTIVE-LEVEL EDUCATIONAL PROGRAM. Contract AF 33(600) 5833, Tech. Res. Rep. 22, Jan. 1954, 34pp. USAF Human Resources Research Institute, Maxwell AFB, Ala. (Educational Testing Service, Inc., Princeton, N.J.).

4335 This study was designed to ascertain the objectives of instruction in the Field Officer Course. As an initial step in the development of a battery of tests to evaluate executive skills in Air Force officers, 502 statements on desired outcome of training were gathered from instructors and were classified into 12 functional categories, e.g., "flexibility," "foresight," "team organization," and "effective evaluation of data." Timberlake, P.W. EVALUATION OF GRADUATES OF THE AIRCRAFT CONTROL AND WARNING OPERATOR COURSE. Proj. APG/ADA/69 A, Oct. 1953, 21pp. USAF Air Proving Ground Center, Eglin AFB, Fla.

4343

To evaluate the ability of the graduates of the Aircraft Control and Warning Operator Course to perform the job for which they were trained, four airmen test students, selected to provide an academic cross section of the class, were brought to Eglin Air Force Base immediately after graduation. They were used as regular replacements in a radar control unit during a 60-day test period. Each graduate was assigned to a supervisor who made his daily work assignments and rated his performance. Interviews were also held with graduates and supervisors in an attempt to determine basic causes of observed weaknesses. Data were tabulated and discussed in terms of advisable changes in the training course.

Putnam, W.L. OPERATIONAL SUITABILITY TEST OF THE MF-1 ATTITUDE INDICATOR. TERMINATION REPORT. Proj. APG/TAT/103 A, March 1954, 10pp. USAF Air Proving Ground Center, Eglin AFB, Fla.

4359

To evaluate the MF-1 Attitude Indicator as a flight instrument and to determine its suitability as a dive angle indicator for use in dive bombing, flight tests were conducted. Approximately 40 hours flying time were accomplished with the instrument installed in the rear seat instrument panel of a T-33 jet trainer (instrument flying phase). The dive bombing phase was accomplished with the indicator mounted in the instrument panel of an F-86F aircraft with runs made at various angles between 20 and 70 degrees at altitudes ranging from 10,000 to 20,000 feet. Pilot opinions were gathered and assessed.

Fleishman, E.A. A FACTORIAL STUDY OF PSYCHOMOTOR ABILITIES. Res. Bull. AFPTRC TR 54-15, May 1954, 43pp. USAF Personnel and Training Research Center, Lackland AFB, Tex.

The present paper has described a large-scale factor analysis study of performance in the relatively unexplored aptitude area of psychomotor skill. A large number of apparatus and printed psychomotor tests were selected or specifically designed to measure certain ability categories hypothesized to exist from the results of previous research in this area. After extensive pretesting, the tests were assembled into a battery and administered to 400 Ss. The correlations among scores on these tests were then subjected to a Thurstone centroid factor analysis. The results of the study appear to confirm the existence of the following relatively independent factors in psychomotor skill: a) wrist-finger speed; b) finger dexterity; c) rate of arm movement; d) manual dexterity; e) steadiness; f) reaction time; g) aiming; h) psychomotor coordination; i) postural discrimination; j) spatial relations. 2 additional factors were isolated but their interpretation or significance remains doubtful. The results were discussed with respect to the factor composition of individual tests, the utility of certain printed tests designed to reproduce apparatus test variances, and the contribution of these factors to certain kinds of more complex psychomotor performance.

Lesiw, W. A COMPARISON OF METHODS FOR ACHIEVING TRIGGER BURST CONTROL. Proj. 7708, Task 77141, AFPTRC TR 54-17, May 1954, 28pp. USAF Armament Systems Personnel Research Lab., Lowry AFB, Colo.

4362

To make a comparative evaluation of two methods for achieving burst-interburst interval control of triggering in the flexible gunner's task, 129 flexible gunnery students in a stage of training preceding air-to-air instruction were studied. Two methods of training for burst control were used: a counting method and a buzzer-synchronizing method. Five days of practice on one of the two methods was given to each S followed by a retest six days after the last practice day. Changes in burst estimates with practice and retention after six days were analyzed for effect of method.

Brandenburg, R.E. FLIGHT TEST EVALUATION OF THE SPECIALTIES AND KOLLSMAN ANGLE OF ATTACK INDICATORS. Tech. Note WCT 53 77, Rep. R.653 1605, Feb. 1954, 23pp. USAF Directorate of Flight and All-Weather Testing, Wright-Patterson AFB, Ohio.

4364

To evaluate two different angle of attack indicators (Specialties and Kollsman) in terms of their practicability during landing approach and in cruise control, flight tests were conducted on T-33A jet trainer aircraft. Both indicators were installed in the same plane and tested simultaneously. Level flight runs were flown at 2,000, 6,000, 8,000, and 25,000 feet throughout the entire speed range of the aircraft at each altitude. Accelerated and unaccelerated stalls were flown at 10,000 and 30,000 feet; two climbs were made to approximately 36,000 feet; simulated cruise conditions and ground control approach runs were made. Repeatability and effect of turbulent air conditions on accuracy are discussed. Recommendations are included.

4373
Henry, F.A. AVIATORS "BENDS" PAIN AS INFLUENCED AT ALTITUDE AND IN FLIGHT DENITROGENATION. Contract AF 18(600) 20, WADC Tech. Rep. 53 227, March 1953, 48pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (University of California, Berkeley, Calif.).

Experiments in the altitude chamber of the University of California (Berkeley) show that descent to a cabin altitude of 31,600 ft. reduces the pain of aviator's "bends" to moderate severity. Below 28,000 ft. the pain is mild; it disappears (on the average) at 21,900 ft. Cases of bends kept at 10,000 or 15,000 ft. show a reduction in aerobolism directly related to "storage" time; in 3 hrs. there is a 13,000 ft. gain in critical altitude. Frequently repeated ascent and descent does not change the critical altitude. With "storage" at 20,000 or 25,000 ft. the pain altitude changes very little within 3 hrs. presumably because there is growth of sub-clinical tissue bubbles. In-flight denitrogenation for the prevention of aerobolism symptoms should therefore be carried out at 10,000-15,000 ft. Oxygen economy can be aided by breathing cabin air at 10,000 ft. during the first hour of a longer denitrogenation period on full oxygen at 15,000 ft. without sacrifice of protection. Available preoxygenation tables give valid predictions of physical exertion is mild; with heavy work, considerably more denitrogenation is required. Protection is achieved by reducing symptom intensity rather than delaying onset of aerobolism. Denitrogenation progresses as the mirror image of denitrogenation.

4377 Morrison, Nina K. & Schaefer, L.A. GROUND STUDY OF THE NONEJECTION METHODS OF ESCAPE FROM B-47B AIRCRAFT. Phase I of Evaluation of Methods of Crew Escape from B-47B Aircraft. WADC Tech. Rep. 54-6, April 1954, 16pp. USAF Aero Medical Lab., Wright-Patterson Center, Wright-Patterson AFB, Ohio.

This report covers Phase I, a ground study of the nonejection methods of escape from B-47B aircraft. Because the cabin space available to the crew members is so limited, it was necessary to make a thorough investigation of these body positions and movements at the disposal of the crew when evacuating the aircraft. This study, done at the Wright-Patterson Air Force Base, led to the establishment of optimum procedures to be followed by each man when leaving his station and reaching the possible escape exits, and the most feasible body positions for leaving the aircraft. Time studies of crew evacuations were conducted at Lockbourne Air Force Base utilizing the procedures presented in this report. These studies covered crew escape through the ventral hatch, with and without the use of an escape bracket, and through the crawlway to the bomb bay. 8 crews participated in the ventral hatch tests and 6 crews in the bomb bay tests. Ground studies of egress through the navigator's ditching hatch and canopy were limited to the timing of individuals making personal leads disconnects and standing at their stations. The feasibility of using these exits will have to be determined during the Air Study Phase. Analysis of the data thus accumulated indicates that the optimum method of nonejection escape from this aircraft is through the ventral hatch in a feet-first, facing-aft position utilizing the Barco escape bracket.

4380 Hote, F.A., Biersdorf, W.R., Kent, G.W. & Myers, J. VISUAL CONTRAST DISCRIMINATION AS A FUNCTION OF PRE-EXPOSURE TO LIGHT. Rep. on Human Engineering Research for Fire Control and Missile Control Systems. Contract AF 18(600)54, WADC Tech. Rep. 54-80, Feb. 1954, 12pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (University of Wisconsin, Madison, Wisc.).

The just discriminable brightness contrast threshold was measured for 12 Ss (6 using the natural pupils, 6 with 2 mm artificial pupils) at 3 values of target luminance following pre-exposure to a constant intensity for 3 durations. Each S went through all 9 combinations of conditions 5 times. The duration of pre-exposure had little effect upon contrast sensitivity when the highest target luminance was used. At the middle value of target luminance, the longer the pre-exposure the higher the contrast threshold upon termination of pre-exposure and the slower the recovery of maximum sensitivity. When the lowest target luminance was used (a value near the dark adapted threshold for the fovea), the effect of pre-exposure was marked. For all durations when artificial pupils were used, the initial threshold following pre-exposure was high and the speed of recovery depended upon the duration; the longer the duration, the slower the speed. When natural pupils were used the initial threshold contrast ratio was about 0.3 and recovery of maximum sensitivity was rapid. At the 2 longer durations there was a delay of the order of 15-50 seconds before an initial setting could be made at maximum contrast (0.5) and the recovery of maximum sensitivity was greatly retarded.

4378 Imber, B.M., Stern, I.D. & Vanderplas, J.W. VISUAL FIELD RESTRICTION AND APPARENT SIZE OF DISTANT OBJECTS. WADC TR 54-23, Jan. 1954, 11pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

4378 To investigate the effect of reduced visual field size upon the apparent size of distant objects when the factors inherent in optical systems are eliminated from the situation, four observers made judgments comparing the apparent size of a variable-sized white square, set at a distance of 500 ft. and viewed monocularly through an aperture, with the apparent size of a standard 20-inch square viewed binocularly at a distance of 30 ft. Aperture sizes from five to 60 degrees were used to restrict the visual field. The findings are discussed in relation to the large decreases in apparent size of objects when viewed through a telescope.

4379 Wyckoff, L.S., Bridgman, C.S. & Tabory, L. THE EFFECT OF AN IMPROVED ORIENTATION AID ON TARGET ACQUISITION WITH THE HEMISPHERIC SIGHT. Contract AF 18(600) 54, WADC TR 54-67, Jan. 1954, 6pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (University of Wisconsin, Madison, Wisc.).

4379 To test the effect of a simple orientation aid on the speed of slowing and acquiring targets that have been spotted outside the periscopic type sight, subjects were tested using velocity hand controls. The aid consisted of eight illuminated lines radiating from the center of the target space and stationary with respect to this space. Such an aid could be incorporated as a moving reticle in the focal plane of sight. Two groups of subjects were tested for a period of eight daily sessions, one with and one without the sight. Cumulative time for acquiring the target was recorded for each run of 38 targets and the two groups were compared at each stage of practice.

4381 Archer, E.J. IDENTIFICATION OF TARGET CONCEPTS AS A FUNCTION OF INFORMATION LOAD. Contract AF 18(600) 54, WADC TR 54-202, March 1954, 9pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (University of Wisconsin, Madison, Wisc.).

4381 To investigate the effect of information load on response time, 12 groups of six Ss each served in an experiment on target identification. The groups corresponded to the cells of a three by four factorial design having one to four bits of relevant and zero to two bits of irrelevant information presented to the S by a single stimulus source. The task was to identify oscilloscope patterns by positioning four lever-action switches and to test identification by pressing a push-button. The response measure was the time required to identify 32 consecutive patterns. Errors were also recorded. Time to respond was analyzed as a function of relevant and irrelevant information load.

4382 Hirsh, I.J. STUDIES ON AUDITORY MASKING, FATIGUE, AND SPEECH INTELLIGIBILITY. Contract AF 11(600) 131, WADC TR 54-203, June 1954, 12pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Central Institute for the Deaf, St. Louis, Mo.).

4382 To specify more precisely the kind of impairment suffered during exposure to loud noise, four experiments were performed. In the first study the threshold of intelligibility (level at which 50 percent of the words in a list are recognized) for spondaic words as a function of the level of 11 bands of noise was measured. In the second study the definition that a critical band of noise should have the same absolute threshold as a pure tone in the center of the band was tested. The third experiment studied masking of different speech materials (four 200-item lists) with the same speakers and listeners. Finally, the effect of filtering on different speech materials was studied. Incomplete research was discussed, and recommendations were included.

Lacey, R.J. SUITABILITY OF THE GRAY INSTRUMENT PANEL FOR USE IN USAF AIRCRAFT. WADC TR 54 12, April 1954, 17pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

4353

An interpretation of the inverse relationship between the duration threshold of a word and its frequency of occurrence is outlined in which the frequency of a word in the Thorndike-Lorge tables serves as an estimate of the frequency with which college students would have used that word at the time the duration thresholds were measured. The validity of this estimate is tested by three experiments based on a rank-correlation procedure with additional experiments providing a check on the method. Some reasons for preferring the proposed interpretations to others that have been suggested are mentioned.

4384 Lebowitz, H.W. & Lomont, J.F. THE EFFECT OF LUMINANCE AND EXPOSURE TIME UPON PERCEPTION OF MOTION. Contract AF 18(600)54, WADC Tech. Rep. 54 780, March 1954, 9pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (University of Wisconsin, Madison, Wisc.).

The isochronal threshold velocity is defined as the minimum rate of target displacement necessary for the detection of movement at a constant duration of exposure. Threshold values were obtained for a wide range of luminance values in foveal vision at various durations of exposure. The function relating motion perception to luminance decreases as luminance is increased, rapidly at first and then more slowly, as the data approach a limiting value. The effect of an increase in exposure time is to shift the entire function to lower threshold values as well as to minimize the effect of luminance in decreasing the threshold velocity. The perception of movement is more precise the higher the luminance and the longer the exposure time. The lowest thresholds, however, are obtained at the longer durations, and it is recommended that exposures of more than 2 seconds be employed when detection of target motion is important. Such long exposures produce the lowest thresholds even under poor conditions of luminance.

Downing, A.L. THE EVALUATION OF VU-GRAPH TECHNIQUES FOR GCI PLOTTING APPLICATIONS. WADC TR 54 37, July 1954, 18pp. USAF Rome Air Development Center, Griffiss AFB, N.Y.

In a Ground Controlled Intercept Station, the present system of data presentation is that of reading the radar-derived data from a PPI scope and telephoning the information to plotter at a large transparent plotting board where it is written (in reverse) on the back of the board. A recommendation to replace the slow teller-plotter links with a standard Vu-graph, a special type of transparency projector enabling an operator to write or draw and have the image he creates projected on a screen, was made and this study evaluates its use. On the basis of various tests, it is recommended that expected difficulties in keeping permanent records by this means would outweigh the possible saving in time and manpower. (HEIAS)

Dunlap and Associates, Inc. A HUMAN ENGINEERING REVIEW OF THE TACTICAL AIR CONTROL PARTY COMMUNICATIONS VEHICLE AN/MRC 43. Contract AF30(602) 21 5, WADC Tech. Note 54 45, Oct. 1953, 7pp. USAF Rome Air Development Center, Griffiss AFB, N.Y. (Dunlap and Associates, Inc., Stamford, Conn.).

The specifications for the AN/MRC-43 state that presently available communications equipment must be utilized and that modifications or redesign of the equipment components is not permitted. Accordingly, a recommended arrangement of the presently available control components is presented. However, any arrangement of these components involves certain undesirable features. Consequently a design is presented which avoids the difficulties but requires some modification of the control units only. This arrangement should be adopted provided modification of these units is permissible.

4388

To determine the functional suitability of a gray instrument panel for use in USAF aircraft, two aircraft were equipped with a gray instrument panel and gray cockpit surround, including right and left consoles and floor. No instruments or control positions were changed. Pilots (33) were randomly assigned for flights in each aircraft; upon completion of each flight, the pilot completed a questionnaire designed to evaluate the functional suitability, visual adaptation, and appearance of the gray panel. Various Air Force Base and one aircraft manufacturer were asked to comment regarding acceptability of gray panels. Recommendations were included.

4390 Schmidt, I. & Bingel, A.G.A. EFFECT OF OXYGEN DEFICIENCY AND VARIOUS OTHER FACTORS ON COLOR SATURATION THRESHOLDS. Proj. 21 31 002, April 1953, 21pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

4390 The effects of oxygen deficiency, alcohol, and coffee on color saturation thresholds were studied. The colors tested were red, green, and blue presented, by the use of filters, to one half of a circular white test area of foveal size. The subject observed the test area with a neutral-adapted eye and named the color of the mixture half if he perceived a color difference. Color was added in an amount close to the color saturation threshold. Percentage of correct response, determined before and after an agent (hypoxia, alcohol, caffeine) was effective, served as an indicator of color sensitivity. Conclusions drawn from the standpoint of aviation medicine are presented. T.G. I. R 22

4391 Gerathwohl, S.J. CONSPICUITY OF FLASHING LIGHT SIGNALS. EFFECTS OF VARIATION AMONG FREQUENCY, DURATION, AND CONTRAST OF THE SIGNALS. Proj. 21 1205 0012, Rep. 1, June 1954, 7pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

4391 To test the conspicuity (signal effectiveness) of flashing light signals in a complex situation designed to simulate that of a person engaged in present-day practical signal problems, two experiments were conducted. A multiple reaction test in which the observer had to respond successively to a complex pattern of light and sound signals over a relatively long period of time was used. In the first experiment, conspicuity of signals of a relatively slow frequency and long duration were compared with that of a relatively fast frequency and short duration at different brightness contrasts. In the second experiment, the separate and joint effects of flash frequency, duration, and brightness contrasts were evaluated. T. G. R 8

4392 Payne, R.B. & Hauty, G.T. THE PHARMACOLOGICAL CONTROL OF WORK OUTPUT DURING PROLONGED TASKS. Proj. 21 1601 0004, Rep. 2, May 1953, 13pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

4392 To determine the relative and joint effects of a motivational technique (different levels of indoctrination as to significance of the study for an important operational problem of the Air Force) and an analeptic drug upon prolonged performance of a perceptual-motor task, preliminary training was given to 80 Ss on a complicated compensatory pursuit task involving simulated aircraft instruments and controls. The Ss then worked for four hours under the various motivational and pharmacological conditions (two analeptic drugs, a sedative, and a placebo). The treatment effects were appraised in terms of general course of performance, terminal levels attained, and the attitudes and feelings generated in the experimental setting. T. G. R 20

4393 Payne, R.B. & Hauty, G.T. THE EFFECTS OF MOTION-SICKNESS PREVENTIVES UPON CERTAIN PERCEPTUAL-MOTOR COMPONENTS OF THE PILOT'S TASK. Proj. 21 1601 0004, Rep. 3, May 1953, 5pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

4393 To appraise the relative effects of two motion-sickness preventives (hyoscine and bendaryl-hyoscine) upon certain perceptual-motor components of pilot skill, 64 subjects received training on a compensatory pursuit task involving simulated aircraft instruments and controls. They then continued work for four hours under conditions designed to appraise the relative effects of the two drugs which differed in protective capacity. The effects were viewed in terms of the general course of performance and the terminal level obtained. Results are discussed with regard to aircrew effectiveness. T. G. R 6

4395 Demsey, M.E., Siskind, R.P., Hanley, T.D. & Steer, H.D. A FUNDAMENTAL FREQUENCY RECORDER FOR COMPLEX SOUNDS. Contract N60r1 104, Rep. SDC 104 2 34, Tech. Rep., Oct. 1953, 55pp. Purdue University, Lafayette, Ind.

The design and development of an electronic-photographic circuit for recording the fundamental frequency of simple or complex speech signals is described. The instrument employs the Purdue Pitch Meter with a revised equalizing section and a new circuit to time electronically the period of the individual cycles of the fundamental frequency. This period measurement is recorded at the end of each cycle as a dot on a cathode ray oscillograph screen, which is calibrated in an approximately logarithmic frequency scale. The 3 scales are 250, 500, and 1,000 cps full scale. Permanent fundamental frequency records are obtained through the use of either a single or a moving-frame 35 mm oscillograph recording camera. The analysis of these records is facilitated through the use of an opaque projector. Although frequency measurements may be taken at other time intervals, for the present, the time interval is 1/26 second. Measurements may be taken at the nearest quarter-tone or 1/24 of an octave. Spilka, B. & Steer, M.D. THE EQUATING OF READING MATERIALS FOR VOCAL RATE-DURATION AND INTENSITY. Contract #6ori 104, Tech. Rep. SDC 104 2 35, Jan. 1954, 25pp. Purdue University, Lafayette, Ind.

An investigation was conducted to select reading passages considered to be equivalent with respect to the voice variables of percent phonation time, average syllable duration, mean vocal intensity, and vocal intensity variance. One hundred and twenty-eight young adult college males took part in this study. Eight reading passages were chosen for analysis and 16 subjects read each of the passages. Recordings of the passage readings were analyzed by means of the Purdue Speech Sound Timer and the Sound Apparatus Company's High Speed Power Level Recorder, Model MPL-2. The results of the analysis may be summarized as follows: a) All eight passages were found to be homogeneous with respect to their means and variances of mean vocal intensity; b) Seven of the reading passages (all except Passage H) were found to be equated in their means and variances of mean syllable duration; c) Six of the reading passages (all except F and H) were found to be equivalent with respect to their means and variances of percent phonation time; d) Seven of the reading passages (all except E) were found to be equivalent with respect to their means and variances of the vocal intensity variance.

Steer, M.D., Weiss, A.L., Green, D.S. & Hanley, T.D. UTILIZATION OF THE SONOGRAPH AS AN INSTRUMENT FOR PREDICTING RELATIVE INTELLIGIBILITY OF TALKERS IN MILITARY COMMUNICATION. Contract #6ori 104, SDC Tech. Rep. 104 2 33, Oct. 1953, 18pp. Purdue University, Lafayette, Ind

As was shown by this experiment the Sonograph is limited in its usefulness as a method of predicting the intelligibility of talkers because of the following factors: a) The limitations which are imposed upon this method by the differences in pronunciation of words on the part of military Ss. b) Shortcomings of the Sonograph itself in offering measurements of the overall intensity of speech and duration of individual speech sounds. c) The need for extensive training and experience on the part of personnel who will be required to interpret the sonagrams.

Newman, R.W. MODEL AND SIZE DATA FOR THE DESIGN OF MEN'S CLOTHING. Proj. 64 02 001, Rep. 217, July 1953, 16pp. USA Environmental Protection Research Div., QM Research & Engineering Center, Natick, Mass.

4399

This study presents average data on bodily dimensions of approximately 25,000 United States soldiers. The series is successively divided into subgroups on the basis of size (Chest Circumference), model (Drop or Chest Circumference minus Waist Circumference), and length (Stature). Mean values on size groups and models within size groups are presented in tabular and graphic form; length groups within the models and sizes are given in tabular form only. It is recommended that the data presented here be considered in any proposed major revision of the U.S. Army men's service uniform.

Daniels, F., Jr., Lyman, J. & Vanderble, J.H. A STUDY OF THE EXPERIMENTAL PACK T 53-8 WITH A REVIEW OF METHODS FOR STUDYING LOAD-CARRYING SYSTEMS. EPD Rep. 225, March 1954, 27pp. USA Environmental Protection Research Div., QM Research & Engineering Center, Natick, Mass.

4400

The T53-8 load-carrying system (an experimental pack designed to balance the load fore and aft, to minimize motion of load, and to stabilize the load) was compared to other systems (Standard Combat Pack, United Kingdom Z-2, and the packboard) by methods aimed at evaluating the effect of the pack on the man at all times during a complex activity. The methods used included: 1) energy expenditure studies, 2) performance tests, and 3) dynamic physical measurements. Findings from the three types of studies were analyzed in terms of comparisons among the packs as well as the value of each test used. A discussion of the rationale for field and laboratory studies for load-carrying systems was presented. Recommendations were made regarding the most promising methods.

Teichner, W.N. & Kobrick, J.L. EFFECTS OF PROLONGED EXPOSURE TO LOW TEMPERATURE ON VISUAL MOTOR PERFORMANCE, FLICKER FUSION, AND PAIN SENSITIVITY. EPD Rep. 230, June 1954, 13pp. USA Quartermaster Research & Development Center, Natick, Mass.

4401

To investigate the effects of prolonged exposure to low temperatures on visual-motor performance; flicker fusion and pain sensitivity, five subjects lived in a constant temperature chamber for 41 days (first 16 days temperature, 75°; next 12 days, 55°; last 13 days, 75°). Radiant heat pain and visual flicker fusion thresholds were obtained. Subjects practiced daily (15 trials) on a pursuit rotor. The threshold data and pursuit rotor data (mean time-on-target per trial) were analyzed for significant changes attributable to low ambient temperatures. Implications of the findings for the design of protective equipment and the training and use of soldiers are pointed out.

Thompson, G.G. EFFECTS OF DISPLAY SIZE AND OF SUPPLEMENTAL RATE INFORMATION COMPENSATORY PURSUIT PERFORMANCE. SUPPLEMENTARY REPORT. Contract N9onr 93103, Doc. 86, Mar. 1952, 39pp. Stanley Aviation Corporation, Buffalo, N.Y.

This study was conducted to explore the relation between some design characteristics of instrument displays and the precision of control obtainable when using these displays. It involved 2 experiments. A compensatory pursuit task, requiring the subjects to move a control and thereby compensate for random disturbances applied to an instrument pointer, was used in both parts of the study. The purpose of the first experiment was to determine the influence of dial size on precision of control. The four dials used were 1 1/2, 2 3/4, 4 and 5 1/2 inches in diameter. Results of this first part of the study showed no significant difference among the four dial sizes in their effect on performance. In part 2, variations in the nature of the information furnished by four different displays were compared for their effect on precision of control. Of major interest here was the effect on performance of adding to a direct indication of the variable being controlled, an incremental indication proportional to the first time derivative of the former. Time integral error scores showed a statistically significant superiority in the performance of subjects using this latter type of display over their performance using as a display indication of the variable being controlled.

Miller, J.G., Southillet, Lorraine & Eldridge, C. A BIBLIOGRAPHY FOR THE DEVELOPMENT OF STRESS-SENSITIVE TESTS. Contract DA 49 083 osa 611, PRS Tech. Res. Note 22, Oct. 1953, 125pp Psychological Research Associates, Washington, D.C.

The items in this bibliography have been selected and assembled with view to providing a survey of the background material useful in the preparation of stress-sensitive tests. It is made up of 2 sections: a) An extensive list of references cited by title only and b) Abstract of those references which were deemed most important and having the most direct bearing on the present research. In both sections the references are listed alphabetically according to author's name. The reference list is based on a thorough search of the pertinent literature. It includes references immediately and specifically concerned with the effects of stress and the measurement of these effects, as well as studies of anxiety and anxiety-measurement, effects of extreme or unusual environmental conditions, studies of combat fatigue and war neuroses, physiological stress reactions, and various other related investigations. In general, research on human, rather than animal, Ss has been emphasized unless the animal studies are of broad theoretical interest which would contribute to the rationale of stress-sensitive instruments. Although the coverage is wide and exhaustive, it was decided to omit certain books of a general nature, especially those which are of essentially of a textbook or handbook type. Standard works in statistics, test construction, etc., are likewise not included. The abstracts of experimental studies are presented in some detail in order to show the population sampled and the procedures used. Theoretical and review articles are summarized more briefly. An asterisk before a title in the bibliography means that the reference has been abstracted.

Williams, P.L. VISIBILITY STUDIES. Prog. Rep., ca. 1951, 16pp. Northrop Aircraft Inc., Hawthorne, Calif.

An evaluation of the optical properties of windshield angle of 35° in high performance aircraft was made in terms of the distances at which a pilot can see and recognize the presence of objects. The study was confined to "Day Fighter" and "All Weather Interceptor" type aircraft, targets of 50, 200, and 500 sq. ft. area, and conditions from twilight to full daytime. Analyses of these problems were made using data on light transmission and distortion of optical materials, target visibility, meteorological range, combat conditions, and the like. Conclusions and recommendations were as follows: windshield angle has a definite effect on pilot's ability to see a target. The probability of visually detecting 50 to 200 ft. targets under broadcast control vectoring in time to make an effective attack at high speeds would be marginal for many daylight conditions at 40,000 ft. even with a 35° windshield and would be very small during dark-daylight and twilight conditions. Recommendations are that further investigations be made in order that design limits be set and substantiated by actual flight tests. (HEIAS)

Marsh-Thesis, Inc., Huntington, N.Y. VOICE INTELLIGIBILITY HANDBOOK. NAVEXOS P 1192, Aug. 1953, 129pp. USN Special Devices Center, Port Washington, N.Y.

4432

This handbook concerns the application of voice communication principles to the problem of training for improved voice intelligibility under combat conditions. It is organized into the following topics: basic information on voice communication in relation to intelligibility, training equipment, specific training procedures, and testing procedures for selection of the best qualified men for key talker posts. The appendix includes material for message drill and test word lists.

Shaffer, W.C. BIOGRAPHICAL INVENTORY FOR NAVAL AVIATORS. Contract Nonr 69405, Series 1953, Inst. Rep. 7, Nov. 1953, 22pp. Institute for Research in Human Relations, Philadelphia Penn.

A preliminary Biographical Inventory consisting of 576 items was assembled from a variety of sources. This inventory was administered to all men entering flight training at NAS Pensacola beginning with class 20-51. During the summer of 1952 an interim analysis was made against a pass-fail criterion. Failures included "Dropped at Own Request" as well as Flight Failures up to Stage D of training (10 months beyond entering date). The validity coefficient based on an independent sample for the interim form was .39. A final analysis involving 2 independent populations of approximately 1,000 each was conducted to establish the scoring keys and validity for 114 items selected by the interim analysis. These populations were drawn from the total group entering training between 14 September 1951 and 9 September 1952. The validity for the final key is .33. It is recommended that additional analysis be made of validity after the inventory has been administered to candidates for flight training rather than to cadets already selected and admitted to flight training.

4434

Courtney, D. & Greer, F.L. LEADERSHIP: A REVIEW AND SUMMARY. Contract Nonr 1229(00), Series 1954, Inst. Rep. 3, Feb. 1954, 23pp. Institute for Research in Human Relations, Philadelphia Penn.

The leadership findings of the Institute are reviewed and summarized and a bibliography of publications growing out of the project is presented. The results are described in terms of attitudinal relationships, behavioral relationships, and methodological findings. In addition, 2 studies are reported on the problem of why some individuals are better liked or more accepted than others in a structured group situation. (HEIAS)

4436

Crook, M.N., Gray, Florence E., Hanson, J.A., Weisz, A., et al. INFOMAX. INTERIM ENGINEERING REPORT. Contract AF 33(616) 362, Rep. 1176 IR 11, April 1954, 18pp. Hogan Laboratories, Inc., New York, N.Y. (Institute for Applied Experimental Psychology, Tufts University, Medford, Mass.).

4436

This interim report set forth the progress made on a research study in development, design, and testing of a system (the Infomax communication system) for transmitting information over long radio circuits where both poor signal-to-noise ratios and bad multipath conditions prevail. An experimental comparison between synchronous and linear detection was completed with a further test of effect of letter size in noisy Infomax copy. A method for printing test copy on 16 mm film for use in the new scanner was devised and equipment for the system has been developed.

Felton, W.W., Fritz, E., & Grier, G.W., Jr. AIR-GROUND COMMUNICATIONS IN TERMINAL AIR TRAFFIC CONTROL. FINAL REPORT. Contract OCA 28538, Rep. F 2185 1, March 1953, 67pp. Laboratories for Research & Development, Franklin Institute, Philadelphia, Penn.

4440

This report contains the principal findings of a two-year study of communications measurements at Washington National Airport and Langley Air Force Base, the purpose of which was to describe and analyze the use of air-ground channels for voice communications in air traffic control. Channel density, types of information transmitted, actual information value (measured in bits), communication difficulties, and suggested modifications of the system are presented.

Miller, J.W. & Ludvig, E. DYNAMIC VISUAL ACUITY WHEN THE REQUIRED PURSUIT MOVEMENT OF THE EYE IS IN A VERTICAL PLANE. Contract Nonr 58600, Rep. NM 001-075-01-02, Joint Proj. Rep. 2, May 1953, 9pp. USN School of Aviation Medicine, Pensacola Air Station, Fla. (Kresge Eye Institute, Detroit, Mich.).

The present investigation demonstrates the manner in which visual acuity deteriorates as the angular velocity of the test object, traveling in a vertical plane, is varied between 20°/sec and 140°/sec. It is shown that the empirical equation, $y = a + bx^2$, may be used to represent the experimental data. In this equation y is the critical detail resolvable, expressed in minutes of arc at the nodal point of the eye, x is the angular velocity of the test object in degrees per second and a and b are parameters characteristic of the dynamic acuity of the individual in the plane of motion tested. The values of the a and b coefficients of the 9 subjects tested were shown not to be significantly dependent upon whether the motion of the test object was in a vertical or a horizontal plane. However, a very high coefficient of correlation (.96) was found between the values of b determined by the use of vertical movement and the values of b determined by the use of horizontal movement. This high correlation indicates that individuals "velocity resistant" or "velocity sensitive" to horizontal movement remain velocity resistant or velocity sensitive when subjected to vertical movement of the test object.

Goodyear Aircraft Corporation, Akron, Ohio. FLIGHT CONTROLS HUMAN DYNAMIC RESPONSE STUDY. FINAL REPORT. Contract NOAS 53 013 C, Rep. AE 61 6, Nov. 1953, 21pp. USN Bureau of Aeronautics, Washington, D.C.

4438

This report describes the construction and use of a movable cockpit capable of providing realistic simulation of aircraft movements in addition to the usual visual display. The basic techniques of the problem are described in an earlier report. A major portion of this report describes the design features of the apparatus. Some data on motion characteristics common to most pilots are given and tests of a simple, linear approximation of pilot dynamics are discussed.

Cookley, J.D. A HUMAN ENGINEERING REVIEW OF THE CONTROL MONITOR GROUP AM/FSA 4. Contract AF 30(602)215, Jan. 1954, 6pp. Dunlap and Associates, Inc., Stamford, Conn.

The results of the review contained in this report are divided into two parts. The first section raises questions regarding some of the general aspects of the equipment. Discussion of specific design features and recommendations for desirable changes are contained in the Appendices. The relative importance of the recommendations can be judged by the three-letter symbol appearing over each recommendation. This symbol takes into account the relative importance of the proposed change with regard to the over-all operation and a rough estimate of the cost to effect the change. The method utilized to obtain these values is described in the supplement attached to the report.

4443

Baldwin Company. REAL-VOICE AND REAL-EAR RESPONSE AM/AIC-10 INTERCOMMUNICATION SET. Contract AF 33(038)23313, Rep. AFAC 10, Final Eng. Rep. on Task 10, Dec. 1953, 51pp. Baldwin Company, Cincinnati, Ohio.

Subjective measurements were made on the real-ear response of the M-70/AIC and M-75/AIC headsets and the research models which preceded them. Several different crews of listeners were used in the measurements. Masking threshold data on these headsets were also obtained in typical simulated aircraft noise spectra. The real-voice response of each of the 3 microphone types used with the AM/AIC-10 Intercommunication Set was measured with a group of talkers. Both production units and research models were tested. Data were obtained in quiet and in different noise spectra. Transmitted noise spectra were also measured in some cases. It is expected that these data will be useful in the writing of specifications for procurement of these equipment items.

4444

USN Personnel and Training Branch. BIBLIOGRAPHY OF UNCLASSIFIED RESEARCH REPORTS. June 1956, 46pp. USN Personnel and Training Branch, ONR, Washington, D.C.

4444

This bibliography includes unclassified reports relating primarily to personnel and training. The reports are grouped under the following general headings: 1) isolation and measurement of basic psychological traits; 2) selection and classification problems; 3) billet analysis and billet classification research; 4) performance criteria; and 5) training and education research.

4451

Miller, R.B., Folley, J.D., Jr., Smith, P.R. & Swain, A.D. SURVEY OF HUMAN ENGINEERING NEEDS IN MAINTENANCE OF GROUND ELECTRONICS EQUIPMENT. Contract AF 30(602) 24, RADC TR 54 31, Feb. 1954, 302pp. American Institute for Research, Pittsburgh, Penn.

4451

The procedures, results, and human engineering research problems derived from a field study of the maintenance of ground electronics equipment at Air Defense sites are described. Verbal and written questionnaires were developed and administered to all available personnel at six sites, observation data were collected, and special techniques of equipment and activity analysis were used. The following problem areas were derived and discussed at length: 1) accessibility, 2) presentation of technical information, 3) test equipment, 4) work conditions, 5) environmental effects, 6) safety, 7) component size, 8) power problems, 9) color-coding of equipment, 10) warning indicators, 11) cable connectors, 12) panel controls and meters, 13) circuit-switching arrangement, etc. T.

de Charms, R., Morrison, H.W., Reitmänn, W. & McClelland, D.C. BEHAVIORAL CORRELATES OF DIRECTLY AND INDIRECTLY MEASURED ACHIEVEMENT MOTIVATION. Contract N7onr 463, Oct. 1954, 13pp. Wesleyan University, Middletown, Conn.

Results from a number of different experiments have been collected to show that measuring achievement motivation directly by asking the S or indirectly by content analysis of his stories tends to produce 2 different scores which signify different things as far as the rest of the S's behavior is concerned. A consciously high desire for achievement tends to be associated with conformity, a high valuation on expert authority, and a low valuation on unsuccessful people. A high need for achievement as measured indirectly through projective material tends to be associated with internalized standards of excellence which lead to superior performance of various sorts in task situations.

Bach, L.M.N., Sperry, C.J., Jr. & Long, R.I. ARTIFICIAL MOONLIGHT PROJECT. SEVENTH TECHNICAL REPORT. Contract DA 44 009 ENG 775, Proj. 8 19 06 001, Sept. 1953, 30pp. Tulane University, New Orleans, La.

4458

This report presents some data on the distribution of illumination from searchlight beam scatter as measured with a physical photometer. Iso-foot candle curves as determined over several distances on three surfaces (parallel to ground and facing sky, perpendicular to ground and facing direction in which searchlight was swung in azimuth, and surface perpendicular to ground facing away from searchlight) are presented. Weather data for those hours during which data were collected are included.

Bach, L.M.N., Sperry, C.J., Jr. & Long, R.I. ARTIFICIAL MOONLIGHT PROJECT. SECOND ANNUAL REPORT. Contract DA 44 009 ENG 775, Proj. 6 18 06 001, June 1953, 15pp. Tulane University, New Orleans, La.

4459

This annual report presents some data on distribution of illumination from searchlight beam scatter and some visual threshold data for the detection of targets under such illumination. Since the report is a continuation of previous reports, there is no discussion of general background. There is discussion of instrumentation problems and presentation of some field measurements obtained with visual photometers of illumination on five surfaces at distances of 3,000, 5,000, 8,000, and 14,000 yards from the searchlight. The visual thresholds were obtained on nine subjects at points 25, 50, and 75 yards in nighttime field trials. Problems encountered in gathering such data are discussed.

4460 Rohrer, J.H., Baron, S.H., Hoffman, E.L., & Swander, D.V. THE STABILITY OF AUTOKINETIC JUDGMENTS. Contract Nonr 47501, Res. Rep., June 1954, 11p. Urban Life Research Institute, Tulane University, New Orleans, La.

The stability of judgmental norms, established as a result of interpersonal interaction was evaluated one year after they were established. The evaluation was made by testing the subjects individually. It was shown that the norms, so established, were stable. Data were presented which showed that social interaction resulted in a rapid modification of response tendencies established in a previous individual training session. The results obtained were interpreted within a reinforcement theory framework.

4463 Blodgett, H.C., Wilbanks, W.A., & Jeffress, L.A. THE EFFECT OF LARGE INTERAURAL TIME DIFFERENCES UPON THE JUDGMENT OF SILENCE. Contract Nonr 52267, DRL A-83, Aug. 1954, 32pp. Defense Research Laboratory, University of Texas, Austin, Texas.

The maximal interaural time difference that could be added to one channel without loss of sidedness was determined for various noise bands. Through the presentation of stimuli by several methods it was found that time values very with frequency of the noise bands, being greater for lower bands. Marked inter-subject differences were found. For the lowest and most effective band used (106-212 ~) times ranged from 7.54 to 20.64 ms.

4464

Sandel, T.T., Teas, D.C., Feddersen, W.E. & Jeffress, L.A. THE LOCALIZATION OF AIRBORNE SOUND. Contract NCBRS 52267, DRL A Rep. 78, Aug. 1954, 22pp. University of Texas, Austin, Tex.

4-54

Three experiments on the localization of sound employing loudspeakers as the sources to be localized were conducted. The first experiment used a single speaker at a time; the second and third used pairs of speakers either in phase or in phase opposition. All three used the same device for indicating direction of signal source--an additional speaker carried by a movable arm and producing a clearly localizable, wideband noise. This source was adjusted in location by the subject until it seemed to be in the same direction as source to be localized. Five subjects were used throughout the experiments. Accuracy of localization and interaural time, intensity and loudness differences were analyzed and discussed. Advantages of the methodology employed were indicated.

Karpovich, P.V. & Hale, C.J. PHYSIOLOGY OF LOAD-CARRYING IV. PRESSURE EXERTED BY PACK STRAPS AS RELATED TO LOAD CARRIED AND CHEST DIMENSIONS. Contract DA44 109.QM 912, Projs. 64 12 001 & 64 12 002, EPB Rep. 213, June 1953, 26pp. USA Quartermaster-Climatic Research Lab., Environmental Protection Branch, Lawrence, Mass. (Physiology Dept., Springfield College, Springfield, Mass.).

4466

To measure objectively the pressure exerted on various parts of the shoulders and chest by pack straps, and to find out the relationship between strap pressure and chest size, the following measurements were made. A special pressure meter was devised to measure strap pressure and used to test 30 male Ss who carried high or low packs weighing from 20 to 70 lbs. while standing still on horizontal, downgrade, or upgrade planes, or walking on the same planes. A mathematical relation between strap pressure and pack weight was established and formulas derived for determining strap pressure in lbs. when pack weight was known. The relation between strap pressure and chest size was studied on 49 men representing a wide range in chest sizes. T. G. I.

4466

Hale, C.J., Coleman, F.R. & Karpovich, P.V. PHYSIOLOGY OF LOAD-CARRYING V. TRUNK INCLINATION IN CARRYING LOW AND HIGH PACKS OF VARIOUS WEIGHTS. Contract DA44 109, QM 912, Projs. 64 12 001 & 64 12 002, EPB Rep. 2161, July 1953, 11pp. USA Quartermaster-Climatic Research Lab., Environmental Protection Div., Lawrence, Mass. (Physiology Dept., Springfield College, Springfield, Mass.).

4466

The effect of low and high packs of various weights on trunk inclination was studied on eight Ss. The loads carried were 0, 20, 40, 60 and 80 lbs. Still pictures were taken while Ss were standing and while walking on horizontal, downgrade, and upgrade planes on a motor-driven treadmill. The speed of treadmill, for walking, was 2.8 mph. During walking, two body positions were photographed: when S's center of gravity was at lowest level and when at highest level. The pictures were analyzed to determine degrees of trunk inclination.

Slade, J.J., Jr., Fich, S., Molony, D.A., Manni, L.F., et al. THEORETICAL AND EXPERIMENTAL RESEARCH IN COMMUNICATION THEORY AND APPLICATION. Contract DA 36 039 SC 42703, Projs. 3 99-12 022 & 17 1329 0, Prog. Rep. 1, March 1954, 25pp. Bureau of Engineering Research, Rutgers University, New Brunswick, N.J.

4470

A progress report of work accomplished on a research program in communication theory and application was presented. Measurements of the characteristics of the random noise generator (described in earlier reports) were made. The study of voice was directed toward the development of electric circuitry capable of continuously determining the frequencies that characterized speech and of synthesizing these frequencies to reproduce speech. A theoretical analysis of several types of coding was made to determine the permissible signal to noise ratio in a system of moment detection having a prescribed bandwidth and speed of signalling.

University of Pennsylvania. UNIVERSAL DIGITAL OPERATIONAL FLIGHT TRAINERS. Contract NONR 55102, Rep. 54 45, June 1954, ca. 200pp. Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia, Penn.

4473

The first phase of research conducted to determine the feasibility of actuating Operational Flight Trainers using a universal digital computer is reported. Two primary developments have been previously reported: 1) development of a stability chart enabling predictions of solutions of flight equations using specified quadrature formulae and quadrature time interval, and 2) the design of a high-speed "sequential" digital computer. In this paper two new quadrature formulae are discussed, the circuits used in the digital OFT are described, changes incorporated into the sequential computer are delineated, flight instrumentation is discussed, and some tests are reported on the essential correctness of the stability chart approach.

T. G. I.

4474

University of Pennsylvania. DESIGN OF DIGITAL FLIGHT TRAINERS. Contract NONR 55102, Rep. 54 08, Prog. Rep. 2, July 1953, ca. 150pp. Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia, Penn.

4474

Progress was reported on research conducted to determine the feasibility of actuating Operational Flight Trainers with a universal digital computer. Major emphasis was placed, during the period reported, on three topics: 1) The logical structure of a serial machine using serial memory has been laid out in almost complete detail, 2) The equations of motion of the F9F airplane have been studied in detail to determine all its possible characteristic frequencies, and 3) a new quadrature method has been synthesized. The results of mathematical studies, the reprogramming of the flight equations, and the logical structure of the serial simulator were described.

Essigmann, M.W., Dolansky, L.O. & Wren, J. VISUAL-MESSAGE PRESENTATION, PART II. SPECIAL EQUIPMENT FOR SPEECH ANALYSIS PURPOSES. Contract AF 19(122)7, Final Rep., May 1945-Feb. 1954. 89pp. Northeastern University, Boston, Mass.

This part of the final report summarizes the design, construction, and test of special equipment developed for speech-analysis purposes. The applications of this equipment are given under Part I (issued separately) of this final report. Equipment covered includes a 12-channel speech spectrograph, an autocorrelator for speech sounds, zero-crossing density meters, 2 different interval filters, an intervalgraph, 2 different squarelaw devices, an electronic function multiplier, an electronic divider circuit, an automatic-amplitude-control circuit, a pitch-period indicator, a mechanical separator for speech sounds, complementary filters, tilting and delay networks, fraction-power filters, a network for harmonic suppression, various types of high-speed cameras, sound ropes, and sound recording and playback devices.

Clark, K.E., Gee, Helen H., Perry, D., Albittz, Diane, et al. MEASUREMENT OF INTEREST PATTERNS. ANNUAL REPORT. Projs. NSCRI 21203 & 212151 248, Task III, Nov. 1953, 87pp. Department of Psychology, University of Minnesota, Minneapolis, Minn.

4479

This part of the final report summarizes the results of theoretical and experimental studies performed during the period from May, 1949, to February, 1954, on the general problems of visual-message presentation and speech compression. Practical details concerned with special equipment for speech-analysis purposes are given in Part I (issued separately). Chapter I defines the general problem under study and provides pertinent background theory. The experimental methods employed and results obtained are given in Chapter II. The last chapter presents conclusions based upon the research and makes specific recommendations for future development of speech-compression systems based upon the phonoid-identification and formant-tracking schemes.

T. G. I. R 132

4482

The several chapters of this annual report describe the work on interest measurement as it has progressed along various lines: 1) description of general scope of project and present status of data collection; 2) summary of work completed on Navy and civilian working keys for the Navy Vocational Interest Inventory; 3) summary of several studies on relation of NWII scores to school achievement in the Navy; 4) a like summary related to on-the-job performance in civilian occupations; 5) comparison of some responses on NWII and the Strong Vocational Interest Blank; and 6) description of methods developed in the project to portray measured interests in profile form with mean profiles given for each of a number of Navy rates.

Chang, S.H., Essigmann, M.W., Pihl, G.E., Stubbs, H.L., et al. VISUAL MESSAGE PRESENTATION. Contract AF 19(122) 7, Quart. Prog. Rep. 16, Feb.-May 1953. 41pp. Northeastern University, Boston, Mass.

Included herein are reports of progress made on the various topics under active study during the period from January 15, 1953 to April 15, 1953. General consideration is given to discussion of specific items involved in the development of a speech-compression system based upon the identification of speech sounds as discrete units. Treated specifically in this connection are a) the automatic determination of the pitch epoch, b) phoneme segmentation, c) the application of discriminatory analysis to vowel identification, d) preliminary results in the identification of fricatives, and e) experiments performed by repeatedly playing back the waveform for a single period of a vowel sound. Also discussed are various topics related to the compression system. These include: a) linguistic studies involving the consideration of phoneme clusters, an international language for air, and some descriptive parameters of fricatives; and b) theoretical study of the joint distribution W_2 as applied to sine waves and Gaussian noise. Descriptions are given of progress made in the construction of certain apparatus for use in speech analysis; namely, a network for harmonic suppression, an anechoic chamber, a pitch-period indicator, a divider circuit, and a high-speed camera for recording the details of speech waveforms.

Fenning, W.H., Jackson, P.L., & Kelley, R.J. REFERENCE SOURCES IN THE PHYSIOLOGY OF EXTREME ENVIRONMENTAL TEMPERATURES. Contract DA 20 018 ord 13146, Proj. TTI 696, Rep. 2167 2 P, May 1954. 59pp. Engineering Research Institute, University of Michigan, Ann Arbor, Mich.

A short discussion and conclusions are presented concerning articles and reports on which the recommendations of physiological criteria for evaluating systems for heating, cooling, and ventilating combat tanks are based. The reports found to be most pertinent are listed, together with short abstracts of their content. 2 sets of recommendations are made. The first set, specific to the present project, suggests the following objectives in designing a system: a) Maximum operational efficiency of the crew should be the primary overall objective; b) No attempt should be made to control relative humidity; c) Air-ventilation rate should be as recommended by the Office of the Surgeon General: 250 cubic feet per minute per man; d) An attempt should be made to keep air velocities below 100 feet per minute; e) in the high extreme ambient range the compartment should be cooled to a minimum of 85°F with a maximum of 90°F; f) in the low extreme ambient range, the compartment should be heated to a minimum of 20°F with a maximum of 25°F. The second set of recommendations, pertaining to future physiological research, suggests the following projects to be conducted by qualified people: a) Experimentally determined ventilation requirements in the tank crew compartment; b) Determination of the effects of radiation between the human body and the vehicle walls; c) Determination of the extent of mutual aggravation of all the annoyances in tank operation, and the conduction of a more extensive literature search, with emphasis on foreign sources and discussions.

Neel, R.G. NERVOUS STRESS IN THE INDUSTRIAL SITUATION. Contract No. ONR 232, presented at the American Psychological Association Meeting, New York, N.Y., Sept. 1954, 14pp. American Psychological Association, Washington, D.C.

4492

To point up some of the factors within the industrial situation which relate to the nervous tension and worries of the employee, data are presented here that represent a small part of a study of psychological factors related to morale and productivity in a heavy equipment manufacturing industry. A one-third sample of the hourly workers (N=5703) is used for analysis. The data were obtained by a questionnaire designed to get at nervous tension and worry. For a criterion measure, answers to a "jumpy-nervous" item were dichotomized and correlated with a number of questions concerned with attitudes toward foremen, work group, working conditions, productivity system, etc.

Whittenburg, J.A. INDICATORS OF BEHAVIOR DECREMENT. A FURTHER EXPERIMENTAL INVESTIGATION OF PERCEPTUAL EFFICIENCY DURING SUSTAINED VIGILANCE. Proj. DA 19 007 MD 222 (OI 19 52), Tech. Rep. 17, ca. 1953, 40pp. Dept. of Psychology, University of Maryland, College Park, Md.

4495

In an investigation on the effects of sustained vigilance on perceptual efficiency, this study was made to provide information concerning the nature of behavior that is measured by the Mackworth Clock Test. Each of 13 Ss performed twice under two experimental conditions: 1) response was made only to occurrence of variable stimulus (double jump of pointer); and 2) response was made to both variable and standard (single jump) stimuli. Each S was tested approximately three hours on each condition. Three dependent variables were used: errors of omission or failure to detect stimulus, critical flicker frequency, and stress experience inventory. Error data were analyzed for individual differences and all scores were studied for relationships with each other.

Katchmar, L.T. A REVIEW AND ANALYSIS OF THE CONCEPT OF STRESS AND RELATED VARIABLES. Contract DA 49 007 MD 222, Tech. Rep. 16, Feb. 1954, 49pp. Psychology Dept., University of Maryland, College Park, Md.

This study was designed to determine the effects of 2 types of stress and manifest anxiety on performance of a perceptual task. The 2 types of stress used were task induced stress and failure stress. The perceptual task was a repetitive color naming at high speed. Performance on this task, as measured by errors of omission, was analyzed for groups of subjects and individuals treated differentially with respect to the independent variables used. 27 college students scoring extremely high, and 27 scoring extremely low on a modified form of the Taylor Scale of Manifest Anxiety, were selected as subjects. 3 subjects from each group performed the color naming task under a combination of one of 3 task induced stress conditions and one of 3 failure stress conditions. Each subject was also given a Stress Experience Inventory immediately after performance on the task. Ratings of the inventories, by trained judges, were also analyzed for groups of subjects operating under the different experimental conditions. The results indicate that task induced stress conditions exhibit a positive relationship with performance as measured by errors of omission; whereas, failure stress conditions exhibit a curvilinear but generally increasing relationship with performance. Anxiety appears to increase susceptibility to the effects of stressful conditions.

Davidson, W.Z. THE EFFECTS OF TWO TYPES OF STRESS AND ANXIETY ON PERFORMANCE OF A PERCEPTUAL TASK. Contract DA 49 007 MD 222, Tech. Rep. 19, Aug. 1953, 44pp. Psychology Dept., University of Maryland, College Park, Md.

This present report was prepared as a background literature review for the Technical Reports Nos. 17, 18, 19, 20, 21, 22 and 23. An attempt has been made to present some of the current conceptions of stress as it is related to motivation and various personality variables. In addition to presenting the recent experimental studies, stress for this review has been defined as an intervening variable, and conceived of as an internal process of the organism which is manifested as an equilibrium seeking response, occurring in the psychological context when the objective situation is cognitively evaluated as one involving a goal, the attainment of which is thwarted, or interpreted as being thwarted. In its maximal form stress is produced when the thwarting of the goal produces a threat to the individual. Motivation in such a definition is, of course, a basic assumption. In view of the discussion and studies presented above we can state that objectively defined stress situations produce impairment in performance on a wide variety of tasks. This impairment has been shown to be related, to some degree, to personality characteristics such as anxiety and rigidity. These personality variables have been found to act, as sensitizers in stress effects. Characteristic of most stress studies is the wide individual difference found. The study of personality variables is an approach to reducing these individual differences. With further work in this area it may be possible to make fairly accurate predictions for individual reactions to stress. More systematic studies with respect to types of stress are needed in this area.

Revis, S.W., Elmudjian, et al. A STUDY OF COMBAT STRESS, KOREA, 1952. PRELIMINARY REPORT. Proj. SAS 6 FAST, Tech. Memo OMD T 41(FEC), Dec. 1952, 203pp. Operations Research Office, Johns Hopkins University, Baltimore, Md.

This report presents a preliminary examination of data gathered by a field team composed of physiologists, psychologists, and one psychiatrist. Physiological and psychological tests were conducted on a group of 23 soldiers at Camp Oniz, Japan; on 24 infantrymen in Korea who were in reserve behind the MRL; on 35 men from an infantry company which led a major assault; and on 13 men from another that had just returned from 5 days active combat. Preliminary findings, pending final treatment of the data, show these general conclusions: Analysis of blood and urine specimens show definite physiological changes occurring as a result of combat. Physiological disturbances resulting from the effects of psychological stress were found to be dehydration and an almost total absence of certain types of adult white blood cells. The adrenal gland, particularly the adrenal cortex, functions normally in the front-line infantryman not in active combat, but shows a high level of adrenal activity following severe combat stress.

Conlay and Associates, Inc. HUMAN ENGINEERING EVALUATION OF THE FERRAND STAR TRACKER. Contract NMR 17719, Mon. Rep. 3, April 1957, 6pp. Conlay and Associates, Inc., Stamford, Conn.

4503

The Ferrand Star Tracker has been evaluated from the human engineering viewpoint in order to identify human operator sources of error in the navigation system. Techniques are suggested for minimizing these errors through design changes in the 1) TV tube display, 2) tracking control, and 3) console design.

4506

Fattor, M.A. & Standlee, L.S. ANALYSIS OF READING DIFFICULTY OF SELECTED NAVY MATERIALS. Contract NMR 90801, Tech. Bull. 54 3, March 1954, 53pp. Institute of Educational Research, Indiana University, Bloomington, Ind.

4506

In order to ascertain the reading difficulty of certain materials used for training in the Navy, a basic training text, a "house organ," some specialized training manuals, and an instructor's manual were analyzed according to the Flesch readability formula. The scores assigned to these materials are discussed with respect to the reading ability of marginally literate and average recruits. Rules for improvement of the readability of training texts are given and illustrated.

Standlee, L.S., Fattor, M.A. & Able, D. FREQUENCY INDEX OF WORDS APPEARING IN FOUR NAVY PUBLICATIONS. Contract NMR 90801, Tech. Bull. 54 2, Jan. 1954, 158pp. Institute of Educational Research, Indiana University, Bloomington, Ind.

4507

A frequency count of words appearing in four Navy publications was performed. Frequency in each publication and mean frequency is tabulated for the 503 most common words in the 121,931-word sample. The relevance of this count to the presentation of instructional materials for a literacy training program is noted.

Fritz, E.L. & Grier, G.N., Jr. EMPIRICAL ENTROPY: A STUDY OF INFORMATION FLOW IN AIR TRAFFIC CONTROL. Contract DA 36-039-SC-56695, Rep. R-54, March 1954, 21pp. Control Systems Laboratory, University of Illinois.

4510

To study information transfer between pilots and tower controllers during landings at an Air Force training base, verbatim transcriptions of the radio messages over a period of several weeks (approximately 100 hours) were made. The messages were broken down into "information elements" and the dependent probabilities of these elements computed. The analysis required the development of new methods which are discussed. The findings on rate of information transfer and redundancy are discussed in relation to other studies on human information-handling capacities.

LBY, W.W. SUMMARY OF CLIMATIC EFFECTS ON RAILROAD OPERATION, MAINTENANCE, AND CONSTRUCTION. Section 2 on Climatic Criteria Defining Efficiency Limits for Certain Industrial Activities. Contract AF 19(605) 416, ca. 1954, 35pp. University of Illinois, Urbana, Ill.

This report presents a summary of the effects of climate on railroad operations. The following conclusions are drawn: a) Railroads, if properly maintained and operated, can function under any known conditions of the inhabited lands of the world. b) All climatic conditions are capable of producing nominal delays of a few minutes to several hours. These can develop into major tie-ups if proper maintenance and operation are not maintained. c) Very severe floods, hurricanes, and tornadoes can block a railroad for a month or more by destroying bridges, or, in the case of floods, washing out long stretches of track and subgrade. d) Tracks may be blocked for several days to a week by a combination of heavy snow, fall, high winds, and low temperatures. (Without sufficient equipment, especially rotary plows, lines may remain closed for over a month.) e) The conditions of items c and d occur infrequently. f) Modern designs of equipment and maintenance and operating methods are making railroads less and less susceptible to the effects of climate. g) Railroads, especially those with modern operation and dense traffic, are especially susceptible to loss of communications, be it from flood, fire, wind, or ice storms.

4513 May, W.V. THE EFFECT OF LOW TEMPERATURES ON RAILROAD OPERATIONS. CLIMATIC CRITERIA DEFINING EFFICIENCY LIMITS FOR CERTAIN INDUSTRIAL ACTIVITIES. Contract AF 19(604)16, 1954, 41pp. University of Illinois, Urbana, Ill.

This report presents the effects of low temperature on railroad operation insofar as these can be isolated from the combined effects of snow, wind and cold. The following conclusions were drawn: a) cold weather will not of itself halt or even slow down rail movements; b) cold effects on freight and locomotives, ice formations, broken rails, etc. will occur and cause delays and tie ups; c) the principal adverse effects of cold weather are reduced train tonnage, hard-rolling cars in yard operation and frozen switches; d) train tonnage are reduced proportionally from no reduction at 30 F. to 50% reduction at 40 F.; e) outdoor personnel can work only in emergencies below 40 F. Their efficiency decreases at about the same rate as locomotive tonnage ratings; f) once a sub-zero condition becomes stabilized there is little more difficulty with switches, rails, etc. until a thaw occurs. (MEIAS)

4515 Beach, C.K., Paolucci, D.J. & Milano, J.E. THE DEVELOPMENT OF A MULTI-PURPOSE ANALYSIS TECHNIQUE FOR NAVY RATINGS. Contract NMR 401(10), Tech. Bull. 53 1, Part 1, Oct. 1953, 163pp. Personnel Analysis Div., USN Bureau of Naval Personnel, Washington, D.C. (New York State School of Industrial and Labor Relations, Cornell University, Ithaca, N.Y.).

4515 The development of a multi-purpose analysis procedure for the Gunner's Mate Billet is described. Particular emphasis is placed on data collection for maintenance, casualty diagnosis and rectification procedure, and operational sequences of new weapons in the field of ordnance. The three-inch/50 Rapid Fire Twin Mount was selected as the vehicle for study. Based on the expressed needs of current and potential consumers within the Bureau of Naval Personnel, methods, instruments, and techniques were developed and applied in the field. Results include a detailed breakdown of weapon casualties in terms of frequency, casualty analysis, rectification procedure, time requirements, personnel proficiency, battle station assignments, etc.

4516 Kuhn, L.A. ELECTROCARDIOGRAPHIC STUDIES OF NORMAL MEN HOUSED AT DIFFERENT SHELTER TEMPERATURES AFTER VARIOUS GRADES OF WORK IN ARCTIC AND TEMPERATE CLIMATES. Projs. 6 64 12 028 & 6 61 12 004, Rep. 160, Jan. 1955, 32pp. USA Medical Research Lab., Fort Knox, Ky.

To investigate the effects of exercise in the cold on electrocardiograms, seven normal subjects were studied in an arctic climate. Electrographic records were made at rest both indoors and outdoors, following twelve minutes of standard exercise equivalent to march rate of 3.5 to 4.0 miles per hour, following twelve minutes of exercise at double the usual rate, and after modified "Hess's Tests." The same tests were performed in a temperate climate preceding and following the arctic tests. The subjects lived in shelter temperatures of either 30° or 70° Fahrenheit. The electrocardiograms were analyzed for effects of cold exposure and shelter temperature following various grades of work. The findings are related to previous studies and recommendations for further work are made.

4517 Leco, R.D. A SURVEY OF THE THEORY OF SELECTIVE INFORMATION AND SOME OF ITS BEHAVIORAL APPLICATIONS. Contract CG 10 54 WDR 264(21) BASR, Proj. MR 042 115, Tech. Rep. 8, June 1954, 137pp. Bureau of Applied Social Research, Columbia University, New York, N.Y.

4517 This document presents a synopsis of the discrete theory of selective communication. The presentation is most deeply influenced by Shannon's work, although there has been some departure from it. The second part of the report is concerned entirely with applications of the theory to problems in psychology: the entropy in printed English, distribution of words in a language, the capacity of the human being and rates of information transfer, reaction time and information transfer, visual threshold and word frequencies, the information transmitted in absolute judgments, sequential dependencies and learning, concept formation, and other such categories. A short summary of Shannon's theory of continuous communication systems is appended.

4521 Royle, L.J., Mopoe, P. & Nayer, Sylvia R. A STUDY OF TWO TESTS FOR DISCRIMINATION OF PROFICIENT PHOTO-INTERPRETER STUDENTS. Contract AF 33(616) 455, Tech. Note 114, Aug. 1953, 37pp. Optical Research Lab., Boston University, Boston, Mass.

2 objective tests have been developed in an attempt to measure certain visual skills judged to be relevant to photo-interpretation. The reliability and validity of the tests are discussed, and some general remarks on the photo-interpretation career specialty are included. The results of the reliability study revealed satisfactory consistency and discrimination indices and it was noted that the tests' discriminative capacity might be further improved if they were administered under speed rather than power conditions. In the validity study, 2 questions were posed: a) Do scores on these tests differentiate proficient from nonproficient photo-interpreter students? and b) Is performance on these tests affected by training in photo-interpretation? In connection with the latter question, no evidence was found to indicate that the perceptual skills measured by the tests were increased as a result of training. The results of the study did indicate, however, that the tests were able to differentiate proficient from nonproficient photo-interpreter students, at least when such proficiency is independently measured by the ratings of school instructors. In the final section, some features affecting the career status of photo-interpretation, and how these relate to preference for training in photo-interpretation and the high turnover among trained photo-interpreters, are presented for consideration.

Mayer, Sylvia P. THE EFFECT OF INDUCED EFFORT, TRAINING AND DRAWING ON VISUAL ROOM LEARNING. Contract AF 33(616) 432, Tech. Note 115, Sept. 1954, 49pp. Optical Research Lab., Boston University, Boston, Mass.

4522
A study was made of the effectiveness of several techniques for training in target identification. The techniques differed in kind of effort and amount of effort employed during the learning of targets: 1) "task-related" effort involved observation, tracing, and drawing of targets; and 2) "task-unrelated" effort was induced in various degrees by use of a hand dynamometer. Identification tests were given after two- and ten-minute intervals. Conditions for maximum retention were identified. The effect of effort was further analyzed with respect to structural complexity of target, nature of identification errors, and individual differences. The findings were discussed in relation to photo- and radar interpretation training.

Neely, K.K. ACOUSTIC PROPERTIES OF HEADGEAR: II. HELMETS LTD. HEADGEAR ASSEMBLY. DRAC Proj. 100 43 72, DRAC Rep. 100 3, P.C.C. 077 82 30 04, April 1954, 18pp. Reference Research Medical Labs., Toronto, Ontario, Canada.

4528
To determine the acoustic insulation properties and the listener-intelligibility properties of crash and inner helmets manufactured by Helmets, Ltd. and General Textile Mills, Inc., two series of tests were run. In the first test, the open-ear threshold of hearing for nine test tones was determined for 15 Ss and compared with thresholds obtained while wearing the various items of headgear. In the second test, six Ss responded to intelligibility tests while wearing the headgear items with a noise level of 110 db. The data from these tests were analyzed for differences attributable to the headgear worn.

Loveless, N.E. MANUAL TRACKING IN THE FOUR QUADRANTS OF A CIRCULAR SCALE - III - LEFT AND RIGHT QUADRANTS. Rep. FPRC 886, July 1954, 13pp. Flying Personnel Research Committee, London, England. (University of Durham, (King's College, Newcastle-on-Tyne) England).

In a compensatory tracking task, Ss were required to control the pointer on a circular scale. 2 targets and 2 display control connections, direct drive and reversed drive, were used. Each S was tested under all 4 experimental conditions. It was found that speed and accuracy are greater with direct than with reversed drive. Superior performance was found on the left-hand target with direct drive. The differences in performance under the 4 conditions tested are attributed to the combined effects of 2 direction-of-motion expectations which may summate or conflict. The dominant tendency is to expect a clockwise movement of the control to result in a clockwise movement of the pointer. There is also a tendency to expect a clockwise movement of the control to move the pointer upwards. It is recommended that direct drive be used for greatest speed and accuracy. (HEIAS)

Zweigbaum, H. HUMAN ENGINEERING EXPERIMENT ON ELECTRON TUBE TEST SET TV 2/U. Proj. Nr 20518 & DA Proj. Nr 3 27 01 013, Tech. Memo. M 1642, April 1955, 6pp. USA Signal Corps Engineering Labs., Evans Signal Lab., Fort Monmouth, N.J.

Consideration of the man-machine relationship involved in the operation of Electron Tube Test Set TV-2/U led to the design of a statistical experiment to ascertain whether or not undue reliability was being placed on the precision of measurement obtained by a normal class of operators. The experiment was carried out with the cooperation and assistance of personnel of the Tobyhanna Signal Depot. Measurement data were obtained by 2 classes of operators, laboratory personnel whose readings were used as a standard of comparison, and depot personnel who had received both instructions in the use of the instrument and several weeks time for familiarization in its operation. Analysis of the components of variance indicated that major contributions to variation in results were those due to lack of reproducibility within a class of operators. Applying an F test to either confirm or deny the hypothesis of equal precision of classes resulted in an unqualified denial of the tenability of this hypothesis.

Brogle, A.P. THE HUMAN BEING AS AN ELEMENT IN CONTINUOUS CONTROL SYSTEMS. Proj. Nr 1544 & DA Proj. Nr 3 29 04 100, Tech. Memo. M 1605, Sept. 1954, 21pp. USA Signal Corps Engineering Labs., Fort Monmouth, N.J.

The similarity in structure of a servo system and the man-machine system is of importance in all areas of human engineering and is fundamental to the study of the control aspects of the human being. Starting with a brief review of the characteristics of any servo-mechanism, a generalized model of the man-machine system is formulated. Considerable attention is devoted to a discussion, from an engineering viewpoint, of the basic functions which the human employs to perform as an integral part of the control system and to the possible forms of man's composite transfer function. From this analysis, a general approach to man-machine design is stated and the applications of the method to manual tracking systems and to flight control systems are illustrated.

Clark, B. & Graybiel, A. DISORIENTATION: A CAUSE OF PILOT ERROR. BuMed & Surg. Res. Rep. NM 001 110 100.39, March 1955, 82pp. USN School of Aviation Medicine, Pensacola, Fla.

This report which is written primarily for flight surgeons summarizes and organizes a large number of studies bearing on disorientation (vertigo) in aircraft pilots. It is organized in terms of the perceptual processes which lead to proper orientation and disorientation in flight and attempts to show their relation to the pilot's task. Disorientation in flight is considered to be due to psychophysiological causes which should be regarded as the inevitable consequence of placing man in a task for which he is not fitted either by endowment or past training. An attempt is made to present explanations of pilots' experiences with disorientation in psychophysiological terms. Some suggestions are made to prevent disorientation and to deal with it when it does occur.

Miller, J.W. & Ludwig, E. A SHORTENED PROCEDURE FOR THE TESTING OF DYNAMIC VISUAL ACUITY. Contract Monr-586(00), ONR Proj. Des. No. NR 142-023, Proj. NM 001 110 501.08. May 1955, 12pp. U.S. Naval School of Aviation Medicine, Pensacola, Fla.

4537

To test the feasibility of shortening the procedure of testing dynamic visual acuity from a forty-five minute test to a twelve-minute test, the data on 200 subjects who were tested by the longer procedure were re-analyzed on the basis of a twelve-minute test. The correlation between results with the two methods as well as the reliability and predictability of each method was computed. The effect of shortening the test on learning curves was also examined. Conclusions about the worth of the short test are stated.

French, G.N., McPhaul, Mary V., & Melton, R.S. SOME EFFECTS OF PHYSICAL TRAINING ON BREATHING, OXYGEN CONSUMPTION, AND OXYGEN EXTRACTION DURING MODERATE EXERCISE. Res. Rep. No. NM 001 105 100.02, June 1955, 5pp. U.S. Naval School of Aviation Medicine, Pensacola, Fla.

Respiratory studies were done on 10 naval aviation cadets during a standard exercise both before and after 3 months of the pre-flight physical training program. It was found that minute ventilation and oxygen consumption were diminished after training but that the per cent oxygen extraction was not altered. 10 enlisted subjects, judged to be relatively unfit physically compared to the cadets, were tested with the same task. Their ventilation was higher and oxygen extraction smaller than the cadets. The enlisted subjects varied more widely in their ventilatory response to exercise than the cadets. The enlisted group and the cadets, both before and after training, showed mean decreases in ventilation with shift to oxygen breathing during exercise. The enlisted group showed a larger ventilatory change in this respect than the cadets. The ventilatory response of the cadets to oxygen breathing was not altered greatly by the training. There was a significant inverse correlation between oxygen extraction and the amount of diminution in ventilation when breathing oxygen.

Black, J.W. & Tolhurst, G.C. THE RECEPTION OF REPEATED SPEECH SIGNALS. Contract N6onr 22525, Proj. Des. NR 145 993, Proj. NM 001 104 500.48, April 1955, 13pp. USN School of Aviation Medicine, Pensacola, Fla. (Ohio State University, Columbus, Ohio).

Recorded monosyllables, comprised of consonant-vowel-consonant (CVC), in a variety of permutations, listened to simultaneously through a direct playback and a delay channel, were found to be successively relatively intelligible and unintelligible depending on different values of delay times. Words, when delayed with a single 0.06 second delay time, were improved in intelligibility only when the direct and delayed channels fed, dichotically, the 2 ears separately. Words were more intelligible when repeated one by one than when the same words were repeated in groups of 3 simulating a connected phrase utterance. These word groups when repeated were no more intelligible than single renditions of the separate words.

4547 Freeman, S., Petty, D.T., Last, J.H., & Faller, Inga L. TOTAL BODY WATER IN MAN: ADAPTATION OF MEASUREMENT OF TOTAL BODY WATER TO FIELD STUDIES. Contract DA 44 109 OH 729, Proj. 7 64 12 002, EPD Tech. Rep. EP 11, July 1955, 27pp. USA Quartermaster Research & Development Command, Environmental Protection Division, Natick, Mass. (Northwestern University, Evanston, Ill.).

A critical comparison was made between the heavy water (D_2O) and antipyrine (ANP) methods for measuring body water. In addition, comparisons were made between values obtained from intravenous and oral routes of administration for each method for the purpose of developing a field method of determining total body water (TBW). It was found that: a) The D_2O space was significantly larger than the ANP space. In 10 non-adipose V.A. Hospital patients, the ratio of D_2O to ANP was 1.06 ± 0.03 ; in 21 healthy U.S. Army soldiers, it was 1.08 ± 0.07 . b) The D_2O space was more reproducible on repeated determinations than was the ANP space. In cases of abnormal water distribution, the time for equilibration of D_2O was prolonged up to 6 to 24 hours, while ANP did not reach equilibrium even after 24 hours. c) Oral ingestion of D_2O can be substituted for intravenous injection, and urine samples can be substituted for blood in measurement of TBW. In 15 subjects the ratio of urinary D_2O space to serum D_2O space was 1.06 ± 0.02 . From these findings a simple field method for determining TBW is outlined in which subjects drink a known amount of D_2O and urine collected after 5 hours of water as has been suggested by other workers. It is concluded that the D_2O method of determining TBW is more reliable than is ANP in "normal" individuals, but that neither method is reliable in situations of deranged body water distribution. A simple field method has been found for determining TBW in which venepunctures are completely eliminated.

4549 Baker, P.T., Daniels, F., Jr., Byron, R.F., & Munro, Ella H. RELATIONSHIP BETWEEN SKINFOLD THICKNESS AND BODY COOLING AT 59°F. Proj. 7 64 12 001, Tech. Rep. EP 14, July 1955, 21pp. USA Quartermaster Research & Development Command, Environmental Protection Division, Natick, Mass.

This study was designed to test the relationship between body fat and body temperatures when men are subjected to a cool environment. 31 men were exposed to an ambient temperature of 59°F. (15°C.) for 2 hours. They wore only shorts and were seated for the total period. Rectal and skin temperatures were recorded at 10-minute intervals. It was found that fat, as measured by skinfold callipers, bore a strong relationship to both rectal and skin temperatures. The greater the percent of fat in the body, the lower the skin temperatures. The correlations were closer between skin temperature and skinfold thickness in specific areas than between skin temperature and the calculated percent of fat in the body. The difference between one and 19 percent body fat made 5.9 degrees (F.) difference in the minimum mean weighted skin temperature. The correlation between minimum rectal temperature and percent of fat was high: the fattest men maintained near normal rectal temperatures, while the thinnest men had rectal temperatures 1.2°F lower. The examination of stature and fat-free weight correlations indicated that the primary relationship of fat to rectal temperature was modified by variations in body surface area.

Lichtenberg, P. & Deutsch, M. A DESCRIPTIVE REVIEW OF RESEARCH ON THE STAFF PROCESS OF DECISION-MAKING. Contract AF 18(600) 404, Proj. 505 036 0004, AFPTC TR 54 129, Dec. 1954, 50pp. USAF Crew Research Lab., Randolph AFB, Tex.

4556

This report presents a digest of research materials that might have pertinence to the central problems of the staff process of decision-making. It is organized under six topic headings: group vs. individual effort, size of group, leadership, coordination as a problem, motivation, and gaps in the literature. The digest emphasizes primarily the experimental social-psychological literature, although there are some items of a more general sociological and social anthropological nature.

McPherson, J.H. PREDICTING THE ACCURACY OF ORAL REPORTING IN GROUP SITUATIONS. Contract AF 18(600) 5, Proj. 505 040 0004, AFPTC TR 54 130, Dec. 1954, 84pp. USAF Officer Education Research Lab., Maxwell AFB, Ala.

4557

This bulletin describes a study of the accuracy of reporting on assigned materials in a course at the Air University. A Reading Distortion Test and a Reactions to Group Situations Test were used to predict which men would be most likely to distort the content of assignments in making oral reports to groups. The tests were given to 100 men. Eight men predicted to be high in distortion and eight predicted to be low on the basis of these tests were then observed as they discussed specially prepared readings in class. Different patterns of behavior tending to bear out the predictions are discussed.

Houston, R.C., Smith, J.F. & Flexman, R.E. PERFORMANCE OF STUDENT PILOTS FLYING THE T-6 AIRCRAFT IN PRIMARY PILOT TRAINING. Proj. 508 016 0002, AFPTC TR 54 109, Dec. 1954, 98pp. USAF Basic Pilot Research Lab., Goodfellow AFB, Tex.

4558

This paper sets forth an objective method for recording performance in flight. Experienced instructor pilots entered on Performance Record Sheets the data furnished by 168 Air Force student pilots at five levels of Primary Pilot Training on 524 different flight checks. Results are presented as frequency distributions of performance values for each item on the Sheets. The implications of this method for the assessment of proficiency are noted.

Fleishman, E.A. EVALUATIONS OF PSYCHOMOTOR TESTS FOR PILOT SELECTION: THE DIRECTION CONTROL AND COMPENSATORY BALANCE TESTS. Proj. 7701, AFPTC TR 54 131, Dec. 1954, 28pp. USAF Skill Components Research Lab., Lackland AFB, Tex.

4559

As part of a continuing effort to develop new apparatus tests that might measure more efficiently the psychomotor skills important to pilot success, two promising tests (Direction of Control, and Compensatory Balance) were administered to over 1200 unclassified pilot cadets along with the complete Aircrew Classification Battery. Reliabilities, distribution statistics, internal consistencies, validities (pass-fail criterion data for primary stage of flying training) and correlations with other Air Force classification tests were computed. The contribution to be expected from the tests if added to the Battery was studied. Complete test descriptions, wiring diagrams, instructions, and stanine tables are given.

Mulsin, F.R. RESPONSES OF MAN TO A HOT ENVIRONMENT. Rep. 139, Dec. 1948, 61pp. USA Office of Quartermaster General, Environmental Protection Section, Washington, D.C.

This paper has been confined to the problem of heat stress, as it is likely to affect soldiers in the tropics. The evidence shows that, from this point of view alone, full clothing is often a disadvantage, and that the uniform should be reduced in amount, and opened to ventilation as far as possible. The design of clothing is complicated by questions of convention and by the need for protection from insects and thorns, which exist in some parts of the tropics. Progress in the study of these related matters bears directly on the clothing problem; for instance, the discovery of a highly effective and permanent insect repellent would do much to simplify and to lighten tropical dress and equipment. This paper suggests several questions which could be made objects of further research with probable benefit to the Army. Among them are the merits of alternative uniforms, the permeability of textiles to water vapor when dry and when wet, the effect of solar radiation on underlying tissues, and the nature of the peculiarities which distinguish heat tolerant individuals from others.

Biser, E. HUMAN ENGINEERING. Signal Corps Proj. 122A, Dept. Army Proj. 3 99 05 021, Tech. Memo M 1477, Dec. 1952, 47pp. Signal Corps Engineering Lab., Department of the Army, Fort Monmouth, N.J.

Human engineering is concerned with analyzing the elements that serve as connecting links between the human and mechanical parts of the man-machine system. The task of the human engineer consists of keeping the operation of the machine within the optimal thresholds of the human sensory and motor capabilities and of eliciting proper operator-responses to facilitate a high level of performance. The design of instruments should be undertaken with a careful study and consideration of the limitations of the motor and sensory capacities of the operator. The design engineer should possess adequate knowledge of the human factors involved in the use and operation of instruments, such as reaction time, the effects of fatigue on the operator, the number of stimuli to which a sensory organ will give the desired response, etc. The instrument engineer should be concerned with such items as: how often the instrument is to be used, where it is to be placed, who is to use it, and how the information is to be utilized.

Clarke, H.H. IMPROVEMENT OF OBJECTIVE STRENGTH TESTS OF MUSCLE GROUPS BY CABLE-TENSION METHODS. Res. Quart. Amer. Assoc. Phys. Educ. Res., 21(4), 399-419. (Physical Education Research Lab., Springfield College, Springfield, Mass.).

This is a report on the improvements of objective strength tests of muscle groups by cable-tension methods. Basically the old methods and their disadvantages are described along with the new methods and their advantages. The major changes in test procedure consist of alternate body positions, the selection of proper joint angles, the location of strap positions and the taking into account of the effect of gravity on the measurements. Clarke, H.H. SINGLE BOUT ELBOW FLEXION AND SHOULDER FLEXION ERGOGRAPHY UNDER CONDITIONS OF EXHAUSTION TESTING. Arch. Phys. Med., April 1953, 240-246. (Springfield College, Springfield, Mass.).

In this research, procedures necessary to achieve precision in single-bout elbow flexion and shoulder flexion ergography under conditions of exhaustion testing were investigated. Objectivity coefficients between 0.75 and 0.85 were obtained for these tests. Inasmuch as the muscle-conditioning effect of repeated exhaustion bouts was found to be pronounced and was not compensated for in the study, these results were considered satisfactory. The essential feature in achieving precision in single-bout ergography was in determining the proper load to place on the ergograph carriage. These loads may be determined objectively for each individual as a proportion of the strength of the muscles directly involved in the movement. For the SS utilized in this research and with an 8-in. ergograph lever arm, the proportions were: 3/8 of elbow flexion strength for elbow flexion ergography; and 5/8 of shoulder flexion strength for shoulder flexion ergography. The greater proportion required for the shoulder flexion movement is attributed to the fact that the muscles are able to exert their greatest strength when the shoulder is fully extended; for elbow flexion, this position is between 100 and 140°, with a 20% decrease in strength at the extended position.

Clarke, H.H. MUSCULAR STRENGTH-ENDURANCE OBSERVATIONS FROM SINGLE-BOAT ERGOGRAPHY. *J. Assoc. phys. mental Rehabilitation*, Jan.-Feb. 1953, 2(1), 4pp. (Physical Education Research Lab., Springfield College, Springfield, Mass.).

The Kelso-Hellbrandt ergograph was used to determine the endurance of the elbow flexor and shoulder flexor muscles. 64 Ss were used. The following conclusions were drawn: a) the amount of weight required to induce exhaustion in a relatively short time varies from individual to individual, depending on the strength of the muscles. The amount of weight for each S to lift may be determined objectively as a proportion of that strength; b) the work output of muscles in exhaustion performances is greater when in positions to apply greatest strength at the point of greatest stress; c) even with a limited number of exhaustion bouts, the training effect, as determined by the increased distance the ergograph load can be moved, is definite and positive. (HEIAS)

Clarke, H.H. & Bailey, T.L. STRENGTH CURVES FOR FOURTEEN JOINT MOVEMENTS. *J. phys. mental Rehabilitation*, Apr.-May 1950, 4pp. (Physical Education Research Lab., Springfield College, Springfield, Mass.).

Research was conducted to assess the amount of muscle strength that is applied throughout the range of motion of certain joints. 14 movements of the joints were investigated. It was concluded that a muscle exerts its greatest power when it functions at its greatest tension, that the angle at which the muscle pulls is of importance, that the mechanical arrangement of the levers sometimes interfere with the full application of strength, even though the muscle may be at their greatest length, and that there probably is an optimal position in which each muscle group functions the best. Clarke, H.H. PRECISION OF ELBOW FLEXION ERGOGRAPHY UNDER VARYING DEGREES OF MUSCULAR FATIGUE. *Arch. phys. Med.*, May 1952, 33, 279-288. (Springfield College, Springfield, Mass.).

Research was undertaken to determine the precision with which ergographic testing of the elbow flexion muscles can be accomplished. Ss were 31 physical ed. majors. The Kelso ergograph was used in muscular fatigue testing. The following results were obtained: a) High degree of precision was obtained under conditions of mild to moderate muscular fatigue; b) Any length lever arm may be used with consistent results; c) The effect of practice was slight when fatigue did not reach exhaustion states; d) Precision was maintained when weight loads were increased, provided 30 min. rest periods between trials were allowed and the fatigue induced fell short of exhaustion; e) Precision of ergographic testing was reduced when exhaustion states were reached. The objectivity coefficient of .78, however, is high enough to suggest that precision procedures might eventually be achieved. (HEIAS)

Stockbridge, H.C.W. & Draper, J. THE VALIDATION OF AN APPARATUS FOR MEASURING THE STEADINESS OF AIM OF A RIFLE. CEPRE Rep: 14, 1954, 15pp. Clothing and Equipment Physiological Research Establishment, Directorate of Physiological and Biological Research, Ministry of Supply, Great Britain.

This validation is an attempt to estimate how much Spring's apparatus for measuring the steadiness of aim of a rifle affected marksmanship, as measured by grouping scores. The assumption made in the present experiment is that if similar scores are obtained with normal fire and with the apparatus then the tremor pattern preceding a normal shot is similar to the pattern using the apparatus. The calibration of the apparatus and the readings taken with it to check an aiming experiment are also discussed. 2 Ss were selected for their good shooting. They each fired 40 rounds grouping, and, on the following day, 40 rounds application. On each occasion the S fired with and without a mirror attached to his rifle, over and without the remainder of the apparatus, 4 conditions in all. X and Y axes were marked on the 2 targets used and the coordinates of each point of impact recorded. The range was 100 yards. The data was subjected to an Analysis of Variance. Under the conditions of the experiment the apparatus does not significantly affect the marksmanship of the Ss.

Egan, J.P., Carterette, E.C. & Thwing, E.J. SOME FACTORS AFFECTING MULTI-CHANNEL LISTENING. J. Acoust. Soc. Amer., Sept. 1954, 26(5), 774-782. USAF Human Factors Operations Research Labs., Washington, D.C. (Psychology Dept., Indiana University, Bloomington, Ind.).

Certain factors were investigated that affect the intelligibility of a speech message which is presented to a listener simultaneously with an interfering speech message. In 2 of the 4 experiments reported, filters were introduced into one of the 2 channels that carried the messages. Thresholds of perceptibility were not reliably decreased by moderate amounts of filtering of the received message. However, articulation scores were considerably increased by the use of a high-pass filter (500 cps) in either of the 2 channels. The great advantage of presenting one message to one ear and the interfering message to the other ear (dichotic presentation) was measured by changes in the thresholds of perceptibility and by articulation tests. Functional relations between thresholds of perceptibility for the message to be received and the intensity of an interfering signal were determined for both monaural and dichotic listening. In separate tests, noise was also used as the interfering signal. Dichotic reception permits a reduction in intensity of the received signal of about 30 db as compared with monaural reception. Articulation-gain functions demonstrated a similar advantage for dichotic over monaural listening. When the message to be received and the interfering message are monaurally received at equal intensities, the articulation scores for the designated messages are about 50 percent. If the message to be received is somewhat less intense than the interfering one, the cue value of the intensity difference offsets the increased masking of the less intense by the more intense message.

Bartlett, T.E. TRANSPORTATION SYSTEMS RESEARCH: I. AN ALGORITHM FOR THE MINIMUM UNITS REQUIRED TO MAINTAIN A FIXED SCHEDULE. Contract Nonr-1100(05), Proj. NR C4V 016, Res. Memo. 4, May 1956, 20pp. ONR, School of Industrial Engineering and Management, Purdue University.

4581

As one of a series of studies on various aspects of transportation systems planning and control, this report develops a method for evaluating the minimum number of "transport units" required to maintain a fixed schedule. The analysis results in an algorithm which employs data usually found in schedules (arrival and departure times of the various runs at the various terminals during the typical time period). The minimum number of "transport units" required are developed in terms of convenient quantities related to minimal lay-over time, running time, and length of typical time period. The focus of the study is rail transportation.

Newman, R.W. & White, R.H. REFERENCE ANTHROPOMETRY OF ARMY MEN. EPS Rep. 180, Sept. 1951, 172pp. Environmental Protection Section, Quartermaster Climatic Research Lab., Lawrence, Mass.

The data presented in this report were derived from an anthropometric survey of approximately 85,000 U. S. Army white males, conducted by the Quartermaster Corps in 1946. A total of 65 dimensions was obtained on each man in this series; 43 of these are considered in varying detail in this report. Of the remainder, the majority are dimensions of the head and face which form a group applicable to special problems. The very large number (2030) of interrelationships between dimensions which are possible in a consideration of the 65 dimensions obtained during the survey has necessitated the exclusion of all but the most obvious relationships in this report. The data derived from the total sample of approximately 85,000 white males proved too unwieldy and time consuming to handle in the mechanical processes of sorting and analyzing. For this reason the analyses presented here are based on a smaller sample. It has been found that a geographically weighted subsample of approximately 25,000 white males did not differ significantly from the larger sample.

Rogers, M.S. AN APPLICATION OF INFORMATION THEORY TO THE PROBLEM OF THE RELATIONSHIP BETWEEN MEANINGFULNESS OF MATERIAL AND PERFORMANCE IN A LEARNING SITUATION. Ph.D. Thesis, RB 52-4, April 1952, 100pp. Princeton University.

4583

To develop a quantitative description of the relation of meaningfulness of material to rate of learning, an information theory of learning was outlined and an equation for learning in the paired associates situation derived. A suggestion, based on the theory, was made that differences in learning which has been attributed to meaningfulness might be related to differences in certain informational characteristics of the learning situation which are related to different kinds of materials. Three paired associates learning tasks were developed and analyzed in terms of information theory, Gestalt theory and transfer theory of meaning. T. G. 1. R 19

Matheny, Beatrice J. TWO SIMULATORS FOR TRAINING PILOTS AND CONTROLLERS IN AIR TRAFFIC CONTROL PROCEDURES. Contract N6ori 71 (16), SPECDEVCEV Proj. 20 L 1, Tech. Rep. 71 16 15, June 1955, 22pp. USN Special Devices Center, Port Washington, N.Y. (University of Illinois, Urbana, Ill.).

In this study 2 simulators for training pilots and controllers in air traffic control procedures were developed and given a preliminary training evaluation. Both methods, one involving very little equipment and the other somewhat more complex, were found to be useful in training both pilots and controllers. It is recommended that a method for training pilots in traffic control procedures be introduced into the Navy pilot training syllabus. The simplest method, using paper and pencil, seems adequate for teaching low frequency and omnirange procedures. The more complex method, using Link trainer crabs, permits training on radar approach procedures as well as low frequency and omni-systems and, therefore, is a more versatile training device.

Lightfoot, C. EVALUATION OF THRESHOLD TRACING AUDIOMETRY AS A METHOD FOR STUDYING EFFECTS OF STRONG ACOUSTIC STIMULATION. Proj. 21 1203 C001, Rep. 8, April 1955, 18pp. USAF School of Aviation Medicine, Randolph Field, Tex. (Northwestern University, Evanston, Ill.).

An audiometric procedure is described which involves the subject's tracing of his threshold by oscillating an attenuator and thus causing a test tone to fluctuate continually between audibility and inaudibility. This procedure was followed by a number of normal-hearing persons both before and after 3 minutes of strong (105 db re 0.0002 microbar) acoustic stimulation. Data were thus provided to facilitate evaluation of the procedure as a possible means of measuring "fatigability," which was assumed to be a correlate of susceptibility to stimulation deafness. 4 combinations of fatiguing sound (white noise or 2-kc. tone) and test tone (3000 or 4000 cps) were each used twice for each subject. In general, traced thresholds compared well with conventionally obtained measures with respect to test-retest reliability. Because of the high test-retest consistency associated with it, and its tendency to differentiate individuals markedly, the noise/4000 cps combination appeared to be the best for fatigability measurement. The threshold tracing procedure revealed not only threshold shift and rate of recovery but also 2 extra-threshold dimensions--namely, directional consistency of recovery and smoothness of tracing.

Bancroft, R.W., Carter, E.T. & Luft, U.C. EVALUATION OF THE HYPOXIA WARNING DEVICE. Rep. 55 60, May 1955, 5pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The results of these studies indicate that the hypoxia warning device based on the principle of oximetry has promising possibilities. However, the fact that the device requires constant attention and adjustment up to the moment of each hypoxic exposure in the laboratory and altitude chamber also indicates that, in its present form, it can not be considered a reliable instrument for signaling the onset of hypoxia under operational flying conditions. The most important limiting factor as far as the reliability of the device is concerned is the physiological problem of maintaining a constant blood flow through the ear pinna on which the oximeter photocell unit is attached. The constriction and dilation of blood vessels in the ear are unpredictable variables, not only in a single individual, but even more so in different individuals, and these vascular changes are difficult to control consistently. For this reason, further study and modification of the photoelectric ear unit is necessary in order to insure the detection of hypoxia and a decreased arterial oxygen saturation under a variety of flying conditions to which a pilot is subjected.

Sells, S.B., Barry, J.R., Trites, D.K. & Chinn, H.I. A TEST OF THE EFFECTS OF PREGNENOLONE METHYL ETHER ON SUBJECTIVE FEELINGS OF B-29 CREWS AFTER A TWELVE-HOUR MISSION. Rep. 55 11, May 1955, 7pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Pregnenolone methyl ether has been reported in the literature as having favorable effects, with psychiatric patients, on subjective reactions of fatigue, irritability, anxiety, and fear. Student B-29 crews were administered this drug or a placebo, in a balanced design, immediately after completing an all-night, overwater mission, to determine whether similar effects might be produced in normal bomber crew personnel. A battery of psychological tests was administered twice to both groups, by crew, with an interval of from 63 to 94 minutes between pre-drug and post-drug test periods. No significant differences were found between drug and placebo groups, although the changes observed support the validity of the tests.

Loving, D.L. AERODYNAMIC MEASUREMENTS MADE DURING NAVY INVESTIGATION OF HUMAN TOLERANCE TO WIND BLASTS. Res. Memo L7025, Nov. 1948, 10pp. National Advisory Committee for Aeronautics, Washington, D.C. (Langley Aeronautical Lab., Langley Field, Va.).
This report presents the aerodynamic measurements made during a Navy investigation conducted in the Langley 8-foot high-speed tunnel to determine the actual human tolerance to wind blasts. Those tests were made at the request of the Naval Medical Research Institute, Bethesda, Md., to obtain direct evidence of the forces involved when the human head is suddenly thrust into a rapidly moving air stream, as is the case in ball-bats from aircraft at high speeds, and also to determine the maximum speed considered safe for the unprotected face to be exposed to wind blasts.

 Bylund, R.M. A GUIDE FOR USE IN PERFORMANCE TESTING
 IN AIR FORCE TECHNICAL SCHOOLS. Prof. 7729, Task
 77142, AFMIL IN 25 1, Jan. 1956, 75pp. DEP. ARMY
 Systems Research Lab., Lowry AFB, Colo.

4608

This performance testing guide is intended to sup-
 plement the information on performance testing currently
 contained in Air Training Command Regulation 50-2, "Gen-
 eral Training," and AFMIL Manual 50-900-9, "Improvement of
 Training Procedures for Air Training Command Schools."
 Following the introduction which defines performance
 testing and the need for such testing, various chapters
 deal with 1) characteristics of performance tests, 2)
 development and administration, and 3) utilization of
 test results. A checklist for use in developing a
 performance test and a primer for measuring test re-
 liability are appended.

Goodrich, J.W. ESCAPE FROM HIGH PERFORMANCE
 AIRCRAFT. Tech. Note 54-7, Jan. 1956, 8pp.
 Directorate of Research, WAC, Wright-Patterson
 AFB, Ohio.

4609

An objective analysis of the problem of escape from
 high performance aircraft is presented in terms of human
 tolerance to acceleration correlated with pertinent com-
 ponents and physical factors. The maximum linear accel-
 eration experienced during escape is computed for the con-
 ventional ejection seat system as a function of alti-
 tude, speed, altitude, and thrust vector. Many of
 conditions are computed as a function of altitude for a
 given initial altitude speed. Correlation of these
 physical conditions with human tolerance to accelera-
 tion reveals the critical human limitations associated
 with conventional ejection seats for successful escape
 from high performance aircraft. Suggestions are included
 for lines of research on escape systems.

Dupree, L. THE JUNGLE SURVIVAL FIELD TEST.
 ADTIC Publ. 7-101, Rep. AC-387-54 RSI, June
 1956, 75pp. Arctic, Desert, Tropic Informa-
 tion Center, Research Studies Institute, Air
 University, Maxwell AFB, Ala.

4617

To evaluate the Air Force survival system (man,
 procedures and technique, equipment) in a simulated
 emergency situation in the rain forest of Borneo, ex-
 perimented Air Force crew members were selected at random
 to participate in the test (with observer-participant the
 crew size was seven). The modified Griffide A-1 sur-
 vival kit, a back parachute, and supplementary items nor-
 mally carried in pockets were provided each man for a
 trek (estimated duration of 14 days) through the jungle.
 A pre- and post-trek questionnaire were given to the
 participants, an objective field diary was kept of the
 observers, and photographic coverage was made. Data
 from these sources were analyzed in terms of the ade-
 quacy of each system component.

 Hall, R.L. PREDICTING BOMBER CREW PERFORMANCE FROM THE AIRCRAFT COMMANDER'S ROLE. Proj.
 7713, Task 7723, AFMIL IN 56 78, Feb. 1956, 16pp. WAC, Personnel Training Research
 Center, Crew Research Lab., Randolph AFB, Tex.

To examine predictive relationships between the aircraft commander's interpersonal role
 during training and the effectiveness of his crew's later performance, three dimensions
 were selected for study: nurturance, intimacy and militancy. Measures for these three
 dimensions were available from a previous study. Performance criteria include one rating
 of performance during training by flight instructors and four measures of combat perfor-
 mance: ratings by superiors, peer ratings, administrative overhead costs, and altitude
 scales. The various measurements were made in 28 B-36 crews during their last training
 phase and after six to eight months of combat experience. The data were studied by cor-
 relational methods to determine how adequately predictions of crew effectiveness were made
 from dimensions of commander role behavior.
 T. R 13

An apparatus and procedure have been described for determining the critical fusion fre-
 quency as a function of intensity for the human eye. Areas with diameters of 1', 2', and 3'
 visual angle in the fovea and at 1', 2', 6', and 14' visual angle centered 20' below the
 fovea have been investigated. The data for the foveal areas seem to indicate the function-
 ing of a single receptor, i.e., cones. Those for the periphery fall into 2 parts which are
 probably due to rod and cone function, respectively. According to intensity level, both sets
 of data show that the critical fusion frequency increases with area of stimulation over a
 wide range of intensities. A comparison of results for the corresponding foveal and peripheral
 areas reveals that at low intensities the periphery is more sensitive to flicker than the
 fovea, while for intermediate and moderately high brightness levels, the situation with com-
 parable areas (1' and 2') is reversed. The superiority of the periphery at low intensities
 is attributed to the greater sensitivity of the rods at these levels. At the very highest
 intensities, the 1' and 2' foveal and peripheral areas show similar maximal critical fusion
 frequencies.

Minter, R.S. VISUAL CUES: LEARNING AS A FUNCTION OF TIME AND INTENSITY OF EXPOSURE. *J. exp. Psychol.* Nov. 1942, 21(5), 421-429. (Brown University, Providence, R.I.).

4613

This study concerns the speed with which an S learns to estimate visual numerosity accurately as it depends on the numerosity and duration of the stimulus at low intensities. An experienced S was required to estimate the number of dots in various arrays presented tachistoscopically, each array being presented until the estimate was correct. The results related the number of presentations to collection and the reaction times for different numbers of dots to duration and intensity of exposure.

Haus, G.T. & Payne, R.S. THE EFFECTS OF DEXTROAMPHETAMINE AND BENZYL-HEXAMINE UPON JUDGMENT. *Rep.* 55 104, Nov. 1955, 11pp. *USAF School of Aviation Medicine, Randolph AFB, Tex.*

At regular intervals during the learning of a unique perceptual-motor task, subjects were told the proficiency score which they had attained during the period just completed and then asked to estimate the proficiency score they expected to attain during the next period of practice. The magnitude and direction of estimation error were determined by computing the absolute and algebraic differences between the proficiency estimated and the proficiency that was then actually attained. When these measures of estimation error were analyzed, it was found that neither dextroamphetamine sulfate (5 mg.) nor diphenhydramine hydrochloride (50 mg.) + scopolamine (0.65 mg.) had significantly affected the judiciousness of these estimations.

Macdonald, N.E. WORK DESIGN AND TRAINING FOR FUTURE INDUSTRIAL SKILLS. Report from "Paper presented to the Institution in London, 9th February 1956". *APD 25.0.56*, Feb. 1956, 211-250. *Medical Research Council, Applied Psychology Research Unit, London, England.*

This paper on two psychological approaches to industrial problems—work design and training—was presented to the Institution of Production Engineers Conference, London, 1956. Part I deals with work design for inspection and decision taking; Part II considers some matters related to the training of electrical maintenance workers. While acknowledging the values in a common sense approach to work design, the discussion points out that such an approach breaks down with complex problems and with entirely new forms of work; here specially devised measures of human achievement are needed. Some typical performance data on such inspection tasks as continuous monitoring for misalignments, consecutive inspection for misalignments or defects and monitoring automatic machines for emergencies are presented and design problems discussed. Work design for decision making for the controller of automatic system, is discussed and many research problems defined. Finally, the increased problems of electrical maintenance in present and future machine systems with consequent training and supply of personnel are set forth. (MEIAS)

McFarland, R.A. FATIGUE IN AIRCRAFT PILOTS. *New Engl. J. of Med.*, 1941, 225, 345-355. (Harvard University, Boston, Mass.).

Some of the more important contributing factors to pilot fatigue are analyzed. It is shown that a pilot whose muscular activity in flight is limited could hardly exhaust the energy reserves sufficiently to explain fatigue and exhaustion often observed in airmen. The essential variables in acute or chronic pilot fatigue are ascribed to psychological factors such as emotional stress. Most of the discussion concerns contributing factors in pilot fatigue, especially lack of exercise, the reduced tension of O_2 during high altitude flights, the poor selection of food and the excessive use of alcohol and tobacco. Also, certain physical variations in the cockpit are discussed, such as noise, vibration, poor illumination, etc. Finally, the results obtained in a study of transoceanic airmen are analyzed to show the effects of long flights at moderately high altitudes. McConnell, R.J.W. DIRECTION OF MOVEMENT OF MACHINE CONTROLS. III. A TWO PHASED TASK IN A DISCONTINUOUS OPERATION. Aug. 1947, Sp. *Ministry of Supply, Psychology Lab., Cambridge, England.*

An experimental study was made of some aspects of the relationship between display and control movements. A discontinuous task was devised in which the direction of movement of the display was either upward or downward, while the direction of movement of the control could be varied—up-down, right-left, forward-backward. This task was performed by the S, working at about maximum speed, with his right hand, while performing simultaneously a fairly difficult, but dissimilar task with his left hand. The mean number of errors made with different combinations of control and display movement were analyzed in order to determine rank order of accuracy of the conditions. The results were compared to a previous study where only the one-handed task was performed. The findings from the analysis and comparison indicate that the order of accuracy is a stable phenomenon and that far fewer errors were made when the control and display system was connected in the "expected" way—an upward to forward movement of the control producing an upward movement in the display. A side-to-side, backward, or downward movement of the control producing an upward movement in the display increased the number of errors. The effect of practice was not investigated. (HE145)

Long, G.E. THE EFFECT OF DURATION OF ONSET AND CESSATION OF LIGHT FLASHES ON THE INTENSITY-TIME RELATION IN THE PULFRICH STEREO. *Univ. Psychol.*, Nov. 1943, 31(11), 743-747. (Columbia University, New York, N.Y.).

4640

To investigate how the variation in the wave form of the light flash, as manifested by the rate of onset and cessation of the stimulus, influences the threshold in the periphery, two experiments are reported. The first studies the intensity-duration function for peripheral threshold stimulation over a range of durations from 0.02 to 0.24 seconds. The flashes were rapid in onset and cessation (nearly rectangular in wave form). The second determines the total energy required for threshold excitation for flashes of various wave forms (different onset and cessation times), the maximum duration always being below the critical duration obtained in the first experiment.

4645 Frazer, D.C. A STUDY OF FATIGUE IN AIRCREW. II. COMPARISON OF THE EFFECTS OF DAY AND NIGHT FLYING. FMAT 915, June 1955, 6pp. Flying Personnel Research Committee, Royal Air Force Institute of Avialling Medicine, London, England.

This paper, a systematic study of fatigue in aircrew, reports the result of an investigation comprising 19 15-hour sorties, 11 by day and 8 by night. One member of each crew was tested by the writer to obtain a measure of variability of judgment (s-function). The same individuals were tested when fresh to obtain a control score. The results show: a) that there is a significant difference (p<0.01) between the control and experimental scores for the day-flying group, and a more significant difference (p<0.001) between the control and experimental scores for the night-flying group; b) the increase in s-function for the night-flying group is significantly greater (p<0.01) than for the day-flying group; c) The variances of the experimental scores in both cases are significantly higher than those of control scores.

4647 Ratovich, P. & Graham, C.H. ASPECTS OF HUMAN ENGINEERING CONCERNING THE AIRCRAFT PERISCOPE. Dec. 1951, 42(6), 367-375. (Ohio State University, Columbus, Ohio & Columbia University, New York, N.Y.).

4647 To investigate the effect on foveal brightness discrimination of changes in the size of both the test and the adapting-fields, a foveal, circular, illuminated adapting-field was presented to one eye of the subject to which was added a concentric, circular test-field, smaller than, or equal in size to the adapting-field. The diameter of the field was varied from 0.17 to 1.34 degrees of visual angle. The test-field was presented for a duration of 0.52 seconds and over a wide range of illuminations. Data from two subjects were analyzed for constant sizes of both fields, for constant test-field size with increasing adapting-field size, and for a constant adapting-field size with increasing test-field size.

MacDonald, D.E. (Director). **QUALITY ASPECTS OF THE AERIAL PHOTOGRAPHIC SYSTEM.** Contracts W33 038 ac 14075 & AF33 038 15615. E.O. 680 & SAIO. Tech. Note 55, June 1952, 24pp. Optical Research Lab., Boston University, Boston, Mass.

An investigation has been made of the relationship between resolution, scale and contrast criteria and the performance of a generalized aerial photographic system. The results imply that: a) the judgment of the relative performance of an aerial photographic system on the basis of high-contrast resolution scores in the laboratory is not infallible, and b) the best operational focus can not be determined in the laboratory from a maximum resolution setting on a high-contrast target. A performance rating is suggested that considers the total number of symbols in the object space that the system will record.

4664

Tonicliffe, W.W. & Ross, G.O. **INVESTIGATION OF TELEVISION PHOTOGRAPHY.** Tech. Note 12, Jan. 1948, 24pp. Boston University, Optical Research Lab., Boston, Mass.

This report deals with the subject of television photography, with particular interest in the application of photography of the kinescope of a television receiver located at a ground station and receiving an image being transmitted from an aircraft. This is one aspect of the larger problem of television aerial reconnaissance. Preliminary tests were conducted using a modified Smeets 5-7 aerial reconnaissance strip camera to photograph the kinescope of the Black television receiver during actual plane to ground television transmission. These, and subsequent laboratory tests are described. The laboratory tests include such factors as exposure, contrast, resolution, field and sweep motion, Smees banding, variable frame rates, electrical fluctuations, and sweep compression. The general conclusion which may be drawn from the tests and analyses described here is that ordinary-strip photography of a field scanned television receiver kinescope does not satisfactorily solve the problem of continuous strip print production. The major difficulties are the lack of resolution due to blurring and the striation effects. The slit scan system has inherently higher resolving power, is not subject to loss of resolution due to multiple exposure to successive frame, and is not subject to the striations discussed in this report. It is recommended that additional studies be made of this system. (RMAS)

4665

Lipkin, M., Bailey, Guido & Hardy, J.D. **THE EFFECT OF ULTRAVIOLET IRRADIATION UPON THE CUTANEOUS PAIN THRESHOLD.** Rep. NADC RA 514, Oct. 1954, 17pp. Aviation Medical Acceleration Lab., USN Air Development Center, Johnsville, Penn.

In order to further investigate relationships which may exist between the onset of cutaneous pain and tissue damage, measurements were made of pain threshold, degree of hyperalgesia, and onset and intensity of erythema during the development of burns caused by ultraviolet irradiation. It was found that the onset of erythema was associated with a fall in pain threshold. The maximum fall of pain threshold, the duration of this lowering, and the intensity of hyperalgesia and erythema increased with the ultraviolet radiation (intensity x time). It is shown that these experimental data are consistent with the hypothesis that, as a result of the ultraviolet irradiation, there is inhibition of some tissue repair processes, thereby causing a pain threshold lowering from roughly 45°C to 35°C. In this state, even a slight (1-2°C) elevation of skin temperature in a burn area evokes pain, and may be sufficient to cause thermal inactivation of cellular proteins at a rate great enough to result in tissue damage.

Burnoff, M. & Myppard, C.W. **DESIGN OF DIGITAL FLIGHT TRAINERS.** Contract NED 551(C2), Res. Div. Rep. 54 09, Sept. 1953, 19pp. Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia, Penn.

4666

This report describes the development and design of a digital flight trainer. Three phases in the development of the trainer are reported: 1) mathematical techniques for fast but accurate solution of flight equations, 2) the logical structure of a special-purpose digital machine capable of ultrahigh-speed computation, and 3) reliable circuits not only for the digital computer but for conversion to and from analog form, multiplexing, and cockpit transformation. The method of "stability charts," a technique developed for assuring solutions to the several differential equations and related information on flight conditions, such as control forces and range, is discussed in considerable detail. A "parallel" simulator, which is about three times faster than the serial machine, is also described. T. G. R 6

Hortman, A.B., Randall, W.C., Peliss, C.M. & Adams, J.D. FACTORS INFLUENCING THE SIGNIFICANCE OF LOCAL SWEATING RESPONSES. THE 12TH OF A SERIES OF REPORTS ON CUTANEOUS HEAT LOSSES. Contract AF 18(600)C, Tech. Rep. 6480, Part 12, Jan. 1954, 20pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (St. Louis University, St. Louis, Mo.)

The desiccating capsule and sweat print techniques of measuring local sweating responses were used separately and together in the study of cycling in sweat gland activity and together in the measurement of the mean rate of secretion per individual gland. Whether recorded by either technique or by both methods simultaneously, cycling in the activity of sweat glands is usually similar but not necessarily identical in extent and timing on adjacent skin areas (same dermatome). Two different regions (dermatomes) (e.g. the medial and lateral aspects of the thigh) may exhibit cycles which are in or out of phase. The longer cycles appear simultaneously in the measurements with both methods, but the shorter cycles are more obvious in the sweat prints. Capsular data for the sweating rates of main body regions were examined and the effects of the regional sweating rates were studied.

Aeroplane 2 Armament Experimental Establishment. COCKPIT APPRAISAL AND NIGHT FLYING ILLUMINATION ASSESSMENT. Second part of Rep. AAE 840/1, Jan. 1954, 6pp. Aeroplane 2 Armament Experimental Establishment, Ministry of Supply, London, England.

4677
An appraisal of the pilot's cockpit and night flying illumination of the aircraft Marathon XA 260, a production of T.Mk. 11, was made. Since a cockpit appraisal of the mock-up T.Mk. 11, VX 229, had already been made, only those items changed in this production version or not previously appraised have been commented upon. The following aspects of the cockpit were discussed: entry and seating, controls, emergency exits, and lighting.

Crumley, L.M., Atkinson, V. & Fletcher, Dorothy C. PART II. VALIDATION OF AN INSPECTION TEST FOR WINDSHIELD DISTORTION. THE DEVELOPMENT OF INSPECTION METHODS AND CRITERIA FOR OPTICAL DISTORTION IN COCKPIT ENCLOSURES. Rep. TED NAV 45405, Pt. 2, June 1954, 21pp. UN-AMSL-NAVAL MEDICAL ESTABLISHMENT, Naval Material Center, Philadelphia, Penn.

In a previous study, an inspection test of aircraft windshield distortion was constructed so that it would agree in ordering windshields with a criterion of pilot judgments of the suitability of the windshields for use in aircraft on the basis of visual quality. The present cross-validation, with a selected set of windshields, indicates that the inspection test reliably predicts this criterion. Individual judges, using the inspection test, agree in relative scoring of windshields but disagree in overall level of scoring.

Cain, S.M. THE EFFECTS OF EXERCISE AND HEAT ON BREATH-HOLDING TIME. Res. Rep. 262, April 1954, 13pp. USA Chemical Corps Medical Lab., Army Chemical Center, Md.

An experiment was conducted to determine the time for which breathing may be voluntarily suspended at various levels of exercise and under various environmental conditions. Conclusions were: a) The average breath holding time (BHT) obtained with 4 is is probably applicable to a larger population group of young white males. b) Under laboratory conditions, men performing moderately severe and very severe exercise will not be able to hold their breaths continuously long enough to do the lightweight service gas mask on the basis of a 14 sec. masking time. c) In a steady state of exercise, the rate of oxygen consumption determines the duration of breath holding and serves as a measure of the effects of exercise on BHT. d) Environment does not affect BHT enough to alter conclusion b) however, there is an indication that an (optimal) environmental condition may produce a large increase in BHT at rest. It is recommended that on the basis of these results, further studies be carried out for the purpose of validating these observations on a greater number of individuals and of applying them to field experimentation.

Vonderhe, J.M. PHYSIOLOGY OF LOAD-CARRYING III. SOME EXPERIMENTAL LOAD DISTRIBUTIONS STUDIED ON THE TREADMILL. Projs. 64 12 001 & 64 12 003, EPB Rep. 212, June 1953, 10pp. USA Quartermaster Clinic Research Lab., Environmental Protection Branch, Lawrence, Mass.

4683

The energy cost of carrying loads of 15 and 45 pounds, in five different distributions, was studied on a horizontal, motor-driven treadmill maintained at 3.5 mph. Eight sets of varied physical characteristics performed the tasks. The hypothesis that extra energy is required for accelerating and decelerating loads that are attached to body parts which undergo rapid changes in velocity during walking was examined in light of the findings. The feasibility of loads balanced fore and aft on the upper thorax is examined along with differences in efficiency for sets placed in "fat" and "lean" groups.

4684 Taylor, C.L. & Huettner, K. THE EVAPORATIVE EFFECT ON HUMAN PERSPIRATION. Contract AF 33 (616)32, WADC Tech. Rep. 53 345, Sept. 1953, 28pp. University of California, Los Angeles, Calif.

Evidence for an "evaporative effect" upon human perspiration has been obtained from a series of experimental data. Plots of skin water losses against average skin temperature, using results from human experiments under conditions of altered temperature, humidity, air movement and air pressure reveal that significant residual evaporation is associated with these environmental influences. Since the direction and magnitude of these effects are such as to increase or decrease evaporation from the skin, the phenomenon has been designated as the "evaporative effect." Explanation for the "evaporative effect" has been sought in skin water transfer not involving sweat gland participation. This brings attention to the processes of diffusion (insensible) losses, skin water storage shifts, and to the much less completely understood processes of penetration, re-penetration and osmotic regulation of the human skin.

4685

A direct-writing ergometer, used principally for field use in measuring the amount of work done in pulling trailed loads, is described. Work loads of men operating under extremes of cold in the field have been measured where it is difficult or impossible to standardize conditions. Principal components for the instrument are a calibrated spring to measure force and a trailed bicycle wheel to measure distances. A stylus attached to the spring marks the forces on a wax-surfaced paper which is fed through the instrument in proportion to the distance traveled by the wheel. Methods of calculating power and efficiency are given.

4688 Loucks, R.B. INTERPRETATION OF AZIMUTH INDICATORS BY NOVICES. I. AIRCRAFT DIRECTION INDICATORS WITH FIXED RUBBER LINES AND AZIMUTH CARDS THAT TURN. Contract WJ3 018 ad 15130, AF Tech. Rep. 5957, Oct. 1949, 24pp. USAF Air Materiel Command, Wright-Patterson AFB, Ohio.

A series of experiments were carried out to compare rotating pointer and rotating card (stereoscopic pointer) azimuth indicators in terms of the ease of interpretation by novices. Several instruments of each type were evaluated in an azimuth ground trainer which provided error and response time records. The rotating scale instruments, in general, produced more turns in the wrong direction which were not corrected; an effect attributed to the incomplete exposure of the scale on this type of instrument. On the other hand, a simple moving pointer indicator was responded to with more starts in the scale instrument. These initial errors on the moving pointer instrument were attributed to the relation between rubber pedal motion and the resulting direction of turn which appeared to be unnatural to the novices.

Warden, C.J., Brown, H.C. & Ross, S. A STUDY OF INDIVIDUAL DIFFERENCES IN MOTION ACUITY AT SCOTOPIC LEVELS OF ILLUMINATION. J. exp. Psychol., 1945, 35, 57-70. Proj. GEN cam-284. (Columbia University)

4692

To study individual differences in motion acuity at scotopic levels of illumination, threshold values were secured for 28 male subjects under two levels of illumination ($\log 3.4$ ml and $\log 4.0$ ml) at six retinal positions ranging from 7 degrees to 55 degrees from the line of sight. Motion acuity functions are plotted for each level of illumination and individual differences in motion acuity at the various retinal positions are analyzed and the implications are discussed.

4693

Warden, C.J. & Brown, H.C. A PRELIMINARY INVESTIGATION OF FORM AND MOTION ACUITY AT LOW LEVELS OF ILLUMINATION. J. exp. Psychol., 1944, 34, 437-449. (Columbia Univ.)

4693

To investigate form and motion acuity at low levels of illumination, tests of form acuity were made with four subjects at various retinal positions, ranging from 5 degrees to about 50 degrees of peripheral angle. Motion acuity was tested at 5, 7, 10, 25, 35, 45, and 55 degrees. A full set of determinations for both form and motion acuity was made at 3 levels of illumination: $\log 1.0$, $\log 3.4$, and $\log 4.0$ ml. In tables and figures, the width of the gap of the stimulus, in terms of degrees of visual angle (for form acuity) and rate of movement of the stimulus, in degrees of visual angle per second (for motion acuity) are given for the various peripheral angles tested.

Rouse, R.O. COLOR AND THE INTENSITY-RING RELATION. J. Opt. Soc. Amer., Sept. 1957, 47(9), 626-630. (Williams College, Williamstown, Mass.).

Measurements of the intensity necessary for monocular differential thresholds for red, green and blue test lights were made at exposures of the test light ranging from 0.002 to 1.000 second. Central fixation was used, the colored test light appearing as a small dot brighter than the surrounding white-lighted field. The adaptation brightness was just above the cone threshold. Adaptation was controlled over 40 degrees of the visual field, including the very center. 3 selected subjects, with normal color vision and acuity, contributed approximately one thousand threshold determinations. The method of limits was used. It was found that there was no differences among the critical durations for the 3 colors.

Schlosberg, H. STEREOSCOPIC DEPTH FROM SINGLE PICTURES. Amer. J. Psychol., Oct. 1941, 54(4), 601-605. (Brown University, Providence, R.I.).

The phenomenon of monocular plastic depth is due to the release of certain monocular factors from overpowering cues, largely binocular, that show the picture to be flat. These 'flatness' cues must be eliminated, and not merely held constant. Holding a factor constant is not always the best method of controlling it. This is true for depth perception, and probably for a number of other psychological processes. As a matter of fact the caution holds true pretty generally throughout all experimental fields. If an engineer were trying to plot speed against horsepower he would scarcely hold certain factors constant--for example, the car brakes firmly applied! Similarly, when convergence or binocular differences are held constant one finds out more about them than he does about the factors he is deliberately varying.

Pollock, W.T. THE VISIBILITY OF A TARGET AS A FUNCTION OF ITS SPEED OF MOVEMENT. J. exp. Psychol., June 1953, 45(6), 449-455. (Johns Hopkins University, Baltimore, Md.).

Monocular luminance thresholds of a 1° circular spot of white light were measured with the spot moving at angular speeds of 50-2000° per sec. The extent of target travel was 20° of visual angle with the midpoint of the target excursion centered on the fovea. The direction of target movement was either vertical or horizontal. The results show that threshold luminance increases systematically with increases in target speed. The function is best characterized as linear with a slope near unity when threshold luminance and speed are plotted logarithmically. However, there is some indication that the function relating target speed and visibility is not continuous. The data show that vertical target movement yields consistently lower luminance thresholds than does horizontal movement.

Boetherage, B.M., Jeffress, L.A. & Blodgett, H.C. A NOTE ON THE AUDIBILITY OF INTENSE ULTRASONIC SOUND. J. acoust. soc. Amer., July 1954, 26(4), p582. (Defense Research Lab. & Psychology Dept., The University of Texas, Austin, Tex.).

Investigation of a tone heard in the water in a beam of a transducer transmitting at 50kc yielded the conclusion that the tone was heard as a result of direct stimulation of the basal end of the cochlea and that the sensation is not due to the creation of any vibration in the head in the sonic range of frequencies. Observations which bear out these conclusions are the phenomenon of changing apparent localization of the tone in the head, and that the pitch of the sound heard under ultrasonic stimulation is the highest pitch a given subject is capable of hearing. Thus it appears that ultrasound is audible by bone conduction. (MEIAS) R 5

Locks, R.E. THE INTERPRETATION OF AZIMUTH INDICATORS BY NOVICES: II. AIRCRAFT INDICATORS WITH FULL-SCALE AZIMUTH CAPS THAT TURN. Contract W33 038 AC 15230, E.O. 694-19, AF Tech. Rep. 5965, March 1950, 13pp. USAF Air Materiel Command, Wright-Patterson AFB, Ohio.

A moving dial azimuth indicator with a 360-degree scale of clockwise figures was found to be very superior to the conventional stationary dial instrument, and to a moving dial indicator with counterclockwise figures. Both 'instrument' and 'contact' flight conditions were used in the evaluation. 3 proposals are presented for modifying the design of moving dial indicators so as to minimize the blurring of the scale which is reported to occur under night flying conditions. It is concluded that the change which is most essential to solve the numerous problems of interpretability in azimuth indicators is to reverse the action of the rudder pedals. Extreme as this proposal may appear to be, it would seem very important to ascertain the actual degree of habit interference induced by reversed pedals because the gains that might ensue from this change might well justify the alteration. Egan, J.P. INDEPENDENCE OF THE MASKING AUDIOGRAM FROM THE PERSTIMULATORY FATIGUE OF AN AUDITORY STIMULUS. J. acoust. soc. Amer., July 1955, 27(4), 737-740. (Hearing and Communication Lab., Psychology Dept., Indiana University, Bloomington, Ind.). (AFRC TR 54 87).

The loudness of a steady auditory stimulus declines during the first few minutes of the application of that stimulus. This decrease in loudness is so great that it is important to know whether or not the masked threshold also changes during the initial period of stimulation. In the present investigation the degree of perstimulatory fatigue and the amount of masking were both determined for the same stimulus. It is shown that the masked threshold is essentially independent of the duration of the masking stimulus. R 7

Twining, E.J. SPREAD OF PERSTIMULATORY FATIGUE OF A PURE TONE TO NEIGHBORING FREQUENCIES. *J. acoust. soc. Amer.*, July 1955, 27(4), 741-748. (Hearing and Communication Lab., Psychology Lab., Indiana University, Bloomington, Ind.). (AFCAP TR 54-78).

When a fatiguing tone is presented to one ear of an observer, and, after a period of time a comparison tone of the same frequency is also presented to the other ear, the intensity of an equally loud comparison tone is considerably less than the intensity of the fatiguing tone. This phenomenon has been referred to as perstimulatory fatigue. The present investigation was designed to determine the extent to which the perstimulatory fatigue induced by a pure tone spreads to neighboring frequencies. Perstimulatory fatigue was measured by means of a series of simultaneous dichotic loudness balances made prior to, during, and subsequent to stimulation by a fatiguing tone of 1000 cps at a SPL of 80 db. Test tones were the same in sound pressure as the fatiguing stimulus. When measuring fatigue at a frequency other than that of the fatiguing tone, the fatiguing stimulus was turned off for a 15-second interval. During this interval, a loudness balance was made at the frequency of the test tone. The findings demonstrate that maximum fatigue is produced at the frequency of the fatiguing stimulus. Fatigue falls off rapidly on both sides of this frequency at a negatively accelerated rate until at 100 cps and at 2500 cps little or no effect is evident. The gradients of perstimulatory fatigue are nearly symmetrical when plotted on a log-frequency scale.

Katz, S., & Schwartz, I. NEW OBSERVATION OF THE PULFRICH EFFECT. *J. opt. soc. Amer.*, July 1955, 45(7), 523-524. (USN Medical Research Lab., New London, Conn.).

The Pulfrich effect has been characterized as a perception of depth produced by image disparity when the stimulus to one eye is less bright than that to the other. A method has been devised which permits ostensible binocular vision but gives a monocular stimulation to each eye in succession, so that no portion of the pathway of the oscillating stimulus is visible to both eyes at the same time. Under this condition, the perception of depth is still reported, thus damaging the latency hypothesis based on binocular vision as an explanation of the phenomenon.

Morris, A., McGuire, F.L., & Van Cott, H.P. ACCURACY OF THE MACBETH ILLUMINOMETER AS A FUNCTION OF OPERATOR VARIABILITY, CALIBRATION, AND SENSITIVITY. *J. opt. soc. Amer.*, July 1955, 45(7), 525-530. (Medical Research Lab., USN Submarine Base, New London, Conn.).

The accuracy of the Macbeth illuminometer was studied by measuring a known source. The mean of a number of measurements from a number of operators gives a precise estimate of brightness. The most adequate measures are obtained when "calibration" acceptance of the working lamp is carefully determined and maintained with precision. To establish the relation between the sensitivity of the eye and brightness measurements, the difference thresholds for lighter and darker were determined. The close similarity of the curves for the threshold data and for the brightness measurements demonstrates that "match" judgments are essentially discriminations of "lighter" and "darker."

Smith, S.W., Morris, A., & Dirmick, F.L. EFFECTS OF EXPOSURE TO VARIOUS RED LIGHTS UPON SUBSEQUENT DARK ADAPTATION MEASURED BY THE METHOD OF CONSTANT STIMULI. *J. opt. soc. Amer.*, July 1955, 45(7), 502-506. (Medical Research Lab., USN Submarine Base, New London, Conn.).

In order to answer a practical question as to the most effective red light to be used in military situations requiring dark adaptation, an experiment was undertaken to compare the effects of 4 "red" filters at constant brightness levels. It was obvious that with traditional methods of measuring dark adaptation, these effects could not be measured with sufficient accuracy to make comparisons. An application of the method of constant stimuli was developed which gave adequate accuracy of measurement. The results show differences in the effects of adapting to light having dominant wavelengths of 601, 626, 640, 675, 690 mμ and neutral. The maximum sensitivity differences occurred early in dark adaptation (before two minutes). Dark adaptation preceded most rapidly following adaptation to 626 mμ. The maximum difference between neutral and 676 mμ was 0.5 logμL and differences between the various "red" conditions ranged from zero to 0.22 logμL. This application of the constant stimuli method gives results which may be more sensitive than the calibrations of standard instruments.

Steinberg, Hannah. SELECTIVE EFFECTS OF AN ANAESTHETIC DRUG ON COGNITIVE BEHAVIOR. Quart. J. Exp. Psychol., Nov. 1954, 6(Part 4), 170-179. (Pharmacology Dept., University College London, England).

The prediction has been tested that under the influence of an anaesthetic drug, nitrous oxide, cognitive performances undergo differential impairment, the extent of which is positively correlated with the "complexity" of the task. 10 kinds of performance were investigated, ranging from speed of finger tapping to reasoning by analogy. The relative complexity of each task was determined, in accordance with conventional criteria, from its respective qualitative category or "level"--relational, associative, and motor--and within each category from qualitative analysis of the component processes involved in its execution. A simple group difference design was used, involving 2 groups of 50 subjects each, matched for age and sex. Significant deterioration as a consequence of drug administration occurred in the performance of all tasks. On the whole, the more complex a task the more did it tend to be impaired. Motor performances were, however, impaired to a greater extent than had been predicted. The possible significance of these findings is discussed.

Renshaw, S. OBJECT PERCEIVED-SIZE AS A FUNCTION OF DISTANCE. Engng. Exp. Station News, Oct. 1953, XXV(4), 44-48. (Psychology Dept., Ohio State University, Columbus, Ohio).

Results of a series of studies on size-constancy were summarized in this paper. In all the studies visual conditions were kept as nearly normal as possible. In one series, the target was viewed in an outdoor situation at various distances and phenomenal size matches were made by adjusting a pair of drill rods to make a square which exactly contained the target. Other tests were run using stereo instruments. The data were analyzed in terms of perceived size as a function of distance.

Rosebrook, Wilde M. SCHOOL ACTIVITIES AND VISION. Engng. Exp. Station News, Oct. 1953, XXV(4), 15-17. (Bureau of Special and Adult Education, Ohio State University, Columbus, Ohio).

A brief summary of a longitudinal study testing the hypothesis that children with visual problems are not able to make progress through the elementary school in keeping with their first six grades in a given school. Records of visual tests, of group intelligence tests, and of group achievement tests were obtained for 74 children; of these, 22 had specific visual problems (high esophoria, high exophoria, tropias, and poor vision). Comparisons of performance of the 22 visually handicapped with the 52 normal were made.

Gersuch, J.W. PSYCHOLOGICAL PRINCIPLES IN THE DESIGN AND OPERATION OF SYNTHETIC TRAINERS WITH PARTICULAR REFERENCE TO ANTI-AIRCRAFT GUNNERY. Contract OMSr 700, Proj. N 105, Memo 19, Feb. 1945. 10pp. National Defense Research Committee, Applied Psychology Panel, Washington, D.C.

On the basis of detailed observations of synthetic anti-aircraft gunnery training devices and their experimental study, several psychological principles are suggested for future design, operation and use. General conclusions concerning the present (1945) devices are as follows: a) Considerable attention has been directed to make synthetic training devices physically similar to the real situations, but psychological relationships have frequently been overlooked. b) Practice without guidance is of questionable value since incorrect habits may be established unless the men are corrected. Scoring, in general, is inadequate for guidance purposes, and coaching is too often given scant attention. c) Properly designed and properly used, synthetic training devices offer an effective and economical method of preparing men for operational weapons. (MEIAS)

Prentice, W.C.W. A STUDY OF THE PERFORMANCE OF NIGHT LOOKOUTS ABOARD SHIP. Contract OMSr 1136, Proj. N 115, Rep. 2, OSRD Rep. 4087, Oct. 1944, 20pp. US National Defense Research Council, OSRD, Washington, D.C. (Princeton University, Princeton, N.J.)

This report presents the findings of a preliminary study made aboard a light cruiser of the USN while she was serving as a convoy-escort. A method of testing and measuring the performance of night lookouts on watch was devised and is reported in detail. It consisted, briefly, in holding lookout "drills" during which each man reported the most distant ship he could see in the formation. Subsequently each report was reduced to a common unit to make it comparable with the others. Analysis of these scores indicated: a) lookouts are moderately consistent from night to night; b) the poorest lookout requires a target to be about 15 times as large in area as that noticed by the best lookout under the same lighting conditions; c) Radiom Plaque Adaptometer scores show no relation to lookout performance as measured in this study. Maximum range for the average lookout under several different conditions were given.

4732

Foxboro Company. INERTIA, FRICTION, AND DIAMETER IN HANDWHEEL TRACKING. Contract OMSr 453, Rep. 4, OSRD Rep. 3474 to Div. 7, Services 74, Sept. 1943, 14pp. US National Defense Research Council, Washington, D.C. (Foxboro Company, Foxboro, Mass.)

Handwheel operated tracking have shown that inertia and friction of the handwheel and tracking mechanism and the size of the handwheel have a pronounced effect on the accuracy and the character of the tracking error. Inertia, either in the form of a heavy handwheel or as flywheel effect inherent in or added to the moving system, reduced tracking error materially. 2 handwheel sizes, 4 1/2" and 9" diameter, were tested. The difference between the 2 sizes did not make large differences in accuracy or smoothness of tracking, except with friction. Small amounts of friction are unavoidable in mechanical systems, and these tests indicate that the detrimental effect of these small amounts of friction was not serious, especially if there is a reasonably high inertia in the system.

4733

The Foxboro Company. RELATIVE ACCURACY OF HANDWHEEL TRACKING WITH ONE AND BOTH HANDS. Contract OMSr 453, Rep. 5, OSRD Rep. 3455 to Div. 7, Services 75, Nov. 1943, 10pp. The Foxboro Company, Foxboro, Mass.

Studies of accuracy of direct tracking with a two-handed crank as compared with a single-handed handwheel showed moderate but significant superiority in the accuracy of the two-handed operation. This superiority was found both with free turning and with frictional load. The double crank handwheel control has certain practical advantages in direct handwheel tracking particularly where the load is appreciable and where the steadying effect from both hands on the wheel is useful. A double crank has the disadvantage that it must be mounted almost directly in front of the operator, for adequate vision and ease of operation. In these tests the double crank handwheel had an advantage of 22% in tracking accuracy over the average of the single handwheels without frictional load. Study was based on a group of unidirectional courses to be followed by direct handwheel tracking using a pointer-matching presentation.

4734

Forbes, T.W., Garner, W.R. & Howard, J.G. FLYING BY AUDITORY REFERENCE ("FLYBAR"). (Relevant to Service Control NK 108). Contract OMSr 658, MHR 107, OSRD Rep. 5123, June 1945, 69pp. National Defense Research Committee, Office of Scientific Research & Development, Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.

The purpose of the project "Flybar" was to devise a series of auditory signals by means of which the ears could take over some of the duties of reading flight instruments. Several experiments were performed to explore the range of useful signals. These were followed by the design and testing of auditory signal combinations. Finally, tests of flybar indications were made on the Link trainer. (MEIAS)

Beverly, R.F. A MEASURE OF RADAR SCOPE INTERPRETATION ABILITY TEST #1. Proj. 506 006 0002, Res. Note AN-229, Dec. 1952, 13pp. NSAF Human Resources Research Center, Lockheed AFB, Tex.

4739
This report is concerned with the development and description of a test of navigational radar scope interpretation ability. The interpretation task was defined as an activity requiring a complex of abilities and knowledge that may be measured by performance of tasks requiring map-scope correlation. A photograph-flight chart test was constructed requiring such performance. The test was given to four classes of rated pilots and the scores were analyzed for reliability. Some evidence for validity of the test is also presented. The problem of validation is discussed in some detail.

Cohner, R. AN IMPROVED STUDENT RESPONSE AND MONITORING SYSTEM FOR GROUP TRAINING. FO COMCOM, NEDAL34 1 (20-377), Rep. 341, Nov. 1952, 8pp. NSAF Electronics Lab., San Diego, Calif.

4740
This report describes a redesign of the AF/UGB-11 student response group trainer in which response, monitoring, and scoring are incorporated in a simply constructed and operated system employing an array of response lights. The system provides an item-by-item score as well as a cumulative score for drill-type material which can be reduced to a fixed number of choice-categories with up to ten choices per category. This device provides a diagnostic display of student responses and automatic indication of right-wrong to the student.

Atkinson, W.H., Crumley, L.M. & Willis, Marion P. A STUDY OF THE REQUIREMENTS FOR LETTERS, NUMBERS, AND MARKINGS TO BE USED ON TRANSLUMINATED AIRCRAFT CONTROL PANELS. PART 5. THE COMPARATIVE LEGIBILITY OF THREE FONTS FOR NUMERALS. Rep. TED NAM EL 609, Part 5, June 1952, 33pp. USN Aeronautical Medical Equipment Lab., NAMC, Philadelphia, Penn.

4742
To evaluate the legibility of new forms for numerals to be used on red transilluminated cockpit consoles (see 4759), they were compared with the Air Force Navy Drawing 10,400 and the font developed by Berger. Tests were conducted under conditions of red transillumination (from 0.10 to 3.30 ft.-L) and daylight illumination (from 11 to 34 ft.-c). Letters were exposed approximately 200 msec. for transillumination and five msec. for daylight illumination. Error scores for individual digits were analyzed for significant differences in form. Recommendations were included.

Brookhill, J.V. PROGRESS IN THE THEORY OF OPTIMUM SEQUENTIAL TESTING FOR RELIABILITY. Rep. AL 1721, May 1953, 8pp. North American Aviation, Inc., Downey, Calif.

4743
The problem dealt with here is a balance between (1) the cost of testing a product for reliability and (2) the risks, because of limiting the testing, of either accepting an insufficiently reliable product or rejecting a sufficiently reliable one. With a suitably defined pay-off function, the optimum parameters are obtained for a sequential test. The validity and reliability of this treatment are discussed. Modifications are also discussed for (1) the optimal sequential test when the pay-off function includes some uncertainty as to what is meant by sufficiently reliable, (2) the sequential test between two rival products, and (3) multidecision sequential test.

Sieker, E.O., Martin, E.E., Ganser, O.H., & Henry, J.P. A COMPARATIVE STUDY OF TWO EXPERIMENTAL PSYCHOMETRIC ANTI-G SUITS AND THE STANDARD CHAP 6-41 ANTI-G SUIT. WADC Tech. Rep. 52-317, Feb. 1953, 13pp. WADC, Aero Med. Lab., Air Res. and Devel. Command, Wright-Patterson AFB, Ohio.

4749

Two new types of pneumatic anti-g suits (which apply pressure to a greater portion of the lower body than the standard G-suits) have been examined and compared with the G-41. The tests entailed accelerations up to 6.5g on the human centrifuge, and were done on 5-11 men wearing each suit consecutively to ascertain the following physiological variables: visual symptoms and subjective observation, arterial and venous blood pressure, and the relation of these pressures to heart-to-head distances. Comparisons are noted and recommendations for subsequent study are made.

USN Air Technical Training Command. GENERAL AVIATION TECHNICAL TRAINING CONFERENCE REPORT. 14-17 APRIL 1953. NE/4/05/A 19, 39pp. USN Air Technical Training Center, Memphis Air Station, Tenn.

4753

This report of the General Aviation Technical Training Conference of 14-17 April 1953 is concerned with problems of training of naval aviation maintenance personnel, evaluation of the adequacy and suitability of specific training courses, and associated problems. Discussions and recommendations are included.

4754

Jogan, L., Millian, L.W. & Harris, M. A STUDY OF THE EFFECT OF CATASTROPHE ON SOCIAL DISORGANIZATION. Tech. Memo. CHO T 194, Dec. 1950, 135pp. Operations Research Office, Johns Hopkins University, Baltimore, Md. (University of Oklahoma Research Institute, Norman, Okla.).

4754

This is the first in a series of studies in which, in the absence of actual combat experience, the reactions of troops to atomic attack are extrapolated from the observed behavior of civilian groups in disasters. The bases for this study are the April 1947 Texas City explosion, four towns hit by tornadoes, and a holocaust fire. Attention is given to 1) the reactions of the participants, 2) the functioning of already existing disaster control organizations, and 3) the problems of individual and group rehabilitation. Conclusions are given regarding the pattern of social reorganization, the effect of previous organization and training, and the best methods of controlling panic.

Brown, F.R., Lowery, E.A., & Willis, M.P. A STUDY OF THE REQUIREMENTS FOR LETTERS, NUMBERS AND MARKINGS TO BE USED ON TRANS-ILLUMINATED AIRCRAFT CONTROL PANELS. PART III. THE EFFECT OF STROKE-WIDTH AND FORM UPON THE LEGIBILITY OF NUMERALS. Rep. TED XAN EL-608, Part 3, May 1951, 38pp. Naval Air Materiel Center, Naval Air Experimental Station, Philadelphia, Penn.

4753
To determine design factors influencing legibility of numerals (presented) under conditions simulating those encountered in reading trans-illuminated cockpit consoles, twenty subjects read numerals (5/32 inch high) presented tachistoscopically. The variables were: numeral design (Serif and sans serif), stroke width to height ratios (1:6, 1:7, 1:8, 1:9, 1:10, 1:12), exposure time (1/8, 1/20 seconds), illumination (40 and 60 footcandles, flood-lighting; 0.25 to 3.50 millilamberts, red trans-illumination). Error data is analyzed for significant differences between the two designs for each digit and its variations. A new series of digits was designed for improved legibility.

Zuckerman, J.V. TESTING WITH A PRE-RELEASE FILMSTRIP AS A MEANS OF PREDICTING FACTUAL LEARNING FROM A TRAINING FILM. TECHNICAL MEMORANDUM REPORT. HSPR Memo Rep. 14, Nov. 1951, 6pp. USAF Human Resources Research Lab., Bolling AFB, Washington, D.C.

4762
An attempt was made to use experimental methods to assess the extent to which a filmstrip made from a story-based art work can serve as a predictive device to secure data on how much people would learn from a completed factual figure. Such a filmstrip was made for preliminary testing of an Air Force training film. The filmstrip or the finished film were administered to groups of student pilots. Both groups were tested before and after administration with an identical factual test. Test results were analyzed after scores, absolute gain and relative gain in learning.

Baillinger, E.R. & Dempsey, C.A. THE EFFECTS OF PROLONGED ACCELERATION ON THE HUMAN BODY IN THE PRONE AND SUPINE POSITIONS. WADC Tech. Rep. 52 250, July 1952, 18pp. USAF Aero Medical Lab., Wright Air Development Center, Wright-Patterson AFB, Ohio.

2 acceleration problems of equal interest were studied simultaneously on the Wright Air Development Center human centrifuge at the Aero Medical Laboratory. Data were obtained in regard to both the evaluation of the prone bed at various accelerations and the concomitant determination of the physiological tolerance to prolonged periods of acceleration in semi-prone and supine positions. The duration of runs depended upon the acceleration, ranging from 15 minutes at 3 g, 8 minutes at 4 g, etc. to 2 minutes at 10 g. There was no appreciable difference in tolerance in the semi-prone or supine positions with accelerations up to 10 g. However, the necessity for a well constructed bed and head-supporting helmet, primarily for the comfort of the subject, was repeatedly demonstrated. In properly designed prone and supine beds, 23 unprotected subjects were able to tolerate accelerations up to 10 g for 2 minutes with only a small amount of discomfort. The security classification of the title of this report is Unclassified.

Pride, A.M. & Hyland, J.J. DEVELOPMENT OF EMERGENCY LANDING TECHNIQUES. Proj. PTR AC-235, May 1953, 130p. USN Air Test Center, Patuxent River, Md.

The circumstances surrounding actual flame out landings were investigated for 4 types of currently operational jet fighters: the F9F-2, F9F-5, F9F-2, and F9F-3. An average of 9.1 hours with 12 actual dead stick landings were flown per aircraft during the project test flying. It was established that all 4 types can be landed with relative ease with engines flamed out. A power setting with speed brakes extended was determined for each type which very closely duplicates the engine-off condition, so that pilots may practice simulated dead stick landings with relative safety. A simple procedure for each type is recommended. Air starting techniques were investigated for the 4 types and the airspeed for the best gliding range with engines shut down was established. Simple plots of possible range extension are presented. The details of engine-off behavior of each airplane type and its affected systems are discussed.

Hattson, J.B. & Hollis, J.B. REPORT ON PRELIMINARY OBSERVATIONS OF HUMAN ENGINEERING PROBLEMS UNDER ARCTIC CONDITIONS. Proj. 731 1000, Rep. 1, May 1953, 31pp. USA Research and Development Div., Ordnance Corps, Washington, D.C.

This report presents the findings of preliminary observations of human engineering problems under arctic conditions. Information was gathered at Big Delta, Alaska, Devils Lake, North Dakota, and Fort Churchill, Canada, to determine current problems and future areas for investigation. Implications of these findings are discussed and, where appropriate, recommendations are made for further study and evaluation.

Brown, R.H. VELOCITY DISCRIMINATION AND THE INTENSITY-TIME RELATION. J. OPT. SOC. AMER., March 1955, 45(3), 189-192. (USN Research Lab., Washington, D.C.).

The visual discrimination of velocity is considered in terms of the observer's response to its direction at different speeds. The hypothesis is advanced that the direct perception of motion in a middle range of speeds involves a single sensory event dependent on the intensity-time relation. To test this hypothesis, 4 subjects discriminated velocity at different speeds for each of 8 durations of exposure. The minimal luminance required for correct judgments of direction was measured by the method of limits. The data indicate that velocity discrimination occurs at intermediate speeds when the energy of the stimulating flash is constant (I₀t=C). The reciprocity relation does not hold for exposures longer than a critical duration of 0.1 sec. The luminance of the flash tends to be the sole limiting factor on velocity discriminations at longer durations of exposure (I₀k). Implications of these results are discussed with reference to other experiments.

Brown, R.H. & Conklin, J.E. THE LOWER THRESHOLD OF VISIBLE MOVEMENT AS A FUNCTION OF EXPOSURE-TIME. Amer. J. Psychol., March 1954, 62, 104-110. (USN Research Lab., Washington, D.C.).

An attempt was made to determine the influence of exposure-time upon the lower threshold. Conditions were obtained that exclude inferences of movement based upon visual comparisons of position. The essential features of the method used are: a) provision for initial fixation of a moving spot, b) presentation of a small-spot of light in the dark, and c) determination of the lowest rate at which the direction of the movement can be discriminated. The results of this study indicate that the threshold of visible movement decreases (becomes better, more acute) as the exposure-time is increased; that the decrease, large at first as the short exposure-times are lengthened by equal steps, becomes progressively less as the exposure-times become longer; and that autokinetic phenomena did not under the condition of this study affect either the observations or the reports of our Ss.

4781
Conklin, J.E., Baldwin, A. & Brown, R.H. APPARATUS FOR MEASURING THE THRESHOLD FOR VISUAL DISCRIMINATION OF DIRECTION OF MOVEMENT. Amer. J. Psychol., April 1953, 66(2), 289-319. (Naval Research Lab., Washington, D.C.).

The apparatus described here was designed to measure the threshold for visual discrimination of the direction of movement as a function of exposure-time. Although the apparatus was specifically constructed for the movement of a spot of light in complete darkness, it can be readily adapted to a situation where faint illumination is required. The equipment incorporates 4 desirable features: a) the presentation is noiseless; b) the movement within a given trial is made at a constant rate; c) the rate of movement may be accurately varied; and d) it has an automatic timing device for controlling the exposure.

4783
 Peckin, J.C. THE RELATIONSHIP OF THE COLOR AND BRIGHTNESS OF BACKGROUND TO THE PERCEPTION OF COLORED TEST OBJECTS. Contract AF 30 (602)-109, Final Rep., RADC-TR-55-90, March 1955, 13pp. University of Rochester.

4783
 To explore the relationship between color and brightness of background and of test object, the just perceptible brightness of a test illumination of a given spectral composition when viewed against a series of colored backgrounds was determined. The subject viewed test flashes presented for 1/5 second at ten-second intervals and decided whether or not it was seen; three successive positive responses was the criterion. Colors for both backgrounds and test flashes ranged from 700 to 400 millimicrons and included white background brightnesses ranged from a just perceptible level to a maximum. Threshold data were analyzed to show the pattern of change over the entire array of conditions. Recommendations governing use of colored presentations against a luminous background are given.

4784
 Headquarters, Air Proving Ground Command. FINAL REPORT ON OPERATIONAL SUITABILITY TEST OF THE POINTER-DRUM ALTIMETER. Proj. APG/SAT/593-A, Dec. 1955, 6pp. Headquarters, Air Proving Ground Command, Eglin AFB, Fla.

4784
 To determine the operational suitability of the Pointer-Drum Altimeter for use in United States Air Force aircraft, evaluations were made by 29 pilots after flying jet aircraft in which the altimeter had been installed. Both day and night flights were made with regulation instrument flight checks. Some evaluations were made during normal visual flight rule flying with special emphasis on rapid ascents and descents. Questionnaires (completed by all pilots) yielded pilot opinions concerning suitability of data presentation during all phases of instrument and night flight, ability to interpret readings accurately during rapid ascents and descents, preferences for new or conventional instrument, and design aspects of the altimeter. Recommendations are included.

4785
 Knowles, W.B. & Newlin E.P. CODING BY GROUPS AS A MODE OF STIMULUS PRESENTATION. Proj. NR 592 030, NRL Prob. Y02 03, Rep. 4604, Sept. 1955, 11pp. USN Research Lab., Washington, D.C.

Using a 5x5 matrix of lights and a similar panel of pushbuttons, 5 subjects were required to respond to sequences of 60 signals presented in sub-sequences of 2, 3, or 4 signals with intervals of 0.37, 0.52, 0.68 or 1.02 sec. between signals. Performance on each of these 12 experimental conditions was compared with a signal-by-signal control condition in terms of speed and accuracy measures. It was found that under limited conditions coding by groups can result in better performance than the item-by-item mode of operation, and that the amount of information rather than the rate at which it is presented seems more critical in determining the temporal organization of the responses to grouped signals.

4789
 Eldredge, D.H. & Hirsh, Shirley K. THE EFFECTS OF BLAST PHENOMENA ON MAN: A CRITICAL REVIEW. Contract Nonr 1151(01), Proj. NR 140 069, Rep. 3, June 1955, 24pp. National Research Council, Committee on Hearing and Bio-Acoustics, Washington, D.C.

The effects of blast phenomena on man are critically reviewed and summarized. Topics covered include: a) The physical stimuli; b) Measurement of the physical stimuli; c) The response of human tissues to transient forces; d) Reported effects of blast phenomena. A selected bibliography of 186 references is included in addition to the references cited in the review. (HEI-3)

4791
 Neely, K.K. ACOUSTIC PROPERTIES OF HEADGEAR: I. RCAF HEADGEAR ITEMS. Proj. 100 43 72, Rep. 100 2, July 1953, 28pp. Defence Research Medical Labs., Toronto, Ontario, Canada.

4791
 To determine the adequacy of various items of Royal Canadian Air Force headgear in the maintenance of efficient voice communications and in the protection of the ear from noise, two series of tests were conducted: acoustic insulation tests and listener-intelligibility tests. Four helmet modifications and two oxygen masks were tested singly and in various combinations.

4792
 Young, H.L. DESIGNS FOR HORIZONTAL PARALLAX AND STAR SHELL SPREAD DIALS OF THE TRAIN RECEIVER REGULATOR MARK 28 MODIFICATION 0. NRL Prob. R13 060 (Bureau Request) 214, Interim Rep., Oct. 1948, 6pp. USN Research Lab., Washington, D.C.

Design recommendations are made for the horizontal parallax and star shell spread dials of the Train Receiver Regulator Mark 28 Modification 0. A list of formulae is given for determining the spacing of star shell spread dial graduations and a table is included to specify the relative directions of turret, dial and knob rotation for forward and aft turrets in terms of starboard and port star shell spread orders. Illustrations of the recommended designs are enclosed. It is recommended that horizontal parallax and star shell spread be indicated on separate dials. This recommendation is based on the fact that the 2 dials have discrete functions and are different operationally. The parallax dial is used only as a checking dial to inform the operator that the instrument is working accurately. The operator reads a specified amount against a fixed index mark located at the top of the dial when a known gun train order is received. On the other hand, the star shell spread dial is an operating dial. The star shell spread orders are received verbally as so many degrees port or starboard and are inserted into the dial with a knob so that the given order is seen against the fixed index at the top of the dial.

Cookley, J.T., Fucigna, J.T. & Dunlap, J.V. HUMAN ENGINEERING REVIEW OF THE AERIAL RECONNAISSANCE CAMERA KA-5. Contract DA 36 039 SC C4647, Proj. 3 99 01-222, Task 2004A, Sept. 1955, 24pp. USA Signal Corps Engineering Lab., Fort Monmouth, N.J. (Dunlap and Associates, Inc., Stamford, Conn.).

Recommendations, with regard to size, shape, location, angle and material, are made for 2 handles on the aerial reconnaissance camera, KA-5. For the left handle, a contoured grip, located in the lower-left front corner of the camera, and adjustable through a range of 45°, is recommended as an optimum design and location. Three alternative locations are also discussed should it be impossible to meet the optimum specifications. A contoured grip is also recommended for the right handle. In addition, the angle of the right handle is modified to equalize further the distribution of weight over the right hand.

4794

Coardren, L.J. THE USE OF RADIOACTIVE SELF-LUMINOUS MARKERS AS SOURCES OF ILLUMINATION. Proj. NR 672 010, NRL Prob. NO2 01, July 1955, 21pp. Photometry Branch, Naval Research Lab., Washington, D.C.

The results of various studies show that radioactive self-luminous deck and personnel markers can be used as simple, inexpensive, and reliable sources of illumination to assist some military operations under dark conditions. Strontium-90 is the most suitable of the present radioactive isotopes for exciting the phosphors in the markers. Experiments were made using single markers and groups of markers in a variety of colors, luminances, and distances. Green markers are the most efficient illuminators since the spectral energy distribution of the light from green markers has its maximum at about the same wavelength as the maximum of the sensitivity curve of the dark-adapted eye. The distribution of luminance of a white wall, illuminated by various groups of markers, was measured to show the extent of useful illumination. Various tests revealed many uses that are possible.

Chambers, A.W. HUMAN ENGINEERING RECOMMENDATIONS FOR A SYNTHESIZED HELICOPTER SIMULATOR. Contract AF 33(616) 2080, Supplemental Agreement 87(55-823), June 1955, 78pp. American Institute for Research, Pittsburgh, Penn.

4795

This report presents human engineering recommendations for a synthesized helicopter simulator to be used for advanced training of pilots. A task analysis of the pilot's job was made to determine the essential discriminations, decisions, and responses required of a pilot to fly a helicopter. Human engineering recommendations are concerned with the equipment required to provide training on the tasks; the physical and functional properties of this equipment, and the use of the equipment for training.

Marks, M.R. & Uhlaner, J.E. EVALUATION OF NEW ARMED FORCES VISION TESTER PLATES. Projs. DA 29560000 & PRB B 6 133 33, PRB Tech. Res. Rep. 1092, Task 133, June 1955, 37pp. USA Personnel Research and Procedures Div., The Adjutant General's Office, Washington, D.C.

Previous research and operational considerations indicated that a vision test, which could be given in an optical instrument at moonlight (mesopic) levels of illumination, warranted development as a predictor of ability to see in night operations. The Armed Forces Vision Tester was modified to permit testing at mesopic levels. Potential vision tests were screened for appropriate psychometric characteristics. In checking test procedure, 10 mins. of dark adaptation preceding the presentation of test targets was found to be sufficient for reliable mesopic testing. A night field detection course was developed on which examinee-observers were required to spot aggressors in various positions at varying distances. Scores of infantrymen on the selected mesopic tests were compared with measures of their performance on the night detection course. The most effective predictor of night visual performance was found to be the Mesopic Line Resolution Test.

Thistlethwaite, D., Moltz, H., Kamenetzky, J. & de Haan, H. EFFECTS OF BASIC TRAINING ON THE ATTITUDES OF AIRMEN. Contract AF 33(638) 25726, Proj. 7705, Task 15, AFPTC TR 55 3, June 1955, 44pp. USA Personnel Research Lab., Lackland AFB, Tex. (University of Illinois, Urbana, Ill.).

4798

This paper evaluates the effects of an eight-week basic military training course on certain attitudes of 900 airmen. The attitudes, measured with questionnaires, pertain to combat, authoritarian leadership, loyalty toward the flight, instructor's competence, motivation to serve, and personal adjustment. Changes in these attitudes are related to characteristics of the instructors and predispositions of the trainees.

Stono, G.R. THE TRAINING FUNCTION OF EXAMINATIONS: RETEST PERFORMANCE AS A FUNCTION OF THE AMOUNT AND KIND OF CRITIQUE INFORMATION. Proj. 7711, Task 57001, AFPTC TR 55 8, June 1955, 22pp. USAF Aircraft Observer Research Lab., Mather AFB, Calif.

4799

This study undertook to determine how different amounts and kinds of feedback (knowledge of results) affect the elimination of wrong answers on a multiple-choice examination. The 55, 240 Air Force cadets divided into five groups, all took the same examination at two different times. Each group was given different amounts of information as to correct and incorrect answers after the original test. Errors on the retest relative to errors on the original test are compared for the five groups.

Gragg, D.B., Kieselbach, D.J., Murphy, M.F., Peckham, R.E., et al. THE 14-WEEK EXPLORATORY STUDY OF MARGINAL-AIRMAN BASIC TRAINING: COMPARISON OF PROFICIENCY OF 8-WEEK AND 14-WEEK TRAINING GROUPS. Proj. 7700, Task 77003, AFPTTC TN 55 10, June 1955, 26pp. USAF Personnel Research Lab., Lackland AFB, Tex.

4500

The basic training period was extended from eight to 14 weeks for a group of 140 marginal (low-aptitude) airmen. This group's proficiency scores for various military tasks and academic skills at the end of 14 weeks were compared with those obtained by a matched control group at the end of eight weeks. The effectiveness of the prolonged training period was evaluated and recommendations for further research were made. T. R 10

Cohen, J.D. & McKelvey, R.K. THE BEHAVIOR OF INDIVIDUALS AND PERSONNEL SYSTEMS IN THE SURVEILLANCE FUNCTIONS OF AN AIR DEFENSE DIRECTION CENTER: III. DISTRIBUTION OF RESPONSES WITH RESPECT TO JOB FUNCTIONS. Proj. 7712, AFPTTC TN 55 11, June 1955, 15pp. USAF Crew Research Lab., Randolph AFB, Tex.

4801

As part of a research program directed toward the development of a method of systematically recording and analyzing the behavior of operators in the surveillance function of an Air Defense Direction Center, observations were collected on activities of 24 Aircraft Control and Warning operators under standard system operations. The data were summarized in terms of distributions of types of responses at three positions (scope operator, plotter, and teller/recorder) and categorized in relation to effectiveness in accomplishing mission. Analysis revealed the characteristic way each of the positions was performed. The results have implications for job specification as well as assessment procedures. T. G. I. R 3

4803

Rowland, G.E., Cornog, D.Y., & Courtney, D. EXTERIOR LIGHTING FOR NAVAL AIRCRAFT. Contract N156a-32795, Rep. 9, Proj. F, Aug. 1956, 150pp. Courtney and Company, Philadelphia, Penn.

4803

This is a second interim report of research on development of an optimum exterior lighting system for Naval Aircraft. The data in this report include an analysis of aircraft movements during operations involving exterior lighting, relationships of perceptual problems of crucial personnel to aircraft movement, and the limiting factors of the working environment. These data were gathered by a research team (1) observing operations, (2) actually participating in operations wherever possible, and (3) interrogating--interviews with senior personnel, unstructured interviews with personnel on the job, and written interviews. Appendices contain data collection devices, coding manual and examples from interviews and the raw data summary. T. I.

McMahon, C.A., & Ford, T.R. SURVIVING THE FIRST FIVE YEARS OF RETIREMENT. J. Geront., April 1955, 10, 212-215. AFPTTC TN 55-22, Aug. 1955. AFPTTC, Maxwell AFB, Alabama.

4804

In order to evaluate the belief that retirement has a negative effect on life expectancy, it was hypothesized that examination of the longevity records of two populations of Army and Air Force officers should reveal a higher mortality rate in the first 5-year retirement period than in two subsequent 5-year periods. Results are discussed with regard to the hypothesis and the particular population utilized in the study. T.R2.

4805 Zwislowski, J. SEMIPLASTIC EARPLUGS. J. acous. soc. Amer., May 1955, 27(3), 460-465. (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.). (PWR 165)

Description of the development of an earplug with soft elastic walls and a viscous core malleable at body temperature. The problems of suitable material, shape, and size are considered as well as the shape and size adaptability. People have found these earplugs sufficiently comfortable to sleep with, and they ensure a sound attenuation equal to or better than any known earplug. One size fitted 90 percent of the ears of the 25 people tested sufficiently well. R 6

4806 Ward, W.D. TONAL MONAURAL DIPLACUSIS. J. acous. soc. Amer., March 1955, 27(2), 365-372. (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.).

2 similar cases of tonal monaural diplacusis are described. When low-intensity sinusoids within a certain range are presented, several distinct tones are heard in addition to the tone presented. The effects are focused at 3610 cps for one subject and at 3155 cps for the other. Pitch-matching and probe-tone techniques show that the additional tones correspond to combination tones expected in a normal ear stimulated by 2 tones, one of which is fixed at one of the above frequencies. Hence some basic instability of the auditory mechanism at these frequencies is indicated for these observers. It is suggested that the defect lies in the "peaking" process of the cochlea, so that an adequate explanation of the phenomena may be of some importance to auditory theory. R 10

Tupes, E.C., Bowles, J.W. & Torr, D.V. PREDICTING MOTIVATION FOR FLYING TRAINING AMONG SENIOR AFROTC CADETS. Proj. 503 002 7701, AFPTTC TN 55 18, July 1955, 8pp. USAF Personnel Research Lab., Lackland AFB, Tex.

4807

Concerned with the general problem of motivation for flying, this report presents an investigation of the relationship between certain test and proficiency variables (physical proficiency, intelligence, personality, attitudes, pilot aptitude, etc.) and a motivation-for-flying training criterion obtained by comparing a group of AFROTC cadets in flight training with AFROTC cadets who did not apply although they believed they could qualify for flight training. Data on approximately 700 cases yields results which are discussed in terms of the relationships found to exist between acceptance versus rejection of flying training and the various test and proficiency variables. T. R 1

4809 Coakley, J.D., Fucigna, J.T. & Barrack, J.E. A FUNCTIONAL APPLICATION OF ANTHROPOMETRIC DATA TO THE DESIGN OF THE WORKSPACE OF PPI SCOPE OPERATORS. Contract AF 33(038) 18'03, WADC Tech. Rep. 53 3, Jan. 1953, 16pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Dunlap and Associates, Inc., Darien, Conn.).

The dimensions and layout of PPI consoles now in production are based on the needs of operators having average body dimensions. The use of averages results in equipment unsuitable both for operators who are larger than average and for those smaller than average. 2 needs assumed to be basic to the operations of a PPI scope operator are the need to see the GCI plotting board and the need to feel comfortable while operating the scope for long periods of time. With these needs as a basic consideration, conceptual dimensions should be chosen to accommodate approximately the middle 95-5% of the military population. These principles are applied to the design of a PPI console and the operator's chair, and to the placement of the PPI scopes in a GCI station.

4811 Bayroff, A.G., Gorsuch, J.H., Mueller, R.A.H., Murphy, D.L., et al. THE OPERATION AND USE OF THE BUREAU OF ORDNANCE GUNNERY TRAINER MARK 3 MOD 2. PART I: OBSERVATIONS ON THE USE AND OPERATION OF THE TRAINER. PART II: EXPERIMENTAL STUDY OF TARGET FLIGHTS SUITABLE AT THE INDOCTRINATION LEVEL. Contract OEMSR 700, Proj. N-105, OSRD Rep. 6229, Memo. 33, Oct. 1945, 34pp. University of Pennsylvania, Philadelphia, Penn.

4811 This is an experimental study undertaken to investigate the characteristics of target films suitable for indoctrination on the Bureau of Ordnance Gunnery Trainer Mark 3. The effect upon difficulty of practice, range setting, and screen employed (lower or upper) was tested with 36 Ss. In addition to the conclusions concerning the level of difficulty of indoctrination target patterns, observations on the operation of the trainer are reported.

Johnson, C.D., Burke, L.K., Loeffler, June C. & Brucker, A.J. PREDICTION OF THE COMBAT PROFICIENCY OF INFANTRYMEN. Proj. 79560000 & FEB Proj. B 8 251 20, PAB Tech. Res. Rep. 1095, July 1955, 16pp. USA Personnel Research Branch, Adjutant General's Office, Washington, D.C.

4813

Research completed and research plans pertinent to the development of aptitude areas for classifying personnel into the Combat Arms are reviewed. A self-description blank, a personal inventory of combat-related traits, and several tests of learning and perceptual abilities were tried out on two combat regiments in Korea. Among the results of this series was a new and promising self-description blank predicting combat performance. Reanalysis of available data indicated that an interest questionnaire developed in a fighter factor study is equally promising. These items are being further investigated for development of the desired aptitude areas.

4818 Poulton, F.C. & Stevens, S.S. ON THE HALVING AND DOUBLING OF THE LOUDNESS OF WHITE NOISE. J. acoust. Soc. Amer., March 1955, 27(2), 329-331. (PMR 159) University, Cambridge, Mass.).

The decibel changes required to halve and to double the apparent loudness of a white noise were determined at 9 sound pressure levels by 36 subjects. The subjects adjusted the level of the noise by means of an "improved control" -- a "tone potentiometer" whose angular turn is roughly proportional to the loudness produced. An attempt was also made to measure and control some of the biasing factors that affect loudness estimations. Results: the median decibel changes required to produce a 2:1 loudness ratio ranged from 6 to 10 db, approximately.

R 6

4819
Stevens, S.S., Rogers, H.S., & Herrstein, R.J. THE APPARENT REDUCTION OF LOUDEST A REPEAT EXPERIMENT. *Acoustics, 1953, March, 1953, 27(2), 326-328.* (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.). (PDR 164)

The experiment of Laird, Taylor, and Wille (1952) showed that the reduction in the intensity of a sound required to produce half-loudness is of the order of 10 db. Since this result is out of line with most other studies in this field, an attempt was made to repeat the experiment with a similar piece of apparatus (acknowledged). The first attempt to copy the procedure of Laird, Taylor, and Wille gave results more like those usually obtained, namely, a required reduction for half-loudness of the order of 10 db. A second experiment, involving the use of comparison tones placed at such as 40 db below the standard, gave results more like those of Laird, Taylor, and Wille. The method they used appears to be overly sensitive to the range and order of presentation of the comparison stimuli.

4820
Miller, R.B., Kelley, J.D., Jr., & Smith, P.R. THE VALIDITY OF MAINTENANCE JOB SKILLS FROM THE PRACTICE OF AN ELECTRONIC EQUIPMENT. PART II. K-1 TROUBLE-SHOOTING SKILLS. Contract AF 33(616) 7001, 7-1-53, 307 OGS 0021, Feb. 1953. *Wright Air Development Center, Dayton, Ohio.*

4821
A procedure developed earlier for the anticipation of maintenance job requirements for an electronic equipment was applied to the K-1 Tracking Navigational Set, an equipment already in field use. The procedure consists mainly of making a detailed analysis, in terms of behavior, of the demands imposed upon the maintenance personnel by the equipment. In the application to K-1, two separate job analyses were made, one from available manufacturer's records kept during the prototype stage of equipment development and one from data available on production models in field installations. A comparison was then made of the two analyses for degree of similarity. Training implications were discussed.

4822
Henderson, D.R. A REVIEW OF MULTIPLE CHANNEL LISTENING EXPERIENCE. *RAF 55/533, CDS 257, April 1955, 9pp.* Royal Naval Research Committee, NRC, London, England. (Applied Psychology Research Unit, NRC, Cambridge, England).

4823
Siegel, A.L., Jensen, J.J., & Dancy, E.R. AN INVESTIGATION AND TEST OF THE TROUBLE-SHOOTING ABILITY OF AVIATION ELECTRICIANS. Contract NRC 1348(00), Series 1953, Inst. Rep. 1, Jan. 1953, 80pp. *Investigation for Research in Human Relations, Philadelphia, Penn.*

4824
A battery of four separate performance tests (AE Trouble-Shooting Performance Examination) was developed. Each test measures the aviation electrician's ability in one of the four critical skills judged necessary for adequate trouble-shooting. The tests were administered to a first sample of aviation electricians and the scores analyzed for evidence of test reliability and test validity. Four written tests, each related by content to an individual "E" school phase, were first developed on the basis of internal consistency and then validated against the AE Trouble-Shooting Performance Examination. A short form of the written test was also developed. Some additional relationships were studied.

4825
This paper contains a review of results of previous experiments on multiple-channel listening, and some practical conclusions which may be drawn from them. The discussion covers listening to two messages at once, listening to a message against irrelevant background, monitoring of several channels, memory of one channel while listening to another, and miscellaneous experiments. In each type of situation two chief problems are discussed: the amount of information a listener can handle, and the physical means by which it is delivered.

4826
Richards, G.W. YELLOW GLASSES FAIL TO IMPROVE SEEING AT NIGHT-DRIVING LUMINANCES. *Highway Res. Abstracts, July 1953, 23(7), 32-36.* (American Optical Company.).

Acuity and contrast were measured for 73 persons (ages 16 to 72) at 11, 1.0 and 0.1 ft.-L. (3025 K.) with and without Noviol C glasses, and without the yellow glasses at an intensity equal to the overall transmission of the yellow glasses. The latter permits evaluation of any effect due to yellowness separate from decreased illumination. Yellowness had little effect at the higher luminances and some loss of seeing found at the lower levels is associated with the Purkinje shift. A small but statistically significant loss of vision occurs from yellow glasses. The loss appears to increase with age. No observers showed any consistent gain in seeing with yellow glasses for both acuity and contrast for all luminances tested, although random small gains were common. Since there is barely sufficient luminance for average night driving, the loss from yellow glasses is potentially dangerous and the data recommend that yellow glasses not be worn during night driving on public roads.

Shapard, R.J. THE EVALUATION OF A NULL-POINT DISCONTINUOUS ELECTROCALORIMETER. *IPMC* 588, Aug. 1955, 177p. Flying Personnel Research Committee, Royal Air Force Institute of Aviation Medicine, London, England.

Description is given of a null-balance electrical pursuit meter based on a Wheatstone bridge circuit. Evaluation in a group of normal subjects shows that it is capable of yielding repeatable measurements of an "initial response time" and a "total response time" for coordinated manual tasks of the type encountered in flying an aircraft. Possible applications include addition and subtraction problems, code substitution tests, and measurements of inhibition and contrast discrimination. "Initial response time" would, in flying, for example, be the time required to read the left-hand dial, memorize the reading and initiate appropriate coordination movements of the wrist. "Total response time" would be the time required to complete a fairly simple coordination task; for example, "initial response time" plus period occupied by muscular movement plus time required for making a final judgment of accuracy. With suitable adjustment the apparatus is capable of testing other psychological functions and of visual contrast discrimination. It is recommended that the apparatus should be tested under conditions of psychological stress.

Smith, A.D. GUIDE FOR THE DESIGN AND EVALUATION OF THE INSTRUCTOR'S STATION IN TRAINING EQUIPMENT. Contract AF 33(616) 2380, Proj. 7157, MOD TR 54 564, Dec. 1954, 272pp. USAF Aerospace Medical Lab., Wright-Patterson AFB, Ohio. (American Institute for Research, Pittsburgh, Penn.).

4825

This report is based on an application of systems analysis to the instructor's station in the training situation. It describes in detail methods for evaluating the effectiveness of the instructor's station, for determining what specific equipment is needed at the instructor's station and how this equipment should be designed and arranged, and for deciding which inputs and outputs to the trainee station the instructor should control and how he should control them. Included also in the report are examples of inadequate human engineering in the design of instructors' stations and sample questionnaires for obtaining information on the function of training equipment from instructors and observers.

Nachwias, J. FIGURAL AFTER-EFFECTS IN KINESTHETIC SPACE. *Amer. J. Psychol.*, 1953, 66, 609-612. (Swarthmore College, Swarthmore, Penn.).

2 experiments were performed to demonstrate that kinesthetic after-effects can be induced by a method closely analogous to that employed in visual experiments. The method is based on the subjective comparison of the stationary position relative to the body of the 2 hands; 20 Ss were studied. The S was blind-folded, then one of his hands was placed for 60 sec. on a bar 4 in. above or below the test-bar; the other hand remained at his side. For the test, both hands were placed simultaneously on the same horizontal bar, and S was asked to report whether his hands now appeared to be at exactly the same height, and if not, which felt higher. If kinesthetic after-effects behave like their visual analogs, the satiated hand should appear displaced away from the previously satiated locus; 16 of the 20 Ss reported such an effect. In a 2nd experiment, an attempt was made to discover whether the magnitude of the displacement passes through a maximum. Both hands were satiated simultaneously, with each hand kept at a different height. In the test-period, the 2 hands were placed on the same test-bar; 72 Ss were tested. There was no evidence of a maximum for an equal number of Ss reported quite opposite effects. Some tentative explanations for this effect are offered.

Newhall, S.M. COMPARABILITY OF THE METHOD OF SINGLE STIMULI AND THE METHOD OF PAIRED COMPARISONS. *Amer. J. Psychol.*, March 1954, 67, 96-103. (Eastman Kodak Company, Rochester, N.Y.).

A group of 12 Os made preferential judgments of three separate series of color prints both by the method of single stimuli and the method of paired comparisons. In all 3 series the original uncorrected product moment correlations of the results by the two methods exceeded 0.95. Even when the 2 different methods were used by 2 different groups of 12 Os, the r 's ranged from 0.77 to 0.99. A different group of 12 Os made preferential judgments of 3 separate series of projected color transparencies, using the same two methods. In all 3 series, the r 's were 0.50 or more; and when the two methods were used by different group of Os the r 's ranged from 0.78 to 0.93. The r 's between the methods proved to be as high when only 1/5 as much data was taken by the method of single stimuli, viz. a simple trial, as when the same amount of data was taken by both methods. The method of single stimuli appears to be the more efficient method. (HEIAS)

4839
To investigate the effect of verbal incentive-related information upon the learning of a motor skill, 400 Ss were required to perform a modified Two-Hand Coordination Test. Three groups of these Ss were told their scores at three periods during practice of the task and instructed that a 25 percent improvement was necessary to achieve a passing score. A fourth group received no information. The results are presented and discussed in terms of the differences in performance among the various groups as indicative of the relative effect of motivation in the acquisition of a tracking skill of this sort.

4839
To investigate the effects of a wide range of amount sets on initial performance and to determine a provisional length-difficulty function for certain psychomotor skills, 160 basic airmen were tested on a self-paced psychomotor apparatus (the Complex Coordination Test). The basic task was to match patterns of green lamps (of known absolute-difficulty) to red ones by manipulating a stick and rudder. Results are discussed in terms of difficulty of task as a function of length of task and the relation between amount set and task length.

Singer, J.L. PERSONAL AND ENVIRONMENTAL DETERMINANTS OF PERCEPTION IN A SIZE CONSTANCY EXPERIMENT. J. exp. psychol., June 1952, 43(6), 420-427. (University of Pennsylvania, Philadelphia, Penn.)

Employing a simple size constancy procedure, 4 experiments were conducted to observe the interaction of personal and environmental determinants of perceptual response. The Ss made size judgments of distant squares under conditions which included changes in the distance and in meaningfulness of stimulus content, 2 types of experimental instructions, and following emotional disturbance. Experiment I presented evidence to support the hypothesis that meaningful stimulus content (a schematic "happy face") led to a significant enhancement in perceived size of a standard square compared with squares containing a nonsense figure, a circle, or blank surface. Experiment II provided results suggesting that this effect of meaningful stimulus content was operative when analytic rather than synthetic or objective perceptual attitudes are demanded of Ss. The Ss also differed markedly in susceptibility to the influence of meaningful content and in mode of compliance with instructions. Experiment III, Ss chosen as extreme thinking introverts and extroverts differed significantly in perceptual response, extroverts showing values closer to constancy. In Experiment IV, the effect of frustration was shown to be more striking when analytic rather than objective perceptual attitudes were called for.

Solomon, P. & Werner, H. STUDIES ON CONTOUR: III. NEGATIVE AFTER-IMAGES. Amer. J. Psychol., 1952, 55, 67-74. (Clark University, Worcester, Mass.)

An investigation of the role of contour in the formation of negative after-images was conducted. A reversible pattern, the sector-disk, was used as the stimulus. Before testing, each S was trained in the deliberate shift of the figure-ground relationship and practiced fixation. The test procedure was to have S fixate the center mark and to organize in such a way that one (white or black) sector was perceived as rotating upon the ground and to maintain that view for 2 min. At the end S had to project the circular negative after-image upon a gray indicator-disk by fixating its center; the gray color of the ring was then varied until the inner disk and the outer ring were reported to be equal in brightness. The results were presented in terms of degrees of whiteness of the after-image as measured on the indicator-ring. For all 10 Ss the after-image was always brighter for black sector on white than for the reverse condition; the difference in group means was significant. Thus, the experiment demonstrated that the degree of brightness of a negative after-image is to a considerable extent dependent on the brightness of the area articulated as figure. It is felt that the differences are explainable in terms of the relative efficacy of figural contour.

Smith, V.M. APPARENT SIZE IN STEROSCOPIC MOVIES. (Princeton University, Princeton, N.J.)

The reduction of apparent size induced by viewing movies with stereoscopic vision (through polaroid glasses) is discussed in this note. Information was obtained from students in a course in introductory psychology by means of a questionnaire asking whether they observed any size changes, if so, what they were, and finally a check-list of physical experiences they might have had during or following the movie, such as watering of the eyes, double vision, strain in and around the eyes, dizziness, etc. The majority of students did observe this intended depth-effect and also noted the size change, 3 symptoms checked with a disproportionate high frequency were experience of strain in and around eyes, difficulty keeping picture in focus, and recurring double images. The author's explanation for the size effect and the symptoms involves the factors of anomalous convergence and accommodation by which conflict in visual perception is produced. The viewing distance calls for adjustment of the accommodation convergence mechanism which is related to a much larger viewing distance.

4844

To determine the quantity and nutrient content of the foods consumed by the soldier in Army camps, under temperate climatic conditions, in the continental United States, five surveys were performed over a period of four years (1952-1956) in ten companies in five Army camps. The data were collected and analyzed both by chemical and "long" inventory methods and include determination of calorie and carbohydrate, food consumed in Army mess, food eaten between meals, total quantity of edible food, food losses and energy requirements of the soldier, based upon food consumption from all sources and the energy equivalent of the gain or loss of body weight during the survey period. A comparison of data obtained by the two methods is made. Recommendations are included. T. R 32

Wilcott, R.C. A SEARCH FOR SUBTHRESHOLD CONDITIONING AT FOUR DIFFERENT AUDITORY FREQUENCIES. *J. exp. Psychol.*, Oct. 1953; 46(4), 271-277. (Human Factors Div., USN Electronics Lab.).

An attempt was made to condition a change in skin resistance (GSR) of ten Ss using 4 separate frequencies with each at an intensity below the absolute threshold. The frequencies chosen were a 200, 2000, and 13,000 cps, and a thermal noise. The UCS was an electrical shock. The absolute threshold was specified as a range between a) the lowest intensity level that S could consistently hear, and b) the highest intensity level that S did not report hearing during five successive trials. The latter level was used as the intensity of the CS. Before each attempt at subthreshold conditioning, each S's GSR was conditioned to a sound 20-db above the subthreshold level. A control study was run which indicated that for intensity levels within 20 db above the subthreshold level the intensity of the CS is not consistently related to the magnitude of the CR. The results indicate that no subthreshold CR's were elicited for any S with any of the four frequencies used.

Verner, H. & Wapner, S. EXPERIMENTS ON SENSORY-TONIC FIELD THEORY OF PERCEPTION: IV. EFFECT OF INITIAL POSITION OF A ROD ON APPARENT VERTICALITY. *J. exp. Psychol.*, Jan. 1952, 43(1), 68-74. (Clark University, Worcester, Mass.).

The influence of the position of a rod at the beginning of a trial (starting position) on the final position in which it is perceived as vertical has been systematically investigated. The main finding is that the apparent vertical is always closest to the position in which the rod was set initially for that trial. These results are viewed here as figural adaptation effects. Taking the results of this study together with those gained from previous investigations on the effect of postural tilts and extraneous stimulation on the perception of verticality, such adaptation is interpreted within the framework of a general theory which emphasizes body-object relationships. The dynamics underlying these adaptation effects are assumed to be equilibration tendencies within a field that encompasses body and object.

Wilcott, R.C. & Gales, R.S. COMPARISON OF THE MASKED THRESHOLDS OF A SIMULATED MOVING AND STATIONARY AUDITORY SIGNAL. *J. exp. Psychol.*, 1954, 47(6), 451-456. (University of Southern California, Los Angeles, Calif. & USN Electronics Lab.).

The masked thresholds of a simulated moving signal produced by a linear stepwise change in interaural time delay, and with movement at two different locations in the phenomenal field, were compared with the thresholds obtained with a stationary signal. A noise band extending from 75 to 850 cps was used as the signal and was presented against an uncorrelated background noise, and masked thresholds were made under the following conditions: a) with a signal moving at a perceptually slow and fast rate; b) with a perceptually fast-moving signal making four excursions across the phenomenal field during each presentation period; c) with the signal movement controlled by 0; and d) during an extended listening period in which 0 was given no cue as to when the signal was to be presented. The results of the threshold comparisons with these different conditions indicate that the masked threshold of a moving signal is a function only of its localization at any given instant in time, and that a moving signal does not elicit a lower masked threshold than does a stationary signal.

Ross, S. & Versace, J. THE CRITICAL FREQUENCY FOR TASTE. *Amer. J. Psychol.*, 1953, 66, 496-497. (University of Maryland, College Park, Md.).

A replication of an early study on fusion-frequencies for periodic electrical excitation of taste (F. Allen and H. Weinberg, The gustatory sensory reflex, *Quart. J. Exper. Physiol.*, 15, 1925, 385-420) is reported in this note. A laboratory signal generator was used to drive a double-diode clipper followed by a clamper. The output thus consisted of positive square-waves variable from 0 to 3.6 v. The electrodes were of low galvanic action dental wire spaced about 1/4 in. apart. 5 Ss were studied. None of them spontaneously reported discrete sensations of taste for frequencies varying from 20 to 2000 cps and none was able to report the appearance of such sensations, even though set by instructions to attend to them. Little or no sensation was elicited at 1 v. and below. Varying complex sensations of cold, sour, and bitter were produced at higher voltages; with excitations exceeding 3 v., pronounced tactual-kinesthetic vibratory sensations were evoked. Fusion occurred between 500 and 1700 cps, and seemed to be related to pressure of electrodes against the tongue and area stimulated. These findings do not confirm the earlier study's data. (HEIAS)

Ross, S. & Fletcher, J.L. RESPONSE TIME AS AN INDICATOR OF COLOR DEFICIENCY. *J. appl. Psychol.*, 1953, 37(3), 211-213. (University of Maryland, College Park, Md.).

Response time measures to 15 selected plates of the AG pseudo-isochromatic test for color perception were secured for 136 college students (28 females; 108 males). Of this group, 110 were classified as normal, 26 as defective, on the basis of their error scores. Each subject was given 2 successive tests: criterion and test trials. Mean plate response times between the normal (0.56 sec.) and the defective (1.93 sec.) groups were found to differ significantly. Practice effects were noted within the normal group. It was concluded that response time measures could be used in the separation of color normal from color defective individuals.

Ross, S., Hussman, T.A. & Andrews, T.G. EFFECTS OF FATIGUE AND ANXIETY ON CERTAIN PSYCHOMOTOR AND VISUAL FUNCTIONS. *J. appl. Psychol.*, 1954, 38(2), 119-125. (University of Maryland, College Park, Md.).

The primary purpose of the experiment was to determine whether or not performance on each of the 5 dependent variables changed significantly as a result of intensive muscular exercise (fatigue) or the fear of bodily injury (anxiety) or the interaction of these conditions in the collegiate competitive boxing situation. 24 boxers were measured under the following 4 conditions: at rest; after heavy exercise; before fighting; and after fighting. The tests were administered 3 times to each subject under each of the experimental conditions. Hand steadiness scores decreased significantly with fatigue, but not with the anxiety conditions. Fatigue and anxiety significantly increased body sway scores. Body sway time scores were found to be unreliable, although the fatigue conditions significantly increased these scores. Tapping was found to be unreliable, possibly due to a learning factor. Significant changes were found, however, in the test scores as a result of both fatigue and anxiety. Critical flicker frequency thresholds were shown to decrease significantly as a result of anxiety. No relationship was found between the dependent variables used and the number of head blows received by the Ss during a boxing bout. Measures of steadiness more than the other variable tested satisfy the criteria for indicators of behavior decrement.

Hecht, S., Ross, S., & Mueller, C.G. THE VISIBILITY OF LINES AND SQUARES AT HIGH BRIGHTNESS. *J. opt. soc. Amer.*, 1947, 37, 500-507. (Laboratory of Biophysics, Columbia University, New York City)

4852

To develop a simple psychophysical method for measuring the relative intensities of rapid substances and to determine the relative sweetness of various compounds at different subjective intensities, the single stimulus method with a nine-category rating scale of subjective intensity (from no intensity to extreme intensity) was used. Sixteen compounds of five logarithmically spaced concentrations were rated for sweetness by ten subjects. Mean intensity ratings based on 20 judgments for each concentration were obtained, and a least squares curve fitted by method of orthogonal polynomials. The relation between concentration and subjective intensity for the various compounds is presented graphically. These results are compared to findings from similar studies that used more complex methods. T. G. R 9

4855

To determine the visibility of lines and squares at high brightness, field experiments were conducted in which the visibility of targets was studied at the limits of their resolution as viewed in silhouette against the open sky. One test object was a long wire, the other was a square. Measurements are given of the frequency with which the presence of a target was correctly recognized in relation to the visual angle it subtended as well as the influence of sunglasses on this visibility.

Ross, S., Ray, W. & Valle, L.D. POINTER LOCATION AND ACCURACY OF DIAL READING. *J. appl. Psychol.*, 1953, 37(2), 131-135. (University of Maryland, College Park, Md.).

The purpose of this experiment was the determination of the relationship between accuracy of dial reading and the sector and specific location of the dial pointer. The 3 dials used were a semicircular upright dial, a semicircular inverted dial, and a circular dial. 10 subjects made a total of 4,100 judgments at 5 exposure times on the 3 dials. Tests of significance for error scores were made and permitted the following conclusions: a) differences in dial shape were not an important source of error; b) differences in sector location of the dial pointer were not an important source of error; c) significant differences in error score were found for readings made at 9, 12, 3 and 6 o'clock positions corresponding to pointer settings at 0, 5, 10 and 20 when compared with intermediate points; d) no significant differences in error scores were found when upper and lower dial halves were compared. These findings suggest that critical regions of a scale should be assigned to the 9, 12, 3 or 6 o'clock positions of a circular dial, and that factors other than errors may be considered in the choice of a dial from among the 3 types studied here.

Lybrand, W.A., Andrews, T.G. & Ross, S. SYSTEMATIC FATIGUE AND PERCEPTUAL ORGANIZATION. *Amer. J. Psychol.*, 1954, 67, 704-707. (University of Maryland, College Park, Md.).

To investigate the hypothesis that perceptual organization is affected adversely by systematic fatigue, 48 Ss in groups of 12 were studied. Performance on three perceptual tasks (Kohs Block Designs, Perception of Hidden Figures, and the Müller-Lyer Illusion) was measured under the presence and absence of 2 independent variables, sleep deprivation (one night's sleep loss) and physical exercise (5-mile march with 40 lb pack at rate of 120 steps per minute). Mean performance scores (adjustments were made for individual differences in basic abilities) were computed and analyzed for all combinations of conditions and tasks and their interactions. The results show that performance on the Kohs Block Designs (time-scores) was more efficient after exercise but less after sleep deprivation; on the Hidden Figures task performance was not affected by exercise but was less efficient after sleep deprivation; while performance on the Müller-Lyer Illusion was unaffected by either. It is suggested that the findings do indicate perceptual organization is a behavioral category sensitive to variations in conditions assumed to induce systematic fatigue and should be further investigated. Warner, H., Kopner, S., & Chandler, K.A. EXPERIMENTS ON SENSORY-TONIC FIELD THEORY OF PERCEPTION: II. EFFECT OF SUPPORTED AND UNSUPPORTED TILT OF THE BODY ON THE VISUAL PERCEPTION OF VERTICALITY. *J. exp. Psychol.*, 1951, 42, 346-350. (Clark University, Worcester, Mass.).

The present study was designed to investigate the effect of postural changes upon the visual perception of verticality. Apparent verticality was studied while S's body was tilted at specified angles. Observations were made under 2 main conditions: a) supported--S was supported by the sides and back of a chair; and b) unsupported--S had to maintain the angle of tilt by his own muscular efforts while sitting on a stool. 40 Ss, 20 men and 20 women, were tested. The task for S consisted in the adjustment of a luminescent rod to a position of apparent verticality. The main results are: a) the apparent vertical was shifted to the side opposite the direction of body tilt; b) with increase of body tilt from 15° to 33° there was a significantly greater shift of the apparent vertical; and c) under identical angles of body tilt, the apparent vertical was displaced to a greater degree when the body was unsupported than when the body was supported. These results are in accordance with specific hypotheses derived from the sensory-tonic field theory of perception.

Dunlap and Associates, Inc. VISUAL STAR TRACKING THROUGH A PERISCOPE. Contract NORD 17719, Memo Rep. 9, July 1957, 11pp. Dunlap and Associates, Inc., Stamford, Conn.

4860

The problem examined in this memorandum is the determination of those values of physical parameters in a periscope system in vibratory motion which will permit and facilitate the detection, acquisition, and tracking of a star by a human observer. The various sections deal with 1) the basic ability of the human observer to detect a point source of light against a background, 2) the facilitation of this ability by addition of magnification, 3) the relation degradation of performance when relative vibratory motion is introduced between observer and star, 4) special problems such as field of view, optical quality, etc., and 5) periscope parameter values for facilitating performance.

Scher, S.H. PILOT'S LOSS OF ORIENTATION IN INVERTED SPINS. Tech. Note 3531, Oct. 1955, 10pp National Advisory Committee for Aeronautics. (Langley Aeronautical Lab., Langley AFB, Va.).

The rising problem of pilot orientation during spins, especially during unintentional inverted spins, is discussed. The free-spinning-tunnel results and reported airplane experiences concerning inverted spins and recoveries are reviewed. Information is provided regarding the nature of inverted spins, optimum control technique for recovery, and some of the factors which apparently contribute to the pilot's loss of orientation. A spin-simulator rig which was recently constructed at the Langley Laboratory for use in an attempt to understand better the problems confronting the pilot of a spinning airplane is described.

Teichner, W.H. & Zigler, H.J. A METHOD OF STUDYING THE TACTUAL-KINESTHETIC SENSITIVITY OF THE HAND. Environmental Protection Div. Rep. 224, Nov. 1953, 11pp. USA Quartermaster Research and Development Center, Natick, Mass.

A method for determining the tactual-kinesesthetic sensitivity of the hand was developed and evaluated. The apparatus consisted of 11 brass discs which the subjects discriminated by hand in terms of difference in size. Both frequency of the judgment, larger-smaller, and latency of the judgment were obtained with the method of paired-comparisons. Since the differences between discs were all suprathreshold, the former measure did not yield a sufficient number of errors to be useful for the construction of a psychophysical scale. The latency measure, however, yielded meaningful results showing that the method being investigated might be useful for making inferences regarding the effects of temperature and handwear on the complex tactual-kinesesthetic sensitivity of the hand.

Navy Electronic Laboratory. SELECTIVE SPECTRUM LIGHTING FOR CIC AREAS. PD 06401, NE 121303 3 (NEL 382c), Rep. 337, Nov. 1952, 7pp. USN Electronics Lab., San Diego, Calif.

Two SSL systems have been examined and found practicable for CIC operations. Without disturbing CRT visibility, ambient light level in a CIC or similar area may be maintained with SSL at approximately 2 foot-candles--enough to permit reading, writing, moving about, and respiring equipment more efficiently. There is no appreciable loss in the detectability of threshold targets on the CRT at this level of illumination. Contrast ratios of the CRT presentation under SSL are greater than those obtained under actual lighting practices of present CIC's. The sodium-yellow system may be installed immediately in CIC's with only superficial changes in equipment.

Moble, C.E. AN ESTIMATION OF THE ABSOLUTE DIFFICULTIES OF COMPONENT TASKS IN THE COMPLEX COORDINATION TEST (CH701E). Proj. 509 020 0093, Res. Note P & M: 52 8: Sept. 1952, 15pp. Air Training Command, USAF Human Resources Research Center, Lackland AFB, Tex.

The object of the present Research Note was an evaluation of the absolute difficulties of representative task components in Complex Coordination performance. By statistically counterbalancing the effects of order and by attenuating the effects of sequence of presentation on difficulty (reaction latency per match), a set of 39 all-or-none-elevator-rudder patterns of known difficulty was developed. The values estimated for this pattern set constitute a first approximation to a scale of absolute difficulty. In agreement with a previous experiment, relative pattern difficulties were positively skewed and multimodal. Coefficients of test-retest ($r=0.92$) and inter-group reliability ($r=0.99$) using median latencies were similar: $r=0.92$, and $r=0.97$, respectively. A directional comparison of the relative difficulties in the 2 studies indicated that the effects of sequence are highly significant ($p<0.001$). Estimated absolute difficulty, based on means of medians for 0th and 18th degree derived lists had a test-retest reliability after 10 minutes of 0.92 ($M=156$). An analysis of the range of absolute difficulty represented in these experiments indicated that the estimated scale values are significantly different among themselves ($p<0.001$). These studies have suggested that a more refined scale of absolute difficulty might be obtained by distributed presentation of the pattern set.

Perryman, D.R. & Girardot, M.F. ADVANCED TASTE TEST METHOD. Food Engng., July 1952, 58-61. (Quartermaster Food & Container Institute, Chicago, Ill.).

A technique offering progress in evaluating consumer preference of foods and called the "hedonic-scale method" is described and discussed. The method uses a variant of the rating scale, introducing the hedonic value concept, which refers to the psychological range of "unpleasant" (dislike) at the lower end to "pleasant" (like) at the upper end. The problem of quality control is completely divorced from this technique. Information concerning the questionnaire form, administration, selection of test people, checking the data, and interpreting the scores is presented. Certain purposes for which the hedonic scale method is considered appropriate are listed along with cautions as to its use. (HEIAS)

Perryman, D.R., Josephson, D.V., Renaley, R.J. & Revold, H.L. NEW FLAVOR EVALUATION METHOD. Food Engng., Aug. 1951, 83-86 & 167.

A new method for evaluating the quality of dried milk, bidding fair to predict the consumer's reaction more accurately than conventional taste panels, was developed at Quartermaster Food & Container Institute for the Armed Forces, Chicago. An index of quality called "Flavor Number" (FN) is set up and defined as "percent of reconstituted milk in a mixture of that material with a fresh whole milk standard such that the difference in taste between it and the standard lies just above the threshold". A duo-trio test with a total of 20 judgments from 5 to 10 trained Ss is used to determine the threshold. An initial test of this method was made showing correlations of $+0.96$ between 2 FN determinations, of $+0.99$ between FN's and consumer preference ratings by 40 untrained Ss, and of $+0.82$ between FN's and ratings of a trained 17-member panel. The potential application of this method to flavor problems of other foods is discussed. (HEIAS)

Prentice, W.C.H. NEW OBSERVATIONS OF 'BINOCULAR YELLOW'. J. exp. Psychol., June 1948, 38 (3), 284-288. (Johns Hopkins University, Baltimore, Md.).

6 Ss were tested under Hecht's conditions for the appearance of binocular yellow. Filters with "tighter" transmission curves for "red" and "green" were used. Also the effects of the brightness of the fixated area and the duration of the observation were varied. The improved selectivity of the filters did not prevent the appearance of "binocular yellow". Although all Ss reported that the brighter lights gave a "better" yellow, there was no mistaking the presence of yellow even with the lowest illumination used. Although long observations (30 sec. and up) produced reports that the fixation point "gets yellower", very short exposures (1 or 2 sec.) also gave rise to the perception of a clearly recognizable yellow. Further, there was no appreciable evidence that the perceived "binocular yellow" is a poor match in saturation for a fair spectral yellow. (HEIAS)

Having questioned the generality of Kohler and Wallach's explanation of Gibson's tilted line phenomena, we performed a series of experiments to test whether the straightening or normalizing of slightly tilted lines near the vertical and horizontal might occur independently of conditions favorable to the figural after-effect. We have been able to show that lines tilted 10 degrees away from the vertical or horizontal show a normalization of about 2 degrees under our conditions. We have shown that this effect is independent of the simultaneous or previous presence of contours that might produce the typical figural after-effect. We have shown that this phenomenon is separate from the disorientation phenomena of Wertheimer and Asch and Witkin inasmuch as it is localized in the visual field and develops only after fairly long periods of fixation. We have shown that it cannot be accounted for in terms of inhomogeneities of the primary visual projection areas, either anatomical or physiological, since the effect appears in full or nearly full strength when the head is tilted to parallel the lines which then fall on the vertical meridian of the retina. A brief theoretical discussion has suggested the necessity for extending the theory of figural after-effects to account for these findings.

Weitz, J. A FURTHER STUDY OF THE RELATION BETWEEN SKIN TEMPERATURE AND CUTANEOUS SENSITIVITY. *J. exp. Psychol.*, May 1942, 30(5), 426-431. (Psychological Lab., Sophie Newcomb College, New Orleans, La.).

Using 6 Ss, the pain threshold (for electric-shock) was measured at different skin temperatures. The changing of skin temperatures was accomplished by means of a radiant heater. It was found that with increasing skin temperature, pain thresholds drop to a minimum, at which point, with further heating, they rise. This function uniting pain and temperature is similar to the function linking temperature and pressure and temperature and vibration. A chemical theory is suggested to explain these results. (HEIAS)

Phillip, B.R. EFFECT OF LENGTH OF SERIES UPON GENERALIZATION AND CENTRAL TENDENCY IN THE DISCRIMINATION OF A SERIES OF STIMULI. *Canad. J. Psychol.*, 1952, 6(4), 173-178. (University of Western Ontario, Ontario, Canada).

The effects of generalization and central tendency were studied in a graded series (6, 7, 9, and 11 stimuli respectively). The task in each series consisted of making an absolute judgment of the predominating color on 11 cards, on each of which were 36 dots of blue and green, randomly distributed. The maximum number of blue dots on any card was 23 so that the number of green dots was 13 on that card; the next card had 22 and 14, and so on. As each card was exposed, S had to determine the relative amount of a previously designated color and locate on a scale (from 1 to 11 for the 11-card series) the point which, in his opinion, represented the relative amount of the designated color. Generalization gradients were determined for 4 Ss. In general, the judgments of the shorter series tended to be distributed closer to the correct position than those of the longer series. There was some tendency to skewness in all series. Regardless of length, the generalization gradients were roughly of the same form. When the median responses for each scale position were computed, measures of the subjective values of the stimuli were obtained. In the shorter series the median values tended to be compressed towards one focus (2.5 value on the objective scale), while the longer series seemed to have 2 foci (around 4 and 8). (HEIAS)

Pilgrim, F.J., Schutz, H.G. & Peryam, D.R. INFLUENCE OF MONOSODIUM GLUTAMATE ON TASTE PERCEPTION. *Food Research*, 1955, 20(4), 310-314. (Quartermaster Food and Container Institute for the Armed Forces, Chicago, Ill.).

3 types of experiments were designed to test the hypothesis that monosodium glutamate (MSG) affects flavor perception by altering gustatory acuity. Absolute and differential thresholds were measured with and without a prior mouth rinse with MSG. The effect of the presence of MSG in solutions of the basic tastes on subjective intensity was determined. MSG raised the absolute thresholds for sweet and sour; it did not significantly alter the differential thresholds for salt and bitter. It increased the subjective intensities of salt and bitter, but had no effect on sour and sweet tastes. No consistent pattern of the effect of MSG emerged. The results do not support the hypothesis that MSG acts as a general intensifier of flavor and suggest no other hypothesis, except the general one that MSG is simply another seasoning that may contribute a flavor of its own to a complex food flavor.

Rethingshafer, Dorothy. MEASUREMENT OF A MOTOR SET. *J. exp. Psychol.*, Jan. 1943, 32(1), 75-81. (University of North Carolina, Chapel Hill, N.C.).

Intervening rates, slower or faster than the natural tapping rate, were forced on subjects who were then asked to return to a rate natural to them. 4 conditions were investigated:

a) Effect on the natural tapping rate when subjects were asked to tap at one-half their natural rate. b) Effect on the natural tapping rate when the intervening rate is the same for all subjects, being one-half the average of the preceding group. c) Effect on the natural tapping rate when the intervening rate is the same for all subjects, but in this case only one tap per second. d) Effect when all the subjects were forced to go faster than their own rate. The results were as follows: The natural rate, though a highly reliable performance, was in all cases changed in the direction of the forced rhythm. The differences between the means of the original natural rate and the return rate were significant except in Condition d). In no condition do the subjects as a group reproduce the forced rhythm, which shows the consistent effect of the natural rhythm. When the return rate is predicted from the original natural rate, the slope of the regression line varies according to the intervening rate. Significant critical ratios of differences are found between the slopes, using only Condition a) as a standard for comparison. Effect of the forced rhythms shows marked individual differences.

Wagner, S., Werner, H., Bruell, J.H. & Goldstein, A.G. EXPERIMENTS ON SENSOR-TONIC FIELD THEORY OF PERCEPTION: VII. EFFECT OF ASYMMETRICAL EXTENT AND STARTING POSITIONS OF FIGURES ON THE VISUAL APPARENT MEDIAN PLANE. *J. exp. Psychol.*, Oct. 1953, 46(4), 300-307. (Clark University, Worcester, Mass.).

3 experiments were carried out concerned with the shifts of the position of the apparent median plane, defined as the straight-ahead. It was found that a test figure extending asymmetrically to the left of fixation produces a shift of the apparent median plane relative to the left compared with a test figure extending asymmetrically to the right of fixation. The effect of asymmetrical figure extent has been found to be significant irrespective of the degree of flux emanating from the figure surface. Furthermore, there was evidence for starting position effects, analogous to those previously found in studies on verticality, i.e., other things being equal, the position of the straight-ahead (apparent median plane) is relatively closest to the position in which a line is placed in the visual field; if a line is initially placed to the left of the objective median plane, the straight-ahead is shifted more toward the left, more toward the center, more toward the right.

Wagner, S., Werner, H., & Morant, R.B. EXPERIMENTS ON SENSOR-TONIC FIELD THEORY OF PERCEPTION: III. EFFECT OF BODY ROTATION ON THE VISUAL PERCEPTION OF VERTICALITY. *J. exp. Psychol.*, Nov. 1951, 42(5), 351-357. (Clark University, Worcester, Mass.).

The present study was designed to investigate the effect of labyrinthian stimulation induced by rotation of the body around its vertical axis (concentric) on the visual perception of verticality. 28 Ss, 14 men and 14 women, were used. The task for S consisted in the adjustment of a luminous rod to apparent verticality under 5 test conditions: control--absence of rotation; clockwise and counterclockwise acceleration; deceleration from constant clockwise and counterclockwise rotation. It was found that visual perception of verticality is significantly affected by accelerative and decelerative rotation around S's vertical axis. The apparent vertical under clockwise acceleration is tilted in a counterclockwise direction, and under counterclockwise acceleration is tilted in a clockwise direction. Deceleration from rotation in one direction affects the apparent vertical like acceleration in the opposite direction. These results are interpreted within the framework of the sensory-tonic field theory of perception.

Wapner, S., Werner, H. & Chandler, K.A. EXPERIMENTS ON SENSORY-TONIC FIELD THEORY OF PERCEPTION: I. EFFECT OF EXTRANEUS STIMULATION ON THE VISUAL PERCEPTION OF VERTICALITY. *J. exp. Psychol.*, Nov. 1951, 42(5), 341-345. (Clark University, Worcester, Mass.).

The present study was designed to investigate the effect of 2 kinds of stimulation from diverse sources--electrical stimulation to the neck muscle, and auditory stimulation--on the visual perception of verticality. 40 Ss, 20 men and 20 women, were used. The task for S consisted in the adjustment of a luminescent rod to a position of apparent verticality. It was found that asymmetrical stimulation affected the position of the apparent vertical significantly. Under stimulation to one side of the body the position of apparent vertical was shifted relatively to the side opposite the stimulation. Electrical stimulation to the neck muscle and auditory stimulation affected perception of the vertical in an equivalent manner. R 2

4911

Wapner, S., & Werner, H. EXPERIMENTS ON SENSORY-TONIC FIELD THEORY OF PERCEPTION: V. EFFECT OF BODY STATUS ON THE KINESTHETIC PERCEPTION OF VERTICALITY. *J. exp. Psychol.*, Aug. 1952, 44(2), 126-131. (Clark University, Worcester, Mass.).

The present experiment was carried out to study the effect of head tilt, body tilt, and concentric body rotation on the kinesthetic perception of verticality. The S, while blindfolded, had the task of adjusting a rod pivoted at the lower end, to the vertical by moving the fingers of both hands along the rod. The results are essentially identical with those previously reported for visual perception of the vertical. That is, the position of the rod that appeared vertical was objectively tilted to the left when: a) the head was tilted right; b) the body was tilted right; c) the body was accelerated around the vertical axis in the clockwise direction; d) the body was decelerated from constant counterclockwise rotation. For the opposite test conditions the respective displacements were in a direction opposite to those mentioned above. The significance of this study consists in the demonstration that the effects of extraneous stimulation and body tilt previously described for visual perception of verticality can be generalized to include kinesthetic perception of verticality. The results, thus, broaden the interpretations given within the sensory-tonic field theory of perception. R 6

Small, A.M., Jr. & Thurlow, W.R. LOUDNESS-RELATIONS IN TWO-COMPONENT TONES. *J. acoust. Soc. Amer.*, May 1954, 26(3), 381-388. (University of Wisconsin, Madison, Wisc.).

A two-component tone was presented under a number of frequency and intensity conditions. The loudness of each component and the total loudness of the combination were traced as the intensity of the higher frequency and were brought from masked threshold to well above masked threshold. Loudnesses were determined by equating the tone or tones under consideration to a comparison tone. When the higher frequency of the pair was at or below 1000 cps, it showed a loudness loss, relative to its loudness when presented alone, at medium intensities above its masked threshold; but as its intensity was increased, it tended to regain its normal loudness. When the higher frequency of a pair was above 1000 cps, it exhibited a greater than normal loudness at medium intensities above its masked threshold which again approached normal with increased intensity. The lower frequency of a pair seemed to be little affected by increases in the intensity of the higher frequency within the limits of intensity used. Total loudness tended to be the algebraic sum of the components' loudnesses. The results indicate that the effect of a tone upon the loudness of another is not so simple a phenomenon as a tone's effect upon the threshold of another. R 14

Young, Marguerite L. PSYCHOLOGICAL STUDIES OF TRACKING BEHAVIOR. PART III. THE CHARACTERISTICS OF QUICK MANUAL CORRECTIVE MOVEMENTS MADE IN RESPONSE TO STEP-FUNCTION VELOCITY INPUTS. NRL Rep. 3850, Aug. 1951, 6pp. *USN Research Lab.*, Washington, D.C.

An investigation has been conducted of the characteristics of quick manual corrective responses made to a visual target moving at a preset constant velocity. Visual errors of 2, 4, 8, and 16 degrees per second to the right and left were presented to 10 subjects in a predetermined irregular order. These errors were corrected through the movement of a joystick. The amplitude, rate, and acceleration (or force) of the response movements increased systematically as the velocity of the target increased. This resulted in all response motions being made in approximately the same amount of time regardless of the distance moved. The major difference between the findings of the present study and of previous investigations of responses to target displacements was the decrease in reaction time with increases in presented stimulus velocity. This result is believed due to the particular motivational and perceptual aspects of the present experimental situation. Although the response situation in the present study appears to be more complex than that in which step-function position errors are studied, due to the continued movement of the target during the reaction and response time, the response movements appear to be executed in a similar manner in both cases. That is, the response is released as a unit at the end of the reaction time and once started runs its course to completion unmodified by visual information arising during the course of the movement.

Werner, N., Wagner, S. & Bruell, J.P. EXPERIMENTS ON SENSORY-TONIC FIELD THEORY OF PERCEPTION: VI. EFFECT OF POSITION OF HEAD, EYES, AND OF OBJECT ON POSITION OF THE APPARENT MEDIAN PLANE. *J. exp. Psychol.*, Oct. 1953, 46(4), 293-295. (Clark University, Worcester, Mass.).

2 experiments were carried out to investigate a) the effect of asymmetrically placed fixated objects and b) the effect of head torsion and of eye turning, on the position of the apparent median plane. The methodology of relating to a place in space that appeared straight ahead (apparent median plane) was used in both experiments. It was found that the position of the apparent median plane shifted in the direction of the fixated object, i.e., in the direction of eye turning; in contrast, with eyes closed, the position of the apparent median plane shifted opposite the direction of horizontal eye turning, and opposite the direction of head torsion. These effects are interpreted to be analogous to those found previously for the perception of verticality; the study therefore provides evidence for the generality of the constructs used within the framework of sensory-tonic field theory.

Wilcock, W.E. LEARNING THE TWO-BAND COORDINATION TEST. *J. appl. Psychol.*, Feb. 1942, 27(1), 41-47.

4919

This experimental study is concerned with improvement of performance during 100 trials on the two-band pursuit rotor. The ten Ss tested were those scoring highest and lowest on a preliminary series of six trials. Each S was then given ten one-minute trials daily for a period of ten days. Recommendations were made concerning the optimum number of trials to be used when employing the test as a predictor of aptitude for this type of coordination.

Teichner, W.H. & Wehrkamp, R.F. VISUAL-MOTOR PERFORMANCE AS A FUNCTION OF SHORT-DURATION AMBIENT TEMPERATURE. *J. exp. Psychol.*, 1954, 47, 447-450. (Quartermaster Research and Development Center.).

Time-on-target measures on the pursuit rotor were obtained from 4 subject groups which practiced for short periods on 5 successive days under ambient temperatures of 55°, 70°, 85°, and 100°F., respectively. Performance was found to be poorer at temperatures above and below 70°F. This result confirms and extends previous studies of the effects of ambient temperature. In addition, the data suggest the possibility that the temperature function falls off more rapidly with temperatures lower than the maximum than it does for those that are higher.

Tinker, M.A. & Paterson, D.G. EYE MOVEMENTS IN READING A MODERN TYPE FACE AND OLD ENGLISH. *Amer. J. Psychol.*, Jan. 1941, 54(1), 113-114. (University of Minnesota, Minneapolis, Minn.).

4926

To study eye movements in reading a modern and old type face, 20 Ss read ten paragraphs from the Chapman-Cook Speed of Reading Test. Form A, set in Cloister Black (Old English) and Form B in Scotch Roman (modern), and their eye movements were photographed. Data on fixation frequency, words per fixation, pause duration, perception time and regression frequency were analyzed for differences due to style of type. The differences were interpreted with respect to difficulties in speed of reading.

Tinker, M.A. EFFECT OF VISUAL ADAPTATION UPON INTENSITY OF LIGHT PREFERRED FOR READING. *Amer. J. Psychol.*, Oct. 1941, 54, 559-563. (University of Minnesota, Minneapolis, Minn.).

4927

To measure the degree to which the illumination intensity chosen for comfortable reading is determined by the illumination level to which the eye is adapted, 144 subjects adapted to 8 footcandles of light at one sitting and to 52 footcandles at another sitting. After adaptation, a paired comparison technique was used to obtain preferences for intensities considered best for ease and comfort in reading 11 pt. type. Frequencies with which various intensities were chosen are given, and the relation to previous adaptation level is discussed together with the implications for the choice of intensity level needed for efficient visual work.

Tinker, M.A. EFFECT OF SLANTED TEXT UPON THE READABILITY OF PRINT. *J. gen. Psychol.*, May 1954, 48(5), 287-291. (University of Minnesota, Minneapolis, Minn.).

4734

To investigate the effect of slanted text (parts of line at varying distances from the eyes) upon speed of reading and visibility of word forms, equivalent forms of reading material (ten-point Excelsior type on eggshell paper) were read under conditions of flat copy, 45 degrees and 60 degrees of slant by 180 Ss. Visibility measurements were made of words with Luckiesh-Moss Visibility Meter under the same conditions. Speed of reading scores and visibility measurements were studied for differences due to slanted text. The results were related to task of reading large books which have marked curvature of lines near inner margin.

4938 Tinker, M.A. FIXATION PAUSE DURATION IN READING. *J. educ. Res.*, 1951, 44, 470-479. (University of Minnesota, Rochester, Minn.).

The purpose of the present investigation is to study the role of fixation pause duration in reading by coordinating the findings obtained in a series of experiments carried out in the writer's laboratory. Minimum pause duration for successive fixation of dots and for successive fixation and identification of single letters averaged 172 and 157 ms. respectively. These durations are more than necessary for cleared-up vision but less than employed in reading connected material. The proportion of reading time devoted to pause duration averages 92.7% to eye movements, 7.3%. These percentages vary somewhat with the comprehension requirements of the material but in no case do the pauses take less than 90% of the reading time. Mean pause duration in reading varies from about 220 to 324 ms. The greater the requirements of comprehension the longer the pause duration. In most reading situations variability in pause duration is relatively small and relatively constant. In certain special reading situations as for test items, however, variability can be relatively great. Reliability of pause duration as an eye-movement measure is relatively high. Variation in typographical arrangements may produce longer pause duration, shorter duration, or no change. Pause duration bears no significant relation to fixation frequency or regression frequency. Pause duration by itself is not a valid measure of reading proficiency. When combined with fixation frequency, however, the resulting perception time is a fairly valid measure of reading proficiency.

Weitz, J. VIBRATORY SENSITIVITY AS A FUNCTION OF SKIN TEMPERATURE. *J. exp. Psychol.*, Jan. 1941, 28(1), 21-36. (Psychological Lab., University of Virginia, Charlottesville, Va.).

With increasing skin temperature, vibratory thresholds decrease to a minimum, at which point, with further heating, these thresholds rise. The function uniting temperature and vibratory sensitivity is similar to that linking temperature and pressure sensitivity, with the minimal thresholds falling at approximately the same point. The similarity of the effect of temperature changes on pressure and vibratory stimulation was assumed to be further evidence of the intimacy of the identity of the mechanisms mediating these 2 sensory experiences. With decreasing skin temperature vibratory thresholds show a continuous rise. The effects of warming and cooling the skin are shown to be not due to changes in skin conductivity; it is further shown that these changes are not a result of gross vascular action. There is no dependence of the temperature function on stimulus frequency. A chemical theory is thought necessary to explain the results.

Werner, H. & Wapner, S. THE INNSBRUCK STUDIES ON DISTORTED VISUAL FIELDS IN RELATION TO AN ORGANISMIC THEORY OF PERCEPTION. *Psychol. Rev.* 1955, 62(2), 130-138. (Clark University, Worcester, Mass.).

Kohler of the Innsbruck Laboratory published results concerned with stages of perceptual adaptation to distorting prisms. The methodology of these experiments is discussed. The authors contend that Kohler's findings can be more adequately accounted for by an organismic than by a sensorial theory of perception. Some aspects of the sensory-tonic field theory of perception are discussed and an attempt is made to show that the essential findings of Kohler are consistent with this theory. The Innsbruck studies advance the understanding of perception by a) demonstrating the involvement of organismic states (oculo-muscular states) in so-called visual adaptation; b) giving evidence in support of the role of sensory-tonic states in regard to a great variety of spatial properties; and c) demonstrating that color is also affected by organismic states. Krus, D.H., Werner, H. & Wapner, S. STUDIES IN VICARIOUSNESS: MOTOR ACTIVITY AND PERCEIVED MOVEMENT. *Amer. J. Psychol.*, Oct. 1953, 66(4), 603-608. (Clark University, Worcester, Mass.).

The hypothesis underlying the present experiment is that of the vicarious relationship obtaining between perception of motion and muscular involvement. If S is confronted with drawings representing objects which suggest motion, it is hypothesized that there will be an increase relation between the frequency of movement responses and the degree of motor involvement. An experimental group of Ss performed a motor task before viewing pictures, and a control group viewed the pictures without performing a motor task. It was found that the introduction of motor involvement has the effect of significantly decreasing perceptual movement as measured by verbal responses to pictorial material. (HEIAS)

Goldman, A.E. STUDIES IN VICARIOUSNESS: DEGREE OF MOTOR ACTIVITY AND THE AUTOKINETIC PHENOMENON. *Amer. J. Psychol.*, Oct. 1953, 66(4), 613-617. (Clark University, Worcester, Mass.).

2 hypotheses pertaining to the relation of motion and motion-perception were formulated: a) Under conditions of inhibition of motor expression perceptual activity is expected to increase; b) Conversely, if motor expression is increased, perceptual activity is expected to decrease. Reaction-time and duration of the autokinetic phenomenon were chosen as measures to test the 2 hypotheses. The assumptions were that reaction-time measures readiness to perceive motion and that greater perceptual activity is reflected in longer duration. The results of this study indicate that the greater the degree of motor involvement: a) the longer the time of appearance of autokinesis; b) the shorter the duration of its first uninterrupted phase; and c) the less complex is its pattern of movement. These results support the postulate of vicarious channelization, according to which an inverse relation is expected between the amount of perceptual movement and motor activity.

Kaden, S.E., Wepner, S. & Verner, H. STUDIES IN PHYSIOGNOMIC PERCEPTION: II. EFFECT OF DIRECTIONAL DYNAMICS OF PICTURED OBJECTS AND OF WORDS ON THE POSITION OF THE APPARENT HORIZON. *J. Psychol.*, 1955, 39, 61-70. (Clark University, Worcester, Mass.).

The present study, consisting of 2 experiments, is a continuation of previous work designed to demonstrate that visual directional dynamics exists as a behaviorally measurable event. The first of these experiments showed that a figure with directional dynamics upwards or downwards has the effect of shifting the physical location of the apparent horizon (eye line) opposite the direction of the dynamics. The second experiment used visually presented verbal symbols connoting upwardness or downwardness, e.g., "rising" vs. "falling." Analogous to the findings with meaningful pictorial material used in the first experiment, the physical position of the apparent horizon shifted opposite the direction of the dynamics conveyed by the words. Thus, in addition to demonstrating that visual dynamics in the upward-downward direction can be measured behaviorally, the study shows that certain semantic aspects of words can be conceived and dealt with experimentally in a theoretical framework developed for problems of perception.

Ogle, K.N. ON STEREOSCOPIC DEPTH PERCEPTION. *J. exp. Psychol.*, Oct. 1954, 48(4), 225-233. (George Washington University, Washington, D.C.).

4957

The relationship between retinal image disparity and stereoscopic depth perception was reinvestigated under the controlled conditions possible with modern instrumentation. The subject was presented a binocular view of a fixation point and central portions of both the reference and test objects (thin steel rods). By an arrangement of baffles, one eye saw the upper portion while the other saw the lower portion of the test line. When there was a vertical gap, both eyes could see the center portion. The task was to adjust the test line as the gap width was changed so that it was in the same plane as the reference line. A falling sphere was substituted for the test rod in some of the experiments.

Canfield, A.A., Comrey, A.L. & Wilson, R.C. THE INFLUENCE OF INCREASED POSITIVE g ON REACHING MOVEMENTS. *J. appl. Psychol.*, June 1953, 37(3), 230-235. (Wayne University, Detroit, Mich.).

From the results of this research, certain conclusions about the effect of increased positive radial acceleration on reaching movements may be advanced. Both the speed and accuracy of reaching movements at increased g levels are seriously impaired, the degree of impairment being roughly equivalent to the amount of force imposed. The kinesthetic cues governing the thrust of the arm under normal circumstances are inadequate to maintain similar accuracy or speed under radial accelerative conditions. Due to the increased weight of the arm and the inadequacy of the normal kinesthetic cues, two types of errors are found, one being the negative inertia error and the other the error of downward tendency. The most favorable location of controls for the pilot of high-speed aircraft, both from the standpoint of speed and accuracy, is to the side of the pilot's preferred hand and below its normal resting point. Emergency controls that might have to be manipulated under conditions of increased positive radial acceleration should be no smaller than two inches in diameter if a pushing motion is required.

Tresselt, M.E. & Mayzner, M.S., Jr. A FURTHER EXPERIMENT IN THE RECOGNITION OF EGO-INVOLVED MATERIALS. *J. Psychol.*, 1954, 37, 135-139. (Dept. of Psychology, Washington Square College, New York, N.Y.).

4986

In a study of the role of overlearning in the recognition of ego-involved materials, 300 subjects were tested for recognition of strong and weak ego-involved materials over periods of 48 hours, 1, 3, 5, and 10 weeks. Recognition was evaluated under conditions of overlearning and non-overlearning. The results are presented and discussed in terms of the relative importance of overlearning and ego-involvement in forgetting and the relative amount of recognition of strong and weak ego-involved materials.

Tresselt, M.E. & Leeds, D.S. THE EINSTELLUNG EFFECT IN IMMEDIATE AND DELAYED PROBLEM-SOLVING. *J. gen. Psychol.*, 1953, 42, 87-95. (New York University, New York, N.Y. & University of Illinois, Urbana, Ill.).

4987

Two problems in mental set (Einstellung) and problem solving were investigated: the relationship between the Einstellung problems given and the Einstellung effect, and the retention of the effect after one, two, and seven days. In the first experiment, seven groups of subjects (ten in each group) were given 2, 4, 6, 8, 10, 12, or 14 Einstellung problems respectively which could be solved by a given formula and two critical problems which could be solved with the formula or by a simple subtraction or addition. In the second experiment, three groups were given practice problems on one day and the critical problems one, two, or seven days later. T. G. R 11

Uhlaner, J.E., Gordon, D.A., Woods, I.A., & Zeidner, J. THE RELATIONSHIP BETWEEN SCOTOPIC VISUAL ACUITY AND ACUITY AT PHOTOPIC AND MESOPIC LEVELS. *J. appl. Psychol.*, June 1953, 37, 223-9.

4989

To assess the possibility of constructing a practical test of night visual acuity, the relationship between scotopic and mesopic visual acuity was investigated. Nineteen subjects, who showed a wide range of scotopic acuity scores on Army Night Vision Tester, were given mesopic and photopic acuity tests on wall charts and on the Ortho-rater. The correlations among scores on the various tests are presented and the practicability of developing a mesopic test of night vision ability is discussed.

Underwood, B.J. STUDIES OF DISTRIBUTED PRACTICE: II. LEARNING AND RETENTION OF PAIRED-ADJECTIVE LISTS WITH TWO LEVELS OF INTRA-LIST SIMILARITY. *J. exp. Psychol.*, Sept. 1951, 42(3), 153-161. (Northwestern University, Evanston, Ill.).

4990

In an investigation of the interaction between distribution of practice and intralist similarity in the learning and retention of serial verbal material, 108 Ss each learned a list of paired adjectives of high or low similarity. Each list was learned under one of three conditions of distribution of practice; retention was tested after one of three intervals. Rate of learning, trials to criterion, errors per trial, errors in recall, and trials to relearn were analyzed with respect to the experimental variables. T. G. R 12

O'Brien, F.E. MOTIVATION OF RESEARCH AND DEVELOPMENT ENGINEERS. A RESEARCH REPORT. 1956, 40pp. University of Chicago, Chicago, Ill.

4992
The problem of motivating the engineer is examined first in terms of the human relations problem basic to any system of motivation of human beings. More specific problems relating to government needs for engineers, work-place adjustment, and factors arising from the complexity of modern society and the resultant attitudes toward the engineering profession are discussed. Prestige and status aspects of the profession are analyzed in both an industry and the community. Finally, the role of leadership is discussed as it affects the morale of individuals.

Underwood, B.J. AN ORIENTATION FOR RESEARCH ON THINKING. *Psychol. Rev.*, May 1952, 59(3), 209-220. (Northwestern University, Evanston, Ill.).

4995
A point of view concerning thinking is developed for the sole purpose of giving direction to research on certain variables which appear to influence efficiency in thinking. The one essential assumption presented is that for new relationships to be acquired, the pertinent responses to stimuli must be contiguous. Predictions concerning the influence of certain manipulable variables (perceptual vs. symbolic presentation of stimuli, number of stimuli, similarity among stimuli, biases) on thinking are made. Some problems are discussed which are not considered in the present orientation.

Vertheimer, H. & Ward, V.O. THE INFLUENCE OF SKIN TEMPERATURE UPON THE PAIN THRESHOLD AS EVOKED BY THERMAL RADIATION--A CONFIRMATION. *Science*, May 1952, 115, 499-500.
This report derives from an investigation of the temporal variation of various sensory thresholds in which skin temperature was measured as a control for pain threshold. On 45 consecutive days pain thresholds were measured on each of 3 Ss. Radiant intensity (275 mc/sec/cm²) was applied to forearm on blackened circular area 1.8 cm in diameter. Threshold measure was the time in sec before S reported burning pain. Skin temperature was measured just before application of stimulus. Correlation coefficients between threshold and temperature were -.70, -.61, and -.72 for the 3 Ss. The data were plotted and fitted by a least square straight line. Extrapolation yielded a value of 44.1°C as the critical temperature at which pain occurred. Comparisons are made with findings from other studies which confirm this figure. (HEIAS)

Wertheimer, M. THE VARIABILITY OF AUDI-
TORY AND VISUAL ABSOLUTE THRESHOLDS IN
TIME. *J. gen. Psychol.*, 1955, 52, 111-47.

5001:

This article presents a review of the literature and the results of experimentation on the phenomenon of variability of auditory and visual absolute thresholds in time. The survey of previous research is presented as follows: variability of visual threshold, variability of auditory threshold, correlations among thresholds in various modalities, and the effects of certain variables (e.g., experience, exercise, etc.) upon the thresholds. The results of experiments designed to evaluate the following aspects of the problem are presented in detail: 1) threshold changes from day to day, 2) threshold changes within a day, and 3) threshold changes within an hour. An extensive discussion is presented concerning the phenomenon of threshold fluctuation in the particular modalities and the interrelations between both modalities. T. G. R 54

Wertheimer, M. A SINGLE-TRIAL TECHNIQUE FOR MEASURING THE THRESHOLD OF PAIN BY THERMAL RADIATION. *Amer. J. Psychol.*, 1952, 65, 297-298.
A technique for measuring the threshold of pain by thermal radiation is described. It involves holding the heat-stimulus constant and measuring threshold in terms of the length of time before S reports pain. Thus a single trial yields a quantitative determination, there is no danger in prolonged hyperaesthesia, and by a simple conversion formula, the measurements can be translated into the usual units. Wertheimer, M. CAN A TRAINED SUBJECT JUDGE HIS AUDITORY SENSITIVITY? *Quart. J. exp. Psychol.* Feb. 1954, 6(1), 21-22.

Auditory thresholds were measured daily on 3 Ss over an extended period of time, and the Ss postdicted whether the level and variability of the day's measured thresholds were higher or lower than on the preceding day, without their having knowledge of their performance. It was found that their judgments agreed with the obtained psychophysical data better than would have been expected on the basis of chance alone. These results raise the question of the possibility that a S's understanding of, or hypothesis concerning, the experimental outcome may influence his behavior.

Adams, R.E. FUNCTIONAL FIXEDNESS AS RELATED TO PROBLEM SOLVING: A REPETITION OF THREE EXPERIMENTS. *J. exp. Psychol.*, Oct. 1952, 44(4), 288-291. (Stanford University, Stanford, Calif.).

5006

To repeat demonstrations of the hypothesis that problem solving may in some instances be delayed through the "functional fixedness" of solution objects using more subjects and better controlled conditions than previous experiments, three experiments were conducted with 57 subjects (29 experimental group, 28 control group). Both groups were given the "box", "gimlet", and "paperclip" problems in that order. Experimental subjects were given each problem after having first used the solution objects in a function dissimilar to that demanded for solution. Control subjects were given the problem without pre-utilization. Number of solutions and time-to-solution were analyzed for differences between the two conditions.

Bakan, P. PRELIMINARY TESTS OF VIGILANCE FOR VERBAL MATERIALS. Contract AF 33(038) 25726, Proj. 507 011 0001, Res. Note 52 7, July 1952, 7pp. USAF Human Resources Research Center, Lackland AFB, Tex.

5008

To determine whether a testing situation using verbal materials is practical in a study of vigilance, a series of digits were recorded on a tape at the rate of one per second for 90 minutes. In the series, sequences of odd numbers were restricted and sequences of exactly three odd numbers occurred every 36 times; six of such sequences occurred in each 15-minute period. The subject's task was to listen to the tape and write down each three-odd-number sequence heard. Eight subjects performed for 90 minutes on four different days. Error scores were analyzed for effect of period and of days. Suggestions for further study are made.

Brown, D.R. STIMULUS-SIMILARITY AND THE ANCHORING OF SUBJECTIVE SCALES. *Amer. J. Psychol.*, April 1953; 66, 199-214.

The effects of anchoring on subjective scales of judgment were investigated. 3 variables were selected: a) similarity of the anchor to the stimulus-series; b) judging the anchor; and c) weight of the anchor. The first variable was tested by 2 types of anchors: a tray dissimilar to a series of weights and a weight identical to the series of weights. The second variable was dealt with by having O either judge or not judge the anchor and the third variable was represented by having 3 physical values of anchors. 72 Os were randomly split into 12 groups of 6 each. Every group was run on one of 12 experimental conditions in which all possible combinations of the 3 variables were included. The Os judged a series of 120 weights by the Method of Single Stimuli using a 5-category scale running from 'very light' to 'very heavy'. It was hypothesized that the degree of shift in the subjective scale of the judgment would be a function of the 3 experimental variables and would go from greatest shift to least shift in this order: weight-anchors furthest from the series judged, weight-anchors furthest from the series not judged, tray-anchors furthest from the series judged, and no effect with tray-anchors not judged. An analysis of variance was run on the 3X2X2 table resulting from the data and all predictions were confirmed with statistical significance. Graphic evidence was presented to demonstrate that the order of effect was as predicted and also to illustrate the operation of the size-weight illusion of the tray. Furthermore, the dimension of similarity was used to illustrate the need for response-derived definitions of psychologically real stimuli.

Bartley, S.H. BRIGHTNESS COMPARISONS WHEN ONE EYE IS STIMULATED INTERMITTENTLY AND THE OTHER EYE STEADILY. *J. Psychol.*, 1952, 34, 165-167.

A study was undertaken to determine whether brightness enhancement occurs when one eye is stimulated intermittently and the other eye steadily. The level of the illumination for the steady target was set at 0.11 ft-c and the level of the intermittent target was adjusted until the 2 targets matched in brightness. Readings were taken with and without a septum dividing the fields of view of the 2 eyes; the septum reached from the eyes to the target plane, so that each eye was confronted with only its own target. 2 Ss were used. The results show that for 1 S, intermittent stimulation with no septum was 85% as effective as steady stimulation; for the second S, 58%. With the septum, the 2 forms of stimulation were equally effective for both Ss. Under neither condition was actual brightness enhancement obtained. (Enhancement is defined as the effectiveness of intermittent stimulation which surpasses that of steady stimulation.) (HEIAS)

Bartley, S.H. CONDITIONS INTENDED TO MANIPULATE ACCOMMODATION AS FACTORS IN PERFORMANCE WITH A VISUAL ACUITY TARGET. *J. Psychol.*, 1953, 36, 409-415.

5035

To determine the effect of the effort of accommodation on responses to targets in which visual acuity is a crucial factor, the distance at which a hairline target appeared, the distance of the circular field or surround, and the illumination of the surround were varied independently. Assuming that deteriorated performance is a function of accommodation difficulties, the effectiveness of performance for 3 observers is presented in terms of percentage of correct responses for orientation of the hairline made under each condition tested.

5036

Bartley, S.H. THE PERCEPTION OF SIZE OR DISTANCE BASED ON TACTILE AND KINESTHETIC DATA. *J. Psychol.*, 1953, 36, 401-408. (Michigan State College, East Lansing, Mich.).

In the several experiments performed in the attempt to find whether vision (through its imagery) operated in tactile and kinesthetic experience, it was found that size and space judgments derived from tactile and kinesthetic information were rather gross. Part of this impression stems from the difficulty in obtaining proper indicators for manifesting size and space perceptions. The more appropriate methods eradicate this. The results indicate that visual imagery plays a very significant and indispensable role, at least if size and space judgments are to be reasonably stable and reliable. This role of visual imagery is evidenced by the lawful change in apparent size with change of distance of exploration from the eye. The results point to the idea that although the blind make extensive use of tactile and kinesthetic information, it must be a sort not describable as the perception of space, but rather the perception of the body moving in the proper way in relation to contact, etc. This is not what we should call true space perception, even though the Ss get around in a spatial world.

Bartley, S.H. INTERMITTENT PHOTIC STIMULATION AT MARGINAL INTENSITY LEVELS. *J. Psychol.*, 1951, 32, 217-223.

An investigation of brightness enhancement produced by intermittent photic stimulation at marginal intensity levels was conducted. In one experiment, frequency was varied, in another, the target area was varied. The targets were 2-in. squares and 11x7 in. rectangles, with the intermittent target on the left. 2 large rectangles were used when frequency was varied (6 steps from 3.6 to 20 pulses per sec.), intensity of the intermittent target was varied at each step to match the brightness of the steady target. It was found that at 20 pulses per sec., all of the 4 Ss judged the effectiveness of the intermittent target to be slightly above the steady one; as the pulse rate was reduced, effectiveness began to rise. For 1 S, the rise began near the critical rate (10 per sec); for another at 13 per sec.; for the other 2 at 7 per sec. When the area was varied, the procedure was the same as before, but the difference in amount of enhancement due to size was not statistically reliable. (HEIAS)

Bartley, S.H. BRIGHTNESS ENHANCEMENT IN RELATION TO TARGET INTENSITY. *J. Psychol.*, 1951, 32, 57-62.

A comparison was made of the brightnesses of intermittent and steady targets where the target was a disk within a ring, each independently variable in intensity. The intensity of the disk was held constant at each of 15 levels varying from 0.11 to 730.0 ft-c. The ring was made the intermittent field, with a frequency of approximately 10 cps. A series of settings of intensity for the disk from the highest to the lowest were made and the level of brightness of the ring was matched to each setting. 3 Ss were used, one highly trained, one slightly experienced, and one completely naive. The data, presented in graphic form, indicate that a) at high intensity levels the intermittent stimulation was more effective than the continuous, b) throughout a small intermediate range the 2 were substantially equivalent, and c) at low levels of intensity the intermittent stimulation was less effective. The same pattern of results was obtained by all 3 Ss although the cross-over point for the trained S was at 35 ft-c and about 50 ft-c for the untrained Ss. (HEIAS)

Bartley, S.H. & Seibel, Jean. A FURTHER STUDY OF ENTOPIC STRAY LIGHT. *J. Psychol.*, 1954, 38, 313-319. (Psychology Dept., Michigan State College, East Lansing, Mich.).

Using the flicker method, an attempt was made to determine the intensity of stray light produced at various distances from the retinal images of targets of various intensities and areas. To provide material for comparing off readings for target and surrounding field, off curves for various target areas and intensities were obtained. Offs for the field 6° from the target matched those obtained throughout a certain low intensity range for one area of target. From this, the actual intensity of stray light on the retina was deduced. Measurements of relative level of stray light to target area and intensity compared well with those previously obtained by Bartley and Fry when they studied the effect of stray light on raising the threshold of a test-object. Field off varied in accord with distance from target, edge for 8° or more.

Bartley, S.H. & Wilkinson, F.R. SOME FACTORS IN THE PRODUCTION OF GAMMA MOVEMENTS. *J. Psychol.*, 1953, 36, 201-206.

The apparent movement observed when all or a portion of the visual field is suddenly raised or lowered in intensity is called here border movement or gamma movement. An examination of some of the possible conditions for the movement was undertaken with variation of 2 factors: target subtense (or its corresponding area) and target intensity. The targets were viewed at 2 distances such that they formed a series of relative areas; from 1 to 512° visual angle; a revolving disk with an open sector produced the pulses at a rate of 1 every 1200 msec. With flashes that, in one case, had an over-all duration of 48 msec. (16 msec. for rise to maximum and 16 msec. for decline), 144 msec. and 128 msec. The procedure consisted in going from intensities that did not produce movement to those at which movement just became apparent. 2 Ss were used. The data are presented graphically showing the relation between target size and intensity for threshold of border movement. As visual angle is increased, the intensity level for threshold border motion rises. Explanations are offered for this finding. (HEIAS)

Bartley, S.H. & Wilkinson, F. BRIGHTNESS ENHANCEMENT WHEN ENTOPIC STRAY LIGHT IS HELD CONSTANT. *J. Psychol.*, 1952, 33, 301-305.

The fact that intermittent light results in a higher level of brightness than continuous light of the same intensity, under some conditions, is called brightness enhancement. The present investigation was conducted to demonstrate what happens when entoptic stray light is held constant, or, in other words, when the amount of interpulse light is varied. 2 rectangular targets (each divided into 2 equal parts) were used to compare a steady with an intermittent stimulation; both parts of the steady stimulus were equally illuminated but the areas of the other gradually illuminated and darkened alternately (thus scattered light remains constant). In a second part of the study only the top halves of each target were used, one steady and one intermittent. When the stray light was held constant, 2 Ss results were as follows. One required the steady field to be about 160% as intense as the intermittent; the other required only 153%. When the stray light was allowed to vary with the intermittent stimulus (Part II), the steady field had to be 207% as intense for 1 S and 200% for the other. These results indicate that lesser brightness enhancement occurs when the otherwise fluctuating stray light is made uniform. (HEIAS)

Bartley, S.H. & Wilkinson, F.R. CERTAIN FACTORS IN PRODUCING COMPLEXITY OF RESPONSE TO A SINGLE PULSE OF LIGHT. *J. Psychol.*, 1953, 35, 299-306.

The present article reports an attempt to study a 2-flash response to a single pulse of light by manipulation of pulse intensity and duration and by varying the area of the image on the retina. Pulse duration was set at each of 10 different values (from 3 to 142 msec.) and the intensity was then varied upward so that the second flash just became apparent, and further increased to the point where the second flash disappeared. 6 different retinal stimulus areas (from 2 to 19°) were used; 2 Ss made observations. The data are presented graphically and show that the goodness (distinctness and general impressiveness) of the second flash diminished with the reduction in size of the retinal image. The curves for the largest retinal area are lowest in the intensity range, and that an orderly sequence is followed in the shift upward in the intensity range as retinal area decreases. This holds for pulse duration up to about 70 msec. where the one-flash to 2-flash transition curves for the smaller retinal areas reverse, and rise as pulse duration is further increased. Explanations are offered in terms of neural events. (HEIAS)

Boldt, R.P., & Ellis, D.S. VOLUNTARY REST PAUSE BEHAVIOR IN A BLOCK-TURNING TASK AS A FUNCTION OF WRIST-CUFF WEIGHT. *J. exp. Psychol.*, 1954, 47, 84-90.

5044

To determine if behavior exhibited in reaching a voluntary rest pause is sensitive to task effortfulness, 80 subjects, 20 at each of four conditions of cuff weight, (0, 0.5, 1, and 3 pounds) performed a block-turning task. Instructions were given to take rests (60 seconds) whenever desired during a ten-minute work period. Knowledge of results was given every thirty seconds in the form of number of blocks turned. The number of responses made and the rate of responding in reaching a voluntary rest were studied by analysis of variance techniques for differences due to weights. The implications for studies of effect of effortfulness on performance are discussed. T. G. R 10

Graybiel, A., Kerr, W.A. & Bartley, S.H. STIMULUS THRESHOLDS OF THE SEMI-CIRCULAR CANALS AS A FUNCTION OF ANGULAR ACCELERATION. *Amer. J. Psychol.*, Jan. 1948, LXI, 21-36. (USN School of Aviation Medicine, Naval Air Station, Fla.).

5045

By use of the human centrifuge records of responses both to constant angular acceleration and to changes in acceleration were obtained using the oculo-gyral illusion as an indicator. Five subjects were tested individually for perception of apparent movement of a collimated star (no movement, left or right movement) under constant acceleration (ten revolutions per minute), acceleration, and deceleration. The responses were to mean conditions over periods of 20 seconds rather than to conditions of the moment. Relationships between direction and amount of change in angular acceleration as expressed in the three responses were analyzed. A threshold for change in acceleration was determined. T. G. R 15

Miller, J.W. & Bartley, S.M. A STUDY OF OBJECT SHAPE AS INFLUENCED BY INSTRUMENTAL MAGNIFICATION. *J. gen. Psychol.*, 1954, 50, 141-146.

The question involved in the investigation reported here is whether a tilted plane figure (2 dimensional, though a figure occupying 3 dimensions with reference to the S) will undergo some change when viewed with optical magnification. A series of plane targets (1 circle and 5 ellipses) varying in minor-major axis ratio from 1 to 0.5 in 5 equal steps was presented to 4 Ss in each of 4 positions (30, 67.5, 45, and 22.5°). All targets were 5 in. on the horizontal axis and were viewed at a distance of 5 ft. Visual clues as to target shape or position were reduced to preclude effective knowledge of them. All targets were viewed first by the unaided eye, and a second time through a 2-power binocular mounted in a fixed position. Nomenclature was used such that the object could be named, its perceived tilt could be designated, and its perceived shape could be indicated by examining the drawing made by the S of the perceived target. Phenomenal regression (tendency not to perceive a shape of the retinal image but to deviate toward the shape of the real object) was examined with and without the use of binoculars. It was found that phenomenal regression did not occur in the latter case to any great extent, or in other words, when the binoculars were used, the seen object was a thinner ellipse than with the unaided eye. With the tilted plane figure (those occupying 3 dimensions in space with reference to the S) the third dimension was found to be reduced when viewed through instrumental magnifiers. (MEIAS)

Ogle, K.N. BASIS OF STEREOSCOPIC VISION. *A.M.A. Arch. Ophthalmol.*, Aug. 1954, 52, 197-211. (Mayo Foundation & Mayo Clinic, Rochester, Minn.).

What are described which suggest that there are 2 aspects of stereoscopic depth perception: a) a true quantitative, or obligatory, sense of depth that necessitates the simultaneous stimulation of horizontally associated disparate retinal elements, and b) a vaguer qualitative, or facultative, percept of depth, also arising from disparate images. This provides the individual with an experience only of "farther" or "nearer" than the point of fixation; this perception appears to be empirical in nature. The obligatory, or true, stereopsis, because of the limitation imposed through the necessity of stimuli falling on horizontally associated disparate retinal points, implies a physiologic and neuroanatomic basis. The facultative depth perception would be classed with the empirical factors of spatial localization. The experiments show that the facultative depth is enhanced by momentary stimuli, but depressed with continuously visible disparate stimuli. Eye movements would enhance this aspect of depth perception.

Ogle, K.N. PRECISION AND VALIDITY OF STEREOSCOPIC DEPTH PERCEPTION FROM DOUBLE IMAGES. *J. Opto. Soc. Amer.*, Oct. 1953, 43(10), 906-913. (Mayo Foundation and Mayo Clinic, Rochester, Minn.).

This study reports data on the question as to how precise is stereoscopic depth localization with double images and what is the relationship between that subjective depth and objective depth. Instrumentation was used which permitted a test object to be adjusted relative to a reference object, when both of these were observed in increasing disparity between the images of the 2 eyes and in increasing peripheral angle. The data show that the precision of the stereoscopic depth seems to decrease exponentially with disparity, becoming very small near the limiting values of disparity for stereopsis. When the test object is adjusted for half the depth of the reference object, and adjusted to be as far in front of the fixation point as the depth of the reference is behind, the data show a remarkable validity for a wide range of disparity, until the limiting disparities are approached. Then the stereoscopic depth levels off to a constant value. These results are discussed in relation to the visual processes and spatial localization.

Ogle, K.W. ON THE LIMITS OF STEREOSCOPIC VISION. *J. exp. Psychol.*, Oct. 1952, 45(4), 253-255. (Section of Biophysics and Biophysical Research, Mayo Foundation, University of Minnesota, Minneapolis, Minn. & Mayo Clinic, Minneapolis, Minn.).

The fact that stereoscopic perception of depth is possible from disparate images which are seen double has been known since the middle of the last century. No systematic investigation of the limiting disparities within which such stereopsis exists, however, has been reported. In this paper an apparatus is described which permits such limiting disparities to be found without its introducing at the same time any of the usual empirical factors to spatial localization. Data on 2 Ss show that there are 2 ranges of depth with double images, the one in which there is a strong patent experience of stereoscopic depth, the second one in which there is a qualitative sense that both double images are seen farther or nearer than the fixation point, depending on the direction of the disparity. Measurements are made by the method of adjustment for the limiting disparities corresponding to these ranges. For a patent stereopsis these disparities range from about 10 minutes of arc at the maculas to 79 minutes of arc at a peripheral angle of 6 arc degrees. The qualitative sense of depth of the 2 double images ceased at disparities of about 15 minutes of arc at the maculas to nearly 2 arc degrees at a peripheral angle of 5 arc degrees. The extent of these regions has never been appreciated before. The existence of these limiting disparities is taken as evidence of neuro-anatomical limitations to be accounted for on the basis of the multiplication and overlapping of neural fibers in the terminal region of the occipital cortex or some other area of the brain. These limiting disparities and the corresponding region in space outside of which no stereoscopic vision exists must be taken into account in any general theory of space perception based on binocular vision.

5060 Westheimer, G. & Conover, D.W. SMOOTH EYE MOVEMENTS IN THE ABSENCE OF A MOVING VISUAL STIMULUS. *J. exp. Psychol.*, April 1954, 47(4), 283-284. (Ohio State University, Columbus, Ohio).

It was demonstrated that eye movements fitting in all respects the conventional description of smooth or pursuit movements can occur in the absence of a moving visual stimulus in a situation where there is no reason to expect a lower reflex arc to be in operation. It has generally been believed that such movements require for their initiation, the presence of a moving visual stimulus. The evidence presented here suggests that, at least in the case of the present 2 Ss, the pathways subserving smooth movements can be activated without a moving visual stimulus.

5061 Westheimer, G. THE EFFECT OF SPECTACLE LENSES AND ACCOMMODATION ON THE DEPTH OF FOCUS OF THE EYE. *Amer. J. Optom. & Arch. Acad. Optom.*, 1953, 32(10), 513-519. (Ohio State University, Columbus, Ohio).

On the basis of first-order imagery, a general formula is derived expressing the depth of focus of the eye in terms of the ametropia, accommodation, eye-spectacle lens separation, the diameter of the pupil and the diameter of the retinal blur circles. The values of the latter are related to visual acuity by the use of experimental data of Reese and Fry. In this manner it is found possible to draw graphs relating the depth of focus for a given acuity to the ametropia, accommodation, and pupil size. When expressed in diopters, the depth of focus is independent of object distance. Examples are given of the application of the graphs in multifocal lens calculations.

5067 Brown, J.S. & Slater-Hammel, A.T. DISCRETE MOVEMENTS IN THE HORIZONTAL PLANE AS A FUNCTION OF THEIR LENGTH AND DIRECTION. *J. exp. Psychol.*, 1949, 23, 84-95.

An investigation was made of the speed and accuracy with which individuals could execute simple discrete movements of the hand and arm. The movements were confined to a horizontal line running parallel to the frontal plane of the body. Each movement was initiated at the sound of a buzzer and consisted in moving the limb as quickly and accurately as possible from one visually-perceived, fixed, reference line to another; 2 directions (left-to-right and reverse) and 3 lengths (2.5, 10, and 40 cm.) were investigated. Detailed graphic records were obtained of each movement for 12 Ss. Qualitative characteristics of the movements include a primary phase, consisting of a rapid initial acceleration and a period of high velocity which does not usually terminate at the target, and a secondary corrective movement to remove the error. Time taken to initiate a discrete movement following the auditory signal is about 0.25 sec. and is independent of distance or direction. Increases in length of movement are accompanied by significant increases in duration of primary movements, speed of movement, and variability of both time and speed. Secondary movements are only slightly affected by increases in length of movement; their duration remains approximately constant for movements within the range of 10 to 40 cm. (HEIAS)

White, B.W. VISUAL AND AUDITORY CLOSURE. *J. exp. Psychol.*, 1954, 48(4), 234-240. (George Washington University, Washington, D.C.).

This study was concerned with discovering whether the closure factors isolated by Thurstone are specific to vision or whether they can generalize to the auditory modality. One auditory test was found which correlated with 2 visual tests of the second closure factor as highly as the 2 visual tests correlated with each other. This finding suggests that the second closure factor may be a central trait of considerable importance in a wide variety of behavior. Supporting evidence was found in other studies reporting significant relationships between this closure factor and tests of reasoning and temperament. A redefinition of this trait of ability was made in order to free it from its specifically perceptual connotations. Under this broadened definition, several other psychological phenomena--simultaneous contrast constancy, and retroactive inhibition--were suggested as additional situations in which this trait might be manifested. Correlation of individual differences in reaction to these situations with performance on a test such as Concealed Figures would throw further light on the generality of this trait, and offer valuable data both for personality research and perceptual theory.

Baxter, B. A STUDY OF REACTION TIME USING FACTORIAL DESIGN. *J. exp. Psychol.*, 1942, 31, 430-437. (Ohio State University, Columbus, Ohio).

An investigation of factors affecting RT was conducted with the primary purpose of evaluating the method of factorial design whereby not only the factors investigated but also the interaction of the factors can be evaluated. 3 factors were tested: the hand used for response, sensory modality (auditory and visual), and difficulty of discrimination (simple RT, discrimination between 2, and between 3 stimuli). These factors were arranged in a 3X2X2 factorial design, in which each of 6 Ss was presented with 6 of the combinations of these levels in a random order. The results were summarized as follows: a) there was no evidence that RT for the right and left hands were different; b) there were significant differences in the RTs to situations requiring different levels of difficulty of discrimination, the more difficult requiring greater time; c) reactions to visual stimuli require more time than those to auditory stimuli; d) there is a significant interaction between sensory modality and difficulty of discrimination; e) RT varies significantly between individuals; and f) consistent results concerning the main factors were obtained with the use of only 3 Ss arranged in factorial design. Comparing the confounded design of the above experiment with one using simple randomized blocks where each S was measured in all 12 situations instead of only 6, the writer believes the latter to be the more desirable.

A LONGITUDINAL STUDY. Genet. Psychol.
Monogr., 1953, 48, 3-54. (Iowa State Coll.)

5075

This investigation has as its primary problem the determination of the effects of a 30-year age increment upon mental functions as measured by the Army Alpha, Form 6. It also concerns itself with the effects of the increment upon individual and trait differences, and the relation of personal-social variables to the observed shifts in mental functions. One hundred twenty-seven males were retested on the Army Alpha after a period of 31 years, and utilizing a personal information inventory, the results were treated in terms of temporal shifts in subtest and total Alpha scores, effects of age upon individual and trait differences, and the specific abilities reflected in the sub-tests. Seitz, C.P. & Barnack, J.E. THE EFFECTS OF 10 MCS. OF BENZEDRINE SULFATE AND LOW OXYGEN TENSION ON THE SPAN OF ATTENTION FOR LETTERS, AND OTHER FACTORS. J. Psychol., 1940, 10, 241-247. (University of Alabama, University, Ala. & College of the City of New York, N.Y.).

5082

The attention span for letters of 18 male subjects was measured under three conditions: 1) normal air and a blank pill, 2) simulated altitude of 16,000 feet and a blank pill, and 3) simulated altitude of 16,000 feet plus ten milligrams of benzedrine sulphate. Each session was approximately one hour. The visual angle of the exposed material was seven degrees. Subjective rating sheets concerning feelings, attention, and the like were filled out at the end of each session. Differences in objective attention span and subjective ratings among the three conditions were analyzed. T. R 5

Quartermaster Food & Container Institute for the Armed Forces. PREFERENCE RATINGS FOR OPERATIONAL RATIONS ITEMS. Proj. 7 84 15 007, Termination Rep., Sept. 1956, 13pp. Quartermaster Food & Container Institute for the Armed Forces, Chicago, Ill.

5083

To obtain relative preference ratings for individual components of operational rations (Army), 97 such components served in small portions were rated on the hedonic scale by 2160 enlisted Army personnel. Where appropriate, based on intended use, more than one form of the item was rated (some meat items rated both hot and cold). Lattice designs were used to assign items in different combinations to each group of subjects. Mean hedonic ratings (9-Like Extremely; 1-Dislike Extremely) were analyzed for reliability of ratings and final preference ratings adjusted accordingly. Some significant relationships are discussed in terms of previous laboratory ratings. Suggested uses for the data are offered. T. R 5

Slater-Hammel, A.T. REACTION TIME AND SPEED OF MOVEMENT. Percept. Mot. Skills Res. Exch., 1952, 4(3-4), 109-113. (Indiana University, Bloomington, Ind.).

Measurements of reaction time and speed of arm movement over an arc of 120 degrees were obtained from 25 physical education majors. It was found that the mean reaction time was .22 secs. and the mean movement duration .238 secs. A correlational analysis of the relationships between reaction time and movement duration revealed values which were well within the limits of the sampling error of a true zero correlation. Some suggestions as to the probable significance of these findings were made. R 5

Slater-Hammel, A.T. EFFECT OF BLINKING UPON REACTION-TIME MEASURES. Res. Quart., Oct. 1954, 25(3), 338-343. (Indiana University, Bloomington, Ind.).

The possible effects of normal involuntary blinking upon reaction time measures were investigated through a comparison of blink rates and the incidence of blinking in relation to preparatory signal, response signal, and the S's response. Analysis of the data revealed that: a) the frequency of blinking was markedly decreased during reaction time responses, b) blinking was generally inhibited between presentation of the preparatory signal and the S's response, and c) blinks coincided with presentation of the response signal in only 0.1 per cent of the cases. The results indicated that blinking has little effect upon reaction time measures. R 8

Slater-Hammel, A.T. REACTION TIME TO LIGHT STIMULI IN THE PERIPHERAL VISUAL FIELD. Res. Quart., March 1955, 26(1), 82-87. (Indiana University, Bloomington, Ind.).

In an experimental situation involving binocular vision, the reaction time to light stimuli both directly and indirectly perceived was investigated. From the results obtained, it was concluded: a) reaction time increased as the distance of the response stimulus increased from direct vision; b) the direction of the response stimulus from direct vision was not a significant variable; and c) reaction time to response stimuli directly perceived provided an excellent relative index of reaction speed to stimuli indirectly perceived. Stoan, L.L. RATE OF DARK ADAPTATION AND REGIONAL THRESHOLD GRADIENT OF THE DARK-ADAPTED EYE: PHYSIOLOGIC AND CLINICAL STUDIES. *Amer. J. Ophthalmol.*, June 1947, 30(6), 795-720.

Data are given showing the range of variation among normal subjects in a) the dark-adaptation curve of a single retinal region and b) the threshold gradient of the fully dark-adapted eye in the horizontal meridian of the retina. The same tests were given to 5 subjects on diets low in vitamin A. 2 showed no significant change in the adaptation curve or the threshold gradient after 30 and 195 days respectively on the diet; 2 showed only slight increase in the thresholds after 41 and 91 days; and one showed a very marked rise in the thresholds after 42 days. 2 of the 5 developed concentric contraction of the visual fields which returned to normal after vitamin A was restored to the diet. Studies were also made of 9 patients with elevated light thresholds which were restored to normal following vitamin therapy. The findings indicate that riboflavin in addition to vitamin A may sometimes be required to bring about complete recovery. The results of these studies suggest that concentric contraction of the visual field occurs frequently in patients with ocular vitamin A deficiency and probably indicates cone as well as rod involvement.

Slater-Hammel, A.T. INITIAL BODY POSITION AND TOTAL BODY REACTION TIME. *Res. Quart. Amer. Assoc. Health, Phys. ed. & Recreation*, March 1951, 24(1), 91-96. (Indiana University, Bloomington, Ind.).

The total body reaction time was measured under the following starting positions: a) The knees straight with weight distributed over feet, b) knees bent with weight on the balls of feet, c) knees bent with weight distributed over feet, d) knees bent with weight on balls of feet. The starting positions with the body weight distributed over the feet were significantly shorter than those positions with the weight over the balls of the feet. For each weight distribution group, no significant differences were found for starting reactions involving the positions of the knees. A post-experiment study of the changes in weight distribution revealed that most subjects consistently rocked back on their heels in completing a reaction. It was suggested that starting reactions from the balls of the feet require more time because the time required to lower the heels to the floor was included in the reaction time.

Stone, L.J. & Jenkins, W.L. RECENT RESEARCH IN CUTANEOUS SENSITIVITY: I. PAIN AND TEMPERATURE. *Psychol. Bull.*, May 1940, 37, 285-311.

This review of research on pain and temperature aspects of cutaneous sensitivity covers a period from 1930 through 1939 in both English language and foreign language publications. The various topics subsumed under pain are as follows: pain as a specific modality, new theories of the neural mechanisms of pain and hyperalgesia, chemical factors in pain and analgesia, visceral and referred pain, phenomena of plural stimulation, localization of pain, and adaptation of pain. Topics treated under temperature are the following: attempts to identify receptors, theories of receptor action, adaptation, mapping, paradoxical warmth, heat, genetic studies, phenomena of plural stimulation, and perceptual phenomena.

Schmitt, W.A. THE EFFECT OF LOW FREQUENCY, HIGH AMPLITUDE WHOLE BODY VIBRATION ON HUMAN PERFORMANCE. Contract DA 49 007 MD 757, Prog. Rep. 2, Jan. 1959, 62pp. *Bostron Research Labs., Milwaukee, Wisc.*

5092

To investigate the effects of low frequency, high amplitude vibration (of the type found in work vehicles) on human performance, 18 subjects were exposed to vibrations (while seated on a wooden chair on a mechanical shake table) of 2.5 and 3.5 cps at two displacements for 90-minute periods. Pre- and post-control measures were taken before and after each session. Their performance was compared to a no-vibration condition on these tests: 1) hand tremor, 2) visual acuity, 3) compensatory tracking, 4) foot pressure constancy, 5) foot reaction time, and 6) body equilibrium. One human subject and three dogs were exposed to frequencies in the one-to-eight cycle range and various physiological measurements were made.

5099 Vanderplus, J.M. THE APPARENT SIZE OF OBJECTS VIEWED THROUGH TELESCOPES. Proj. 6334, WADC Tech. Rep. 54-459, Oct. 1954, 15pp. Air Research and Development Command, USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

When objects are viewed through telescopes or periscopes having restricted fields of view, they often appear to be of a different size or distance than when they are viewed with the naked eye. This creates a serious problem in certain aircraft uses where it is important that size and distance judgments be accurate. While no completely satisfactory explanation of this phenomenon has been offered, a previous study has ruled out the effects of refraction in the visual field as major contributors. This report reviews several factors, inherent in the design of optical systems, which might conceivably operate to produce apparent size and distance alterations. Some phenomena of visual perception of size and distance are discussed and these phenomena are related to factors in the design of sighting telescopes for accurate perception of size and distance. Several possible theoretical approaches are suggested to the solution of the problem of object appearance when viewed through telescopes and periscopes.

5103 Hansen, R.G. THE EFFECT OF STATIC AIR PRESSURE IN THE EXTERNAL AUDITORY MEATUS ON HEARING ACUITY. WADC Tech. Rep. 55-95, April 1955, 61pp. Air Research and Development Command, USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

The specific purposes of this study were to determine the effects of various static air pressures in the external auditory meatus on a) threshold sensitivity and b) hearing acuity at 2 loudness levels above threshold. To determine the effect of a pressure differential across the tympanic membrane on the threshold sensitivity, measurements were obtained by the Method of Adjustment for 10 ears at each of 41 frequencies from 100 to 8000 cps at each of 4 pressure conditions (-10, -20, +10, +20 cm H₂O). For all pressures used, threshold sensitivity was generally decreased for frequencies below 1500 cps with a slight increase in sensitivity for frequencies between 1500 and 2300 cps and a general decrease in sensitivity for frequencies between 2300 and 8000 cps. To test the effect of pressure on loudness, 5 subjects made equal loudness balance judgments for 6 frequencies (200, 400, 1000, 1600 and 4000 cps) at 30 db and at 60 db above threshold under each of the 4 experimental pressure conditions. As in the threshold sensitivity study, results indicated a general decrease in sensitivity for frequencies below 1000 cps, and only slight effects on the higher frequencies. The effect of static pressure on speech intelligibility was also studied and in the range investigated was found negligible.

5102 This review and interpretation of literature integrates the results of observation and research on the role of human variables in causing or contributing to motor vehicle accidents. Those findings most useful for the prevention of accidents are identified and areas for research and continued study are indicated. The various chapters include: the magnitude of the vehicular accident problem, analysis of causes of accidents, susceptibility to accidents of driver, other characteristics of the driver in relation to accidents (sensory, psychomotor, intellectual, emotional, biographical), temporary states and limiting conditions (fatigue, toxic substances), selection and training of drivers, vehicular factors (defects, design), environmental factors (visibility, weather, highway design), and driver behavior and the social environment. A topical index is included. R 1031

5104 Ferris, H.M., Fox, R.H., & Lind, A.P. PHYSIOLOGICAL RESPONSES TO HOT ENVIRONMENTS OF YOUNG EUROPEAN MEN IN THE TROPICS: VII. THE ENERGY EXPENDED IN THE COMPONENT ACTIVITIES OF A STEP CLIMBING ROUTINE. R.N.P. 54/818, C.E.S. 417, T.R.U. 51, June 1954, 14pp. Medical Research Council, Royal Naval Personnel Research Committee, Cambridge, England.

These experiments formed part of a series of experiments performed at the Royal Naval Tropical Research Unit, Singapore, designed to investigate the effect of work on the responses of naturally acclimatized young men exposed to hot climates. The aim of the experiments described here was to measure the energy expended by 4 Ss while resting seated and while step-climbing on and off stools, 1 ft. high, 12 times a min. The mean energy expenditure of the 4 Ss was 54.8 kcal/m²/hr. while resting and 166.9 kcal/m²/hr. while step-climbing. The results are compared with those of 2 earlier series, one at Singapore and one in London. The resting energy expenditure of the Ss in the present series was higher than in the earlier Singapore series, probably as a result of a small difference in the posture adopted by the Ss in the 2 series. With this qualification, the 2 Singapore series are in agreement and suggest that when performing the same standardized exercises the Singapore Ss expended less energy than those in London. Possible causes for the differences between the results obtained in London and in Singapore are discussed. It is considered that with the data available, it would be most unwise to attribute the difference to an acclimatization effect.

Arnoult, M.D. LOCALIZATION OF SOUND DURING ROTATION OF THE VISUAL ENVIRONMENT. *Amer. J. Psychol.*, Jan. 1952, LXV, 48-58. (University of Texas, Austin, Tex.).

5108
To investigate the effect of visual-auditory interaction on the localization of sounds, the experience of rotating was induced visually by rotating the entire visual environment--a large striped cylinder in which the subject was seated. Ten subjects tested individually were required to report the location of a sound in the horizontal plane under three conditions: 1) while experiencing rotation to the right, 2) the same to the left, and 3) while stationary. The sound stimulus was a loud buzz made by headphones placed in the horizontal plane at ten degree intervals (40 degrees left to 40 degrees right). Mean localizations, latencies, post-rotational effects, and eye movements were analyzed.

5109
Arnoult, M.D. SHAPE DISCRIMINATION AS A FUNCTION OF THE ANGULAR ORIENTATION OF THE STIMULI. *J. exp. Psychol.*, 1954, 47(5), 323-328.

Pairs of 2-dimensional nonsense figures were presented tachistoscopically to Ss who were required to judge them for identity of shape. Each shape could be rotated clockwise or counterclockwise in its own plane to any of 8 angular positions. The combinations of the angular positions of the 2 shapes in each pair resulted in angular separations of the shapes in multiples of 30° between 0° and 180°, inclusive. The accuracy and latency of shape discrimination were studied as a function of the angular separation of the shapes. The results may be summarized as follows: On the trials on which the 2 shapes were actually identical, errors increased as a function of increased angular separation. The range of errors was from 20% to 40%. On the trials on which the 2 shapes were actually different, errors showed an initial decrease (30° separation), followed by an increase (60°-150°) and a final drop at 180°. The range of errors on these trials was from 12% to 15%. Latencies on the "S" trials were consistently higher than on the "D" trials. The changes in latency as a function of angular separation were statistically significant, though irregular. Generalization of these results is limited by the fact that, in the case of both errors and latencies, a significant interaction was found between angular separation and the variable of shape. The use of 'shape' as an independent variable is difficult because it is impossible to specify the procedure for selecting a representative sample of shapes to be used as stimuli.

Berdie, R.F. EFFECT OF BENZEDRINE SULPHATE ON BLOCKING IN COLOR NAMING. *J. exp. Psychol.*, Sept. 1940, 27, 325-332.

An experiment was conducted to determine the influence of 15 mg. of benzedrine sulphate on blocking during a color naming task and of speed of response. 15 Ss were each given 4 10-min. trials in naming 100 colored squares (yellow, blue, black, red, and green) arranged on a square card. Responses, time in secs, and errors were recorded. The first trial was for practice; the second was also alike for all Ss; in the third the Ss were randomly divided into 3 groups (drug, placebo, nothing); the final trial was alike for all Ss and was given 4 days later. The analysis of data warrants the following conclusions: a) 15 mg. benzedrine sulphate has no effect on length or number of blocks occurring in color naming; b) the same amount of the drug slightly increases speed in color naming; and c) most of the variation in blocking and speed of response is due to individual differences. (HEIAS)

Berkeley, A.W. LEVEL OF ASPIRATION IN RELATION TO ADRENAL CORTICAL ACTIVITY AND THE CONCEPT OF STRESS. *J. comp. physiol. Psychol.*, Oct. 1952, 45(5), 443-449. (Worcester State Hospital, Worcester, Mass.).

31 normal men performed a level of aspiration test under both success and failure conditions. The stressfulness of this task was evaluated in terms of change in rate of urinary 17-ketosteroid excretion during the test period as compared with a pretest control period. The extent of discrepancy between aspiration and achievement with respect to both success and failure conditions was related to increase in rate of 17-ketosteroid excretion. Greater discrepancies were accompanied by increases in steroid excretion, a coefficient of multiple correlation of .70 taking both conditions into consideration. These results are related to previous psychological interpretations of goal behavior in the level-of-aspiration setting. The concept of stress is discussed with reference to the synthesis of divergent findings in the area of level of aspiration and as a means of bringing goal behavior into the framework of the integrated adaptive activity of the organism.

Bevan, W. & Dukes, W.F. VALUE AND THE WEBER CONSTANT IN THE PERCEPTION OF DISTANCE. *Amer. J. Psychol.*, Oct. 1951, 64(4), 580-584. (Emory University, Atlanta, Ga.).

Using the method of average error of classical psychophysics, 40 college students each made 20 judgments of distance with a modified Howard-Doman distance-perception apparatus. Stimulus-objects were 2 light green cardboard rectangles, equal in size to U.S. currency. On the basis of both the Ss' average and constant errors, 2 comparable groups were formed. Several days later the control group repeated the original task while the experimental group made their judgments with \$20 bills as stimulus-objects. Comparison of the results from the second-session performance of the 2 groups showed a significantly smaller average error for the experimental group ($t = 3.00$, $df. = 38$, $P < 0.01$). These results emphasize the role of motivational variables in a response system traditionally described in terms of purely cognitive functions.

R 13

5117 Bevan, W. THE INFLUENCE OF FIGURAL AFTER-EFFECTS UPON VISUAL INTENSITY THRESHOLDS. *J. gen. Psychol.*, 1951, 45, 189-207.

3 series of experiments were carried out in order to explain the influence of the figural after-effect upon visual intensity thresholds. The general procedure consisted of determining thresholds for certain figures (test figures) using a modified form of the method of limits, before and after the S had fixated other figures (inspection figures) for a set period of time. 98 Ss were used in the tests. In Series I, in which the inspection figures were simple geometrical outlines and the test figures were pairs of small dots or geometrical figures presented inside and outside the inspection figure area, it was found that the thresholds for test figures presented inside the inspection figure area were higher than those falling outside this region. This increase in threshold level was statistically reliable both in terms of magnitude and frequency of occurrence. This effect was more systematically explored in 2 further series. In these the inspection figure was a narrow vertical line of light, the test figure a dot of light presented various distances from the locus of the inspection figure. The results of these series confirmed those of Series I and in addition indicated that the strength of figural after-effect (amount of increase in threshold) varied with the distance between inspection and test figure positions.

5123

To investigate the relation of the length of a simple addition problem to the time required for solution, the probability of success, and the age of the individual performing the task, 413 subjects ranging from 16 to 90 years of age were required to add single columns of digits ranging in length from 2 to 25 digits. The results are treated in terms of performance differences among age groups, per se, and as a function of problem length and number of operations required to solve the task.

Birren, J.E. & Shock, N.W. AGE CHANGES IN RATE AND LEVEL OF VISUAL DARK ADAPTATION. *J. appl. Physiol.*, Jan. 1950, 2(7), 407-411. (National Institute of Health, Bethesda, Md. & Baltimore City Hospitals, Baltimore, Md.).

5125

To investigate the relation of age to rate and level of visual dark adaptation, a Hecht Shlaer adaptometer was used to measure the light thresholds of 91 Ss ranging in age from 40 to 83 years. The pupils of all Ss were dilated with ephedrine for both light and dark adaptation periods. Results are discussed in terms of rate of cone and rod adaptation and individual thresholds as related to age.

Slankenship, A.B. & Whitely, P.L. PROACTIVE INHIBITION IN THE RECALL OF ADVERTISING MATERIAL. *J. soc. Psychol.*, 1941, 13, 311-322. (Franklin and Marshall College, Lancaster, Penn.).

5126

In a test of proactive inhibition in the recall of advertising material, 85 students were required to study a grocery advertisement for five min. and to recall the items on it immediately and after an interval of 48 hours. Prior to this task, the Ss learned a list of similar material, learned a list of dissimilar material (nonsense words), or underwent no prior training. Proactive inhibition is measured in terms of the difference in mean number of items correct on the immediate and delayed tests of retention.

Boring, E.G. A COLOR SOLID IN FOUR DIMENSIONS. *Année Psychol.*, Cinquantième année, Vol. Jubilaire, 293-304. Presses Universitaires de France.

The tridimensional color system is based on an attributive analysis of color and places every color in relation to the others with respect to hue, brightness, and saturation. The double pyramid (Ebbinghaus), the double cone (Troland), and the sphere (Mundt) are the familiar forms of the color solid. A different conception of the relations of the colors is given by component analyses where there are assumed 7 fundamental components corresponding to 7 unique colors: red, green, yellow, blue, white, black, and gray. This leads to a 4-dimensional figure; the complementary colors are paired as mutually exclusive plus gray. The possibility of constructing and using an orthogonal figure is considered and rejected since such a figure lacks didactic and demonstrational value. (HEIAS)

Boring, E.G. THE SIZE OF THE DIFFERENTIAL LIMEN FOR PITCH. *Amer. J. Psychol.*, 1940, 52, 450-455.

The size of the differential limen for pitch has always been of especial interest because it is supposed to fix the minimal differentiation in the inner ear that a place theory of pitch, like Helmholtz's must have. The conventional values that are usually cited for the chief investigations are inspected; it appears from casual appearances that the limens, consistently small in the early days, got suddenly larger about 1900. This paper presents a critical investigation of methods used in each investigation and of the factors besides the fundamental frequency of the stimulus that affect the size of the differential limen: practice, individual differences, method of limits vs. method of right and wrong cases, continuous change vs. abrupt change, fixed vs. variable inequality between the standard and comparison stimuli, presence of overtones and transients, and loudness. In conclusion, the writer feels that at the present time there is no way of determining the maximal sensitivity of the ear to difference of frequency without artifacts, but he does present some guides by which maximal sensitivity and comparable results might be obtained. Boring, E.G. THE MOON ILLUSION. *Amer. J. Physics*, 1943, 11, 55-60. (Harvard University, Cambridge, Mass.).

The moon illusion (horizon moon is perceived larger in size than moon in heavens) is discussed in terms of several explanations that have been put forward. Some experiments regarding to the conditions of the illusion are summarized with the following conclusions: There is no satisfactory further theory for explaining the phenomenon. It is not due to physical causes outside the visual mechanism since differences do not appear in photographic measurements. It is not due to the greater brightness of the moon in elevation, when the atmospheric haze is diminished. It does depend on raising or lowering the eyes. Movements of head, neck, and body do not cause it. A tentative suggestion is made that the effort of raising or lowering the eyes shrinks the perceived size of the moon - a theory of inhibition or drainage might be plausible. (HEIAS)

Bridgman, C.S. THE LUMINOSITY CURVE AS AFFECTED BY THE RELATION BETWEEN ROD AND CONE ADAPTATION. *J. opt. soc. Amer.*, Sept. 1953, 43(9), 733-737. (University of Wisconsin, Madison, Wisc.).

Previous experimental determination of the luminosity curve of the eye at intermediate intensities has shown a series of transitional curves intermediate between rod and cone, the appearance of which has been attributed to rod-cone interaction. However, examination of mesopic curves predicted on the basis of no interaction indicates that their major characteristics are dependent instead on the relation between rod and cone functional levels. Residual discrepancies between predicted and empirical curves require the assumption of summation between the 2 mechanisms at wavelengths for which sensitivity is nearly equal for both. In addition to contributing to an understanding of relations between rod and cone function, the analysis emphasizes the lack of validity of mesopic curves for photometric calculation.

Bridgman, C.S. AN ANALYSIS OF TAYLOR'S DATA ON RELATIVE LUMINOUS EFFICIENCY OF VARIOUS COLORS. J. opt. soc. Amer., May 1954, 44(5), 391-396. (University of Wisconsin, Madison, Wisc.).

Taylor's data on the relative luminous efficiency of various filter colors at intermediate intensities have been examined for evidence of rod-cone interaction. Shorter wavelengths show relatively less evidence of combined rod-cone function, with the "transition range" limited to approximately one log unit of intensity. Longer wavelengths show evidence of a broader transition range. Relationships of this sort are of significance to the theoretical basis of intermediate level photometry and to the understanding of the transition between rod and cone vision.

Peters, R.W. THE EFFECT OF CHANGES IN SIDE-TONE DELAY AND LEVEL UPON RATE OF ORAL READING OF NORMAL SPEAKERS. J. Speech & Hearing Disorders, 1954, 19, 483-490. (USN School of Aviation Medicine, Pensacola Air Station, Fla.).

This article is concerned with the effect of accelerated side-tone transmission times upon rate of oral reading. The results would seem to indicate: a) that speakers, under instruction to read naturally, read at faster reading rates under conditions of accelerated side-tone delay than they do under the condition of side-tone delay which approximates the transmission time of normal side-tone; and b) that speakers, under instruction to read naturally, read at a progressively faster reading rate as the sound pressure level of side-tone is decreased. Similar results of retarded rate of speech with increased side-tone delay time and increased side-tone sound pressure level were noted with the speakers reading at their maximum rates. To the extent that the experimental conditions duplicated the normal side-tone experience, the normal external side-tone transmission time may be said to constitute a retarding influence upon the rate of oral speech.

Riopelle, A.J. & Bevan, W. THE DISTRIBUTION OF SCOTOPIC SENSITIVITY IN HUMAN VISION. Amer. J. Psychol., Jan. 1953, 66, 73-80. (Emory University, Atlanta, Ga.).

Estimates of monocular scotopic brightness sensitivity were obtained from 8 Ss for 8 positions on each of 16 equally-spaced radii using a modified method of limits. Isometric sensitivity contours constructed from these estimates are generally ovoid in character with the major axis in the horizontal dimension. Maximal sensitivity is found on either side of the fovea on the horizontal meridian in the neighborhood of 20-30° eccentricity. While thresholds are generally lower for the superior than for the inferior retina, the range of low thresholds is not as wide as for the horizontal meridian. These results are discussed in terms of available information on the distribution of retinal structure.

Wallach, H. & O'Connell, D.M. THE KINETIC DEPTH EFFECT. *J. exp. Psychol.*, April 1953, 45(4), 205-217. (Swarthmore College, Swarthmore, Penn.).

When a 3-dimensional form, solid or wire-edged, is turned behind a translucent screen and its shadow on the screen is observed, the shadow will appear as a real as a 3-dimensional rigid object which turns quite similar to the physical object behind the screen. This happens notwithstanding the fact that S actually looks at a plane figure which is being deformed. One condition seems to be essential for the occurrence of this effect: the shadow must display contours or lines which change their length and their direction simultaneously. If this condition is not fulfilled, a plane distorting figure like the one on the screen is perceived unless an influence of previous perception operates. This effect is believed to operate widely under ordinary circumstances. When one moves about, objects near one's path are successively seen from different angles, and this change in orientation of the object to S is the same as comes when the object is turned by an equivalent angle. Thus, the object's retinal projection undergoes the same deformations as do shadows in our experiments, and the same perceptual processes should result.

The effects of color constancy and of color contrast were compared and were found to be identical. In every experiment a situation yielding a constancy effect was presented for simultaneous comparison with a contrast situation of a geometrically similar arrangement of colors. When the colors in the 2 situations were so chosen that the lights reflected by corresponding regions were equal as to brightness and hue, the constancy and the contrast effects were found to be equal in every respect. It turned out that the mode of appearance of the effective color by which constancy was supposed to be distinguishable from contrast was without influence. Only the quality of the reflected lights and their geometrical arrangement seemed to matter.

Webster, J.C., Miller, P.M., Thompson, P.O. & Davenport, E.M. THE MASKING AND PITCH SHIFTS OF PURE TONES NEAR ABRUPT CHANGES IN A THERMAL NOISE SPECTRUM. *J. acoust. soc. Amer.*, March 1952, 24(2), 147-152. (USN Electronics Lab., San Diego, Calif.).

In an investigation of the effects of a thermal-type noise with a rapidly changing spectrum upon the detection of pure tones, thermal noise was passed through highpass and lowpass filters used separately and in combination to produce noise spectra of the following types: flat noise, highpassed noise, lowpassed noise, and gapped noise. The masked thresholds of pure tones at frequencies near the filter cutoff frequencies were determined by a constant stimulus psychophysical method. It was concluded that: a) pure tones at frequencies near the center of an octave gap in a thermal noise can be detected at levels 25 db below the intensity necessary for detection at frequencies outside the octave gap; b) a false indication of doppler may be observed when pure tones are partially masked by thermal noise, since under these conditions the pitch of the tone is raised; c) when thermal noise is passed through a lowpass filter, the pitch of a pure tone is 1) slightly raised at the filter cutoff frequency and 2) inordinately raised at frequencies immediately above the filter cutoff point; d) when the flat noise is passed through a highpass filter, the pitch of pure tones at frequencies immediately below the filter cutoff point is either unaltered or lowered slightly; e) the loudness of pure tones is affected by frequency components in the noise that are one octave or more removed from the frequency of the pure tone. It is recommended that an investigation be made of the effectiveness of introducing shaped thermal noise into electronic or other work areas in order to reduce the distracting effect of unwanted sounds.

Webster, J.C. & Schubert, E.D. PITCH SHIFTS ACCOMPANYING CERTAIN AUDITORY THRESHOLD SHIFTS. *J. acoust. soc. Amer.*, Sept. 1954, 26(5), 754-758. (Res. Rep. 570, USN Electronics Lab., San Diego, Calif. & State University of Iowa, Iowa City, Iowa).

A method was developed for getting a continuous and running record of pitch matches between the 2 ears, using a) the synchronized frequency and paper-drive features of a "Bekes" type audiometer and b) the S's adjustment of the frequency knob of a second oscillator to drive the recording pen. A one-second tone from the motor-drive (standard) oscillator (controlling the pen writing mechanism) is presented alternately to the other ear. The S, who controls the frequency of the variable tone, is instructed to keep the 2 alternating tones matched in pitch. 10 music students made these pitch matches (90 matches per octave) from 150 to 9500 cps. In the ear in which the standard tone was heard various types and amounts of hearing loss were simulated by masking noises. The pitch tended to shift away from a region of hearing loss to a region of no, or less hearing loss. Downward shifts were observed but were never as marked as the upward shifts.

White, C.T., Cheathan, P.G. & Armitage, J.C. TEMPORAL NUMEROSITY: II. EVIDENCE FOR CENTRAL FACTORS INFLUENCING PERCEIVED NUMBER. *J. exp. Psychol.*, Oct. 1953, 46(4), 283-287. (USN Electronics Lab., San Diego, Calif.).

The purpose of this experiment was to determine if the perceived number of flashes was limited by temporal characteristics of the retina. Human ERG records were studied to ascertain the relationship of retinal response to the objective number of flashes at several flash rates. The ERG results showed that the light-adapted retina reacted to each separate flash in a series of flashes, up to the highest flash rate used, 45/sec. It was concluded that the retina is not responsible for the temporal patterning of perceived number, but that this phenomenon must be determined by some higher process. Perceptual data from stereoscopic studies supported the conclusions based on the ERG results.

Mize, L.G. & Dransbarn, N.C. PHYSIOLOGICAL NEED, WORD FREQUENCY, AND VISUAL DURATION THRESHOLDS. J. exp. Psychol., July 1953, 46(1), 25-32. (Ohio State University, Columbus, Ohio).

This experiment was designed to test the hypothesis that with increased deprivation, need-relevant stimulus words would be recognized more rapidly than neutral words, and to determine what part word frequency played in this process. 3 groups of 20 Ss each were deprived of food and water, and their recognition thresholds for need-relevant and neutral words were obtained at 0-, 10-, and 24-hr. deprivation. The stimulus words were matched for commonness and food-water relevance. The principal findings were: a) that word-commonness was the single most important factor, b) that need-related words were recognized more rapidly as need increased, and c) that word-commonness was not a significant interactive factor. The relationship between physiological deprivation and recognition thresholds for need-relevant stimuli is not a simple linear one, however, for there is a slight increment in the recognition-time thresholds at the 24-hr. period. Analysis of the presolution responses revealed that at 10 hr. there was an increase in the number of need satisfiers and "eating" and "drinking" words, with a drop at 24 hr.; while the responses denoting acts instrumental to obtaining need-satisfaction decreased at 10 hr. and increased at 24 hr.

Witkin, H.A. INDIVIDUAL DIFFERENCES IN MODE OF SPACE ORIENTATION. Brooklyn College, Brooklyn, N.Y.

A series of investigations were conducted to examine the nature of individual differences in mode of space perception when the upright indicated in the visual field is in a different position than that indicated by postural impressions. 3 tests (tilting room - tilting chair, rod- and-frame, rotating-room) were given to large groups of Ss, resultant intercorrelations among the tests and among basic parts of each test showed that individual differences were consistent from test to test. A second testing after an interval of a year established the stability of individual differences (correlations of .85 and .86 for men; .86 and .87 for women). Relations between perceptions in varied conditions (embodied figures, body balance, auditory-visual conflict, etc.) was found to maintain the same consistency. Sex differences were significant and in the same direction - women tend to go with the visual field more than men and responding less to bodily experience. The relationship between perception and personality (Interview, Morscnach, Thematic Apperception, etc.) revealed positive findings. Further, developmental changes were shown in studies with children. On the basis of these findings it is concluded that any theory of perception will have to include psychological factors within individuals along with field and sensory factors. (HC:AS)

Porchel, P. THE VESTIBULAR ORGANS IN SPACE ORIENTATION. Percept. Mot. Skills, 1955, 2, pp64. (University of Texas, Austin, Tex.).

In a previous study compensatory functioning of the kinesthetic organs was proposed as an explanation for the superior performance of the vestibular-deficient Ss. It was suggested that had the experiment involved longer distances, the results might have been different. The present report deals with the role of the vestibular organs over long distances. 2 groups of 15 totally deaf Ss were divided on the basis of the presence or absence of vestibular sensitivity. Each S was blindfolded and fed over the 2 72-ft. legs of an isosceles triangle laid off on the playground, and was then asked to return over the 114-ft. base to the original starting point. Each S was given 5 trials, and both distance from the starting point and angular deviation from the base were calculated. The results showed no significant differences between the 2 groups on angular deviation, but the group with no significant differences between the 2 groups on angular deviation, but the group with vestibular organs returned significantly closer (between 10% and 5% level) to the starting position than the vestibular-defective group. It was concluded that kinesthesia is effective over short distances, but the vestibular organs play a dominant role over long distances.

Edwards, W. & Boring, E.G. WHAT IS EMERT'S LAW? *Amer. J. Psychol.*, 1951, 64, 416-422. (Harvard University, Cambridge, Mass.).

The question of just what Emert's Law says is the subject of this note. The author points out that Emert was not the first to note that the apparent size of after-images increases with their projection distance, but his paper on this subject pointed out that the ectopic images increase in apparent size as the distance of their projection is increased and that the apparent size of entoptic after-images were usually smaller than the object, thus inferring that their estimated distance must be small. It was the fact that Emert's paper was, for the most part, about apparent size that led the senior author of this note to characterize Emert's "law" as a function between apparent size and projection distance, not a law of the physical sizes of after-images. Fletcher, J.L. AN INVESTIGATION OF PURE TONE THRESHOLDS FOLLOWING NARROW BAND FILTERED NOISE. AMRL Proj. 6 95 20 001, Rep. 214, Dec. 1955, 21pp. USA Medical Research Lab., Fort Knox, Ky.

Pure tone pre-exposure thresholds were found for subjects who were then exposed to filtered or unfiltered noise stimuli at either 20 or 100 decibel (db) sensation level (SL). Post-exposure thresholds were determined for the tone and the pre- and post-exposure thresholds were compared. Subjects stimulated with unfiltered noise had higher post-exposure thresholds for pure tones within the filtered gap than did subjects exposed to the filtered noise. Fatigue resulted for all test-tones after stimulation by 100 db SL unfiltered noise. Following 20 db SL filtered noise, only the 100 and 600 cycles per second (cps) tones were fatigued. The 100 db SL filtered noise stimulation produced sensitization for the 162 and 255 cps test-tones, and fatigue for only the 100 and 600 cps tones. Following filtered noise at 20 db SL, sensitization was found only at 350 cps.

THE EFFECT OF DIFFERENT WORK ROUTINES, HAVING THE SAME TOTAL ENERGY REQUIREMENTS, ON SWEAT PRODUCTION. R.N.P. 54/817, C.E.S. 416, T.R.U. 50, June 1954, 21pp. Medical Research Council, Royal Naval Tropical Research Unit, Royal Naval Personnel Research Committee, Cambridge, England.

The experiments described here were performed in the tropics and were designed to investigate certain aspects of the effect of work on the responses of naturally acclimatized young men exposed to hot climates. The specific aim of the present experiment was to determine whether experimental routines having the same total energy expenditure over a reference period but with different patterns within the period would produce the same total sweat losses. 4 young Ss were divided into pairs and studied while resting seated or walking on a treadmill at one climatic temperature (90°F dry-bulb temperature, 80°F wet-bulb temperature, and air speed 300 ft/min). The 3 routines were a) 15 min. periods of resting alternating with 15 minute periods of working. It was found that the amount of sweat loss for each kcal. of energy expended on walking did not differ significantly in the 3 routines. Measures of rectal and skin temperature levels gave evidence that total heat exchanges were the same. (HEIAS)

Ferres, H.M., Fox, R.H. & Lind, A.R. PHYSIOLOGICAL RESPONSES TO HOT ENVIRONMENTS OF YOUNG EUROPEAN MEN IN THE TROPICS. VII. THE RESPONSES OF FOUR SUBJECTS WALKING ON A TREADMILL AT SIX SPEEDS AND AT ONE LEVEL OF CLIMATIC STRESS. R.N.P. 54/816, C.E.S. 415, T.R.U. 49, June 1954, 81pp. Medical Research Council, Royal Naval Personnel Research Committee, Cambridge, England.

Experiments reported here were designed to investigate certain aspects of work on physiological responses of young men exposed to hot climates (tropics). Energy expenditure, sweat production, skin and deep body temperatures, and pulse rates were measured on 4 naturally acclimatized Ss while resting and while walking at 6 graded levels of energy expenditure (2-4 rph) and at one climate level (dry-bulb temperature 90°F, wet-bulb temperature 80°F, air speed 300 ft/min). Rates of energy expenditure of 3 Ss were in close agreement with values reported for unacclimatized individuals residing in a temperate climate; one S showed unusual economy in energy expended while walking. It was found that sweat loss provided the most accurate indication of changes in thermal load produced by changes in rate of working and also reflected most accurately differences between individuals in their patterns of energy expenditure. In the climate studied here, a change in level of activity from resting seated to walking 4 rph produced 5-fold increases in sweating rate; sweat rate was more than doubled when speed increased from 2 to 4 rph. A good agreement was found between heat gains through metabolism and heat losses from Ss to their environment; major avenue of heat loss was by evaporation of sweat. A possible form for a heat stress index based on magnitude of heat exchanges is tentatively suggested. (HEIAS)

Bauer, H.J. DISCRIMINATION OF TACTUAL STIMULI. *J. exp. Psychol.*, Dec. 1952, 44(6), 455-459. (Loyola University, Chicago, Ill.).

This experiment was designed to determine which, of a number of randomly designed tactual stimuli, are sufficiently discriminable to be feasibly employed for the purpose of texture coding typical control knobs, levers, and push buttons. 10 different surface textures were used. 3 different methods of serial exploration were permitted. It was found that simple, 1-sec. tactual contact with the textures was not as efficient as 1-sec. exploration permitting movement. Even the introduction of a thin cotton glove between the stimuli and the finger tips did, in some instances, facilitate identification. The stimuli were ranked according to per cent correct identifications. The cues used by Ss were found to be based primarily in touch, perception of form, kinesthesia, vibration, and sound. Accuracy of discrimination between textures was, in the majority of cases, significantly better than would be expected by chance alone. It was deemed feasible to investigate the extent to which textured surfaces, such as those used in the experiment, might be utilized in coding control surfaces of levers, knobs, and push buttons on military and naval devices.

Divita, S.P. MEASUREMENT OF STAFF WORK. Dissertation for the Degree Master of Business Administration, Ohio State University, 1956, 57pp.

5167

To study the problem of measurement in staff work, a search of pertinent literature and conferences with individuals intimately concerned with the problem was made. The need for measurement was determined, existing techniques of measurement were analyzed, and the method of work sampling was analyzed in detail. Work sampling was defined, its mathematical basis presented, the application of the method to staff work was outlined, and the limitations of the method discussed.

Bitterman, M.E., Krauskopf, J. & Hochberg, J.E. THRESHOLD FOR VISUAL FORM: A DIFFUSION MODEL. *Amer. J. Psychol.*, June 1954, 67, 205-219. (University of Texas, Austin, Tex.).

Foveal form thresholds for luminous figures briefly exposed in a dark room were measured in terms of the intensity of illumination required for correct identification. In accordance with a diffusion model derived from the Köhler-Wallach theory of figural after-effects, form threshold was found to vary directly with the ratio of perimeter to area and inversely with the magnitude of critical detail. Data on the pre-threshold appearance of selected forms were related to results obtained with a physical diffusion model.

Shepherd, A.J. PERFORMANCE CHARACTERISTICS OF THE NITROGEN METER, WITH PARTICULAR REFERENCE TO THE EFFECT OF CARBON DIOXIDE. *FPAC 936*, Sept. 1955, 5pp. Royal Air Force Institute of Aviation Medicine, Flying Personnel Research Committee, London, England.

Some performance characteristics of an A/C nitrogen-meter are described. A discharge current of 4.0 mA allows operation over wide range of vacuum pressures (400 - 3,000 μ Hg.), and the discharge stability is then little below the optimum. Water vapour produces a decrease in the nitrogen-meter readings, apparently by decreasing the nitrogen content of the gas mixture. Temperature has no significant effect over the physiological range. Carbon dioxide produces an increase of scale readings although the effect decreases progressively as the vacuum pressure is increased. In the range 1500 - 2500 μ Hg., the scale reading approximates to a linear function of carbon dioxide concentration; several practical difficulties limit the use of this relationship as a method of rapid gas analysis. The vacuum pressure selected for nitrogen measurements (2500 μ Hg.) is a compromise between maximum nitrogen discharge and minimum carbon dioxide effect. If measuring low concentrations of nitrogen, it is advisable to estimate or absorb carbon dioxide.

5175

This paper reviews the general changes which have occurred in the development of Royal Air Force Survival Equipment. The equipment is described under five headings: (1) environmental protection (clothing, dingy, sleeping bags); (2) rapid location (radio, sea cells, flares, etc.); (3) water; (4) food; and (5) auxiliary aids (stoves, watches, compasses, fishing nets and lines, first-aid equipment). General trends are discussed together with principles guiding the design and development of survival equipment.

Anastasi, Anne. AN EMPIRICAL STUDY OF THE APPLICABILITY OF SEQUENTIAL ANALYSIS TO ITEM SELECTION. *Educ. Psychol. Measmt.*, Spring 1953, 13(1), 3-13. (Fordham University, New York, N.Y.).

In summary, the application of sequential analysis to 2 sets of test items showed very close agreement between the decisions reached through sequential sampling on a total of 30 cases, and the item-criterion correlations obtained on larger samples of 188 and 100 cases, respectively. The 2 parts of the study differed in a number of respects. The 1st was high school students in one, Air Force student pilots in the other. The first was concerned with items from an achievement test, the second with items from a non-verbal, projective personality test. One employed Pearson correlations estimated from the upper and lower 27% of the total sample; the other, phi coefficients on 50 upper and 50 lower criterion cases. Finally, in the first, most of the items had high validity, while in the second none reached an acceptable level of validity. The results obtained in both parts of the study provide empirical evidence for the effectiveness of sequential sampling techniques in the evaluation of psychological test items. A further aid to the selection of the most valid items may be found in the consistency of decision regarding any 1 item in successive samples. Finally, the amount of separation between the 2 extreme samples, with regard to the criterion variable, is an important factor in the successful application of sequential analysis to item selection.

5196

Two models are described to handle the problem of how best to transmit information in the presence of an intelligent noise source whose objective is to prevent transmission. In the first model times for switching frequencies, sending messages, searching and jamming are deterministic. In the second model these times are given only subject to probabilistic distributions. Problems of: 1) determining suitable codes for given channels, 2) need to know the courses open to the jammer simultaneously with the transmitter, and 3) of lost transmission time while switching frequencies, are discussed separately and as they are related. Strategies and counter strategies are developed and a diagram of possibilities is given. Rather than conclusions, suggestions for further work are made. I. R. 3

Orlansky, J. THE EFFECT OF SIMILARITY AND DIFFERENCE IN FORM ON APPARENT VISUAL MOVEMENT. *Arch. Psychol.*, 1940, No. 246, 85pp.

This is a quantitative study of the effect of similarity and difference in form on apparent visual movement. Combinations of similar and dissimilar figures were presented under conditions favorable for the apprehension of apparent movement. Determinations were made of the range of time-intervals between successive stimulations within which apparent movement occurred, the types of movement effects observed, and the S's estimate by ranking of the ease with which the combinations seemed to move. The following relationships were observed: a) The greatest ranges of movement are found for combinations of the most similar figures; range decreases as the differences between forms increase; differences due to area, spatial separation and plane of spatial orientation are less potent factors than those in form. b) Similar effects on the range can be produced with combinations of equal figures by varying their relative spatial arrangements. c) Stimulus-combinations of figures objectively dissimilar show the smallest of all ranges. d) The appearance of different types of movement is determined to some extent by the time-interval between successive stimulations; longer intervals favor movements over longer apparent distances while shorter ones favor direct courses. e) Fusion is a movement effect that appears when different stimulus-figures unite to form a novel figure composed of parts of each. Smith, K.R. INTERMITTENT LOUD NOISE AND MENTAL PERFORMANCE. Contract AF 33(038) 786, E.O. 695 63, AF Tech. Rep. 6368, Dec. 1950, 8pp. USAF Air Materiel Command, Wright-Patterson AFB, Ohio. (Pennsylvania State College, University Park, Penn.).

An attempt was made to ascertain the effects of the administration of intermittent 100-db noise upon performance in 2 standard mental tests. A pool of 69 human Ss was randomized into a control group and an experimental group; only the latter worked in the noisy environment. Group comparisons indicated that the effect of the sound was to increase quantity and decrease quality of response, but the differences discovered appeared to be negligible for practical purposes.

Smith, K.R. INTERMITTENT LOUD NOISE AND MENTAL PERFORMANCE. *Science*, Aug. 1951, 114(2953), 132-133. (Psychology Dept., Pennsylvania State College, State College, Penn.).

It has thus been found that the effect upon short-term mental performance of bursts of intense noise is to increase the quantity and decrease the quality of response, but that these effects are of such magnitude as to suggest that they are practically negligible. It may be that the allegedly malignant effects of extraneous noise are to be found primarily in terms of depreciation in sustained performance, or of interference with functions other than adequate output.

Payne, R.B. THE AFSAM COMPENSATORY BALANCING TEST MODEL A. Proj. 21 02 011, Rep. 1, Nov. 1948, 8pp. USAF School of Aviation Medicine, Randolph Field, Tex.

This is the first of a series of reports describing the development and evaluation of the AFSAM Compensatory Balancing Test, Model A. 2 copies of this test have been administered to some 1800 Naval Aviation Cadets at Pensacola Naval Air Station, Florida, for the purpose of validation against a flight proficiency criterion. Although criterion data have not yet matured, the test data of 1339 of these cases have been analyzed in order to evaluate score reliability, score distribution characteristics, and operational stability of equipment. The performance scores obtained were found to be reliable to a degree which is satisfactory in view of the purpose for which the test was intended. Score distributions were found to be sufficiently normal for the performance of conventional statistical operations on the data. Such differences as were found to exist between copies of the test were discussed in relation to electromechanical features of the equipment.

Ross, B.H., Rupe, J.W. & Grant, D.A. EFFECTS OF PERSONAL, IMPERSONAL, AND PHYSICAL STRESS UPON COGNITIVE BEHAVIOR IN A CARD SORTING PROBLEM. J. abnorm. soc. Psychol., April 1952, 47(2), 546-551. (University of Wisconsin, Madison, Wisc.).

The effect of impersonal distraction, personal "heckling," and physical threat upon abstract behavior as defined by the Wisconsin Card Sorting Test (WCST) was studied in a tri-factorial design involving 160 college students as Ss. The WCST consists of response cards, each of which may be sorted for color, number, or form under 4 stimulus cards. The task requires Ss to sort according to color, and then, after 10 correct responses, to shift to form, then to number and back through color, form and number in 6 stages. No cues are given to shifts except that each card sorted is called "right" or "wrong". The WCST provides 3 scores: a) total correct responses required to learn each new response; b) the number of perseverative errors; and c) the number of nonperseverative errors. These scores are available for each of the 6 stages. The principal findings were as follows: a) Electric shock, the physical threat, alone or in combination with other factors, was the only variable which degraded performance on the WCST to a statistically significant extent as revealed by the analysis of variance. b) The deterioration of performance which did take place was general in that all the 3 objective scores were affected. c) The Ss seemed to recover rapidly from the effects of shock, because no significant effects were found at Stages 3, 4, 5 and 6. It was pointed out that the relative imperviousness to extrinsic threat exhibited by the abstract behavior was remarkable. The fact that nonperseverative error scores and total correct response scores showed more deterioration than did perseverative errors indicated that the degradation of behavior was general and provided little or no indication that G.V. Hamilton's "persistent nonadjustive reaction" was present.

Taubman, R.E. STUDIES IN JUDGED NUMBER: I. THE JUDGMENT OF AUDITORY NUMBER. *J. gen. Psychol.* 1950, 43, 167-194. (Columbia University, New York, N.Y.).

An experimental study was conducted of the functional relation which obtains between judged auditory number, where the stimuli are series of short tones, and a) stimulus number (1 through 10) and b) time interval between successive tones (.125, .100, .083, .071, .062 sec.). 5 trained Ss were studied. The following results were found: a) The primary direction of the mean judged number is towards underestimation of the stimulus magnitude. All numbers are correctly perceived at .125 sec.; 1 and 2 are generally perceived correctly at all time intervals; thereafter, underestimation increases as a function of increasing number within a particular time interval. b) The per cent correct judgment data also show a fall as a function of stimulus number and time interval between tones. c) An absolute scale for I's developed in terms of response category usage, bears an orderly relation, to the stimulus continuum at the various time intervals between tones. The obtained category threshold data, when plotted for each time interval in relation to response category, constitute a family of straight-line functions for intervals shorter than .125 sec. d) The mean stimulus number necessary to evoke each of the response categories at all times is shown. Practical implications for Morse Code learning are discussed. (HEIAS)

Taubman, R.E. STUDIES IN JUDGED NUMBER: II. THE JUDGMENT OF VISUAL NUMBER. *J. gen. Psychol.* 1950, 43, 195-219. (Columbia University, New York, N.Y.).

An experiment was conducted to obtain the functional relation between judged visual number where the stimuli are series of successive short light flashes, and a) stimulus number, and b) time interval between successive flashes. The stimuli ranged in number from 1 to 10, each flash equal to .04 sec., with 5 intra-stimulus intervals: .500, .333, .250, .200, and .143 sec. 5 trained Ss were studied. The main findings are a) The mean judged number indicates a predominant tendency toward underestimation of stimulus number which increases from 0 at interval .500 sec. as a function of both stimulus number and intra-stimulus time interval. b) The percent correct data indicate that interval .500 sec. is a 100% interval at all stimulus magnitudes, and that from this interval on, interval curves can be constructed which are generally differentiated from one another on the basis of percent correct. There is a trend for the percent correct to fall as a function of stimulus number and time interval. c) An absolute scale was developed for I's on the basis of response category usage; it is stimulus-anchored with respect to the various intra-stimulus time intervals. The category thresholds, when plotted for each interval as a function of response category, constitute a family of straight-line functions. d) Data on the mean stimulus number necessary to evoke each of the categories of response indicate, in general, that the rise in mean stimulus number is a function of interval and response category magnitude. Verplanck, W.S., Collier, G.H. & Cotton, J.W. NONINDEPENDENCE OF SUCCESSIVE RESPONSES IN MEASUREMENTS OF THE VISUAL THRESHOLD. *J. exp. Psychol.*, Oct. 1952, 44(4), 273-282. (Indiana University, Bloomington, Ind.).

This experiment was performed in order to determine whether the successive responses of S given in measurements of his visual threshold are statistically independent of one another. This is implicit in several theories of sensory thresholds. 16 Ss were presented, on 4 successive days, with 300 consecutive stimuli of a luminance which had been found previously to be reported 50% of the time. On 2 days these stimuli were presented automatically at 5-sec. intervals. On the other 2, S presented them to himself. Critical ratios of serial-correlation coefficients were computed on the time-ordered sequences of responses at Lags 1, 3, 5, 7, 9, 11 and 20. Under the conditions of this experiment the mean 50% absolute visual threshold for each subject elicited, on the average, 50% frequencies of responses on immediately subsequent days. When S is presented with a discrete, dim flash of light, his response to it will depend not only upon the luminance of the flash, but also, among other things, on how he has responded to preceding flashes of light of the same luminance. Each response is dependent upon previous responses, or perhaps both are dependent upon a third variable which varies in time. This nonindependence is exhibited with statistical significance when as many as 10 responses intervene between the correlated responses. The value of CR_p seems to be a monotonically decreasing function of the lag. No statistically significant differences appeared between the data obtained under the 2 conditions of stimulation.

Baker, Katherine E. & Gagne, R.M. TRANSFER OF TRAINING TO A MOTOR TASK IN RELATION TO STIMULUS SIMILARITY. Contract N70NR 316, Proj. NR 783 003, SDC-Prof. 20 M 1A, SDC TR 316 1 8, Aug. 1949, 33pp. USN Special Devices Center, Port Washington, N.Y. (Connecticut College, New London, Conn.).

5233

In a study of the relation between transfer of training and stimulus similarity, five matched experimental groups, each consisting of 25 Navy men, learned to respond differentially to one of six stimulus lights separated by equal j.n.d. units. Each group then performed a similar task with a different critical stimulus. Errors per stimulus light on the second task were compared for each group and a matched control group that had no prior training. Response time scores and amount of transfer per similarity step were also presented.

Baker, Katherine E. & Wylie, Ruth C. TRANSFER OF VERBAL TRAINING TO A MOTOR TASK. J. exp. Psychol., Oct. 1950, 40(5), 632-638. (Connecticut College, New London, Conn.).

5237

In a study of the transfer of verbal training to a motor task, 54 female college students were required to learn the appropriate manual response to each of four visual stimuli presented sequentially. One group of Ss was pretrained for 24 trials to give a word descriptive of the required response when presented with the word descriptive of the stimulus. A second group was given eight such trials, and a third group was given none. Time and error scores were compared for the three groups. Results were interpreted in terms of stimulus and response generalization.

Baker, Katherine E., Wylie, Ruth C. & Gagne, R.M. THE EFFECTS OF AN INTERFERING TASK ON THE LEARNING OF A COMPLEX MOTOR SKILL. J. exp. Psychol., Jan. 1951, 41(1), 1-9. (Connecticut College, New London, Conn.).

5238

In an investigation of how an interfering task introduced at different stages of practice affects the course of learning, six matched groups of 22 male Ss performed the S.A.M. Complex Coordination Test for six blocks of 26 settings. Each group was required to perform an additional task concurrently on the Coordinator beginning with a given block. Interference for each group is measured by time scores on the main task.

Alluisi, E.A., Harker, G.S., Enoch, J.M., Wicksarham, R.A., et al. BINOCULAR STEREOPTIC ACUITY AND SPATIAL LOCALIZATION AS CRITERIA FOR THE EVALUATION OF CONTACT LENSES. Projs. 6 95 20 001 & 6 64 12 028, Rep. 70, Dec. 1951, 25pp. USA Office of the Surgeon General, USA Medical Research Lab., Fort Knox, Ky.

An exemplary experimental evaluation of 2 contact lenses has been presented. A preliminary test has been made of the hypotheses that changes in binocular stereoptic acuity and changes in spatial localization take place when contact lenses are worn. The hypothesis concerning binocular stereoptic acuity is neither strengthened nor weakened by the results because the absolute values of all these scores obtained were too great to be considered due to anything other than to weaknesses in apparatus and procedure. The hypothesis concerning spatial localization appears tenable in light of the findings of some statistically significant differences between mean rangings when contact lenses were worn. After modification as recommended, both the apparatus and the procedure should be suitable for the experimental evaluation of contact lenses with measures of binocular stereoptic acuity and of spatial localization as criteria.

Chapanis, A. SOME APPLICATIONS OF EXPERIMENTAL PSYCHOLOGY TO MACHINE DESIGN. Res. Rev., June 1954, 4-11. Office of Naval Research, Department of the Navy, Washington, D.C. (Johns Hopkins University, Baltimore, Md.).

The partnership between experimental psychologists and practical engineers in the field of human engineering - the engineering of machines for human use and the engineering of human tasks for operating machines - is discussed. Fundamental contributions made by psychologists are said to lie in their knowledge of the field of individual differences and their use of experiments for experience and facts for opinions. A few typical studies in visual means of communication from machines to man are described to show what has been done in this new field of engineering psychology. (HEIAS)

Chapanis, A. & McCleary, R.A. INTERPOSITION AS A CUE FOR THE PERCEPTION OF RELATIVE DISTANCE. J. gen. Psychol., 1953, 48, 113-132. (Johns Hopkins University, Baltimore, Md.).

5251

To investigate the stimulus condition of interposition (if, at the intersection of two figures, one contour turns a sharp corner, it will be seen behind the other), a series of stimulus figures containing two overlapping figures were varied at intersection points to provide clear, ambiguous, or contradictory cues, and varied in meaningfulness from nonsense figures to familiar figures. In a series of experiments over 600 Ss made judgments as to which figure was in front of the other, or in the same plane, or impossible to judge. Analysis of the results was made in terms of relative importance of junction-point cues and Gestalt (overall form) cues.

Chapanis, A. SUMMARY AND EVALUATION OF THE STATUS OF RESEARCH ON THE EFFECT OF THE OPTICAL QUALITY OF TRANSPARENT AIRCRAFT PANELS ON VISION. TSEAA 696 93, Aug. 1946, 14pp. USAF Aero Medical Lab., Randolph Field, Tex.

A considerable amount of experimental evidence and research data has been summarized briefly in this report to show the effect of the optical quality of transparent aircraft panels on vision. These studies, without exception, emphasize the fact that the angle of incidence of the panel to the pilot's line of sight is relatively more important than the inherent flaws or defects in the panel. This means, in effect, that panels with extremely few inherent defects become objectionable when they are used at high angles of incidence. There are 3 important aspects of this problem which require further investigation: a) The relationship between the optical quality of panels and visual functions, other than those already investigated, should be explored further. b) A satisfactory method of specifying and measuring distortion should be devised and incorporated into appropriate specifications. This method of test should take into account the fact that distortion is essentially a change of deviation of light rays; it should be easy to use, and should be rapid enough to permit the grading of panels coming off a mass-production line. c) The specification of the maximum amount of distortion tolerable in aircraft panels should be subjected to frequent critical reevaluation. This specification should attempt to effect a rational compromise among the conflicting requirements of visibility, aerodynamic efficiency of the aircraft, weight, and cost.

5253

To compare the effectiveness of Type AAF-1 and AAF-2 charts for demonstrating the effects of anoxia at altitude, 100 men were tested at simulated altitudes of 15,000 and 16,000 ft. The results are summarized statistically, discussed, compared for the two charts, and the author includes certain recommendations.

5255

This is a report of experiments designed to demonstrate the effect of distortion in the front section of the P-80 canopy on depth perception and to assess the nature of the visual impairment of depth perception through distorted glass. Utilizing the Howard-Dolman apparatus to measure depth perception, experiments were conducted in which the subjects' performance occurred under conditions of sighting through various portions of the P-80 canopy, through five samples of glass graded in amount of distortion, and with glass samples at various angles of incidence. The results of each of the experiments are presented in terms of the relative effect of the sighting condition upon depth perception.

5254 Chapanis, A. & Halsey, Rita M. PHOTOPIC THRESHOLDS FOR RED LIGHT IN AN UNSELECTED SAMPLE OF COLOR-DEFICIENT INDIVIDUALS. Contract NSORI 166, T.O. 1, Proj. Design. NR 507 470, Unpub. Res. Rep., Oct. 1952, 13pp. Naval Research Lab., Systems Coordination Div., Office of Naval Research, Washington, D.C. & Johns Hopkins University, Baltimore, Md.

It is generally assumed that luminosity losses in the red end of the spectrum can be used to distinguish protanopes and protanomalous trichromats from deutanopes and deutanomalous trichromats. To test this hypothesis, we studied 47 color-deficient men, selected solely on the basis of their being "color blind." 16 color-normal persons were also examined. Each subject viewed a flashing light of 640 mμ monocularly, using central fixation, and adjusted an optical wedge to locate his threshold. The results show that the average amount of energy required for threshold vision, and the variability between subjects, is less for color-normal than for color-deficient persons. For the color-deficient group, the thresholds form a continuous distribution rather than 2 distinct groups. There is, however, some slight evidence of bimodality in the distribution. A few of the color-deficient subjects make chromaticity confusions characteristic of deutans, but appear to have luminosity losses in the red characteristic of protans. Taken as a whole, the data support the hypothesis that "darkening of the red" is not uniquely characteristic of a particular group of color-deficient individuals.

5256 Chapanis, A. SPECTRAL SATURATION AND ITS RELATION TO COLOR-VISION DEFECTS. J. exp. Psychol., Feb. 1944, 24(1), 24-44. (Yale University, New Haven, Conn.).

Saturation thresholds were measured at 19 spectral points by finding the proportion of hue which had to be added to white of 5000°K. to make the mixture appear just discriminably colored. 8 Ss, 2 normal and 6 with varying degrees of color vision defect, were used in the experiment. The results may be summarized as follows: a) Spectral saturation for the color blind observers is generally lower than for the normal observers. The extent of this difference appears to be related to the degree of color defect; the curves for the true dichromats deviate most from the normal values, while those for the color anomalous lie between the 2. b) A shift in the relative saturation of various spectral hues is related to the degree of color defect. The greatest change in saturation occurs in the blue-green region of the spectrum and the least in the yellow and yellow-green regions. Blue-green for the normal observer is a highly saturated hue, for the color anomalous it is less saturated, and for the dichromat it is completely desaturated, i.e., it matches white. 2 hypotheses regarding the nature of color blindness are possible with a tri-receptor color theory. The data reported here are inconsistent with both of these hypotheses. The practical value of the findings is that they may provide a basis for the construction of a quantitative scale of color blindness.

Brozek, J. QUANTITATIVE CRITERIA OF COORDINATE PERFORMANCE AND FATIGUE. *J. appl. Physiol.*, Nov. 1949, 2(5), 247-250. (University of Minnesota, Minneapolis, Minn.).

The consistency of 5 eye movement characteristics, measured in photographic records obtained for each of 6 normal young men on 6 occasions, varied from very high (fixation time, rate of movements), high (extent of corrective movements during fixation), moderate (movement time) to low and very low. In the course of a "stress" consisting in shifting the line of regard through about 14° at a submaximal rate for 5 minutes, all eye movement characteristics changed in the direction of deterioration but none of the changes reached the level of statistical significance. In a more severe stress which involved eye movements carried out at the maximal attainable rate for 4 minutes, the rate of movements declined, due primarily to a marked increase in the fixation time; the velocity of movements decreased and the extent of corrective movements during fixation increased. In the third stress situation consisting of 3 hours of hard inspection work at a very inadequate illumination, the fixation time and the corrective movements increased, while the rate of movements decreased. The changes were much less pronounced than in the preceding experiments. The lengthening of the fixation time, reaching at times the magnitude of a "central block," as well as the increase in the corrective movements during fixation were interpreted as fatigue phenomena localized in the central nervous system. Muscular fatigue was much less evident or was absent.

Brozek, J., Simonson, E. & Keys, A. A TEST OF SPEED OF LEG AND ARM MOVEMENTS. *J. appl. Physiol.*, March 1952, 4(3), 753-750. (University of Minnesota, Minneapolis, Minn.).

A test for measuring the speed of flexion movements of the leg and forearm was described. Practice had little effect, beyond the initial stage of getting thoroughly acquainted with the procedures, on the speed of the movements. The standard error of the individual test scores, based on 5 repeated measurements, was about 5 msec. Data were presented on deterioration of the speed of movement under conditions of physiological stress (anemia deficiency and starvation) and in disease (poliomyelitis). The test of the speed of leg and arm movements represents a useful addition to the existing measures of the neuromuscular aspects of "fitness".

Brozek, J. & Simonson, E. VISUAL PERFORMANCE AND FATIGUE UNDER CONDITIONS OF VARIED ILLUMINATION. *Am. J. Ophthalmol.*, Jan. 1952, 35(1), 33-46. (University of Minnesota, Minneapolis, Minn.).

The effects of varied intensity and spectral composition of mixed white light were studied using a specially designed work test, a series of tests of visual functions measured before and after 2 hours of work, and a discomfort questionnaire administered at the completion of each testing session. The visual work involved recognition of small, moving details, briefly exposed to the view, and thus represented a schematic miniature of industrial inspection of objects transported on a conveyor. The design of the main series of experiments involved 3 factors—intensity of illumination (3 levels), spectral quality of illumination (3 illuminants), and subjects (6)—with replication of each experimental condition. The results were analyzed in terms of a complex analysis of variance, yielding sensitive tests of the statistical significance of the differences between the mean scores obtained under different conditions of illumination. In addition, a biologic evaluation of the relative importance of the differences between the experimental conditions was attempted. It consisted in expressing the differences as percentages of the maximum difference (difference between the best and worst score for a given function). The stress conditions used to establish the limits of deterioration involved strenuous visual work carried on for 2 hours at 2 foot-candles and for 4 hours at 5 foot-candles, and were close to the limit of tolerance.

Brozek, J., Simonson, E. & Taylor, H.L. CHANGES IN FLICKER FUSION FREQUENCY UNDER STRESS. Contract AF 33(072) 21914, Proj. 21 32 004, Rep. 3, Oct. 1953, 5pp. *USAF School of Aviation Medicine*, Randolph Field, Tex.

Within a framework of studies on changes in "fitness" the flicker fusion frequency (FFF) was determined during a control period and under the following conditions: a) moderate visual strain; b) strenuous visual strain; c) nutritional stresses; d) miscellaneous severe stresses—hard physical work, work in hot environment, and lack of sleep. The mechanism involved in the depression of fusion level in situations where such a change has been demonstrated (starvation, strenuous visual work) is not clear and most likely it varies. From the results presented in this report it seems clear that the decrease of the fusion level cannot serve as an index of the degree of involvement of the central nervous system in biologic stresses of the type applied in this study or that this involvement is minimal.

Schachter, S. & Chapanis, A. DISTORTION IN GLASS AND ITS EFFECT ON DEPTH PERCEPTION. Expen. Order 655 42, Serial TSNAL 3 655 428, April 1955, 35pp. Aero Medical Lab., USA Air Forces, Air Technical Service Command, Engineering Div.

Depth perception, as measured by the Howard-Dolman apparatus, is impaired when pieces of glass which contain distortion are placed in the line of sight. At all angles of incidence the amount of impairment is directly proportional to the amount of distortion in the glass. Large angles of incidence increase distortion and decrease depth perception markedly for all glass samples. The difference between the amount of distortion at a large angle of incidence e.g., 70°, and distortion at a small angle of incidence, e.g., 20°, is much greater than the difference in distortion between a Grade A and Grade C type glass viewed normally. This impairment of depth perception is not caused by simple deviation and/or loss of transmission through the glass at large angles of incidence

Office of Naval Research, Physiological Psychology Branch. SYMPOSIUM ON PHYSIOLOGICAL PSYCHOLOGY. Rep. ACR-1, Mar. 1955, 302pp. ONR, Physiological Psychology Branch.

5273

This is the report of a symposium representing the research program of the Physiological Psychology Branch of the Office of Naval Research. Included are 23 papers, and discussions relating to them, dealing with recent research conducted by each of the participants. The papers are arranged in a definite functional sequence beginning with nature of the stimulus and continuing through the appropriate sensory modality to the level of perception or integration with other systems. Major topics: taste, cutaneous senses, vision, and audition.

Ferreos, H.M., Fox, R.H., Jack, J.M., John, R.T., et al. PHYSIOLOGICAL RESPONSES TO HOT ENVIRONMENTS OF YOUNG EUROPEAN MEN IN THE TROPICS. V. THE EFFECT OF INCREASING THE MEAN RADIANT TEMPERATURE OF THE SURROUNDINGS. ANP 24/812, CES 413, Feb. 1956, 145pp. Medical Research Council, University of Malaya, Singapore, China.

3 series of experiments were performed to assess in terms of physiological measurements (sweat loss, skin and rectal temperature, and heart rate) the effect of increasing the mean radiant temperature under varying conditions of air temperature, humidity, and air speed. 28 young men were studied under alternate periods of rest and exercise (step-climbing), wearing shorts or overalls. Examination of the physiological measures show that variation in the amount of sweat loss, when expressed in terms of body weight, provides a satisfactory measure of the increase in environmental stress produced by the effect of increasing the mean radiant temperature varied with the existing level of other factors and no absolute value can be assigned. However, as measured by sweat loss, increasing mean radiant temperature 30°F above air temperature, at air temperature of 100°F, produces approximately the same strain increase as air temperature increases from 10° to 110°F. Even at the highest levels of radiant heat employed (132.4°F), the wearing of overalls imposes a greater strain than the wearing of shorts alone. (HEIAS)

Belanger, J.E. & Woods, J.A. A STUDY OF THE RELATIONSHIP BETWEEN PHOTOPIC AND SCOTOPIC VISUAL ACUITY. Bull. 43, Nov. 1951, 17-32. Highway Research Board, Washington, D.C. (USA Human Factors Research Branch, Adjutant General's Research & Development Command, Washington, D.C.)

To determine the relation between photopic and scotopic visual acuity in order to ascertain the feasibility of a single instrument for measuring both, 202 soldiers after 30 min. dark adaptation, were given the Army night-vision tester, NVT-222, modified Landolt ring, Army Snellen, quadrant variable contrast chart, line resolution, and Orthonator tests. Light under scotopic conditions varied between 3.51 and 5.26 microns/lamberts and, under photopic conditions, was 10.5 ft.-c on charts and between 6 and 10.5 ft.-c in the booth. Photopic and scotopic measures were correlated and the practical implications of the findings were discussed.

Harvett, J.H. & Pasco, A.C., Jr. FIELD AND LABORATORY EVALUATION OF ROADSIDE SIGN SURFACING MATERIALS. Bull. 43, Nov. 1951, 32-42. Highway Research Board, Washington, D.C.

Physical and optical characteristics of sign materials and design and application of a reflectometer devised by the Kentucky Department of Highways are discussed. Accelerated weathering procedures and specification standards are described. Field studies paralleling laboratory work and a possible correlation between the two are described. The field work includes several thousand observations covering 30 different sign surfacers made during night visibility conditions. Ordinary sealed-beam headlights, polarized headlights, and viewers are used.

Stilaon, C.B., & Nello, E. FIELD EVALUATION OF PLASTIC CUSTOM-MOLDED EAR DEFENDERS. Rep. 55-63, Aug. 1956, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

5279

To evaluate the acoustic protection provided by custom-molded earplugs and by standard (NSA) ear defenders, personnel at Randolph Air Force Base exposed to 100 db of noise level or above were fitted with the plastic earplugs. Free-field audiometric tests were given to 43 individuals without ear defenders, with NSA defenders, and with custom-molded ear defenders. The arithmetic mean of attenuation provided by each type of defender was calculated with the difference indicating relative excellence of protection. The potential protection offered by the two ear defenders is discussed.

Sternberg, R.E. SOCIO-PSYCHOLOGICAL FACTORS IN INDUSTRIAL MORALE: I. THE PREDICTION OF SPECIFIC INDICATORS. J. Appl. Psychol., 1952, 36, 73-82. (Dept. of Psychology, Los Angeles State College, Los Angeles, Calif.).

5280

Various tests of morale were constructed to analyze the relative predictive value of two major hypotheses for specific indicators in the work situation. The hypotheses were 1) that morale is a group phenomenon and 2) that morale is the acceptance of formal organization by members of the group. The indicators of morale were performance variables such as tardiness, short time absences, trips to medical aid unit for reasons other than injury or disease, and merit rating. Hourly-paid employees of a large aircraft manufacturing plant completed the questionnaires. Union and management established the qualitative criteria.

T. R 8

5281

Sternberg, R.E. SOCIO-PSYCHOLOGICAL FACTORS IN INDUSTRIAL MORALE. III. RELATION OF AGE TO MORALE. Psychol., Astoria, 1954, 2(3), 395-399. (Los Angeles State College, Los Angeles, Calif.).

5281

To investigate differences in morale attributable to age, data from a study of 850 hourly paid employees of an aircraft plant were analyzed by making covariance adjustment for length of service in the work organization. Available data included age, length of service, and scores on two morale tests—a group test and an attitude test. A separate analysis was made with respect to each morale test when adjusted for age and for length of service. Suggestions are made for differential reward systems for younger and older workers.

Zeitlin, L.B., & Cramer, R.L. FURTHER STUDIES ON FREQUENCY DISCRIMINATION OF PURE AND COMPLEX TONES. Proj. 6-95-20-001, Rep. 248, Jan. 1957, 7pp. AMRL, Fort Knox, Ky.

5282

To investigate the ability to discriminate small changes in frequency of pure and complex tones for frequencies over 1000 cycles per second, sixteen subjects made judgments as to whether the middle tone (sequence of three) was higher or lower than the end tones. Tone frequencies were 1500, 3000, and 6000 cycles per second for two sets of sixty stimuli (sinusoidal and complex 15 microsecond pulse duration). Error data were analyzed for differences due to type of tone. The data were combined with data from a previous study which used frequencies below 1000 cycles per second and an empirical formula is given for determining the relative efficiency of discriminating frequency changes of complex over pure tones.

Lauer, A.R. FILTER STUDY OF THE EFFECT OF CERTAIN TRANSMISSION FILTERS ON VISUAL ACUITY WITH AND WITHOUT GLARE. *Bull.* 43, 1957, 45-51. Highway Research Board, Washington, D.C.

To determine the effect of filters on visual acuity throughout the spectral range, 20 representative filters were selected for study. Eleven Ss of near-normal vision made 15 separate sets of observations using one eye at a time. Each S's visual acuity without filters was measured first, and then acuity with the filters was obtained with an opposing light and under normal conditions of vision. The relation between acuity and filter transmission factors and decrement due to filter were calculated.

Peckham, R.H. EFFECT OF EXPOSURE TO SUNLIGHT ON NIGHT-DRIVING VISIBILITY. *Bull.* 56, Jan. 1952, 17-25. Highway Research Board, Washington, D.C.

To study the effect of exposure to sunlight on night-driving visibility, a group of 24 young men were required to drive automobiles along country highways for six hours per day for five days without sunglasses. Critical flicker rates were measured at two levels of brightness both morning and evening. The difference between average rates for the two periods was calculated and analyzed for changes in retinal sensitivity due to exposures. These data are used to predict safe driving conditions. The effect of use of sunglasses is discussed.

Stalder, H.L. & Lauer, A.R. EFFECT OF PATTERN DISTRIBUTION ON PERCEPTION OF RELATIVE MOTION IN LOW LEVELS OF ILLUMINATION. *Bull.* 56, Jan. 1952, 25-36. Highway Research Board, Washington, D.C.

To study effect of pattern distribution and driving speed on discrimination of relative motion in low illumination, a simulated night driving test (scotometer) was administered to thirty subjects (19 to 54 years of age). Three target treatments were presented at 10, 20, 30, 40 and 50 miles per hour, both with and without opposing lights (calculated to give lighting conditions equivalent to standard road-light illumination). The task was to report whether the target was moving toward or away from observer and to estimate speed difference between target and observer, difficulty of judgment and distance of target ahead. The data were analyzed for differences due to type of target and speed of target. Findings are discussed with reference to night driving safety.

Chernikoff, R. & Taylor, F.V. REACTION TIME TO KINESTHETIC STIMULATION RESULTING FROM SUDDEN ARM DISPLACEMENT. *J. exp. Psychol.*, Jan. 1952, 52(1), 1-8. (OSR Research Lab., OOR, Washington, D.C.).

To determine the role of kinaesthesia in the control of precise hand and arm movements, it is first necessary to know how rapidly a human can respond to a kinaesthetic stimulus. This study was an attempt to determine the reaction time to a kinaesthetic stimulus initiated by suddenly dropping S's splinted arm which was held horizontally by an electromagnet. In one situation S responds by releasing a key with his other hand upon awareness of arm fall, and in the second situation he responds by dropping his falling arm as quickly as possible. For purposes of comparison, auditory and tactile reaction times were obtained, with the key release as the response. The kinaesthetic reaction time with the arm-stop response differed significantly from the other 3 conditions; no other differences were significant. The difference in kinaesthetic reaction time with the arm-stop response and the key release response was confirmed by a supplementary study. The shorter kinaesthetic reaction time obtained with the arm-stop response is probably a function of the use of an accelerometer to indicate the onset of the response. However, it is still within the range of reaction times for other modalities. It is concluded that kinaesthetic reaction time is too long to permit continuous voluntary control of short duration hand and arm movements by information furnished through feedback. A dual mechanism of control is suggested, wherein the volitional processes serve the function of intermittently issuing "orders" and the nonvoluntary, lower centers execute these orders without additional voluntary guidance.

Crampton, G.H. & Young, F.A. THE DIFFERENTIAL EFFECT OF A ROTARY VISUAL FIELD ON SUSCEPTIBLE AND NONSUSCEPTIBLES TO MOTION SICKNESS. *J. comp. physiol. Psychol.*, Dec. 1953, 46(6), 451-453. (State College of Washington, Pullman, Wash.).

2 groups of Ss, one susceptible and the other not susceptible to motion sickness, were subjected to a rotating room situation in which they remained stationary. The resulting nausea symptoms were categorized on an arbitrary 4-point scale. The results indicate that individuals susceptible to motion sickness are also susceptible to nausea in a rotary visual field situation, and, conversely, nonsusceptibles are resistant. It is concluded that some of the individual differences in regard to nausea found in previous studies utilizing rotary visual fields may be related to the motion sickness susceptibility of the Ss.

Berrien, F.X. & Young, C.W. THE EFFECTS OF ACOUSTICAL TREATMENT IN INDUSTRIAL AREAS. *J. Acoust. Soc. Amer.*, Oct. 1946, **18**, 453-457. (Psychology Dept., Colgate University, Hamilton, N.Y.).

In this study of the influence of acoustical installations on manufacturing personnel, employee comfort and morale plus a systematic evaluation of intelligibility was made in 3 plants where acoustical treatments had already been completed and in 3 plants before and after acoustical treatment. Individual interviews; tests of attitude toward the company, and working conditions; tests of intelligibility before and after treatment; and studies of records pertaining to production, turnover, absenteeism, quality controls, accidents, and health were the techniques used. The following conclusions appear to be justified: a) Acoustical treatment results in increased ease and accuracy of verbal communication with at least 15% improvement; b) Both management and employees are generally convinced that acoustical treatments lessen noise discomfort and there is some indication that headaches, ringing in the ears and nervousness are reduced; c) No support to the thesis that morale and attitude toward the company are generally improved by acoustical treatment was found; d) There is considerable indication that accident rates are reduced; and e) There was no significant increase in production as a result of treatment. Berrien, F.X. THE EFFECTS OF NOISE. *Psychol. Bull.*, March 1946, **52**, 141-151. (Colgate University, Hamilton, N.Y.).

This review summarizes critically those studies pertaining to the effects of noise on human beings with occasional reference to studies of animals to point up certain areas. The literature included was primarily produced during a 17-year period, from 1925 through 1945. Consideration is given in turn to the effects of noise on output speed and accuracy, fatigue and energy expenditure, the course of noise-adjustment, stimulation deafness, and to the examination of these problems. The methods of measuring noise and their limitations are summarized. (MEIAS)

5291

This Handbook presents tabular data, graphs, charts, and diagrams in the broad areas of plant, animal, and preclinical medical sciences. The data are arranged under the following categories: (1) biochemical and biophysical characteristics; (2) genetics, cytogenetics, and reproduction; (3) development and morphology; (4) nutrition, digestion, and metabolism; (5) respiration and circulation; (6) other physiological activities and performance; (7) biologically active compounds; (8) environment and survival; (9) symbiosis and parasitism; and (10) ecology and biogeography. Tables present for each variable, whenever possible, a representative value and the range of variation. Essential information as units, methods, and conditions of measurement, conversion factors, glossaries, and taxonomy lists are given. An appendix and index are included. T. G. I. R

5295

To obtain information that could be used to design flight simulators and in conducting training programs for teaching pilots to cope with emergencies, an analysis of 215 accidents that occurred in the F-80, a high performance jet aircraft, was made. From this analysis a machine relationship was hypothesized which covered most of the accidents reported. Additional data were obtained from interviews with pilots who had experienced near accidents in some type of aircraft. The implications of the results for training are discussed.

Corso, J.F. EVALUATION OF OPERATING CONDITIONS ON A BEKESY-TYPE AUDIOMETER. *A.M.A. Arch. Otolaryng.*, June 1955, **61**, 649-653. (Pennsylvania State University, University Park, Penn.).

A Reger model of the Bekesy audiometer was used to obtain test-retest right ear audiograms on a group of 90 volunteer male and female subjects between the ages of 17 and 25 years. A 2-factor analysis of variance design was used with 3 testing times (5, 10, 20 min.) and 3 rates of signal attenuation (0.5, 1, 2 db/sec.). Each of the 9 operating conditions was assigned at random to each of 10 subjects. No subject served for more than a single one-hour session. All threshold measurements were made in a soundproof room and all retest audiograms were obtained after a 5-minute rest period. In the treatment of data, analysis of variance techniques were used to evaluate the effects of testing time and attenuation rate on 3 criterion measures. The results of the study showed that a) testing time and attenuation rate have no effect on mean threshold value at 1000 cps; b) attenuation rate has a significant effect on threshold variability, and c) attenuation rate has a significant effect on test-retest reliability. It is concluded that, with respect to the 3 criteria considered simultaneously, optimal performance on the Bekesy audiometer is obtained by using an attenuation rate of 0.5 db/sec. combined with a total testing time of 5, 10 or 20 minutes.

Lillehei, J.P. & Balke, B. STUDIES OF HYPERVENTILATION. *Rep.* 55 62, July 1955, 6pp. USAF School of Aviation Medicine, Randolph AFB, Tex.

Lowering the alveolar carbon dioxide tension below 25 mm. Hg by hyperventilating normal young men caused a significant impairment of psychomotor performance as tested on the USAF SAM Complex Coordination Apparatus. Hyperventilation of normal young men resulted in tetany with severe spasms of the wrists and fingers when on the average approximately 3.5 liters of CO₂ per square meter of body surface area were lost from the reservoir of carbon dioxide in the body. The size of this reservoir was apparently not affected by the ventilation rate or total time of hyperventilation within the ranges tested (25-52 liters/min. and 15-60 minutes respectively).

Thring, E.J. MASKED THRESHOLD AND ITS RELATION TO THE DURATION OF THE MASKED STIMULUS. *J. Acoust. Soc. Amer.*, 1956, 28 (4), 606-610. Contract AF 15(500)-571, AFOSR-15-56-50. Operational Applications Laboratory, AFOSR, Bolling AFB, Washington, D.C. (Indiana University).

5299

This study attempts to determine the dependence of the masked threshold of a pure tone on its duration. Eight male listeners adjusted the loudness of a 100-5000 cps flat noise in accordance with two judgments: (1) to just mask a 1000 cps pure tone in loudness, and (2) to just mask the same tone. They were exposed to the same pure tone for 0 to 12 minutes after making two pre-exposure sets of judgments. Two further experiments (24 and 4 subjects respectively) examined the effects of the frequency of the pure tone, and in a fourth experiment (4 subjects) a pure tone of 700 cps was substituted for the masking noise. The implications of the results with respect to the assumed excitation pattern of a pure tone are discussed in relation to adaptation.

Irwin, I.A., Milosky, E.W. & Levy, B.I. A PROCEDURE FOR EVALUATING INSTRUCTOR TECHNIQUE DURING CRITIQUES OF CREW PERFORMANCE. *Proj.* 7712, Task 7723, AFHRC TX 56 37, Feb. 1956, 32pp. USAF Crew Research Lab., Randolph AFB, Tex.

5299

The characteristics of effective instructor behavior in critiques were first outlined. A critique-scoring procedure was then designed to measure how well instructors conformed to the model. Critiques of 32 student crews were scored by specially trained observers; most of these crews were observed twice. The reliability of the measurement procedure was tested by calculating correlation coefficients for interobserver agreement, interrelationships of critique items, and consistency of measures from first to second observation. Also examined were relationships between critique score and student reaction, instructor perception of student reaction, student attitude change, end-of-training attitude, and instructor ratings of crew effectiveness. Brogden, H.E. STATISTICAL THEORY AND RESEARCH DESIGN. *Annual Review of Psychol.*, 1954, 2, 377-400.

The literature on statistical methods and research designs appearing in 1952 and the early months of 1953 were reviewed in terms of trends in the area having special interest to psychologists. Special topics covered were test theory; correlation, regression and selection; personnel classification; factor analysis; analysis of variance and related designs; tests of significance; truncated distributions; scaling; and general texts. No very definite or novel trends seemed noticeable in the literature on statistical methods and research designs during the period covered by this review. Increasing specialization seemed pretty generally evident. Although few publications have appeared on the topic, increased activity in applications of statistical problems to high speed computers suggests that such devices will soon have marked influence in this field. Foreseeable effects include the tabling of functions hitherto regarded as unmanageable, and the use of more exact but computationally difficult methods, such as principal component solutions in factor analysis. It was concluded that some of the more significant advances were achieved in the areas of test theory and personnel classification methods.

Tallierico, R.B., Montague, W.F. & Denenberg, V.J. THE MAP-USING PROFICIENCY OF BASIC TRAIN-
CES. Tech. Rep. 11, Sept. 1954, 52pp. USA Human Research Unit No. 1, Fort Knox, Ky.

4 basic training companies were tested in evaluating map reading as taught by the Army Training Program (ATP). 2 were examined before instruction, 2 after. These latter 2 com-
panies plus 4 more were employed in evaluating the special lesson plan. On the basis of ap-
titude tests the soldiers were separated into high and low intelligence groups. Findings:
a) before training high-intelligence trainees read maps significantly more skillfully than
trainees with low intelligence. b) both groups benefit from ATP instruction, but the high-
intelligence group does so more. c) after training the low-intelligence trainees is still less
skilled than the high-intelligence trainees before instruction. d) soldiers who had an oppor-
tunity to review or apply what they have learned in the classroom tended to retain or improve
their skill. e) practical field training seems preferable to classroom training, particularly
for trainees of low intelligence. f) there is a need for simplifying the vocabulary of map
reading; g) the Map Patrol Test and the Map Skills Test could be used as general training
techniques, and could be adapted for operational use by the Army. (MCTAS)

IN THE DESIGN OF SMALL ARMS. FINAL SUMMARY REPORT.
Contract DA 19 020 ORD 3461, Proj. TD 1 1000, Nov.
1955, 11pp. Institute for Psychological Research,
Tufts University, Medford, Mass.

5304
This is the final report of a research project concerned with the application of human engineering to the
design of small arms and the assessment of the effects
of rifle recoil on marksmanship performance. A sum-
mary of the project's results is presented along with
the results of subsidiary research on such aspects as
the following: (1) a recoil simulator; (2) a rifle
steadiness apparatus; (3) the use of high speed motion
photography in investigating recoil; and (4) the percep-
tual discriminability of levels of recoil energy. Spe-
cific recommendations for the design and conduct of
marksmanship research are offered.

Saul, E.V. & Jaffe, J. THE EFFECTS OF RIFLE RECOIL ON MARKSMANSHIP PERFORMANCE. Contract
DA 19 020 ORD 3461, Proj. TD 1 1000, Nov. 12, Nov. 1955, 41pp. Springfield Armory, Spring-
field, Mass. (Tufts University, Medford, Mass.)

The purpose of this experiment was to assess the effects of variation in rifle recoil on
marksmanship performance, subjective report of comfort, observable tissue damage, and fre-
quency of voluntary termination of firing. The experimental procedure required each of 4
groups of 5 (5 males/group) to fire one, and only one, lot of 4 lots of experimental am-
munition. The 4 lots of ammunition gave comparable dispersion patterns when fired from the
M-1 rifle but produced 4 recoil energies of 11.0, 14.8, 19.3 and 25.5 ft. lbs. respectively.
The 5s fired up to 100 test rounds on each of 3 successive days from a standing position with
rifles resting on a sandbag emplacement. The range was 200 yards. The results of the ex-
periment indicated that variations in rifle recoil were associated with differences in mark-
smanship performance, shooter comfort, tissue damage, and frequency of voluntary termination
of firing. An upper limit of rifle recoil for moderately proficient marksmen appears to be
approximately 19.3 ft. lbs. of free recoil energy. Implications of the obtained results for
military application and future research are discussed.

Travis, R.C., Kennedy, J.L., Mead, L.C. & Allphin, W. MUSCLE ACTION POTENTIALS AS A MEASURE OF VISUAL PERFORMANCE COST. *Illum. Engng.*, 1951, 45, 182-187.

A study of the use of muscle action potentials to measure physiological cost of visual performance was conducted. Reading rate and tension level were measured for different levels of illumination, the level changing so slowly as to be unnoticed by the reader. Eye-movement recordings were used as a measure of reading rate and muscle action potentials for tension level measurement. Illumination changes were from 40 down to 0.2 ft.c. 4 Ss were studied. Although the preliminary nature of the tests precludes more than tentative conclusions, the data show that for reading 10-point type in a surround providing comfortable brightness ratios, the physiological cost (tension levels) does not increase at very low levels of illumination for periods of from 10 to 30 min. Under the same conditions, except that reading rate is maintained, the physiological cost increases somewhat at low levels of illumination. When the severity of the task is increased (8-point type of poor contrast) reading rate becomes more directly proportional to the illumination and physiological cost increases both with lower illumination and elapsed time. Travis, R.C. PERCEPTION AND BODY ADJUSTMENT UNDER CHANGING ROTARY ACCELERATION: A NEW TECHNIQUE. *Amer. J. Psychol.*, 1944, 52, 466-481. (Stanford University, Stanford, Calif.).

The primary purpose of this paper is to describe a new apparatus and technique for producing and recording accelerative movements in the rotation-chair and to record experiments carried out with it upon the perceptive and the adjustive effects of rotation. In view of the facts that the tasks of the experiments simulate rudder-control and sensory experience in airplane flight, that learning is manifested in a steady progressive manner in one task and not in another, that great individual differences are evident, and that wholly unlike functions were under study in the 2 tasks, the author believes that his method seems to warrant further research of an experimental nature. (HEIAS)

Travis, R.C. AN EXPERIMENTAL ANALYSIS OF DYNAMIC AND STATIC EQUILIBRIUM. *J. exp. Psychol.*, 1945, 35, 215-234. (Stanford University, Stanford, Calif.).

An experimental analysis of various components of dynamic and static equilibrium and a number of correlations among these components are reported in this paper. The various measures were taken on 22 college men and 22 college women. The major conclusions are summarized as follows: The dynamic component of equilibration is unrelated to the static component as indicated by a practically zero correlation between performance on a stabilometer and the amount of body sway at the head in standing position. There is practically no correlation between balancing skill on the stabilometer and ability to maintain manually orientation of a rotation chair which is continually being displaced. A disparity between perceptual sensitivity to passive body motion and voluntary motor adjustment is revealed by low correlations between perceptual and motor components of body orientation on the rotation chair. Relatively, weight is of great and height of little importance in dynamic stabilometer performance. Weight and height have no bearing on body sway scores, rotation scores, steadiness, and manual pursuit. Both types of equilibrium are aided when visual cues are present. Mild exercise has little effect on dynamic stabilometer performance, but increases body sway. A steadiness factor in balancing skill and eye-hand coordination is indicated. (HEIAS)

Travis, R.C. BALANCING SKILL AS A MEASURE OF RECOVERY FROM ROTATION. *Amer. J. Psychol.*, 1945, 58, 351-378. (Stanford University, Stanford, Calif.).

2 experiments were conducted to investigate the rate of recovery from the effects of bodily rotation. Balancing skill in the standing position was measured on 156 men and women before and after 5 rotations at rate of 10 revolutions in 22 sec.; rate of recovery was considered to be ratio of the 2. The same procedure was again used but the number of rotations varied from 2 to 8; 60 Ss were used. Reliability coefficients for balancing performance on the stabilometer ranged from .68 after 2 rotations to .92 in normal performance. A significant increase of about 14% in performance from first to second trials was found. A definite tendency for weight to influence recovery from rotation adversely was found with negative correlations of -.43 and -.42. Recovery rate varied inversely with the number of rotations. No relation was found between reported incidence of motion-sickness of various kinds and recovery rate scores. Adequacy of normal balancing skill before rotation has a definite bearing on rate of recovery of postural balance after rotation ($r=.52$). (HEIAS)

Travis, R.C. A NEW STABILOMETER FOR MEASURING DYNAMIC EQUILIBRIUM IN THE STANDING POSITION. *J. exp. Psychol.*, 1944, 34, 418-424. (Stanford University, Stanford, Calif.).

The stabilometer, an instrument for measuring dynamic equilibrium in a standing position, is described and details of the design are given. It meets the objectives a) of presenting a real challenge to the individual, b) of being duplicable in other laboratories, and c) of giving an objective score. Experimental data obtained on 164 college men and 157 college women are presented: mean performance scores and the variability for each weight group and each height group; the relationship between height, weight and balancing scores; sex differences; reliability correlations for first 3 trials (.86, .85 and .80); practice effects; and effect of visual cues. Touss, R.C. VOLUNTARY RESPONSE TO VESTIBULAR STIMULATION WITH SMALL AMPLITUDE OF PASSIVE ROTARY OSCILLATION. *J. exp. Psychol.*, 1941, 23, 248-251. (Western Reserve University, Cleveland, Ohio).

This experiment was conducted to investigate what part or phase of a bodily movement constitutes the real stimulus in eliciting a vestibular response and thus perception of body motion. A rotation platform was used for subjecting 5 to passive motion; 3 rates of oscillation (from 0.27 to 1.86/sec.) for each of 3 amplitudes ($1/2$, $1/4$, and $1/8$) were used. Ss were blindfolded and instructed to move a stylus in the direction of and at the same rate as any perceived movement. 21 Ss were studied. The results were analyzed in terms of adequacy of response to the perception of passive rotary oscillation with varying rates and amplitudes of oscillation; the following conclusions were drawn. Magnitude of change in acceleration and deceleration was the significant factor in vestibular stimulation. Changes in amplitude alone did not affect the adequacy of voluntary response and average velocity was a direct one. The 75% threshold for perception of rotary oscillation in terms of average velocity was about 0.90/sec. (NCIAS)

Smith, W. & Wilson, Edna A. A MODEL OF THE AUDITORY THRESHOLD AND ITS APPLICATION TO THE PROBLEM OF THE MULTIPLE OBSERVER. *Psychol. Monographs*, 1953, 67(9), 1-35. (University of Washington & Massachusetts Institute of Technology).

5323

To present an adequate theory of the multiple observer a model of the threshold that takes false reports into consideration was developed. Two sets of experimental data were fitted to the model. In the main experiment 23 groups of five observers each listened for an 800-cycle tone; 0.41-second duration, against a background of noise; 12 groups were instructed to be conservative in reporting tones as heard and 11 were given liberal instructions. In addition, ten observers were given a large number of trials with instructions to make a four-category judgment on each tone. A theory of the multiple observer was worked out from this model. Agreement of theory and observation was checked.

Smith, M.H., Jr. INSTRUCTIONAL SETS AND HABIT INTERFERENCE. *J. exp. Psychol.*, Oct. 1952, 44(4), 267-272. (University of Washington, Seattle, Wash.).

5324

This is a study of the interactions between instructional sets and previous practice as factors in habit interference. Thirty-six Ss were shown a series of letters one at a time with instructions to respond motorically when any one of a set of pre-designated letters appeared. After five trials the Ss were divided into three groups on the basis of being assigned: 1) the same letters, 2) an entirely new set of letters, and 3) half new and half old letters. The results are treated in terms of the degree of positive and negative transfer reflected by each of the groups.

Jenkins, W.L., & Olson, M.W. THE USE OF LEVERS IN MAKING SETTINGS ON A LINEAR SCALE. *J. appl. Psychol.*, 1952, 36, 269-271. (Institute of Research, Lehigh University).

5326

This study was designed to define the significant factors involved in the utilization of levers in making linear scale settings. Levers were compared with knobs in a total of six experiments in which the subject was required to match the position of a lighted insert in a black bakelite scale with a pointer controlled either by a lever or knob. Scales were varied in terms of tolerance, levers in terms of length, inserts in terms of width, and a variety of lever-knob ratios were employed. The results are discussed in terms of specifying the optimal criteria for each of the specific experimental variations as well as indicating the primary factors which define the efficient performance.

Jenkins, W.L., Kaas, L.G., & Rigler, D. INFLUENCE OF FRICTION IN MAKING SETTINGS ON A LINEAR SCALE. *J. appl. Psychol.*, 1950, 34, 434-439. (Institute of Research, Lehigh University).

5327

Having defined an optimal ratio between pointer-movement and knob-turn in previous experiments, the present study concerns itself with evaluating the effect of artificially equalizing the friction at all ratios on the optimal ratio and the general performance in making settings on a linear scale. Four subjects were required to match the position of a lighted insert in a black bakelite scale (with a knob-controlled pointer) under conditions of equalized friction, requiring a pull of 300 grams, and varied friction at the optimal ratio (i.e., 100, 400, 700, 1000, and 1300 grams). Results are discussed in terms of the relative influence of equalized friction and added friction upon adjusting time, travel time, and action potentials of the active forearm.

Jenkins, W.L., & Marr, A.C. THE USE OF A JOY-STICK IN MAKING SETTINGS ON A SIMULATED SCOPE FACE. *J. appl. Psychol.*, 1954, 38, 457-461. (Institute of Research, Lehigh University).

5328

This study was designed to evaluate the role of certain variables in the utilization of a joy stick in making settings (in two dimensions) on a simulated scope face. A series of experiments were conducted in which a total of approximately 80 subjects were required to bring a cursor controlled by a joy stick onto a lighted insert under varied experimental conditions. Mean setting times, variability, and mis-settings were computed for the following variables: lever length, movement of lever tip and movement of pointer (L/P) ratios, starting positions of cursor, direction of movement, and so forth, and varied combinations of these variables. The relevant variables are outlined and discussed.

Gebhard, J.V. PSYCHOLOGICAL PROBLEMS IN CODING THE INFORMATION FOR VISUAL DISPLAYS. Contract NS 01 166, T.O. 1, Proj. NR 784 031, Rep. 166 1 93, May 1949, 7pp. USM Special Devices Center, ONR, Washington, D.C. & Johns Hopkins University, Baltimore, Md.

It is important that the individuals who make crucial decisions from displays be given information which is already partially interpreted in a form that is easy to understand. An analysis of the psychological problems in visual coding of displays and of interpretability of coded displays led to the following statements: a) The conventional 2-dimensional display is only satisfactory for presenting 2-variable information; b) It is desirable to get more variables into a 2-dimensional display; c) Coding the target spots provides a way of doing this; d) Coding may be done by varying the target spots in color, brightness, size, intermittence, and shape. These may be used in combination; e) To assess the utility of these codes will require much fundamental research on discriminability, scaling, and learning; and f) A display of many targets, each complexly coded, may make a single display completely incomprehensible. Therefore, the problem of interpretability must be studied in the final phase of the work on coding. (HEIAS)

Garner, W.R. & Miller, G.A. DIFFERENTIAL SENSITIVITY TO INTENSITY AS A FUNCTION OF THE DURATION OF THE COMPARISON TONE. J. exp. Psychol., 1944, 34, 450-463. (Harvard University, Cambridge, Mass.).

In order to show the relationship between the duration of the comparison tone and the intensity necessary to excite one additional neural unit, i.e., to produce the judgment of one j.n.d. in loudness, 3 functions were obtained with each of 2 Os. Each function had a different frequency and sensation level of loudness as constant parameters. A ratio as high as 3 was found between the highest and the lowest ΔI ratio in any one function. The reciprocal of ΔI was used as a measure of the sensitivity of the organism to intensive changes, and several hypotheses were presented to explain the form of the sensitivity function, all of which were rejected as being inconsistent with the obtained data. 2 possible explanations of the too rapid bending of the lower portions of the curves are given: a) there may be a mechanical as well as a neural threshold which the stimulus must overcome, and which would make the wave front of the stimulus exciting the neurons different for the short and for the longer tones, or b) transients in the tone which may be below the neural threshold for the longer tones (with a smaller amplitude) will come above the threshold for the shorter tones (with an increased amplitude).

Garner, W.R. THE VALIDITY OF PREDICTION FROM LABORATORY EXPERIMENTS TO NAVAL OPERATIONAL SITUATIONS IN THE AREA OF HUMAN ENGINEERING AND SYSTEMS RESEARCH. Rep. 156-I-133, Reprint June 1957, 13pp. Psychological Lab., Institute for Cooperative Research, The Johns Hopkins University.

5332

This discussion deals with the feasibility and validity of predicting what will happen in operational situations from data obtained in laboratory research. The general philosophy of experimental work in laboratories is explored. Two criteria of prediction - precision and generality - are discussed in relation to experimental and operational research conditions with advantages and disadvantages of each considered. Examples of prediction from laboratory data as to the comparative value of two machines or systems, of relative performance of systems, and of absolute numbers are discussed.

Burnham, R.W. A COLORIMETER FOR RESEARCH IN COLOR PERCEPTION. *Amer. J. Psychol.*, Oct. 1952, 65, 603-608.

The colorimeter described here has several desirable features for research in color perception. It operates by the additive mixture of colored lights and is unique only in the method by which the colors are mixed. In general, an illuminated frame containing the filter-primaries is moved across one end of an optical integrating bar to introduce desired proportions of the primaries into the integrating system, and the integrated light is then viewed as a uniform color at the other end of the bar. The obvious advantages of the instrument are that it is small and compact, it gives large test-fields, and depending upon the reflectance and luminance of the surround, its test-patch may be seen as a surface or aperture color. Heade, R.D. & Eckenrode, R.T. PSYCHOLOGICAL AND PHYSIOLOGICAL EFFECTS OF GUN BLAST WITH SPECIAL REFERENCE TO RECOLLUS RIFLES. A PRELIMINARY LITERATURE SURVEY. Proj. TS4 4018, Rep. R 1283, Human Engng. Rep. 7, Sept. 1955, 34pp. Pitman-Dunn Labs., Frankford Arsenal, USA Ordnance Corps, Philadelphia, Penn.

The effects of blast have been discussed with orientation toward the problem of the maximum blast that man can tolerate with no permanent ill effects. Gross anatomical trauma from intense blast, effects on lungs and viscera, effects on the nervous system and acoustic mechanisms are elaborated. It appears that the acoustic mechanism tolerance will determine the upper physiological limits that man can withstand. This upper limit is not yet settled due to lack of experimental data. Effects of blast on various psychological processes suggest that these, rather than permanent physiological damage, may set the limits. A brief discussion of individual differences is presented and the need for development of tests for the detection of men unusually susceptible to blast damage is expressed. A glossary of terms is included in an attempt to bridge any possible communication gap that may exist between individuals schooled in different disciplines.

Gelbard, J.M. ASHBURN'S STUDIES ON ELECTRIC EXCITATION OF THE HUMAN EYE. *Psychol. Bull.*, March 1953, 59, 73-111. (Applied Physics Lab., Johns Hopkins University, Silver Spring, Md.)

A preliminary review of the main results of the experiments of electric excitation of the human eye by Prof. Naoki Ashburn and his associates at the Physiological Laboratory of the Tokyo University, Sendai, Japan, is presented here. These workers have been ingenious in their use of the threshold of an electrical phosphene (visual perceptions caused by inadequate stimuli are called phosphenes) as a means of analyzing the effect of phosphenic stimulation on the activity of the visual mechanism. In some 40 papers from about 1949 through 1952, they have touched upon matters of brightness and color discrimination, color blindness, contrast, spatial summation, inhibition, flicker effects, visual illusions, and a new visual method of measuring fatigue. The details of Ashburn's method, apparatus, procedure, and measurements are described. His results are organized and presented under the following sections: a) The excitability of the eye--sensitization, adaptation level, time, position, and intensity; b) Color discrimination--wave length, intensity, color deficiency, color inhibition, and micro-stimulation; c) Summation, contrast, and optical illusions; d) The stimulus strength-frequency relationship; and e) A new measurement of general fatigue. Critical comments are included. (NEIAS)

Gelbard, F.A. HEARING THROUGH THE SKIN. *Res. Rev.*, Oct. 1954, 15-20. (Psychological Lab., University of Virginia, Charlottesville, Va.)

An analysis of the possibility of exploiting the receptive properties of the human skin for communication purposes is made. On the basis of known factors, mechanical vibration is suggested as the preferred communication medium. Experimental results have shown that the dimensions of mechanical vibration that can be put to work in such a system are intensity, duration, and body locus. Experimental investigations have been made in which the chest region was selected as the body locus for practical reasons; it was then determined that with an amplitude of the order of 0.5 mm, there are from 3 to 5 absolutely identifiable steps; for durations within the range of 0.1 to 2.0 sec. there are from 3 to 7 steps. Employing 3 levels of intensity, 3 durational steps, and 4 well-spaced contact areas on the chest, a system of communication has been worked out with these 36 elements that can communicate in much the same way as the 36 elements of the alphabet plus the digits. Other kinds of information could be transmitted such as directional signals, warning signals, and the like. The possibilities of successful communication here are many. (NEIAS)

Monbray, G.W. & Gelbard, J.M. DIFFERENTIAL SENSITIVITY OF THE EYE TO INTERMITTENT WHITE LIGHT. *Science*, Feb. 1955, 121, 173-175. (Applied Physics Lab., Johns Hopkins University, Silver Spring, Md.)

In a study of the eye as a temporal analyzer, speed of response was measured by obtaining DL's for intermittent white light at 16 frequencies (1 to 45 cps). At least 20 thresholds were determined by each of 2 practiced Ss for all frequencies. The average deviation (average absolute error) of the comparison frequency from the standard was found never to exceed about 0.6 cps while for the lower frequencies it was sometimes less than 0.1 cps. The range for relative difference limens was 0.005 to 0.030 with 10 of the points below 0.02. The number of j.n.d.'s for photic flicker between 1 and 45 cps was found to be 280 by integrating the DL's by graphic methods. Comparisons of these visual data were made with auditory DL's for interrupted white noise as reported in the literature. (NEIAS)

5361. Black, J.M. SOME EFFECTS UPON VOICE OF HEARING TONES OF VARYING INTENSITY AND FREQUENCY WHILE READING. *Speech Hlth. Dis.*, 1950, 12, 3-6. (Ohio State University Research Foundation, Columbus, Ohio).

A study was made to find in what manner the reading voice was influenced in pitch (frequency of the fundamental) and overall intensity when the speaker hears tones of varying intensity and frequency as he reads. Stimulus tones of 5 frequencies were chosen to be within the limits of the fundamental of the human voice (90, 121, 161, 216, and 287 cps). Recordings of these tones were made in 2 series: a) at intensity levels such that the play back would produce 55, 75, and 95 db intensity; b) so the levels would correspond with 3 Fletcher-Munson equal-loudness contours of 40, 60, and 90. Ss heard the tones through earphones for 4 sec, then read syllables from a pack of cards. Records of the intensity of reading voice and frequency of the fundamental were made and analyzed. The data indicate that significant changes in both vocal intensity and frequency accompanied gross increases in the intensity of the stimulus tones, whether successive levels were equal in loudness or not. Significant changes in both intensity and frequency also accompanied stimuli of differing frequency and like intensity. No significant differences accompanied stimuli of like loudness levels. Black, J.M. THE PRESSURE COMPONENT IN THE PRODUCTION OF CONTINUANTS. *J. Speech Hearing Disorders*, Sept. 1950, 15, 207-210. (Ohio State University, Columbus, Ohio).

An investigation was made of the relative amounts of air pressure in the mouth that accompany the saying of consonants of different types: voiced-voiceless and continuant-plosive. A Kollsman altimeter and a Hill stall-pressure indicator were selected from instruments that respond directly to quasi-stationary pressure and were used for measuring in-the-mouth air pressures. 3 consonants were selected to represent the 2 types and arranged in 3 positions (initial, medial, and final) with 3 vowels -- 7 stimuli in all. 21 Ss read successive stimuli (typed on cards) with each measuring instrument. The data were treated by analysis of variance. The 2 devices were found to yield essentially the same results, however the rate-of-climb indicator had the greater range of raw values. Further analysis of the data from this instrument showed that voiceless consonants had greater amounts (1% level of confidence) of pressure than the voiced ones at all positions. The consonant was accompanied by diminishing pressure as it receded in the word in both cases. These differences were significant. Relative pressures for plosive and continuant consonants in the 3 positions showed greater pressures with the continuants except in the medial position. The difference in pressure attributable to position is again apparent. (HEIAS)

Black, J.M. ACCOMPANIMENTS OF WORD INTELLIGIBILITY. *J. Speech Hearing Disorders*, Dec. 1952, 17, 409-418. (Ohio State University, Columbus, Ohio).

A study was made of the relationships between the relative intelligibility of words and aspects of their syllabic pattern, word familiarity, and phonetic characteristics. A sample of 3697 words of medium intelligibility were drawn from Thorndike's *Teacher's Word Book*, were recorded in quiet by 10 speakers in lists of 150 words, and were played back to panels of 9-12 listeners in quiet and in noise. A complete analysis of the various aspects of the words in relation to intelligibility (accuracy of write-down tests) indicate that the more familiar words (assuming that the Thorndike word list conforms to a cultural pattern of listener-familiarity with words) possess a characteristic of being more accurately identified. Words with many sounds and more than one syllable are more intelligible than ones with few sounds and only one syllable. Phonetic elements are associated with the correctness with which a word can be identified (18 sounds tend to enhance and 7 to detract) but the prediction of word intelligibility from phonetic content alone would be virtually impossible. (HEIAS)

Black, J.M. THE EFFECT OF DELAYED SIDE-TONE UPON VOCAL RATE AND INTENSITY. *J. Speech Hearing Disorders*, 1951, 15, 56-60. (Office of Naval Research, Washington, D.C. & Ohio State University Research Foundation, Columbus, Ohio).

A study of the effect of delayed side-tone upon vocal rate and intensity was conducted on 22 Ss. Each S read 11 series of short phrases (equal in duration and intensity) with each of 10 periods of delayed side-tone and with 1 condition of no-delay: .30, .03, .06, .09, .12, .15, .18, .21, .24, .27, and .30 sec. Measures of the duration and intensity in the reading of the phrases were analyzed. The general effect of delaying the side-tone was found to be a retarding of speech with rate progressively retarded with increase in delay. The effect of increasing the delay from .33 to .06 sec. was disproportionately greater than the effect of any other comparable .03 sec. increment within the range of the study. Numerically, intensity of reading increased progressively as delay of side-tone was introduced and extended throughout the range. Changes beyond the ones produced by delay of .09 sec. were not statistically significant. (MEIAS)

Goss, A.E. TRANSFER AS A FUNCTION OF TYPE AND AMOUNT OF PRELIMINARY EXPERIENCE WITH TASK SIMILAR. *J. exp. Psychol.*, 1953, 46(5), 419-428. (University of Massachusetts, Amherst, Mass.).

5371

This is a study to determine whether experimentally introduced verbal responses will result in positive transfer to a discriminative motor task over and above the facilitative effects attributable to one or both of these processes, and whether prior habit arousal inhibits newly learned verbal discriminations. One hundred and four Ss were presented with a verbal-motor discrimination task following various degrees of pre-motor and verbal learning experience. The results are discussed in terms of the comparative effects of verbal learning and pre-motor experience upon the performance of the task.

Black, J.M. & Tomlinson, V.B. LOUD VOICE: IMMEDIATE EFFECTS UPON THE SPEAKER. *Speech Monographs*, 1952, 19, 299-302. (Office of Naval Research, Washington, D.C. & Ohio State University Research Foundation, Columbus, Ohio).

The aim of this study was to measure the changes in the O_2 - CO_2 balance of the blood in a speaker during a period of sustained intense speaking (oral reading). Secondary measures were obtained relative to pulmonary flow and reading performance. 40 Ss participated in the study, reading as loudly as possible for 20 min., followed by a 30 min. rest period. The principal analyses of physiological data obtained during reading and recovery periods indicate that Ss underwent continuous physiological changes of a type related to exertion and fatigue. Hyperventilation occurred, and with cessation of reading the O_2 content of the blood dropped markedly. Normal O_2 - CO_2 balance was restored within a 30 min. rest period. Rate of progress in reading (words/min.) was reduced during reading period, however error-rate was not affected. (MEIAS)

Bornstein, A.M. A STUDY OF AUDITORY "BRIGHTNESS". *J. exp. Psychol.*, 1952, 39, 45-49. (Rutgers University, New Brunswick, N.J.).

This experiment attempted to demonstrate that brightness, as a sensory attribute, is specific to the visual sense. In one part of the study, 24 Ss made judgments as to which of 2 visual stimuli (either two of a series of grays ranging in brightness from black to white or two of a series of hue-red, orange, yellow, green, blue, and purple, matched for chroma and brightness) was most like a tone (150 dz) which was sounded simultaneously with the visual presentation. Using the method of paired comparison with each series of stimuli, a total of 162 judgments was obtained from each S. In the second part, the procedure was identical except for the tone, now a high-pitched 5750 dz. When using a low tone, there was a high percentage of 15.0 preference for the middle gray; with the high tone the choice shifted to a near white with 75.2%. For the hue dimension, the high percentages for the low tone favor yellow, red, and purple but shift with the high tone toward blue and green. The interpretation of these data is that since it is possible to correlate both visual hue and visual brightness with auditory pitch in a consistent manner, it cannot be stated that brightness is a sensory attribute common to all modalities. Bulgal, M.C. THE INFLUENCE OF BODY POSITION ON MENTAL PROCESSES. *J. clin. Psychol.*, 1952, 8, 190-199. (Long Island University, Long Island, N.Y.).

An experiment was conducted to test the possibility that the physical position of the body influences the expression of thoughts and feelings. A stimulus (picture or letter) calling for interpretation and other responses was applied to each of 12 Ss, once in each of 3 positions—sitting, standing, and reclining. Hypnosis was used so that analysis could be induced after each stimulation. An analysis of the responses leads to the following tentative conclusions. The reclining position tends to remove the processes of perception, thinking, and emotion from reality considerations, favoring expansion of suggestions and associations but inhibiting the tendency to action. The standing position stimulates action and forceful expression of emotion but the field tends to be narrowed and less suggestive of new thoughts. The sitting position seems to favor an equalization between these tendencies but is closer to standing than reclining. Possibilities for further research are advanced. (MEIAS)

Bergatta, E.F., Bales, E.F. & Crook, A.S. SOME FINDINGS RELEVANT TO THE GREAT MAN THEORY OF LEADERSHIP. *Ann. Soc. Res.*, Dec. 1954, 19(6), 755-759. (Russell Sage Foundation, New York, N.Y. & Harvard University, Cambridge, Mass.).

5377

To explore some aspects of the great man theory of leadership, data gathered from 166 sessions of three-man groups are presented. The subjects were 126 Air Force personnel. The purpose of the sessions was represented as being the observation of how small groups work together and the task set was that of role-playing. Eleven great men were selected on the basis of their performance in the first session; the indices of performance were task ability (ratings from co-workers and I.Q. score), individual assertiveness (number of initiated acts per unit of time), and social acceptability (sociometric ratings). In subsequent sessions, as the great men were shifted about, scores were obtained for great man and non-great man groups on productivity, tension, and solidarity. T. R 6

Brown, K.T. METHODOLOGY FOR STUDYING FIGURAL AFTER-EFFECTS AND PRACTICE EFFECTS I. THE MÜLLER-LYER ILLUSION. *Amer. J. Psychol.*, 1953, 66, 629-634. (USAF Aero Medical Lab., Wright-Patterson Air Development Center, Wright-Patterson AFB, Ohio).

On the basis of recent findings of the author, certain controls are required in two kinds of experiments. One kind is often used to study figural after-effects (FAE); the other deals with "practice effects" in the Müller-Lyer illusion. The first involves the use of an outline inspection-figure on one side of a fixation point. After a period of viewing, the figure is removed and 2 outline test-figures are shown, one on each side of the inspection point and the FAE measured by apparent differences in size. The author describes his experiments in which differences in apparent size between opposite halves of the visual field have been found, even without an inspection figure. Thus the common method produces contaminated results. The second instance discusses this same finding with regard to the Müller-Lyer illusion which usually diminishes with repeated testing. The author's interpretation is that some of the characteristics of change are caused by factors not specific to the illusion. (MEIAS)

Black, J.W. & Tolhurst, G.C. THE RELATIVE INTELLIGIBILITY OF LANGUAGE GROUPS. *Quart. Rev. Speech*, 1955, 41, 57-60. (Ohio State University, Columbus, Ohio).

An investigation of the relative intelligibility of English dialect as spoken by different language groups and the effect upon intelligibility of the listeners' familiarity with a dialect was conducted. 12 French, 12 British, and 24 American Ss were studied. The results indicate that intelligibility of test items in English, spoken in a French dialect, were equally unintelligible to French listeners and to British and American listeners. When the test was read by either British or American, the native language listener groups obtained higher scores than the French. Irrespective of whether the test items were read in a foreign dialect or a native language dialect (British), reception scores were improved when listeners were familiarized with the particular dialect of the speakers for 1 hr. Davis, E., Eldredge, D.E., & Usher, J.R. (Eds.). THE TESTING OF HEARING IN THE ARMED SERVICES. Contract N6on-1151 (Q1), CEAS Rep. 5, Tech. Rep. 5, Oct. 1955, 124pp. OHE, Committee on Hearing and Bio-Acoustics; Central Institute for the Deaf.

5337 This report presents the proceedings of the third meeting (1957) of the Committee on Hearing and Bio-Acoustics. The major topics in the testing of hearing in the armed services is divided into three sub-topics: what is normal hearing? why do we use audiometry? and problems in getting the job done. The first topic includes papers on the American and British standards for audiometric zero and problems of measurement. Tests of audiometry by industry for placement and compensation for hearing loss, standards of physical fitness as established by the Army, Navy, and Air Force, and other relations between hearing and military service make up the second topic. And last, technical problems in audiometry are treated. Working group reports are included. T. O. R 22

Grilovsky, J. STUDY OF EXTERIOR LIGHTING FOR NAVY AIRPLANES: III. FLIGHT TESTS OF SOME EXTERIOR LIGHTING SYSTEMS TO FACILITATE RENDEZVOUS AND FORMATION FLYING OF NAVAL AIRCRAFT AT NIGHT. Rep. TED N6on-313335, July 1946, 45pp. USN Air Materiel Center, Philadelphia, Penn.

This is the third in a series of reports on a long-term study of exterior lighting for Navy aircraft and reports the results of flight tests evaluating several new systems of lights for night rendezvous and formation flying. The following conclusions were drawn on the basis of these results: a) standard lights are likely to cause confusion in the air and are least preferred by pilots who have had an opportunity to observe other lighting systems; b) with some modifications of standard equipment (described in text) 2 80 cpi section lights form the basis of a color-coded and automatic letter-blinking system of lights found to be extremely effective for night rendezvous of aircraft; they are easily distinguishable at distances up to 14 mi; c) lights for formation flying should permit brightness control (levels reported in text). Extremely low candlepower settings are preferred for close-in formation flying, or lacking that, no lights at all. Medium settings are far too bright. A system of lights for formation flying is described which embodies: downward formation lights, dim section lights, wing-tips simultaneously flashing on-and-off, and a tail light alternately flashing white-and-amber. McCleary, R.A. PSYCHOPHYSIOLOGICAL EFFECTS OF COLD. I. THE ROLE OF SKIN-TEMPERATURE AND SENSORY SENSITIVITY IN MANUAL PERFORMANCE DECREMENT. Proj. 21-1202-0004, Rep. 1, Jan. 1953, 16pp. USAF School of Aviation Medicine, Randolph Field, Tex.

72 Ss were timed on a manual performance test at 6 different ambient temperatures (70°, 32°, 0°, -10°, and -20°F.). Percent decrement in performance increased as a positively accelerated function over this temperature range. The rate of decline of digital skin-temperature and sensory sensitivity to cold as measured in a separate test session in the cold were both shown to differentiate the Ss significantly with regard to their ability to perform in low temperatures. Cold tolerance may also be related to complexion differences. R-14

McCleary, R.A. PALMAR SWEAT AS AN INDEX OF ANXIETY. A FIELD METHOD SUITABLE FOR LARGE GROUPS. Proj. 21-1207-0004, Rep. 1, Oct. 1953, 11pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

5385 A method for measuring palmar sweat, as an index of anxiety, in large groups of Ss simultaneously under non-laboratory conditions is described. The method requires an S to grasp a bag of crystals whose color shifts with increasing hydration. The color of the crystals, as judged by comparison with a set of standards, yields a measure of the amount of palmar sweat secreted over a 15-minute test period. An experiment involving both anxious and nonanxious Ss studied at three ambient temperatures (40, 70, and 100 degrees F) is also reported. A further field study involving 248 infantry troops under simulated combat conditions is described to indicate the general usefulness of the technique. G. I. R-7

Hastorf, A.H. & Way, K.S. APPARENT SIZE WITH AND WITHOUT DISTANCE CUES. J. gen. Psychol., 1952, 47, 181-188. (Dartmouth College, Hanover, N.H.).

This study was concerned with what would happen to the phenomenon of size constancy when all distance cues to an object were eliminated. This was accomplished by means of making Ss view monocularly, darkening the surrounding milieu, and placing a reduction screen between S and the stimulus. One series of judgments were made under these conditions with the physical size of the standard stimulus directly proportional to the distance from S (retinal image was maintained a constant size); a second series of size judgments were made with visual cues present but using the same standard stimulus; a third series of judgments were again made with all distance cues eliminated but this time the standard stimulus remained constant in size regardless of the distance. The results of the first 2 series of judgments demonstrate conclusively that there must be cues to the distance of an object if there is to be apparent size constancy. The results of the third series showed that apparent size was in direct proportion to the retinal stimulation under conditions of reduced distance cues. (HEIAS) R 5

Geldard, F.A. THE PERCEPTION OF MECHANICAL VIBRATION: II. THE RESPONSE OF PRESSURE RECEPTORS. *J. gen. Psychol.*, 1940, 22, 271-280. (Psychology Dept., University of Virginia, Charlottesville, Va.)

Using an improved method of measuring vibratory thresholds, one based on direct observation of movements stroboscopically, the order of vibratory sensitivity of 2 selected populations of skin spots has been determined. In an area of 4 square centimeters on the volar side of the wrist there were found 40 spots meeting an arbitrary criterion of high pressure sensitivity and 19 spots unresponsive to relatively strong mechanical pressure. The vibratory threshold of each of the 59 spots was measured for a frequency of 256 cycles. Pressure sensitive spots had an average threshold of 13.6 micro whereas that of the pressure insensitive points was over 8 times as large. Phenomena of conduction of forced vibrations and primary summation were observed and interpreted. The conclusion is drawn that vibratory sensations fall into a perceptual pattern of feeling of which pressure is but another temporal expression.

5391
Geldard, F.A. THE PERCEPTION OF MECHANICAL VIBRATION: III. THE FREQUENCY FUNCTION. *J. gen. Psychol.*, 1940, 22, 281-288. (University of Virginia, Charlottesville, Va.)

The problem of the range of frequencies yielding sensations of vibration is reviewed and, whereas it is found that little agreement exists as to what the upper and lower limits are, various curves uniting frequency and threshold amplitude are somewhat univocal. Recomputation of the data of several previous investigations permits the conclusion that, for relatively large vibratory contactors applied to the finger tip, the frequency function is a concave one revealing maximum sensitivity in the region of 250 cycles. An experiment is reported in which 2 populations of spots on the volar side of the wrist, selected for their high and low sensitivities to pressure, were measured for vibratory sensitivity. 5 test frequencies were employed: 64, 128, 256, 512, and 1,024 cycles. The pressure sensitive spots yielded low and reliable vibratory thresholds; spots insensitive to pressure gave high and variable values. Differences in average thresholds between the 2 populations were reliable at all frequencies. Of chief interest was the form of the frequency function for the sensitive spots. It proved to be a practically flat one and thus contrasts sharply with all previous determinations of the frequency-amplitude relation. Regardless of the frequency of stimulation vibratory thresholds of local spots having high sensitivity to pressure remain constant. The skin, in its response to vibratory movement, is thus not to be regarded as an energy transformer. Amplitude of movement or size of deformation, not energy, is the stimulus correlate of intensity of vibratory sensation.

5392
Geldard, F.A. THE PERCEPTION OF MECHANICAL VIBRATION: IV. IS THERE A SEPARATE 'VIBRATORY SENSE'? *J. gen. Psychol.*, 1940, 22, 291-308. (University of Virginia, Charlottesville, Va.)

The literature of the problem as to whether there is a separate vibratory sense abounds in arguments for such a sense as distinct from all others. Arguments for the vibratory sense are stated and formal answers to them are supplied by the writer who contends that since it has already been proven that pressure receptors, and presumably only pressure receptors, participate in the vibratory response, there is no reason to postulate a separate vibratory sense. (HEIAS)

Collier, R.M. THE EFFECT OF INSTRUCTIONS AND TYPE OF TASK UPON ANTITROPIC BILATERAL MOVEMENT. *J. exp. Psychol.*, 1940, 27, 172-183. (University of Vermont, Burlington, Vt.)

The present experiment was designed to investigate the effects of instructions and type of movement upon motor leads when continuous antitropic pronation-supination movements are contrasted with discrete movements of the same character. The method included 4 variations or series. In Series I the S made rapid continuous pronation-supination rotations of both forearms from signal 'Go' to 'Stop'. Series II was different only in one respect; the S read aloud. In Series III each pronation and each supination was a separate or discrete movement. The S attempted to initiate movements in each of the 2 directions simultaneously. Series IV was the same as Series I except that the work period was extended in order to study the effects of decrement upon motor leads. The results permit the following conclusions: a) When bilateral antitropic forearm movements are continuous, frequency and temporal extent of motor lead correspond with the normally preferred side. b) Both a distracting task and a prolonged work period operate slightly to accentuate this lead. c) When type of task and instructions require separate or discrete responses rather than continuous movements, there tends in some cases to be no consistent motor lead; in other cases the motor lead tends to correspond with the non-preferred side. d) With a continuous series of movements the average lateral priority of response is about 25 to 30 milliseconds with a standard deviation of approximately 25 milliseconds.

Brennan, Josephine G., Burnham, R.W., & Newhall, S.M. COLOR TERMS AND DEFINITIONS. *Psychol. Bull.*, 1948, 45, 207-230. (Eastman Kodak Company, Rochester, N.Y.).

The list of terms and definitions presented here was abstracted from the new Comparative List of Color Terms compiled by the Color Terms Subcommittee of the Inter-Society Color Council. The aim of that comparative list is to bring together in one place the color terms used by various branches of industry and science, and to show in a logical way the relationships of the terms as defined by the various groups. The present list is intended to include only the terms and usages which are of interest to psychologists. A strictly psychological definition of color was adopted as the type most likely to be acceptable to psychologists; and then, with this as a basis, numerous existing definitions were revised as necessary and a number of new terms and definitions were added. Warren's *Dictionary of Psychology* was used as an important though partial check list and Harry Nelson supplied some essential terms with definitions not to be found there. A Comparative List of Color Terms, based on a survey of terminology by the Problems Committee of the Inter-Society Color Council, also was consulted. This list was compiled by Forrest L. Birnack and mimeographed at Hobart College in 1939. Quite a few recent definitions by Deane B. Judd of terms relating to defective color vision were adapted and included in the new list. All of the members of the A.P.A. Delegation to the Inter-Society Color Council were asked to suggest desirable terms and definitions. As is quite evident, the scope of the list was not confined strictly to color but includes numerous allied terms having to do with vision and light. R 2

Burnham, R.W., Evans, R.M. & Newhall, S.M. INFLUENCE ON COLOR PERCEPTION OF ADAPTATION TO ILLUMINATION. *J. opt. soc. Amer.*, Sept. 1952, 42(9), 597-605. (Eastman Kodak Company, Rochester, N.Y.).

6 experienced observers made consistent determinations of various colors which appeared the same with adaptation to tungsten light and to artificial daylight. These observations were made with each eye viewing a different color patch and with the patches appearing juxtaposed at the middle of a fused binocular field. The method was to make the juxtaposed patches match by adjusting one of them, sometimes when both eyes were adapted to the same illumination and sometimes to the different illuminations. Plots of the data in the CIE chromaticity diagram indicate a systematic shift in color appearance toward the blues when adaptation was changed from daylight to tungsten; or toward the yellows when adaptation was changed from tungsten to daylight. The magnitude of this color shift was substantial, at least in the considerable color region investigated, for here the average length of the representative vectors was 0.10 in CIE terms or of the order of 20 just perceptible color differences. Qualitatively, the results confirm those of Hunt and of Minch and Young. The theoretical implications will be discussed in a later paper. R 11

5402

Corklin, J.E. THE HUMAN OPERATOR. *Northwest Science*, 1954, 28(4), 139-150. (Department of Psychology, Montana State College).

5402

This paper holds that the field of engineering psychology is devoted to the analysis of the human operator as an integral link in a man-machine system. The need for an adequate understanding of man's engineering properties (sensory and motor limitations and capacities) is discussed. Evidence is cited supporting the notion that many of man's characteristics are non-linear (response intermittency, sensory discontinuity, and the like). Further evidence is given showing a linearity of response (tracking situation where prediction is possible). An attempt is made to explain these two opposing ideas. R 33

Evans, R.M. & Brewer, W.L. OBSERVER ADAPTATION REQUIREMENTS IN COLOR PHOTOGRAPHY AND COLOR TELEVISION. *J. SMPTE*, July 1954, 63(1), 5-9. (Color Technology Division, Eastman Kodak Co., Rochester, N.Y.).

5404

The assumption of response-independence at threshold for series of psychophysical judgments was tested on seven subjects. The method of constant stimuli was used, the subjects being instructed to report on intensive differences between standard and variable tones of 1000 cycles. Five equally spaced intensities were used as the variable--two above, two below, and one identical with the stimulus. Each subject made 100 judgments including 20 where the standard and variable were identical. Threshold responses were analyzed as a function of the preceding supra-threshold responses by autocorrelation method. G. R 2

5403

This paper discusses color requirements for photography and television in terms of producing colors conforming to those required by the adaptation conditions prevailing for the observer of the reproduction. Colorimetric measurements are considered in relation to state of observer eye adaptation and the "first and second black" conditions of color photography are applied to color television. G. I. R 9

Evans, R.M. ON SOME ASPECTS OF WHITE GRAY AND BLACK. *J. opt. soc. Amer.*, Sept. 1949, 39 (5), 774-779. (Eastman Kodak Company, Rochester, N.Y.).

In any system which defines color on the basis of the non-spatial, non-temporal properties of light it is shown that white, gray, and black are not colors. The perception of white is shown to be caused by a physical property of the object not associated with its selectivity. This property is the diffusion of light. White is shown to be one extreme of a series starting at clear and passing through various degrees of pale white to a maximum. Gray is shown to be the perception of the relative visual effectiveness of the light from 2 areas and cannot be seen unless at least 2 areas are present. Black is considered the extreme in lack of relative effectiveness.

5406

Evans, R.M. LIGHT SOURCES AND COLORED OBJECTS. *Illum. Engng.*, 1949, 44, 47-54.

This paper describes the effect of different light sources on colored objects and the physical principles involved as well as the physiological conditions of the eye. Briefly, the author says that when light from a source falls on one or more colored objects either separately or in succession we are dealing with successive absorptions of energy. At each step in the process if the light is viewed by an observer he evaluates this energy distribution by 3 specialized receptors in a definite adaptation state and sees a color determined by the ratios of their outputs. Because of this fact it is not possible for the observer to predict the result of the next step from the color which he sees. A knowledge of the exact energy distribution in the source and the wavelength absorption distribution properties of each object does permit such a prediction and this is the only way it can be done. (HEIAS)

5407

Evans, R.M. PSYCHOLOGICAL ASPECTS OF COLOR AND ILLUMINATION. *Illum. Engng.*, 1951, 46, 176-181. (Eastman Kodak Company, Rochester, N.Y.).

This report to the Committee on Color in Light and Illumination presents the concepts and question of possible psychological factors concerned in color and illuminating engineering. The concepts so presented are the following: absolute white; white; gray and black; selective surfaces; modes of appearance; attributes of the modes of appearance; brightness and lightness; absolute brightness; hue; saturation; size, shape, and location; sparkle, transparency, glossiness, and luster; hue and saturation vs. lightness; diffuse and directional illumination; color of walls; illumination and illuminant; engineer--decorator--designer--architect--consultant; affective response to colors; aesthetic response; character or mood of an environment; attention value of color; warm and cool colors; and psychosomatic effect. The task of the committee is felt to be to collect, analyze, study and publish as much as possible of the above material so that the knowledge can be reduced to practice in the form of a true engineering approach to color in lighting. 5408

Evans, R.M. & Klute, Jeannette. BRIGHTNESS CONSTANCY IN PHOTOGRAPHIC REPRODUCTIONS. *J. opt. soc. Amer.*, Sept. 1944, 34(9), 533-540. (Kodak Research Laboratories, Rochester, N.Y.).

An experimental study of the problem of photographing a simple scene showing the "brightness constancy" phenomenon supports the following statements: a) All objects in the picture whose illumination is not visibly related to that of the main object must be lighted to nearly the same illuminance as the main object. b) The illuminance in shadowed portions of the main object must be greatly increased. c) The gradation of illuminance from the main source of light must be decreased by auxiliary lighting. d) Distortion of the tone reproduction scale cannot, in the general case, compensate for loss in the brightness constancy effect. e) The density of the print must be so adjusted that the main object appears to have the correct reflectance. With a white border and no simultaneous contrast effects between object and background, this occurs when the lightest part of the main object in the reproduction ("catch lights" excepted) has the same reflectance as that of the object photographed.

5409

Evans, R.M. VISUAL PROCESSES AND COLOR PHOTOGRAPHY. *J. opt. soc. Amer.*, 1943, 33, 579-614. (Eastman Kodak Company, Rochester, N.Y.).

The possibility that with color photography it is not impossible to obtain a reproduction which may be mistaken for the object itself has led many workers to assume that this is the goal of color photography and that if the reproduction were to meet the requirement that every point of the final picture shall match the corresponding point of the object in chromaticity and luminance, the picture would look exactly like the object. This article considers the subjective phases of color photography in their bearing on the above point. Present knowledge of the subjects involved is reviewed and relative importance indicated by a consideration of the effects observed in the actual operation of color processes. Part I considers brightness relations under the following topics: luminance vs. brightness in photography; brightness constancy in nature; photography of brightness constancy phenomena. Part II treats color adaptation and color constancy under these headings: visual adaptation for color; general color adaptation--point constancy; lateral color adaptation--simultaneous color contrast; local color adaptation--successive color contrast; indeterminacy of color perception; problems of reproduction and viewing. Part III deals with the effect of adaptation level, the nature of this process, and various problems of reproduction and viewing. (HEIAS)

Burnham, R.W. & Clark, Joyce R. A TEST OF HUE MEMORY. *J. Appl. Psychol.*, 1955, 39(3), 164-172. (Color Technology Division, Eastman Kodak Co., Rochester, N.Y.).

5412

This report deals with the development of a test of hue memory. Utilizing a wheel upon which two sets of hues are mounted, the S is shown one line on the test circle (20 color chips) and following a spin of the wheel is asked to find the corresponding line on the comparison circle (43 color chips). The tests of reliability and validity with 100 Ss are presented and discussed in terms of differential learning effects, correlations with other color memory tests, and the possible influence of such factors as set, motivation, etc.

Burnham, R.W. COMPARATIVE EFFECTS OF AREA AND LUMINANCE ON COLOR. *Amer. J. Psychol.*, Jan. 1952, LXV, 27-38. (Color Technology Div., Eastman Kodak Co., Rochester, N.Y.).

5418

To determine the relative color changes in surface colors for variations in area and luminance, eight observers mixed colorimetric primaries to match test colors (five) subtending visual angles of two and 12 degrees at test-field luminance levels of 0.64 and 6.30 ft.-L. Each match was recorded as the readings of three scales representing the amount of primaries used. Mean values were transformed to the I.C.I. system of color specification and analyzed in terms of direction and extent of color changes relative to area and luminance. Practical applications are noted.

5413

Burnham, R.W. BEZOLD'S COLOR-MIXTURE EFFECT. *Amer. J. Psychol.*, July 1953, 66, 377-385.

A study was undertaken to determine what factors were involved in the production of Bezold's color-mixture effect. Reported here are 2 experiments, primarily concerned with testing the effect of eye movements and suggestion. In the first, 6 Ss judged the lightness of physically identical blue patches presented with surrounds intended to show the effects of mixture and of contrast to varying degrees; 7 surrounds were used, some with white and some with black borders or overlays. The cards were presented in pairs by the method of paired comparisons and Ss judged whether the left or right patch was the lighter of the two; 4 Ss made judgments while fixating a point between each pair of cards and 2 Ss judged while actively looking back and forth from 1 card to the other. In general the results showed that the effect of color mixture prevailed for the eye-movement group whereas the effect of contrast was dominant for the eye-fixation group. In the second experiment 9 Ss made judgments of lightness of blue as it appeared in 3 border designs, presented this time tachistoscopically for 2 exposure intervals; 0.1 sec. and 2.0 sec. Half of the group was instructed to attend closely to the blue color patch and disregard border lines and background. The reports of these Ss were not affected by differences in exposure-time, complexity of stimuli, or instruction. The mean of all observations showed that 96.6% of all the judgments of "lighter" were made on the basis of color mixture effects. (HEIAS)

Burnham, R.W. COMPARISON OF COLOR SYSTEMS WITH RESPECT TO UNIFORM VISUAL SPACING. *J. opt. soc. Amer.*, May 1949, 39(5), 387-392. (Color Control Dept., Eastman Kodak Company, Rochester, N.Y.).

The present study is a comparison of ten systems of color specification, for a restricted chromatic area around the neutral at a single luminance level, with respect to their relative adherence to uniform visual spacing. A sample of 20 visually equi-spaced (Munsell renotation) chromaticities at the same luminance were used. Chromatic coordinates for these colors were expressed in each of the 10 systems and plotted in their respective chromaticity diagrams. Then all data were reduced to the same scale, after which radial saturation distances and hue angles were compared to those in the Munsell renotation criterion. Rank orders of departure from the criterion were determined for hue and saturation separately. Results show that all the 10 systems include visually significant departures from a uniform color space. These results may be generalized beyond the present sample because, if other more saturated colors were added to the present sample, there would be even greater departures from uniform spacing. The use of any particular system in any particular instance depends on circumstances, the time and personnel available, the number of points to be transformed, and the accuracy with which it is desired to illustrate visual relationships. Where the accurate expression of visual relationships is of prime importance, Munsell renotation is recommended because it was designed specifically to show equal visual intervals.

Burnham, R.W. & Newhall, S.M. COLOR PERCEPTION IN SMALL TEST FIELDS. *J. opt. Soc. Amer.*, Oct. 1953, 43(10), 899-902. (Color Technology Div., Eastman Kodak Co., Rochester, N.Y.).

5417

To investigate some factors affecting perception of color in small test fields, two trained observers viewed a test color with one eye and matched it with a variable mixture presented to the other eye. Three series of test fields were used: 1) both area and size varied in five steps (constant width of five min., length varied from five to 100 min. of visual angle), 2) shape constant (square), area varied to equal five areas in first series, and 3) area constant with shape and orientation varied. The matching data were transformed to the C.I.E. standard coordinate system and analyzed as functions of area, shape, and orientation. Practical applications are discussed.

Burnham, R.W. THE DEPENDENCE OF COLOR UPON AREA. *Amer. J. Psychol.*, Oct. 1951, LXIV, 521-533. (Color Technology Div., Eastman Kodak Co., Rochester, N.Y.).

5419

To measure differences in the appearance of colored surfaces as a function of area, five experienced observers mixed colorimetric primaries to match test colors (red, yellow, green, blue, and purple) varying in visual angles from two to 77 degrees, with uniform field brightness of 1.7 ft.-L. Each judgment was recorded as the amount of red, green and blue primaries mixed to make the match. Averages for each color and area combination were transformed to I.C.I. values and analyzed for direction and extent of color mixture changes with respect to area.

5420
To extend the satisfactory fit range for the V-51R ear defender, two additional sizes--extra small (XS) and extra large (XL) were added to existing standard sizes. The new sizes have dimensions approximately 10% smaller and 10% larger than the standard small and large sizes respectively. Compression molds were made and sample earplugs produced. A fitting survey was conducted to determine what percentage of the adult male population could be fitted by the extended range.

Carmichael, L., Kennedy, J.L. & Mead, L.C. SOME RECENT APPROACHES TO THE EXPERIMENTAL STUDY OF HUMAN FATIGUE. *Proc. nat. Acad. Sci.*, Dec. 1949, 35(12), 691-696. (Tufts University, Medford, Mass.).

5421
This paper summarizes briefly three different experimental approaches to the study of fatigue and its characteristics as exhibited in the performance of the total normal adult human being. The first approach was the continuous recording of eye movements during long periods of reading and the testing of reading comprehension changes. A second approach was used to determine conditions under which a decrement could be measured in subjects performing certain military tasks. Sleep deprivation, hard physical labor, environmental stress were some of the factors studied. The third approach used a sensitive measure of muscle tonus to measure lapses in alertness under various conditions.

Hoag, M.W. AN INTRODUCTION TO SYSTEMS ANALYSIS. RM-1678, April 1956, 21pp. Rand Corporation, Santa Monica, Calif.

5423
This paper is an elementary exposition of some conceptual issues that are relevant for a critical understanding of Systems Analysis. All issues of analytic technique are avoided. Systems Analysis is briefly defined as systematic examination of a problem of choice in which each step of the analysis is made as explicit as possible. Three problems of choice are discussed: (1) What are the relevant alternatives? (2) What test of preferredness should be applied in choosing among alternatives? and (3) How do we go about the process of weighing objectives against costs? The advantages and disadvantages of Systems Analysis as compared with intuitive or staff decisions are discussed.

Flanagan, J.C. THE CRITICAL INCIDENT TECHNIQUE IN THE STUDY OF INDIVIDUALS. *Modern Educational Problems: Report of the 17th Educational Conference*, New York, N.Y., Oct. 1955, 61-70. American Council on Education, Washington, D.C.

In summary, the use of the critical incident technique in studying individuals has been outlined. The first task is to obtain a comprehensive definition of the activity in terms of critical behavior. This is usually, although not necessarily, done by asking competent observers to report on incidents they have recently noted. The second task is to collect specific critical incidents regarding the behavior of individuals with respect to the categories formulated from the original set of critical incidents. Observations of critical incidents in typical activities afford an excellent source of data. If these data are to be adequate in quantity and quality, many observers must make frequent observations and, preferably, daily records of the incidents observed. Another source of useful descriptive information regarding the individual is the situational performance test. For such a test, standard samples of the individual's behavior in carefully structured situations are observed and recorded on the spot. Results from studies of combat leadership suggest that reliable and valid measures of personality factors can be obtained in this way. Although additional research is needed to develop the full potentialities of this type of test, it is believed that the critical incident technique can be employed in many practical school situations at the present time to obtain valuable, descriptive information about individuals.

Kimble, G.A. & Shatel, R.B. THE RELATIONSHIP BETWEEN TWO KINDS OF INHIBITION AND THE AMOUNT OF PRACTICE. *J. exp. Psychol.*, Nov. 1952, 44(5), 355-359. (Duke University, Durham, N.C. & Brown University, Providence, R.I.).

5428
To determine the shapes of the curves relating reactive inhibition and conditioned inhibition to the amount of practice, 20 Ss were given ten daily practice sessions and a total of 150 50-sec. trials on a pursuit rotor. Half the group received five sec., and the remainder 65 sec. between trials. The results are presented in terms of amount of conditioned inhibition and reactive inhibition as a function of practice and the comparative learning curves of both groups. The results are interpreted in terms of Kimble's theory of motor learning.

Schlesberg, M. & Smiley, W.C. A SIMPLE TEST OF THE NORMALITY OF TWENTY-FOUR DISTRIBUTIONS OF ELECTRICAL SKIN CONDUCTANCE. *Science*, 1953, 117, 35-37. (Brown University, Providence, R.I.).

A graphic test of the normality of electrical skin conductance data at various levels of tension is described. The test is simple and much less time-consuming than conventional statistical treatment. A graphic illustration is provided showing cumulative percentage distributions of 20 5s electrical skin conductance during one period of long division and another period of complex reaction time tests. It is suggested that the square root of conductance is the best measure to use where it is important to have the closest approximation to normality. For most reaction purposes, however, conductance would seem to be an adequate measure. (MEIAS)

Richards, W.J. THE EFFECT OF ALTERNATING VIEWS OF THE TEST OBJECT ON VISUAL AND KINESTHETIC ACTIVITY. J. Gen. Psychol., 1954, 48, 376-388. (University of Arkansas)

5431

To investigate the effect of size of alternation of stereoscopic and pseudoscopic views of targets on the threshold for depth and the effect of size of alternation of R and L views of the targets on the under threshold, a Bruckholz-type stereoscopic target was used. Alternate views of the targets were presented to each eye by means of prism and motor-driven views. Data were obtained from three subjects by the method of constant stimuli. Threshold values are plotted and the results under the various conditions are discussed and related to possible underlying cortical processes.

5434

Kelly, W.F. THE EFFECT OF KINESTHETIC, VISUAL, AND TACTILE CUES ON THE ACQUISITION OF A LEVER-POSITIONING SKILL. Contract AF 33(616) 21254, AFFORD IN 34 40, Sept. 1954, 25pp. (USAF Personnel & Mater. Studies Lab., Lackland AFB, Tex. (University of Wisconsin, Madison, Wisc.); (Quartermaster School, Fort Monmouth, N.J. 07033), 372-380).

5436

In a determination of the effective time in the acquisition of a lever-positioning skill, 60 college students practiced for 10 sessions each consisting of 60 trials, on a modified Mauthner apparatus. Visual or kinesthetic cues were eliminated and kinesthetic or verbal cues were emphasized for four experimental groups during the middle eight sessions. A control group performed the standard task throughout the sessions. Time and error scores are compared among the various groups. G. 2 22

Battig, W.F., Gregg, L.V., Nagel, E.H., Small, A.M., Jr., et al. TRACKING AND FREQUENCY OF TARGET INTERMITTENCE. J. Exp. Psychol., May 1954, 47(5), 309-314. (USAF Human Resources Research Center, Lackland AFB, San Antonio, Tex. & University of Wisconsin, Madison, Wisc.).

Measures of proficiency of tracking on the Pedestal Sight Manipulation Test were obtained at frequencies of intermittent target presentation of 4, 7, 10, 21, 41, 60, 82, and 16.1 cps. Since fusion frequency was at approximately 12 cps, the target at 16.1 cps was perceived as steady. The 15 Ss of the experiment, all male undergraduate college students, received one trial of 8 attacks for each frequency in each of 4 experimental sessions. Separate analyses of variance were completed for the AE and AER measures. A significant differential effect for frequency of intermittent target presentation was obtained. The relation is that of a bowed curve concave downward. As frequency of target intermittence increases, there is an initial rapid rise in tracking proficiency to 1.0 cps, a more gradual increase to a maximum at 8.2 cps, and a decline at 16.1 cps. A significant practice effect was obtained only for the AE measures. Since a light-dark ratio of 50/50 could not be obtained at 4, 7, and 16.1 cps, and since target brightness declined consistently as frequency increased, the obtained curves cannot be said to be a simple function of frequency of intermittent presentation of the target. The gains in tracking proficiency between 1.0 and 8.2 cps, however, are not differentially affected by the constant light-dark ratio of 50/50, and the only effect of target brightness could be one of decreasing the magnitude of the increments. There is, therefore, evidence for a relation of tracking and frequency of the intermittent presentation for which neither light-dark ratio or brightness may be responsible. The obtained curves, however, will require confirmation under conditions that permit adequate control of light-dark ratio and target brightness as parameters. R 6

 EFFECTIVENESS OF MESSAGE MESSAGES IN SMALL INFANTRY UNITS.
 Tech. Memo. OMD T 338, May 1952, 10pp. Operations Research
 Office, Johns Hopkins University, Baltimore, Md.

5436
 To determine the contribution of miniature radios to
 the effectiveness of small infantry units, experiments
 were designed to measure significant aspects of performance.
 Platoon and squad leaders used a transceiver to
 transmit messages; all men in the squad were a receiver.
 Three representative tactical situations were chosen. In
 each situation, critical segments were repeated a number
 of times with and without radio, while measurements were
 made of time required, variations in hit rates on targets,
 exposure of leader and runners, and correctness of re-
 ceived messages. All troops were interviewed immediately
 following participation. Comparison of the data was made
 for the two types of communication systems. Recommendations
 are included.

 Paper presented at the Fourth Undersea Warfare Symposium,
 May 1949, Serial NRC:OW:0044. Committee
 on Undersea Warfare, National Research Council,
 Washington, D.C.

5439
 This paper reviews briefly the general outcome
 of the first two years of work by the Committee on
 Human Resources, Research and Development Board to
 meet the needs of the military for analysis, evaluation
 and planning of research in the sciences of human
 behavior. Four major sub-divisions have been studied:
 human engineering and psychophysiology; personnel and
 training; man-power; and human relations and morale.
 The status of military research in these areas is
 discussed.

5440
 Allphin, W. SCHOOL LIGHTING AND POSTURE. May 1953, 4pp. Sylvania Electric Products Inc.,
 Salem, Mass.

A study of the relationship between school lighting and the posture assumed by students
 in writing tasks was conducted at the Bowditch School, Salem, Mass. The building contained
 classrooms with windows on one side only and with windows on both sides; some with dark desks
 fastened to the floor and some with light, movable desks; all wall finishes were light with
 artificial lighting from enclosing globes providing low illumination levels. Photographs
 were taken of students engaged in writing; all photographs were unposed. An analysis of
 postures in relation to light source, illumination level, and handedness revealed no connection
 between illumination and posture but distinct differences did exist with handedness.
 Other factors causing tilting and twisting that occurred when the eyes were brought close to
 the work were speculated as being desk height, manner of holding pen, and interest in the
 work. (HEIAS)

 American Institute for Research. AGING AND AIRCRAFT PERFORMANCE. RESEARCH NOTES. Res. Note 7, March 1953, 4pp.
 American Institute for Research, Pittsburgh, Penn.

5442
 This report summarizes a study of the type of age-
 related changes in the ability of aircrews to perform
 their jobs. Following a pretest with civilian
 subjects in order to evaluate data - collecting techniques,
 critical incidents were collected from 631
 subjects who were primarily bomber and fighter pilots.
 The results are discussed in terms of effective and
 ineffective behavioral symptoms observed as a function
 of age. Results of the pretest are presented in terms
 of four symphonological areas, e.g., cognitive processes,
 sensory-motor processes, attention and temperament,
 and interpersonal relations and personal adjustment.

 SULPHATE AND CAFFEINE CITRATE ON THE EFFICIENCY OF
 COLLEGE STUDENTS. J. Biol. Psychol., April 1943,
 27(2), 124-131. (Lawrence College, Appleton, Wisc.).

5444
 To evaluate the effects of benzedrine sulphate and
 caffeine citrate on speed of action, reading rate, reading
 comprehension, and thinking ability, 129 college
 students were divided into three groups equated as to
 intelligence and sex. The three groups were administered
 one of the two drugs or a placebo (sugar or milk). Tests
 given over a 50-minute period were 1) tapping speed for
 ten seconds, 2) reading test for speed and comprehension,
 3) a second tapping test, 4) multiple-choice vocabulary
 tests with a time limit imposed, and 5) a third tapping
 test. Differences in test scores among the three groups
 were analyzed for measurable drug effects.

Finger, F.W. & Spelt, D.K. THE ILLUSTRATION OF THE HORIZONTAL-VERTICAL ILLUSION. *J. exp. Psychol.*, June 1947, 37(3), 243-250. (University of Virginia, Charlottesville, Va. & University of Florida, Tallahassee, Fla.).

72 Ss attempted to equate in length the horizontal line and the vertical line in each of 4 figures. In one figure (C) the horizontal line was bisected by the vertical, in the second (B) the vertical was bisected by the horizontal, and in the other 2 (A and D) the lines did not intersect. The 3 predictions underlying the experiment were clearly borne out: a) The error in C was greater than the error in A; b) The error in C was greater than the error in B; c) The error in B was greater than the error in D. The hypothesis on which these predictions were based was thus confirmed: that the error of perception in the inverted T figure is an illustration not simply of the horizontal-vertical illusion, but of the 'bisecting-line' illusion as well.

Battersby, W.S. & Jaffe, R. TEMPORAL FACTORS INFLUENCING THE PERCEPTION OF VISUAL FLICKER. *J. exp. Psychol.*, Sept. 1953, 46(3), 154-161. (Neurology Dept., The Mount Sinai Hospital, New York, N.Y.).

A study of the temporal factors influencing CFF was performed. Using a "square" wave stimulator, an electronic interval timer, and a gas discharge tube, measures of CFF were taken from 2.0s when the over-all duration of exposure of the intermittent light was varied from 140 to 1000 msec. for each of 3 relative light percentages (light-dark ratios). For both Os, the plot of CFF vs exposure time was a rising function of negatively accelerated slope. The magnitude of the slope of these functions varied with the percentage of the period occupied by light (in the order 50%, 20%, 80%). When the data were replotted in terms of number of light flashes at fusion vs exposure time (as contrasted to frequency of flashes, or CFF, vs exposure time), a linear curve for each light-dark ratio was found. These findings indicate that CFF, expressed in cps, varies systematically as exposure time is shortened, but that the number of flashes per unit time is relatively constant at fusion. When the raw data obtained with each light-dark ratio were equated for total energy content, it was found that the longer the relative dark interval in an intermittent light cycle, the greater the ability of 0 to discriminate between successive flashes. These results are compatible with concepts of "excitation" and "recovery" in the visual system, but are equally predictable from either neural or photochemical theory. It is suggested that the relative merits of these theories can only be appraised in experiments where neural or photochemical factors are directly manipulated.

Viteles, H.S. & Smith, K.R. AN EXPERIMENTAL INVESTIGATION OF THE EFFECT OF CHANGE IN ATMOSPHERIC CONDITIONS AND NOISE UPON PERFORMANCE. *ASHVE J. Section*, Jan. 1946, 6pp. (American Society of Heating and Ventilating Engineers, New York, N.Y.).

An experimental investigation was conducted on the effect of diverse atmospheric and noise conditions upon output, feelings, and physiological functions during the performance of tasks roughly analogous to operations carried on by personnel in the plotting and charting rooms of Naval vessels. Experimental tasks: discrimination tests, mental multiplication, number checking, code and location tests, tracking and tracing; atmospheric conditions: effective temperature (ET) of 73°, 80°, 87°, and 94°; noise levels: 72, 80, and 92 db. 6 Ss were studied 6 days per wk, for a period of 7 wks. under various combinations of the above conditions. Performance data were analyzed for significance of differences due to the several experimental conditions. No adverse effects on performance were found at ET's of 72 and 80°, but did appear at 87°; at 94° the Ss could not complete the tasks because of adverse physiological reactions. Noise levels used here did not adversely affect performance. Discomfort, distress, and annoyance were found at the higher levels of temperature but not with increasing noise levels. (HEIAS)

Birnack, F.L. & Olson, R.M. THE INTENSIVE DIFFERENCE LIMEN IN AUDITION. *J. acoust. soc. Amer.*, April 1961, 12(4), 517-525. (Moberg College, Geneva, N.Y.).

In spite of its interest for acoustics, the intensive difference limen for sound has not been determined over a comprehensive range of frequency and amplitude. In the present experiment we have determined the difference limens for discrete intensive discrimination at 5 frequencies ranging from 128 cycles to 1000 cycles with intensities from 0.02 bars rms pressure to 3.4 bars (-65 db to -15 db). Both the physical conditions and the psychological judgment have been carefully controlled. The data yield a value for Δ db of 2.4 db in the middle range of intensities (-35 db to -15 db or 35 SL to 70 SL).

Bruell, J.M. & Albee, G.W. NOTES TOWARD A MOTOR THEORY OF VISUAL EGOCENTRIC LOCALIZATION. *Psychol. Rev.*, 1955, 62(5), 391-400. (Western Reserve University, Cleveland, Ohio & Highland View Hospital, Cleveland, Ohio).

The relationship between phenomena of visual egocentric localization and processes of involuntary and voluntary oculomotor innervation has been pointed out by many earlier investigators. This paper has attempted to describe the nature of this relationship more precisely. From an examination of empirical data relating to visual egocentric localization, 2 hypotheses were derived to account for the perception of direction and for some phenomena of egocentric apparent movement. Hypothesis 1 states that when dextro- or levorotators of the eye receive voluntary innervation, the space values for points on the retina change in relation to the direction and degree of innervation. Corresponding changes of retinal space values occur with voluntary innervation of the elevators and depressors of the eye. Hypothesis 2 states that when eye position is determined by reflex innervation alone, retinal points do not change their space values. Factors responsible for voluntary and reflex innervation of eye turners were examined, permitting the knowledge of patterns of innervation under various stimulus conditions. Predictions from the hypotheses concerning the effects of voluntary and reflex innervation on space perception were compared with empirical data, and were found tenable for a variety of perceptual experiences.

Bruell, J.M. & Albee, G.W. EFFECT OF ASYMMETRICAL RETINAL STIMULATION OF THE PERCEPTION OF THE MEDIAN PLANE. *Percept. Mot. Skills*, 1955, 2, 133-139. (Western Reserve University & Highland View Hospital, Cleveland, Ohio).

An experiment was conducted to ascertain the effect of asymmetrical retinal stimulation on the perception of the median plane. 21 Ss adjusted the left or right edge of luminous rectangles to what appeared to them to be straight ahead using binocular vision. Conditions of retinal stimulation included 7 conditions: straight ahead and 16.7°, 11.3°, and 5.7° to both right and left of center. It was found that with asymmetrical retinal stimulation the apparent median plane does not coincide with the objective median plane, but shifts in the direction of stimulation. The magnitude of the displacement was a function of the degree of asymmetry of retinal stimulation. These findings were explained in terms of underlying processes of involuntary and voluntary innervation of the extra-ocular muscles. (HEIAS)

Gogel, W.C. PERCEPTION OF THE RELATIVE-DISTANCE POSITION OF OBJECTS AS A FUNCTION OF OTHER OBJECTS IN THE FIELD. *J. exp. Psychol.*, May 1954, 47(5), 335-342. (USA Medical Research Lab., Fort Knox, Ky.).

An illusion in depth was produced by using a series of similar objects of different sizes. It was found that the adjustment of a binocular disc to apparent distance equality with a part of the binocular illusion was influenced by the line-of-sight position of the disc with respect to the illusion. It is hypothesized that a binocular depth illusion will least disturb the apparent relative distance of the disc from S with respect to that part of the illusion which is most nearly in line-of-sight with the disc. It is suggested that the binocular disparity between the disc and a frontally adjacent (line-of-sight) object is functionally more important than that between the disc and a frontally displaced object, regardless of which of these binocular disparity relations S attempts to use.

Kratwohl, M.C. A THEORY OF WORK HABITS OF INDUSTRIALNESS. J. appl. Educ., 1951, 41(3),
157-163. (Illinois Institute of Technology, Chicago, Ill.).

A study was made of some aspects of work habits of industrialness with particular refer-
ence to college achievement. An index of industrialness was derived from differences be-
tween aptitude and achievement scores of 1255 engineering freshmen in the field of mathemat-
ics. These scores were then used to measure such properties of work habits as industrious-
ness, persistence, and achievement through correlations of the index with grades in college
algebra received from 5 to 10 months later. A further test was made using 308 25 in the field
of English. The following conclusions were drawn: a) The index of industrialness was a
valid measure of industriousness; b) Work habits do affect achievement; c) There
is a tendency for industrious vs. indolent work habits to persist over a period of time; d)
work habits affect the ability of a student to remain in college; and e) Work habits of the
industrialness act very similarly to social habits of honesty, truthfulness, and morality in
that they are specific, instead of general, and that with increasing industrialness comes in-
creased consistency and predictability. (McL)

SOLUTIONS BY TEAMS AND BY INDIVIDUALS TO A FIELD
PROBLEM AT DIFFERENT LEVELS OF REALITY. J. educ.
Psychol., Jan. 1955, 46(1), 17-24. (Columbia
University, New York, N.Y.).

5480
To estimate the difference in the quality of the
solution to a practical field problem presented in four
settings differing in their degree of remoteness from
reality (verbal description, photographic representa-
tion, miniature scale model, with and without manipu-
lation of parts and materials), ten teams of five men
and ten men as individuals were asked to solve the prob-
lem at each of the four levels. The Mined Road Problem,
which requires a plan for getting a group of five men
across a mined road, was adapted for use. A quality
point scoring system was used to evaluate the written
plans and the differences between group and individual
solutions as well as among levels of remoteness from
reality were analyzed.

Mishkin, M. & Forgy, D.G. WORD RECOGNITION AS A FUNCTION OF RETINAL LOCUS. J. exp. Psychol. Jan. 1952, 42(1), 43-48. (McGill University, Montreal, Canada).

4 experiments were performed to investigate the accuracy of tachistoscopic recognition of words placed in the left and right peripheral fields of vision. Experiments I and IV demonstrated that Ss recognized significantly more words placed in certain parts of the right visual field than in corresponding parts of the left, confirming the hypothesis of a selective retinal training arising from the reading situation. Several alternative interpretations of this phenomenon were ruled out in Experiments II and III. The results support the theory that a particular perception depends on the excitation of particular nerve cells, and are inconsistent with the theory of a general equipotentiality in vision.

Note, F.A. & Briggs, G.E. THE RELIABILITY OF MEASUREMENTS OF HUMAN DARK ADAPTATION. J. exp. Psychol., July 1954, 48(1), 69-74. (University of Wisconsin, Madison, Wisc.).

Measurements of dark adaptation were made with a Hecht-Shlaer adaptometer following pre-exposures to 1,244 m. intensity for 2-min. duration. The exp. was carried out over a period of 11 months, the authors serving as Es and Ss. For each S a total of 24 dark-adaptation curves was obtained, 2-curves of 40-min. duration per session for 12 sessions. Statistical analyses were carried out to determine the influence of several factors for the initial threshold value, the value at the rod-cone "break" and the final threshold values. The main results were as follows: a) For each S the total extent of change in threshold values for each curve was approximately 4 logarithmic units. All curves clearly showed both cone and rod dark-adaptation components. b) No significance at any stage in dark adaptation was found to be associated with the factors of forenoon versus afternoon, or first curve versus second curve in a session. c) The factor of experimenter-subject combination was found to be significant at the 5% level of confidence for the initial threshold values and for the values at the rod-cone "break." Further analysis revealed that for the initial threshold values, this is not to be attributed to the Ss, but to 2 of the Es, and is attributable to variation in experience in taking measurements. The significance found for the threshold values at the rod-cone "break" was associated with Ss, not Es, and is an expression of the fact that individuals differ in the threshold level at which the adaptation of the cones is replaced by that of the rods. d) The influence of any factors during the early phase of rod adaptation could not be determined because of day-to-day variability among the individual dark-adaptation curves. e) No practice effect was found.

5493 Note, F.A. & Briggs, G.E. THE EFFECT OF HIGH INTENSITY AND SHORT DURATION VERSUS LOW INTENSITY AND LONG DURATION OF INTERMITTENT PRE-EXPOSURE UPON HUMAN DARK ADAPTATION. J. exp. Psychol., Aug. 1952, 42(8), 521-525. (University of Wisconsin, Madison, Wisc.).

The influence of intermittent pre-exposure upon subsequent dark adaptation was investigated for 2 intermittent conditions. In one condition the intensity was increased in the same proportion as the amount of light-time in the light-dark ratio was decreased, keeping duration constant. In the other, intensity was constant but the duration was extended to compensate for variations in light-time. Both control intensities were compared with equivalent control pre-exposures to continuous light. The control intensities and durations were 140, 281, and 562 m. and 1 and 3 minutes. The rate of intermittence was 1 cycle/second, and 4 light-to-dark ratios were used. The curves of dark adaptation obtained after intermittent pre-exposures of constant duration but different intensities were almost identical with those after the equivalent control pre-exposure. This was not so for the intermittent pre-exposures of constant intensity but different durations; after the longer durations, dark adaptation was much slower than after the equivalent control condition.

Note, F.A. S. Reed, Eleanor C. THE EFFECT OF EXTENDING THE DURATION OF VARIOUS LIGHT-DARK RATIOS OF INTERMITTENT PRE-EXPOSURE UPON DARK ADAPTATION IN THE HUMAN EYE. *J. opt. soc. Amer.* May 1952, 42(5), 333-338. (University of Wisconsin, Madison, Wisc.).

The influence of intermittent versus continuous preadaptation upon subsequent dark adaptation was investigated for 2 durations of the continuous: 1 1/2 and 3 minutes. The rate of intermittence for the discontinuous condition was 1 cycle/sec. and 4 light-to-dark ratios were employed. The pre-exposure intensities were 8860, 886, 88.6 and 8.86 m. Differences were found for most of the cases in which a comparison was made between the curves of dark adaptation following the 2 conditions of preadaptation. For the intermittent condition at the highest pre-exposure intensity it was found that the shorter the light-time in the ratio; the lower the initial threshold tended to be and the more rapidly the final dark adapted thresholds for both the intermittent and continuous curves were approximately the same, but the curves for the intermittent were markedly retarded in reaching the final level of dark adaptation.

Mull, Helen K., Ord, Nancy & Locke, Nan. THE EFFECT OF TWO BRIGHTNESS FACTORS UPON THE RATE OF FLUCTUATION OF REVERSIBLE PERSPECTIVES. *Amer. J. Psychol.*, June 1954, 67(2), 341-342. (Sweet Briar College, Sweet Briar, Va.).

A study was conducted on the effect of 2 brightness factors (contrast between contour and background and illumination) upon the rate of fluctuation of reversible perspectives. 36 Ss divided into 6 groups were studied. A 2 in. Necker cube, drawn with dark gray contour lines, was presented a) on a white ground with 200-w. illumination, b) on a medium gray ground with same illumination, c) on white ground under 15-w. illumination. S fixated a neutral point at center of cube and reported shifts in perspective as they occurred until 10 changes occurred; procedure was repeated 20 times with short rest intervals. Each group observed under all conditions. In condition a) the average length of 20 periods was 30.6 sec.; in b) 29.5 sec.; and in c) 30.0 sec. The critical ratio between averages of a) and b) was 0.31; a) and c), 1.65. Rates of shift were highly irregular for all conditions. Neither of the brightness factors, then, were found to influence fluctuation rate. (HEIAS)

Stevens, S.S. DECIBELS OF LIGHT AND SOUND. *Physics Today*, Oct. 1955, 8(10), 12-17. (Harvard University, Cambridge, Mass.).

The usefulness of logarithms in the measurement of many stimuli to which human beings are sensitive is discussed, with particular reference to the problems of psychophysics. Where relative magnitudes and ratios between magnitudes of 2 stimuli are of great interest. The use and advantages of the decibel notation in the field of acoustics to express ratios between 2 amounts of power are discussed. Other uses for decibels, particularly in the field of optics, are then indicated. The author argues that since light intensity involves power (radiant energy flow) it would be appropriate to measure light in decibels; the advantages of such a measure are enumerated and illustrated by a comparison between vision and audition. A decibel scale for light and sound is presented, showing the approximate levels of luminance and of sound intensity produced by various sources, together with a few important threshold levels. Warrick, M.J. DESIGN AND USE OF COUNTERS FOR AIRBORNE EQUIPMENT. RDO 694 17, Tech. Note WCRD 52 80, Oct. 1952, 8pp. *Aero Medical Lab.*, USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

It is suggested that counters may be used most advantageously for the presentation of precise quantitative information requiring no interpolation between numbers. It is not recommended that counters be used to present information from which the operator is to derive directional or rate information or to present information which will be used for check-reading purposes. In reference to the design of counters, it is recommended that the numbers snap into place, normally following each other at a rate no faster than about 2 per sec. It is recommended that an upward movement of the counter drum indicate an increase and that an up or clockwise motion of the associated control produce an increase in the counter reading. If a toggle switch is used as a reset control, it is suggested that the reset speeds be no greater than 10 digits per sec. If a manually operated rotary knob reset control is used, it is recommended that it be located to the right of the counter and that for accurate reset to a new number a ratio of about 36° control knob rotation for one-digit counter movement be used.

Collier, G. PROBABILITY OF RESPONSE AND INTERTRIAL ASSOCIATION AS FUNCTIONS OF MONOCULAR AND BINOCULAR STIMULATION. J. exp. Psychol., Feb. 1954, 47(2), 75-83. (ONR, Indiana University, Bloomington, Ind.).

The effect of monocular versus binocular fixation and viewing conditions on probability of response (Pr) and the amount of intertrial association was investigated. The binocular Pr was found to be greater than the monocular Pr under all conditions, and it was argued that this result was not an artifact of the conditions of observation. Evidence was advanced for the hypothesis that stimulation of 2 eyes is functionally equivalent to doubling the area of stimulation in a single eye under the conditions of the present experiment. On the assumption of the peripheral origin of the associative effect, the expected reduction of the intertrial associative effect was not found, and it was concluded that the effect is nonperipheral in origin.

Darley, J.G., Gross, N. & Martin, W.C. STUDIES OF GROUP BEHAVIOR: FACTORS ASSOCIATED WITH THE PRODUCTIVITY OF GROUPS. Reprint Series 12. Laboratory for Research in Social Relations, University of Minnesota, Minneapolis, Minn. (Reprinted from: J. appl. Psychol., Dec. 1952, 36(6), 396-403).

5510

This is one of a series of papers reporting the results of a study of the relations among selected sociological and psychological variables in the behavior of small organized groups. An analysis of factors related to group productivity is presented here. The groups studied were 13 women's small residence units organized as a cooperative housing project. An attempt was made to get an estimate of relative productivity of the groups when engaged in a common and meaningful task--preparing a plan for better cooperative living--as a criterion measure against which certain group variables were correlated.

Davis, H. & Eldredge, D.H. NOISE AND THE COMMUNITY. CHABA Rep. 4, Oct. 1954, 32pp. National Research Council, Committee of Hearing and Bio-Acoustics, Washington, D.C.

These proceedings of the second meeting of the Committee on Hearing and Bio-Acoustics held jointly with NACA Special Subcommittee on Aircraft Noise were assembled from notes taken at the meeting where 11 papers were presented dealing with problems of neighborhood responses to noise, particularly aircraft noise. Papers dealing with human aspects of the problem include an assessment of community responses to noise; various community aspects of aircraft annoyance and methods for measuring such attitudes; and a report on some Air Force experiences with noise and the community. The physical aspects of the problem discussed were noise sources and "near source propagation problems"; atmospheric and terrain factors in sound propagation; Air Force planning with regard to noise and the community; other noises in the community; and noise level data applied to the control of community response. A summary paper on present status of research on the physical aspects of sound propagation concluded the presentations. (HEIAS)

5512 Davis, R.C. THE STIMULUS TRACE IN EFFECTORS AND ITS RELATION TO JUDGMENT RESPONSES. J. gen. Psychol., Dec. 1952, 44(6), 377-390. (Indiana University, Bloomington, Ind.).

4 groups of Ss were presented with pairs of tones under 4 different experimental procedures with Ss pressing a key in response to each pair in certain of the conditions constituting a judgment of the relative intensity of the second stimulus. Search for stimulus trace effects was made in the concurrent muscular activity in 4 body locations by electromyographic methods, and the relation of some of these to ensuing judgments was investigated. Under all the experimental conditions there was an increase in muscular activity associated with the first stimulus of each pair, at least in those muscles likely to be involved in the subsequent key pressing. For the simple reaction situation the excitation was highly localized; for the choice-response situations it was more widespread. The temporal course of the excitation varied with the following factors: a) simple vs. choice response; b) regularity vs. irregularity of time interval between stimuli of a pair; and c) duration of the first stimulus of a pair. The proportion of judgments of "stronger" and "weaker" bears no discernible relation to its total amount of activity in the 2 arms prior to the judgment, but is related in a variety of circumstances, to the difference in prior activity of the arms designated to give "stronger" and "weaker" judgments, the more active arm giving the greater number of responses.

Esso, M.E. & Kafka, J.S. DIAGNOSTIC IMPLICATIONS OF A STUDY IN TIME PERCEPTION. J. gen. Psychol., 1952, 46, 169-183. (New York State College for Teachers, Albany, N.Y. & Emory University, Emory University, Ga.).

5514

In an attempt to relate time perception to other psychological phenomena, 76 subjects were required to estimate two time intervals (15 seconds, two minutes) under four conditions. These were: 1) a tone was heard for five seconds, after which the subject was directed to silence it (key pressing) for the estimated interval, 2) the subject was asked to switch off a light and keep spring switch down for the estimated interval, 3) the reverse of the preceding condition, and 4) the subject switched on the tone and listened to it for the estimated interval. No knowledge of results was given. Differences between estimated and clocked time were analyzed for serial position and for differences among usual and unusual conditions.

Gibson, Eleanor J. IMPROVEMENT IN PERCEPTUAL JUDGMENTS AS A FUNCTION OF CONTROLLED PRACTICE OR TRAINING. *Psychol. Bull.*, Nov. 1953, 50(6), 401-431. (Cornell University, Ithaca, N.Y.).

5516

This paper reviews the literature on improvement with practice of perceptual judgments. Among the perceptual processes covered are visual and tactual acuity; absolute and differential thresholds for hue, pitch, weight, and visual space; absolute estimation of weight, pitch, hue, brightness, pressure, and visual and kinesthetic extent; and the recognition of patterned stimuli under reduced conditions. Factors influencing perceptual learning, including amount and distribution of practice, reinforcement, and names and labels, transfer, and retention are also discussed.

Williams, A.C., Jr. & Hopkins, C.O. ASPECTS OF PILOT DECISION MAKING. Contract AF 33(616) 5135, WADC TR 58 522, Dec. 1958, 50pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Hughes Aircraft Company, Culver City, Calif.).

5518

To provide an operational definition of pilot decision-making, a detailed analysis was made of the tasks performed by the pilot of a modern airborne weapon system and was presented in a diagram. A way of conceptualizing decision-making so as to include instances of pilot decision-making was proposed. Applicability of each of the more prominent decision theories to this problem was considered. Areas requiring further study were discussed and some approaches to this problem were suggested.

Grether, W.F. & Williams, A.C., Jr. PSYCHOLOGICAL FACTORS IN INSTRUMENT READING. II. THE ACCURACY OF POINTER POSITION INTERPOLATION AS A FUNCTION OF THE DISTANCE BETWEEN SCALE MARKS AND ILLUMINATION. *J. appl. Psychol.*, Dec. 1949, 33(6), 594-604. (USAF Aero Medical Lab., Wright-Patterson AFB, Ohio & University of Illinois, Urbana, Ill.).

Measurements were made of the accuracy of interpolating pointer position between scale marks as a function of dial diameter and the angular spacing between divisions. Ss were required to estimate the pointer position to within 1/10 the space between graduations. The experimental dials were painted with yellow fluorescing paint on a black background and were read under simulated daylight (45 ft.c.) and night (ultra-violet) illumination conditions. The major results of this investigation may be summarized as follows: a) Dial diameter and angular spacing of the scale marks could be combined into the single variable of length of graduation interval; b) The relative error of interpolation decreased as the length of the graduation interval increased up to approximately 0.5 in., and was very nearly constant at higher intervals. c) The absolute error of interpolation increased very nearly as a linear function of the length of the graduation interval. If there is an optimum interval for absolute accuracy it would appear to be below the interval lengths used in this study. d) Except in the case of the most closely spaced divisions the accuracy of interpolation was independent of the 2 illumination conditions. e) The speed of dial reading was not systematically related to either dial diameter or angular spacing of the divisions, although the measurements were admittedly crude.

5520 Grether, W.F. INSTRUMENT READING. I. THE DESIGN OF LONG-SCALE INDICATORS FOR SPEED AND ACCURACY OF QUANTITATIVE READINGS. *J. appl. Psychol.*, Aug. 1949, 33(4), 363-372. (USAF Aero Medical Lab., Wright-Patterson AFB, Ohio).

An evaluation was made of the speed and accuracy with which quantitative readings could be made of 9 experimental altitude indicators. The results are considered to apply also to other types of quantitative indication which require very great scale length. Evaluation of the various indicator designs was made by having 57 USAF pilots and 79 college men read 12 settings on each instrument. The instrument faces are reproduced in test booklets which provided spaces for writing in the readings. Both accuracy and speed of reading data were obtained for each of the 9 indicator designs. The major conclusions indicated by the results of this investigation are as follows: a) The combining into a single numerical value of the indication from 2 or more pointers, or from a pointer and rotating subdials, is a relatively difficult task for human beings. Such instruments are conducive to very large errors in readings. b) The ease with which long scale indicators can be read quantitatively appears to depend upon the extent to which the digits are already combined in the proper sequence by the instrument. c) A multiple pointer instrument such as the altimeter with continuous motion of the non-sensitive pointers is frequently read too high by a complete revolution of the sensitive pointer. d) The speed and accuracy of instrument readings are positively correlated, indicating that gains in reading speed can normally be expected to improve accuracy also. e) College men without altimeter reading experience showed virtually the same pattern of results in this study as highly experienced USAF pilots, suggesting that instrument reading difficulties are quite basic in nature and not readily modified by experience.

Hilgard, E.R. & Smith, M.B. DISTRIBUTED PRACTICE IN MOTOR LEARNING: SCORE CHANGES WITHIN AND BETWEEN DAILY SESSIONS. *J. exp. Psychol.*, Feb. 1942, 30(2), 136-146. (Stanford University, Stanford, Calif. & Harvard University, Cambridge, Mass.).

5521

The literature on the acoustic attenuation of ear protective devices is reviewed. Typical attenuation values are given for some standard plugs, muffs, and helmets. The variability of the attenuation measurements on a single device is shown for (1) different measurement methods, (2) different laboratories using the same method, (3) different trials on a single person and (4) different persons. Some recommendations are included.

G. I. R 14

5525

This experiment is concerned with the effect of distribution of practice on motor learning--specifically, with the occurrence of reminiscence or warm-up decrement at different stages in learning. The Ss, 78 college students divided into three groups, practiced on a pursuit rotor for 25 one-min. trials a day for four days. For each group the intertrial interval was different (20 sec., 3 min. or 5 min.). Overnight gains and losses and within-session gains in performance are compared for the three groups.

5522

To study the effect of past experience on the perception of color, five observers viewed three pairs of colored stimulus figures (one member of each pair was a meaningful figure with a characteristic color--apple, heart, lobster--the other was nonmeaningful) against a variable background (from red to yellow) and reported the point at which the figure could no longer be distinguished from the background. The data were given as degrees of red in background color required for indistinguishability of each class of objects and were analyzed for differences due to past experience.

T. R 3

5528

This experiment was designed to test hypotheses concerning rate of psychological oversatiation among group members as a function of characteristics of their groups. The group characteristics were those presumed to affect the difficulty of decision in setting goals for the task. The task itself was a simple assembly of a jigsaw puzzle, repeated as often as possible over a two-hour period. Each member of the group was required to set a goal (speed and accuracy) for each repetition independently of other members of his group. Satiation was measured by means of degree of negative valence exhibited on successive rating scales of interest in the task.

Karlin, L. THE INFLUENCE OF EQUALITY JUDGMENTS ON THE CONSTANT ERROR. *J. exp. Psychol.*, Nov. 1951, 44(3), 300-301. (New York University, New York, N.Y.).

When stimuli of equal objective magnitude are compared, the CE determined with the use of an equality category is greater than the CE determined with the use of only 2 categories, providing that the former CE is determined from a proportional division of the equality judgments. This result is discussed in terms of an hypothetical tendency to avoid repeating a previous judgment. In general, the evidence in the present study is interpreted to mean that the 3-category situation provides a more valid estimate of the CE.

Karlin, L. THE TIME-ERROR IN THE COMPARISON OF VISUAL SIZE. *Amer. J. Psychol.*, Oct. 1953, 66, 564-573. (New York University, New York, N.Y.).

This study was undertaken to determine the time-error (constant error resulting from the successive comparison of 2 stimuli) for visual size as a function of stimulus duration and interpolated interval. The stimulus (a black, surface circle, 92 mm. in diameter) was tachistoscopically presented on a clear ground for 1, 3, and 5 sec. with interpolated intervals of 1, 4, and 8 sec. to 9 Ss at 9 different sessions. In each session the method of successive comparison (same stimulus for standard and comparison) was used with stimulus duration and interpolated interval constant for that session. 3 categories of judgment were used: larger, equal, smaller. Individual time-errors were computed and mean errors analyzed in terms of the variables. The results of the present study suggest that the time-error for the successive comparison of circles becomes increasingly negative with increasing length of interpolated interval. It was pointed out that these functions are similar to those obtained in previous studies for stimuli varying in intensive magnitude. It was concluded that the function of the negatively directed time-error may be characteristic of judgments of magnitude in general. These results were further discussed in terms of possible relationships to Gestalt theory based on the phenomena of gamma movement. It was also found that the time-error tends to become less negative when stimulus duration is changed from 1 to 3 sec.; there may be a tendency for this trend to reverse when stimulus duration further increases from 3 to 5 sec.

Knehr, C.A. & Fuller, Muri. SENSORY VS. AUTONOMOUS CONTROL OF SPAN OF APPREHENSION. *J. Psychol.*, 1954, 37, 65-73. (Payne Whitney Psychiatric Clinic, New York Hospital, New York, N.Y.).

A span of apprehension experiment using 39 subjects was designed to test the hypothesis that varying the size of the visual area over which stimulus dots appeared would alter the response to those stimuli. A second hypothesis assumed that the effect would be differential between control subjects and persons with schizophrenic or other psychopathological characteristics. The evidence provides no significant support for either hypothesis. On the positive side, we have found indications of persistent individual patterns of responses when the results were plotted as scattergrams. The patterns remained on retest from 2 to 15 weeks later in 10 subjects. The factors underlying these individual patterns are unknown to us. No significant relationships were observed between the individual response characteristics and available personality data.

Knox, G.W. THE RELATION OF DYNAMIC FACTORS TO FLICKER AND FUSION. *Abstr. Doc. Dissertation*, 1941, (35), 67-74. (Ohio State University, Columbus, Ohio).

5533

The author presented a series of experiments designed to investigate the relation of central or dynamic factors to flicker and fusion. The experiments investigated the following aspects of critical flash frequency (C.F.F.): the effects of learning under different attitudes (induced by task instruction) on the C.F.F.; the effect of perceptual shape on C.F.F.; and the phenomenon of auditory-visual flicker induction. The results were discussed in terms of the relative role of the various factors investigated in the C.F.F. experience.

5534

Knox, G.W. INVESTIGATIONS OF FLICKER AND FUSION. I. THE EFFECT OF PRACTICE, UNDER THE INFLUENCE OF VARIOUS ATTITUDES, ON THE CFF. *J. gen. Psychol.*, 1945, 33, 121-129. (Department of Psychology, Ohio State University, Columbus, Ohio).

5534

To investigate the role of practice and attitude on the CFF, three groups of two Ss each made 200 CFF determinations over a period of ten days. Conditions were identical except for instructions: Group I was "set" for flicker, Group II for fusion, and Group III for change of experience. Half the determinations were made with an artificial pupil. Thresholds were plotted for each S as a function of practice and compared for the effects of the different attitudes induced by instructions.

Knox, G.W. INVESTIGATIONS OF FLICKER AND FUSION: II. THE EFFECT OF THE STIMULUS PATTERN ON THE CFF. *J. gen. Psychol.*, 1945, 33, 131-137. (Ohio State University, Columbus, Ohio).

This study investigated the question of whether a series of figures, differing in their degree of stability (simplicity and symmetry), would have the same arrangement in regard to their CFF, but in reverse order. A series of 9 geometric figures having equal areas but differing in degree of stability were selected. CFF's were determined on 5 Ss, with and without an artificial pupil, for each of the 9 stimulus patterns. Both individual and average CFF readings of all Ss for all the patterns and conditions were analyzed. There was no consistent relationship of the results to perceptual stability. (HEIAS)

Knox, G.W. INVESTIGATIONS OF FLICKER AND FUSION: III. THE EFFECT OF AUDITORY STIMULATION ON THE VISUAL CFF. *J. gen. Psychol.*, 1945, 33, 139-143. (Psychology Dept., Ohio State University, Columbus, Ohio).

A study was made of the effect of auditory stimulation on CFF. 5 Ss were used and a total of 800 CFF readings were taken; each S went through the same procedure (simultaneous visual and auditory stimuli) except that 2 were instructed to attend to the visual stimulus, 2 to attend the auditory stimulus, and 1 had no instructions. The visual CFF readings (half during increase and half during decrease of flash frequency) were taken during one of 4 auditory situations: silence, fusion, fine flicker, and coarse flicker. Under the above conditions no significant effects on the CFF were found for any of the 4 auditory situations. (HEIAS)

Knox, G.W. INVESTIGATIONS OF FLICKER AND FUSION: IV. THE EFFECT OF AUDITORY FLICKER ON THE PRONOUNCEDNESS OF VISUAL FLICKER. *J. gen. Psychol.*, 1945, 22, 145-154. (Psychology Dept., Ohio State University, Columbus, Ohio).

A study of the effect of auditory flicker on the pronouncedness of visual flicker was made. The experimental procedure involved a method of measuring the relative increased degree of visual flicker induced by various degrees of auditory flicker. 3 Ss were used, 1 with an auditory set, 1 with a visual set, and 1 with a neutral set. 5 min. of dark adaptation were given before each sitting, and an artificial pupil was used throughout. The auditory stimulus was varied in steps from 15 to 30 cps with the visual flash frequency to give the same degree of visual flicker as was previously present when a non-intermittent sound stimulus was present with either 16 or 24 cps. It was concluded that visual flicker already present does increase in pronouncedness in the presence of auditory flicker. The slower the auditory flash frequency, the more pronounced is both the auditory and visual flicker. When no intermittent auditory stimulus is present, the visual flicker rate tends to increase as the visual flash rate is increased, but when the auditory intermittent stimulation is present, then the visual flicker rate becomes almost independent of the visual flash rate, and tends to keep in step with the auditory flicker rate. Attitude or set may affect the degree of auditory-flicker inter-influence. (HEIAS)

Knox, G.W. SOME EFFECTS OF AUDITORY STIMULI ON THE PERCEPTION OF VISUAL FLICKER. *Amer. J. Optom. & Arch. Amer. Acad. Optom.*, 1953, 30(10), 520-525. (School of Optometry, Ohio State University, Columbus, Ohio).

A report of 2 investigations on the measurement of auditory influences on visual flicker is presented. a) 5 Ss made a total of 800 CFF judgments taken during 4 auditory situations: auditory silence, auditory fusion, a fine auditory flicker, and a coarse auditory flicker. Half the readings were taken during increase of visual flash frequency and half during decrease. b) 3 Ss attempted to match visual flicker to auditory stimuli of 15, 18, 21, 24, 27, and 30 cps; 1 S was instructed to attend to the visual stimulus primarily, 1 to the auditory stimulus, and the third was given no instructions. Under the conditions of the first study no S showed any significant effects of auditory stimulation on the visual CFF with or without the use of an artificial pupil. Although the auditory stimulus did not induce a visual flicker not already in existence, it did increase the pronouncedness of the flicker if it was already present. In the second study it was possible to match visual and auditory experience of flicker; the influence of instructions was present in that the curve of greatest slope represented the data of the S who concentrated on the auditory stimulus, while the curve of the least slope was for the S who concentrated on the visual stimulus; the neutral S slope was intermediate. Landis, C. & Humei, Violet. THE EFFECT OF CERTAIN PHYSIOLOGICAL DETERMINANTS ON THE FLICKER-FUSION THRESHOLD. *J. appl. Physiol.*, March 1954, 6 (9), 566-572. (N.Y. State Psychiatric Institute, New York, N.Y.).

Flicker-fusion thresholds (CFF) in groups of 10 determinations were obtained from 10 normal observers at hourly intervals during 10 working days, together with oral body temperature. Basal metabolic rates were obtained on 9 of the 10 observers and pulse rates on 2 of these observers. Analysis of this material demonstrated that there is a fairly constant diurnal CFF rhythm, the pattern of which is specific for each individual. In 3 out of 10 instances this CFF rhythm was correlated positively with oral temperature; in 5 out of 10 instances it was negatively correlated; and in 2 instances no relationship was found. Various features of the metabolic rate were more highly correlated with the variability of the CFF measures than with the mean of such measures. The relationship between pulse rate and CFF was not clear.

Landis, C. CROZIER AND WOLF ON FLICKER-FUSION, 1933-1944. *J. Psychol.*, 1954, 37, 3-17. (Psychiatric Institute, Columbia University, New York, N.Y.).

A critical survey of the publications of Crozier and Wolf dealing directly or indirectly with the problem of flicker-fusion is presented. The prime reason for this survey was the relative inaccessibility of their work to many investigators working in the field of vision. The following topics are considered: theoretical assumptions; notation; nature of flicker-fusion; methods and materials; determinants; the F-log I contour; the slope of F-log I contours; Tau prime or the inflection point; and F max; fovea vs periphery; rods vs cones; duplexity theory; area, size, location; intensity; brightness; frequency; time-energy relation; Talbot's Law; light-dark ratio; temperature; genetics; binocular vs monocular effects; division of field; striation; Pecten effect; hue; and sensory effects. Critical comments are placed at the end of the paper. (HEIAS)

Krendel, E.S. NOTES FROM THE FRANKLIN INSTITUTE LABORATORIES FOR RESEARCH AND DEVELOPMENT. *J. Franklin Inst.*, March 1952, 253 (2), 251-253.

A simplified airplane simulator was built which consisted of a bucket seat, joy stick, and an oscilloscope mounted at eye-level before the pilot. This device was used in preliminary experiments to indicate whether the method of spectral density analysis is applicable to the study of human tracking responses in the larger and more complicated dynamic airplane simulator. The visual stimulus, or input, is presented as a series of step deflections in the horizontal dimension on the oscilloscope screen. The program of deflections of the pip consists of a time series of pulses whose average number of crossings is determined by sampling a Poisson distribution. Frequencies of from zero to about 3 cps constitute this statistical input. The pilot's task is to manipulate the controls to keep the pip on a central vertical reference line; the error signal is the instantaneous position of the pip, and diminishes as the pilot restores the pip to the vertical reference line. Spectral density comparisons for 1 well-trained S are presented graphically. (HEIAS)

Lorr, M. & Fields, V. A FACTORIAL STUDY OF BODY TYPES. *J. clin. Psychol.*, April 1954, 10 (2), 182-185. (US Veterans Administration, Washington, D.C. & USN Bureau of Naval Personnel, Washington, D.C.).

This study tested the hypothesis that there are 3 differentiable independent groups into which the adult human male body type can be classified. The populations consisted of photographs of hospitalized male psychotic patients; 15 photographs were chosen, 5 for each of the 3 somatotypes of Sheldon—the extreme endomorph, ectomorph, and mesomorph. Using 3 aspects of the S's photograph, linear morphological measurements were made; height and weight were taken from information recorded on the photographs, and ratings were made of fatness and muscularity by the 2 authors on a 6-point scale and averaged. The 36 measurements and ratios were converted to standard scores, intercorrelations computed, and the correlational matrix factored by the centroid method. 2 factors were extracted: a) Person factor A was bipolar and defined at either end by the endomorphs and ectomorphs and relates to fatness primarily; b) Factor B was defined by the mesomorphs as a group and relates to muscularity primarily. The existence of 3 distinguishable groups and 2 body factors has been demonstrated; the 3 groups exhibit morphological trait patterns that closely resemble the patterns descriptive of Sheldon's components. The findings also suggest that the 76 somatotypes identified by Sheldon can more simply and economically be defined in terms of measurements on only 2 type factors. (HEIAS)

Recherer, S. & Scheritz, Anita. A HOMEOSTATIC EFFECT OF MOOD ON ASSOCIATIVE ABSTRACTNESS AND REACTION TIME. *J. Personality*, Sept. 1952, 21(1), 59-67. (Kings County Hospital & State University of New York, College of Medicine, Syracuse, N.Y. & Manhattan State Hospital, New York, N.Y.).

RT and the level of abstraction characterizing responses on Word-Association tests are customarily taken as indicators of affectively charged complexes and as expressively symptomatic of characteristic personality attributes. The hypothesis tested here holds that, in line with the concept of homeostatic defense these 2 measures fluctuate also as a function of the correspondence or noncorrespondence of the affective tone of the stimulus word with the S's prevailing mood. 31 adult Ss were tested with the Depression Scale of the MMPI (criterion for prevailing mood) and with an association word list of 30 positively and 30 negatively toned adjectives. Correlations between MMPI depression and association-test depression were a) for contrast responses .46; b) for adjective-noun responses .33; and c) for RT .45. It was concluded that the prevailing mood of the respondent does operate homeostatically, exercising a selective influence on associative abstraction and RT, depending on the mood implication of the stimulus. Abstract associations (contrast responses) are facilitated when the stimulus word threatens the S's prevailing mood, while concrete associations (adjective-noun responses) are facilitated when the stimulus word corroborates the mood. RT is decreased when the word threatens prevailing mood, and lengthened when it corroborates mood. (HEIAS) R 11

Feyer, D.R. THE STABILITY OF HUMAN GUSTATORY SENSITIVITY DURING CHANGES IN TIME OF FOOD DEPRIVATION. *J. comp. physiol. Psychol.*, Aug. 1952, 45, 373-376. (Ohio State University, Columbus, Ohio).

In this experiment 9 human Ss abstained from all foodstuffs for a period of 34 hr., during which time successive determinations of sweet, salt, and bitter thresholds were made at 3-hr. intervals. The hypothesis under examination was that changes in the threshold concentration of glucose would accompany the reduction of readily available energy compounds. Salt and bitter thresholds were studied to provide controls for the effects of extraneous variables. No systematic changes were found for any of the 3 modalities. The data do not support the suggestion that one concomitant of need is a sensitization of receptors to need-reducing substances in the environment. R 4

Morin, R.E. & Gagne, R.M. PEDESTAL SIGHT MANIPULATION TEST PERFORMANCE AS INFLUENCED BY VARIATIONS IN TYPE AND AMOUNT OF PSYCHOLOGICAL FEEDBACK. Proj. 509 020 0007, Res. Note FAMS 51 7, Oct. 1951, 13pp. USAF Human Resource Research Center, Lackland AFB, Tex.

5553

This study dealt with variations in the kind and amount of supplementary feedback supplied to a ranging response as they affect subsequent performance without on-target information. Performance on the Pedestal Sight Manipulation Test was measured under four experimental conditions: with supplementary feedback (visual or auditory) supplied on a given percentage of trials (100 or 50 percent). Five groups of 20 basic airmen each practiced under a given condition for 11 trials. Adjusted scores for time on target on a final trial with no supplementary feedback were compared with scores obtained by a control group that had had no previous extra feedback. T. G. R 7

Murphree, O.D. MAXIMUM RATES OF FORM PERCEPTION AND THE ALPHA RHYTHM: AN INVESTIGATION AND TEST OF CURRENT NERVE NET THEORY. *J. exp. Psychol.*, July 1954, 48(1), 57-61. (US Veterans Administration Hospital, North Little Rock, Ark.).

Cyberneticists and mathematical biophysicists have hypothesized synchronous scanning neurologic processes, particularly the alpha rhythm, which mediate the visual perception of form or shape. From these hypotheses certain deductions (for the most part concerned with a quantum time factor as implied in any scanning process) were made and experimentally tested. The results show: a) There is a significant relation between the alpha rhythm and the temporal aspect of rapid successive spatial perceptions. This relation may be considered as curvilinear, or possibly, linear to the difference between alpha and some other value which in central tendency nearly coincides with alpha. b) Strong support is indicated for the view that maximum rates of form perception, apparent motion, figure-ground reversals (at appropriate rates), and fusion of separate spatial elements into simultaneously perceived composite forms or shapes are mediated by a nerve net of which the alpha rhythm is an integral part. Rubin, L.S. THE EFFECT OF ATROPINE ON THE DARK ADAPTATION THRESHOLD. CWLR 2019, Proj. 4-06-02-019-01, April 1956, 15pp. Chemical Warfare Laboratories, Army Chemical Center, Md.

5557
To determine the effect of a small (two milligrams) injection of atropine sulfate on dark adaptation and to determine the effect of practice on threshold measurements, twelve naive subjects were tested. The course of dark adaptation was determined (eight subjects) in a preliminary session, one practice trial per day for three days was given and final measurements were made twenty minutes after injection with a saline or atropine sulfate solution. Absolute threshold determinations (four subjects) were obtained over a twenty-minute period beginning 58 minutes after injection and after practice had been given on three previous days. The data were studied by analysis of variance for effects of practice and drug. Recommendations are included.

Kinney, Jo Ann S. SENSITIVITY OF THE EYE TO SPECTRAL RADIATION AT SCOTOPIC AND MESOPIC INTENSITY LEVELS. J. opt. Soc. Amer., July 1955, 45(7), 507-514. (USN Medical Research Lab., USN Submarine Base, New London, Conn.).

Spectral sensitivity curves were established for 3 intensity levels above scotopic threshold with a 2-degree field placed 10 degrees from fixation against a dark surround. These curves were compared with the minimum scotopic luminosity curve determined for the same retinal position for each observer. The results showed that a) there is a range of intensities over which relative spectral sensitivity does not change appreciably from the scotopic luminosity function, b) there are irregularities in these mesopic curves which may be attributed to cone activity, and c) the first change in spectral sensitivity with increased intensity is found in the long-wavelength half of the spectrum.

Gerathwohl, S.J. BRIGHTNESS CONTRAST AND TARGET IDENTIFICATION THRESHOLDS ON THE RADAR PPI. J. Aviat. Med., Oct. 1955, 26, 399-408.

An exhaustive study of brightness contrasts at the various target identification thresholds and appearance levels was completed just recently, which covers the practical range of sweep brightness during radar PPI interpretation. The data have not been evaluated statistically, but they may prove to be a gold mine for the statistician as well as for the engineer. Brightness and contrast differences seem to exist between the 2 types of sweep rotation, 2 degrees of basic sweep brightness, 5 target identification thresholds or video gain settings. This conclusion is made after an inspection of the graphically plotted raw data. These differences, and the effect of the many variables controlled in this experiment, can be expressed quantitatively after a thorough statistical analysis of the results. The major variables in radar scope interpretation, namely, brightness contrast and the uniformity of the viewing conditions, were discussed. Some of the functions relating the visual to the physical variables of the radar display will be better understood, and more improvements in equipment and working conditions furnished when we learn more about the action and interaction of the perceptual factors involved in the interpretation of radar PPI presentation.

Hanawalt, N.G. THE METHOD OF COMPARISON APPLIED TO THE PROBLEM OF MEMORY CHANGE. J. exp. Psychol., Jan. 1952, 43(1), 37-42. (New Jersey College for Women, New Brunswick, N.J.).

5561
In an experimental test of progressive changes in the memory trace of visual form, 447 Ss (female college students) were presented with six simple visual forms and were required after one of three intervals to view the form again and to report whether each was greater or less than the "original" with respect to some specified characteristic. Results were presented as percentage of "greater" judgments for comparison after each interval and were compared with those obtained by other investigators who used a method of successive comparison.

Davidson, A.L., Devoe, D.B., Spragg, S.D.S. & Green, R.F. ACCURACY OF KNOB SETTINGS AS A FUNCTION OF: I. THE PLANE IN WHICH THE KNOB TURNS; AND II. THE DIAMETER OF THE KNOB. Contract N600R 241, T.O. 6, Mech Engrg. Rep. SCU 241 6 8, Jan. 1953, 10pp. University of Rochester, Rochester, N.Y.

5563
To determine how the plane in which the control knob rotates and the diameter of the knob affect accuracy of knob settings, an apparatus was constructed permitting the variation of plane of rotation, knob size, and size of angle. The limits of each angle were indicated by a pair of mechanical stops. The subject sampled the angle by turning first one way, next the other, and then made his final setting (bisection or duplication). In the first experiment, tests were made in three planes--front, side, and top. In the second, eight knob diameters, ranging from 0.5 to 5.0 inches, were used. In both, the angular extents tested were 20, 40, 60, and 160 degrees. Design recommendations are included.

Deese, J. SOME PROBLEMS IN THE THEORY OF VIGILANCE. Psychol. Rev., 1955, 62(5), 359-368. (Johns Hopkins University, Baltimore, Md.).

5566
This paper is concerned with specifications for a concept of vigilance. The basic assumption is that the maintenance of a given level of vigilance in an observer depends to some extent upon stimulus events extrinsic to the observer. Alternative hypotheses--reinforcement and expectancy--concerning the exact nature of the stimulus events, sufficient for the control of vigilance, are discussed. Experimental evidence is drawn from studies in which observers search for small signals, at near-threshold value, the exact location and time of occurrence being unpredictable. A brief consideration of the need for an inhibitory construct is presented.

Fruchter, B. MEASUREMENT OF SPATIAL ABILITIES. Educ. psychol. Measmt., 1954, 14, 387-395. (University of Texas)

5569
To compare the magnitudes of errors of aim and errors of extent in simple discrete movements carried out at high rate and in different directions relative to the position of the body, 48 subjects were required to draw four lines in succession from a starting point to a target as fast as possible. Four directions of movement were compared. Errors of extent (under- and over-shooting) and errors of aim (deviations to right or left) were recorded as was duration of movement. It is suggested that the results be considered as important for future design of displays and controls for certain specific equipments.

Gerathwohl, S.J. INVESTIGATION OF PERCEPTUAL FACTORS INVOLVED IN THE INTERPRETATION OF PPI-SCOPE PRESENTATIONS. Proj. 21 24 009, Rep. 1, Sept. 1950, 17pp. USAF School of Aviation Medicine, Randolph Field, Tex.

This report is a survey of literature dealing with a) tests used for the selection of radar operators, b) psychological experiments in radar, and c) perceptual problems of PPI-scope interpretation. The validity of selection tests for radar observers after World War II showed no well-defined correlation between the individual test scores and the results of radar training. The investigations of the visibility on radar scopes are concerned mainly with the physical and psychophysiological sides of the problem; however, there has been no study of the factors underlying the perceptual processes on the basis of Gestalt psychology. Under actual conditions, however, the radar observer must interpret scope presentations which are due to brightness differences. Therefore, the investigations of the figure-ground relationships, the phenomenon of figure development, the significance of contours, the perception of contrasts, and signal localization on the scope constitute basic problems in target identification. The contribution of Gestalt psychology to the problem of target identification is discussed. The experimental approach to the use of the Supersonic Trainer is outlined.

Gerathwohl, S.J. CONSPICUITY OF STEADY AND FLASHING LIGHT SIGNALS: VARIATION OF CONTRAST. J. opt. soc. Amer., July 1953; 43(7), 567-571. (Ophthalmology, USAF School of Aviation Medicine, Randolph Field, Tex.)

In the past, 2 measures have been used to express the comparative effectiveness of steady and flashing light signals. These are comparative intensities a) required for threshold; and b) required for equal apparent brightness above threshold. The 2 measures agree in showing that the effectiveness of flashing signals is less than that of steady signals, when the intensity of the light phases of the flashing signal equals the intensity of the steady signal. The present study compares steady and flashing light signals with respect to conspicuity, defined as the speed of response to a signal above threshold. For large signal contrasts the conspicuity of steady and flashing signals is approximately equal. For small contrasts the conspicuity of flashing signals is considerably greater. These results suggest that flashing rather than steady signals be used for warning purposes.

Gerathwohl, S.J. EYE MOVEMENTS DURING RADAR OPERATIONS. J. aviat. Med., Dec. 1952, 23; 597-607. (USAF School of Aviation Medicine, Randolph Field, Tex.)

The eye movements involved in radar operation are more complex than under normal observational conditions. Using an ophthalmograph in combination with radar equipment, eye movements were recorded during simple tasks of orientation, navigation, target identification, and bombing missions. Special attention was given to the duration and number of interfixation movements and fixation phases, direction and kinematic pattern of the movements, as well as to their stability and synchronization. The following results were obtained: a) During radar observation the eyes do not "ride the sweep" but follow the sweep in jerks, the number of which depends mainly upon the operational task. This number is highest during orientation and decreases with navigation and target identification. b) The duration of the movement depends upon their extension. During orientation, navigation, and target identification the interfixation time amounted to about 30-35 ms; during bombing to about 20 ms. c) The duration of fixation depends upon what the observer is after. It increases from about 430 ms during orientation, to about 475 ms during navigation, to about 830 ms during target identification, finally, to about 1,270 and 1,815 ms for the 2 types of sweep movements during bombing. d) A characteristic kinematic pattern was found with alternating phases of circular and linear eye movements, the periodicity of which is imposed by the continuously rotating sweep. No circular eye movements were recorded during bombing. e) 2 characteristic types of eye movements were recorded: search movements during orientation and also during navigation, and probing movements during target identification and bombing. f) Synchronization of the movements of the 2 eyes and stability of fixation declined with increasing angle and frequency of the eye movements.

Gerathwohl, S.J. PHYSICS AND PSYCHOPHYSICS OF WEIGHTLESSNESS-VISUAL PERCEPTION. J. aviat. Med., Aug. 1952, 23; 373-395. (USAF School of Aviation Medicine, Randolph Field, Tex.)

The rationale of this study was an investigation of the problem: whether and how visual perception will be affected during the transition of man in the sub-gravity and zero-gravity states. An extrapolation from the literature on the relationship between proprioceptive and visual perception, an extrapolation to the conditions of weightlessness was made on a purely theoretical basis. A consideration of the pertinent anatomical and physiological characteristics of the eye led to the conclusion that the effect of weightlessness would not be important here. However, there is a high probability that visual perception will be affected by psychophysiological stimulations and that visual illusions will occur. The types of illusions are analyzed and their importance for the position and direction orientation in the state of weightlessness are discussed. (HEIAS)

Gerathwohl, S.J. CONSPICUITY OF FLASHING AND STEADY LIGHT SIGNALS. I. VARIATION OF CONTRAST. Special Rep., April 1951, 8pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A question of some importance in the design of visual warning devices concerns the type of light stimuli used. In order to investigate the conspicuity of steady light stimuli and intermittent light stimuli, which are frequently employed for this purpose, a series of 4 experiments was conducted with constant and flashing light signals at contrast ratios of 100, 74, 52, and 33 percent. In these experiments, the response time to the 2 types of light was considered a measure of their conspicuity. The results obtained demonstrate a) that the conspicuity of the signals is a function of contrast, b) that when a multiple complex reaction test must be performed by the observer--flashing light signals are more conspicuous than steady light signals at medium levels of brightness contrast. The applicability of these findings to the construction of warning devices and in radar research is briefly discussed.

Gerathwohl, S.J. STUDY OF ACCLIMATIZATION DURING A TWO-WEEK EXPOSURE TO MODERATE ALTITUDE. *J. Aviat. Med.*, April 1954, 25, 156-163. (USAF School of Aviation Medicine, Randolph Field, Tex.).

Complex reaction experiments were made at ground level (761 ft.) and at moderate altitude (10,152 ft.) in order to study the effects of mild hypoxia on psychomotor performance, and to find out whether or not acclimatization occurs during a period of 13 days. From our results the following conclusions can be made: a) Although the statistical analysis of the group scores obtained at ground level and at altitude did not differentiate between the periods at an accepted level of confidence, the group mean scores of correct responses obtained at the first altitude tests are consistently lower than the mean scores of the last pre-altitude tests. This and another statistical analysis of these data (not reported in this paper) indicate a real decline of performance interpreted as a mild hypoxia effect. b) No correlations seem to exist between the total number of responses and altitude. c) The statistical analysis yielded large variations between individuals. This and an inspection of the individual curves revealed characteristic differences in sensitivity to hypoxia. After all, 2 of the 9 SS showed a pronounced loss in performance during the whole altitude period. d) On the other hand, 7 out of the 9 test SS became acclimatized with a period of 13 days. From this it seems desirable to acclimatize flying personnel to the level of cabin pressure used in high-altitude flying, and to eliminate those persons who do not show the altitude adaptation needed for flying safety.

Fiedler, F.E. SOCIAL PERCEPTION AND GROUP EFFECTIVENESS. Contract N6ori 07135, Proj. NR 170 106, Feb. 1956, 10pp. University of Illinois, Urbana, Ill.

5576

To test the effects upon team productivity of complexity of assigned tasks and conditions of time pressure, 24 three-man teams performed two practical tasks, one relatively simple and one more complex. Each task involved the successive assembly and disassembly of an easy wooden replica of a non-representational construction model as possible within a 20-minute work session. Time pressure was manipulated, by varying the frequency of interrupted oral signals giving the amount of time remaining, to establish low, medium and high levels. Productivity data (weighted total of number of correct task operations performed) were analyzed for effects of task complexity, time pressure, order of work session and their interactions. Some implications for research and practical situations are noted. T.I. R 5

5578

This is the fourth annual progress report of a research study concerned with the identification of psychological variables which differentiate between effective and ineffective team work and the development of principles and methods for assembling teams. The progress in each of the following studies of group effectiveness as related to social perception is reported briefly: open hearth steel manufacture which requires the coordinated efforts of several interdependent crews, instructor and student groups engaged in Navy formation flight training, and the board of directors and management in a sales cooperative organization. Two methodological studies are noted as being in progress. A list of reports and publications is appended.

Gerathwohl, S.J. COMPARATIVE STUDIES ON ANIMALS AND HUMAN SUBJECTS IN THE GRAVITY-FREE STATE. *J. Aviat. Med.*, Aug. 1954, 25, 412-419. (USAF School of Aviation Medicine, Randolph Field, Tex.).

A survey of the work done on the investigation of weightlessness, and the progress made during 5 years of research in this field of space medicine is made in this paper. The discussion is limited to the psychophysiological aspects of the problem. These concern mainly the question whether the powers of orientation and sensorimotor coordination are disturbed under subgravitational conditions. Animal studies have shown, by and large, that there are movements and symptoms of disorientation at first but animals learn to compensate by cues of visual orientation. Human studies made during parabolic flight indicate that man also shows symptoms of disorientation and loss of motor coordination during the transition into weightlessness and during its early stage. They perform better when more tactile and visual cues are provided and they become better oriented with successive tests. These findings are taken as indications that it may be possible to adapt to the gravity-free state. (HEIAS)

Gerathewohl, S.J. & Cibis, P.A. THE SPACE BETWEEN DISTINCT CONTOURS. *Amer. J. Psychol.*, July 1953, 66(3), 436-448. (USAF School of Aviation Medicine, Randolph Field, Tex.)

In a series of experiments the appearance of homogeneous and heterogeneous surfaces was investigated as to their apparent slant and curvature. For this purpose a white H-shaped target was used as test figure. The target was viewed with different retinal illumination in the 2 eyes and when parts of it were shaded. 4 professional draftsmen served as Ss; their task was to reproduce the appearance of the size and position of the target (front view and projection as seen from above) while target was exposed. No time limit was imposed. The results were qualitative in nature representing an analysis of the drawings of the 2-dimensional target, all of which were represented as appearing partly or totally deviated from their actual plane. In all tests the vertical bars were seen as plane; but the horizontal bars as curved in most cases. In the case of shadows producing sharp boundaries, there was an apparent breaking and dislocalization of the illuminated parts of the target, while blurred or faint boundaries elicited an apparent curvature of the surface. The results are interpreted as suggesting that the perception of visual space depends (among other things) upon a) location, size and shape of surface contours or their alteration through differences between the retinal illumination of the 2 eyes and b) the total or partial brightness (luminance) of the object determining apparent shape, slant and curvature of a surface. Gerathewohl, S.J., Haber, H., Byrnes, V.A., Ripple, P.H., et al. A STUDY OF RUNWAY MARKINGS Proj. 21 24-001, Rep. 4, Jan. 1951, 22pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Based on the findings of the reports on runway markings the usefulness of the chevron as a basic marking and the effectiveness of runway marking patterns were tested under field conditions. Using tar paper frames individual chevrons varying in size and apex angles, groups of chevrons, and longitudinal lines were laid out. Furthermore, 2 systems of marking patterns were painted on both the Zuehl and the Mertindale auxiliary fields. The various patterns were tested with a total number of 6 flight tests and a larger number of passes and simulated landings with various types of aircraft. About 60 observers took part in the field tests. As a result of these tests a runway marking pattern was devised. This pattern, described in detail in this report, is believed to constitute the best compromise between all factors involved.

Gerathewohl, S.J. & Taylor, W.F. EFFECT OF INTERMITTENT LIGHT ON THE READABILITY OF PRINTED MATTER UNDER CONDITIONS OF DECREASING CONTRAST. *J. exp. Psychol.*, 1953, 46(4), 278-282. (USAF School of Aviation Medicine, Randolph Field, Tex.)

The utilization of the Bartley effect for the improvement of readability under conditions of low contrast was investigated. A reading chart with gradually decreasing brightness contrast was read under steady and flicker conditions with 4 different light-dark ratios and 2 flicker frequencies (9 and 15 cps). The number of lines read was accepted as index of readability and, in a more general way, as index of visibility under low $\Delta L/L$ conditions. It was found that the effect of flicker was to lower the number of lines read especially at low illumination levels. For this reason it seems doubtful that flicker can be used for the improvement of visibility under conditions of low contrast.

Gerathewohl, S.J. & Strughold, H. MOTORIC RESPONSES OF THE EYES WHEN EXPOSED TO LIGHT FLASHES OF HIGH INTENSITIES AND SHORT DURATION. *J. aviat. Med.*, June 1953, 24, 200-207. (USAF School of Aviation Medicine, Randolph Field, Tex.)

A series of experiments were conducted to obtain information about the complete motoric response pattern of the eyes when exposed to light flashes of high intensity and short duration. Responses of the eye were recorded photographically. 20 Ss were studied under various conditions. In the case of an unexpected flash, a blinking reflex occurred in most cases with a latent period from 60 to 80 msec, thus occurring too late to be of any protective value to the eye. The blinking period lasted about 0.3 sec. Only slight eye movements were sometimes observed and seemed to be reactions associated with the lid reflex. In the case of voluntary eye movements (S expected flash and was instructed to move eyes away; S did not know when light would occur and was instructed to move eyes to it) the latent periods are about 3 times longer than those of the blink reflex. Such movements cannot be used as protection against light flashes.

5591
In a study on the relation between certain personality variables and the learning process, 11 college students in a social science class were given Rorschach tests. Scores on their personality traits inferred from performance on the Rorschach test—Anxiety, rigidity, and negativism—were correlated with scores on college aptitude tests, placement examinations, and scores on a comprehensive examination on the social science course. Verbally recalled "thoughts" during class discussion were analyzed for each subject with respect to source, emotionality, orientation, and objectivity.

5594
To study factors governing information flow in task-oriented groups, ten groups of five subjects each were conditioned in one communication network and tested in another. The task was to discover, through seeking and receiving written messages, the number assigned to each member of the group. Attitude and information questionnaires were filled out upon completion of each problem. Group results for time, number and content of messages, and errors were analyzed. Individual message destinations and time data were studied. Subject's knowledge of the network and attitudes toward experiences in the group were examined. Conclusions from this and previous studies were drawn with some generalizations concerning future developments and applications.

Miller, G.A. & Mitchell, S. EFFECTS OF DISTORTION ON THE INTELLIGIBILITY OF SPEECH AT HIGH ALTITUDES. *J. Acoust. Soc. Amer.*, Jan. 1947, 19(1), 120-125. (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.).
With mask-microphone combinations having relatively uniform response characteristic at high altitudes, no significant improvement in the intelligibility of speech was obtained by frequency distortion in the associated equipment. Amplitude distortion in the form of sharp, symmetrical peak clipping had several advantages: a) a more favorable S/N ratio was established, b) a constant percentage modulation can be obtained for A.N. radio speech communications, and c) the range of speech levels at different altitudes was somewhat compressed. Before speech at high altitudes is peak clipped, however, it may be necessary to filter out frequencies below about 500 cps, and for radio transmission it is probably advisable to insert a simple, low pass filter after the clipping circuit in order to reduce the possibility of interchannel interference.

5601
A statistical model is presented describing free recall after verbal learning. It is based on the assumption that the probability of recalling a word on a given trial is determined completely by the number of recalls of the word made on previous trials. Three specific cases of the models (1-, 2-, and 3-parameter cases) are examined, each of which makes certain assumptions about the proportions of stimulus elements sampled during conditioning and during recall and about the possibility of the attaining of perfect performance. These three cases are applied to three sets of experimental data obtained from the recall of monosyllables.

Miller, G.A. THE MASKING OF SPEECH. *Psychol. Bull.*, March 1947, 44(2), 105-129. (ONR, Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.).

A wide variety of sounds have been investigated to determine the extent to which they interfere with vocal communication. The masking of speech has been determined by articulation-testing methods, and estimates of annoyance have been obtained by the method of paired comparisons. The sounds are classified as noises, tones, and voices. For all 3 types of sound, the stimulus-dimensions determining both masking and annoyance are the intensity, the frequency or spectrum, and the temporal pattern of the sound. Masking depends primarily on the speech-to-noise ratio over the range of frequencies involved in speech. Sounds of low frequency mask this range more effectively than sounds of high frequency. Interruptions in the sound decrease the masking effectiveness. Annoyance also increases as the intensity is raised; but low-frequency sounds are less annoying than high-frequency sounds, and intermittent, irregular sounds are more annoying than continuous sounds. There is no evidence, however, that annoyance interferes with vocal communications in the laboratory situation.

Miller, G.A. SENSITIVITY TO CHANGES IN THE INTENSITY OF WHITE NOISE AND ITS RELATION TO MASKING AND LOUDNESS. *J. acoust. soc. Amer.*, July 1947, 19(4) Part 1, 609-619. (ONR, Rep. PNR 28, Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.).

Sensitivity to changes in the intensity of a random noise was determined over a wide range of intensities. The just detectable increment in the intensity of the noise is of the same order of magnitude as the just detectable increment in the intensity of pure tones. For intensities more than 30 db above the threshold of hearing for noise the size in decibels of the increment which can be heard 50% of the time is approximately constant (0.41 db). When the results of the experiment are regarded as measures of the masking of a noise by the noise itself, it can be shown that functions which describe intensity discrimination also describe the masking by white noise of pure tones and of speech. It is argued, therefore, that the determination of differential sensitivity to intensity is a special case of the more general masking experiment. The loudness of the noise was also determined, and just noticeable differences are shown to be unequal in subjective magnitude. A just noticeable difference at a low intensity produces a much smaller change in the apparent loudness than does a just noticeable difference at a high intensity.

Miller, G.A. THE PERCEPTION OF SHORT BURSTS OF NOISE. *J. acoust. soc. Amer.*, March 1948, 20(2), 160-170. (ONR, Rep. PNR 42, Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.)

Short bursts of random noise were used to study the perceptual growth and decay of the noise experience. Noise, unlike sinusoidal tones, does not change materially in spectrum as the duration of the sound is varied. A short burst of noise must be more intense in order to be equal in effectiveness to a longer noise. Thus the threshold of hearing is lowered by increasing the duration of the noise up to durations at least as long as 1 sec. The loudness of an intense noise, however, depends upon its duration up to durations of only 65 msec. Judgments of the slowest rate of decay of a noise which sounded indistinguishable from an abrupt termination also led to the concept of a critical time of approximately 65 msec. for the sensation to decay to threshold from any steady magnitude of stimulation. From these data it is inferred that the auditory system acts as if the growth and decay periods of the noise perception depend upon differences in latencies among the various neural paths in transmitting the cochlear activity to the higher centers in the brain. According to this hypothesis, the activity in the slowest pathways arrives at the higher center 65 msec. after the activity of the fastest pathways. By means of this hypothesis it was possible to predict the judgments of time of termination of noises in the 2 ears when the intensity of the noise differed between the ears.

Geldreich, E.W. SOME PHYSIOLOGICAL CONCOMITANTS OF MENTAL WORK. *Psychol. Monogr.*, 1953, 67(8), No. 358, 1-28. (San Diego State College, San Diego, Calif.).

A study of some of the physiological variables of mental work was conducted. The task was to identify 5 colors presented serially in random order by manual response at rate determined by the practiced facility of each of 10 Ss. Continuous records were made of changes in respiration and heart beat, relative blood pressure, finger volume, palmar skin conductance, and GSR. On 10 different days each S spent 55 min. as follows: a) 4 days of color naming responses; b) 2 days random tapping of the 5 keys while blindfolded; c) 2 days of passively looking at the color presentations; and d) 2 days of rest. On the basis of data analysis and comparisons for the various conditions the conclusions were as follows. The trends of changes in the rate of color naming and blocking are not due to chance but to factors present in the mental work operation and the organization of the worker. Changing physiological activities reflect changes in energy mobilization. As color-naming work output decreases, the amount of energy mobilized decreases. Mental work output is a function of the momentary mobilization of energy, the momentary and previous conditions of the circulatory and neuromuscular systems, and the momentary receptivity of the S to further stimulation. Fiedler, F.E. ASSUMED SIMILARITY MEASURES AS PREDICTORS OF TEAM EFFECTIVENESS. *J. abnorm. soc. Psychol.*, July 1954, 49(3), 381-388. (University of Illinois, Urbana, Ill.).

5621
To test the hypothesis that group effectiveness is related to the interpersonal perceptions which members of the group have toward one another, a series of correlated studies were made. Interpersonal perceptions were measured by correlating identical questionnaires which subjects were instructed to fill out 1) describing themselves, 2) predicting the responses of their preferred co-worker, and 3) predicting the responses of their rejected co-worker. The first studies used basketball teams and the last used surveying teams. Criteria of effectiveness were proportion of games won and instructor rating on accuracy respectively. The usefulness of this approach to team effectiveness is discussed.

Bender, H.G. & Feldman, D.S. EXTINCTION OF TASTE SENSATION ON DOUBLE-SIMULTANEOUS STIMULATION. *Neurology*, May-June 1952, 2(3), 195-202. (Mt. Sinai Hospital, New York, N.Y. & Neurology and Psychiatry Dept., New York University College of Medicine, New York, N.Y.).
Studies in taste sensation were made in patients with lesions of the brain. In a patient with a glioma in the right parieto-occipital region there was extinction of taste on the left side of the tongue when both sides of the tongue were simultaneously stimulated. Taste threshold obtained with single stimulations was equal and apparently normal on the 2 sides of the protruded tongue. Alterations in cutaneous sensibility most marked on double simultaneous stimulation were also demonstrated. There was crossed extinction between simultaneous taste and cutaneous stimulation. The significance of these phenomena in relation to patterns of alteration of cutaneous sensibility are discussed.

Clark, B., Graybiel, A. & MacCorquodale, K. ILLUSORY ROTATION OF A TARGET DURING TURNS IN AN AIRCRAFT. Amer. J. Psychol., Jan. 1948, 61(1), 50-58. (San Jose State College, San Jose, Calif.)

This study was designed to collect evidence on the apparent motion and displacement of a fixed target in the dark associated with radial and angular accelerations. During both aircraft flights and laboratory simulation, Ss reported on only one aspect of the phenomenon; namely, an apparent rotation of a collimated star about its central axis. Verbal reports were transcribed and analyzed. Both apparent motion and displacement occurred at all degrees of bank from 10° to 60° during entry and also recovery periods; motion was in direction of plane's banking motion and persisted a few seconds beyond recovery. Percentage of occurrence and degree of apparent rotation increased with angle of bank (at 40° it was found at all times); maximal rotary displacement was 15°. The 2 phenomena did not necessarily occur simultaneously. Time lag reported was 4-6 sec. from beginning of maneuver to first appearance with duration of 8.8 sec. for 10° bank to 27.8 sec. for 60° bank. The evidence is interpreted in terms of this illusion being a special case of the oculo-gyral illusion. Effects such as these will occur in the air at night during maneuvers involving angular accelerations above threshold. (HEIAS)

Clark, B. & Graybiel, A. VISUAL PERCEPTION OF THE HORIZONTAL FOLLOWING EXPOSURE TO RADIAL ACCELERATION ON A CENTRIFUGE. J. comp. physiol. Psychol., Dec. 1951, 44(6), 525-534. (San Jose State College, San Jose, Calif. & USN School of Aviation Medicine, Pensacola Air Station, Fla.)

3 experienced subjects were exposed to a series of radial accelerations on a human centrifuge to test the hypothesis that changes in the perception of the horizontal will occur during and following stimulation by radial acceleration. The subjects observed a single, isolated horizontal line in the dark while they rotated counterclockwise on a human centrifuge. Part I of the exp. the subject's task was to maintain the line at a horizontal position by means of a switch, during acceleration to a predetermined rate of rotation which was immediately followed by deceleration. In Part II the procedure was the same as in Part I except that the maximum radial acceleration was maintained for 15 minutes before deceleration began. In each experiment a comparison was made between the subject's judgment of the position of the line and the direction of resultant force determined from theoretical calculation. Within the limits of measurement in this experiment significant changes which could be attributed to prolonged exposure to radial acceleration did not occur. Measures of the threshold of perception showed no significant change following stimulation by the radial accelerations. Settings of the line to horizontal showed no change in constant or variable errors 1 min. following rotation. There were no significant differences between the accelerative and the decelerative phases with regard to the accuracy of setting the line, but the subjects tended to set the line at an angle from the horizontal which was greater than the deviation of the resultant force from gravity. Within the limits of the measures used and for the variables studied in this experiment, prolonged exposure to radial acceleration did not produce consistent aftereffects on the perception of the horizontal.

R 10

5630 Clark, B. & Graybiel, A. APPARENT ROTATION OF A FIXED TARGET ASSOCIATED WITH LINEAR ACCELERATION IN FLIGHT. Amer. J. Otol., April 1949, 32(4), 549-557. (USN School of Aviation Medicine, Pensacola Air Station, Fla.)

The purpose of this study was to determine the effects of linear acceleration and deceleration on the visual perception of a target in the dark. Three Ss observed a collimated "star" in the dark while the pilot of an SNJ-6 aircraft executed various degrees of linear acceleration. The Ss gave a running account of the behavior of the "star" using a throat microphone connected to a wire recorder. When the Ss faced to the left in the aircraft, the radiating lines of the star appeared to rotate about the central point to a new position. This rotation was clockwise during deceleration and counterclockwise during acceleration. As the force became smaller, the star appeared to rotate back to its normal position. This illusory rotation occurred at all stimulus levels. There was also a positive relation between the maximum force and the duration of the illusory effect. The results are similar to those observed on a human centrifuge and show that linear acceleration and deceleration during flight have a marked influence upon visual perception in the dark. Although the observed rotations were small, they were clearly defined and may be considered to be factors contributing to disorientation in pilots.

Clark, B., Johnson, M.L. & Dreher, R.E. THE EFFECT OF SUNLIGHT ON DARK ADAPTATION. *Amer. J. Ophthalmol.*, July 1946, 29(7), 828-836. (USN School of Aviation Medicine, Pensacola Air Station, Fla.)

Individuals exposed to sunlight for 3 to 4 hours a day over a period of 2 weeks show a marked elevation of the night visual threshold immediately following exposure. The degree of elevation persisting overnight is sufficient to cause approximately a 50-percent loss in night visual efficiency. Furthermore, it appears that persons exposed to sunlight for extended periods daily, without protection to their eyes, require in excess of one hour of adaptation to achieve a practical maximum of night visual efficiency. Exposure to brilliant sunlight has been reported as the cause of night blindness that is more or less permanent. However, the present studies on normal individuals indicate that the effects of daily exposure for 3 to 4 hours are only temporary, since the threshold returns to normal after one day's protection from the sun. Persons wearing 12-percent transmission polarizing sunglasses during prolonged exposure to sunlight had significantly lower night-visual thresholds than those who did not. In view of these results, personnel engaging in night duties requiring a high degree of night visual efficiency at starlight intensities should be provided with low-transmission sunglasses to be worn during any daytime activities which expose them to excessive sunlight.

Clark, B. & Malone, R.D. TOPOGRAPHICAL ORIENTATION IN NAVAL AVIATION CADETS. *J. Educ. Psychol.*, Feb. 1954, 45(2), 91-109. (USN School of Aviation Medicine, Pensacola Air Station, Fla.)

A test of topographical orientation and 7 other tests were given to 248 Naval Aviation cadets to study the types of errors in orientation they make, to identify the factors which contribute to this type of disorientation, and to determine what relation there is between topographical orientation and certain other psychological factors. In the test of topographical orientation, large errors were found to be the rule for orientation to individual geographical points. Deviations of the group from proper orientation were as great as 65.1, while some individual deviations from the proper orientation approximated 180°, the maximum possible error. Errors for cities located abroad were greater than for cities within the United States. Deviations from Mercator headings were large, but these errors were much less than for deviations from great circle headings, particularly for cities outside of the continental limits of the United States. Correlations between total score on the test of topographical orientation and other psychological tests were .21 or below; only 3 of them being significantly different from zero. Naval Aviation cadets are poorly oriented to geographical points, particularly as they actually occur on the globe. The notion of great circle relationships between distant cities does not appear to enter significantly into their judgments of the geographical points. Topographical orientation appears to be a unique characteristic which is independent of the factors measured by the current selection battery for cadets as well as certain other factors such as mathematics, spatial orientation, and spatial visualization.

Harris, J.D., Ramsley, Anita I. & Kelsey, Patricia. STUDIES IN SHORT-DURATION AUDITORY FATIGUE: I. FREQUENCY DIFFERENCES AS A FUNCTION OF INTENSITY. *J. exp. Psychol.*, Dec. 1951, 42(6), 430-436. (USN Medical Research Lab., New London Submarine Base, Conn.).

The method of short-duration auditory fatigue allows for rapid accumulation of data since all effects of stimulation with brief tones disappear in usually less than a second. In this experiment, Tone A of 300 msec. was followed after 80 msec. by Tone B of 30 msec. Both A and B were the same frequency, either 256, 512, 1,024, 2,048, 4,096, 5,747, or 8,192 cps. Tone A was set at intensities ranging from 20 through 70 db sensation level. Fatigue was calculated as the difference in threshold of Tone B preceded and not preceded by Tone A. A comparison of fatigue among frequencies was made when they were equated as to intensity, loudness, and sensation level. Equating as to intensity led to curves which bear similarities to isophonic contours, and lends some support to Lüscher and Zwislocki's view that the frequency characteristic depends upon intensity rather than loudness. A family of fatigue curves equated for loudness shows that, especially at equal-loudness levels of 40 phons and above, fatigue is a decided function of frequency. At the 70-phon level, a tone of 8,192 cps suffers 27 db more fatigue than a tone of 256 cps. This differential effect is considerably less evident when frequencies are of equal sensation level.

Kleemeier, Lyla B. & Kleemeier, R.W. EFFECTS OF BENZEDRINE SULFATE (AMPHETAMINE) ON PSYCHOMOTOR PERFORMANCE. *Amer. J. Psychol.*, Jan. 1947, 60, 89-100. (Northwestern University, Evanston, Ill.).

This study was designed to test the effects of benzedrine sulfate on psychomotor performance as measured by a series of tests composed of a number of relatively simple tasks so arranged that the S must exhibit the ability to change his "set" (that is, possess flexibility) in order to fulfill the test demands. 32 Ss were given the tests at 5 different sessions, each separated by 1 wk; the first session was the same for all Ss; at the remaining 4 sessions the Ss were divided into 2 groups. Each group was given glucose or benzedrine alternately 1-1/2 hr before testing. Ingestion of benzedrine sulfate reliably facilitated performance on these tests: multiplication, selective substitution, and arithmetic speed. Facilitation was noted on letter series, paper and pencil motor, over and under, and word completion tests but was not highly reliable. These findings are taken as support to the hypothesis that the drug exerts its facilitating influence in part by increasing flexibility of performance. No differential effect was found between the performance of "fast" and "slow" workers on the tests. (HEIAS)

Kleemeier, R.W. AGE CHANGES IN PSYCHOMOTOR CAPACITY AND PRODUCTIVITY. *J. Business*, 1954, 27, 146-155. (Moosehaven Research Laboratory, Orange Park, Fla.).

5644

This is a review of some of the experiments dealing with age change as reflected in psychomotor capacity and productivity and covers such areas as reaction time, muscular strength, vision, hearing, complex psychomotor activities, job performance, and accidents. The implications of these studies for further research and for understanding the process of ageing are discussed. T, G, R-28.

Kleemeier, R.W. THE RELATIONSHIP BETWEEN ORTHO-RATER TESTS OF ACUITY AND COLOR VISION IN A SENESCENT GROUP. *J. Appl. Psychol.*, 1952, 36, 114-116. (Moosehaven Research Laboratory, Orange Park, Fla.).

5645

This is a study of the relationship between visual acuity and color vision in a senescent group of 128 subjects, ranging in age from 65 to 85 years. Correlations are obtained between the Ortho-Rater color test and tests of visual acuity. The results are treated in terms of the role of acuity in evaluating the color vision function of older individuals. T. G. R 4

Kleemeier, R.W. & Dudek, F.J. A FACTORIAL INVESTIGATION OF FLEXIBILITY. *Educ. psychol. Monst.*, Spring 1950, 10(1), 107-116. (Northwestern University, Evanston, Ill.).

5646

To investigate the nature of flexibility, a battery of 13 tests was constructed. The tests were designed to measure numerical, perceptual speed, and verbal factors. Within each area an attempt was made to make some of the tests univocal (factorially pure) with one test designed to measure flexibility by requiring a shift from one simple task to another. Scores for 205 subjects were intercorrelated and the matrix of intercorrelations was factorially analyzed. The factors extracted were identified and discussed in relation to the postulated factor of flexibility. T. R 7

Kryter, K.D. EFFECTS OF EAR PROTECTIVE DEVICES ON THE INTELLIGIBILITY OF SPEECH IN NOISE. *J. acoust. Soc. Amer.*, Oct. 1944, 18(2), 413-417. (ONI & Harvard University, Cambridge, Mass.).

Articulation tests were conducted to determine the intelligibility of speech in the presence of noise when listeners did not wear earplugs and when listeners wore earplugs (BNC Ear Muffs). It was found that with a reverberating signal from a public-address system and in the presence of noise that raises the open-ear speech threshold by 60 db or more, the wearing of Ear Muffs increases the intelligibility of speech. But, with direct person-to-person speech, the ambient noise must be of sufficient intensity to raise the speech threshold by 80 db or more before Ear Muffs may be used without interfering with the reception of speech. Since in some military and industrial situations noise is generated that raises the threshold for hearing speech by more than 80 db, the use of suitable earplugs, under these conditions will: a) maximize the reception of speech and b) afford protection against the deafening, fatigue, and annoyance effects commonly attributed to sustained intense noise.

Kryter, K.D. EFFECTS OF HIGH ALTITUDE ON SPEECH INTELLIGIBILITY. *J. appl. Psychol.*, Oct. 1948, 32(5), 503-511. (OSAB, Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.).

Intelligibility of discrete words over a standard aircraft interphone is shown to decrease during flight from about 65% words correctly heard at 5000 feet to near 40% at 35,000 feet. This deterioration in speech intelligibility is attributable to a depression in the operating efficiency of the voice, the microphone and the earphones as the result of the reduced pressures encountered at high altitude. Anoxia did not play a role since oxygen equipment insured an adequate supply of oxygen to the Ss at all altitudes. The facts show that if speech intelligibility is to be kept at sea level or low altitude efficiency, which is under some circumstances none too high to begin with, adequate compensation in terms of additional interphone amplifier gains must be provided at high altitudes.

Lauer, A.R. A NOTE ON COLOR NOMENCLATURE. *Iowa Acad. Sci.*, 1953, 60, 524-528. (Iowa State College, Cedar Rapids, Iowa).

It is stated that the basic principles of color constitute a unitary system throughout although interpretations are sometimes at variance. Color is a subjective phenomenon and, as such, often results in the stimulus error being made by psychologists as well as by physicists and artists. It is recommended that quantitative statements be used in describing color by using the wave lengths reflected by physical objects. An extension of the concept of complementary colors to include all possible pairs is presented. In general, a proper understanding and description of color phenomena would eliminate confusion in the science and application of principles of color.

Lauer, A.R. & McOnagle, J.C. DO ROAD SIGNS AFFECT ACCIDENTS? *Traffic Quart.*, July 1955, 322-329. (Iowa State College, Ames, Iowa & Planning and Traffic Div., Michigan State Highway Dept.).

The effect of roadside advertisements upon driver efficiency was investigated both experimentally and by a statistical analysis of accident data. In the first instance, the driving efficiency of 170 Ss was measured on a laboratory driving apparatus under conditions where the normal features of the landscape were present but with no signs; with the same features of landscape but with signs placed 15-30° to the side, and with signs placed 15-45° at the side. Using RT as the criterion of possible differential efficiency, no significant differences were found among the conditions. The accident data were drawn from a study that included a comprehensive inventory of all design and roadside features with regard to location of each accident. Various analyses of possible effects of advertising signs (one of the design features) included rate of accident-occurrence per large and prominent advertising sign, and accident rate and sign density. None of these analyses were significant. Multiple correlations of all the design and roadside variables and accidents were determined for accidents occurring at intersections and non-intersections. In neither instance did roadside advertising signs have any significant effect; the significant variables at intersections proved to be taverns, vehicle miles, gas stations, other establishments, and stores; at non-intersections they were vehicle miles, private drives, other establishments, restaurants, and taverns. 5652

To study the perception of stimuli under given conditions of opposing light, three experiments were conducted: 1) acuity measurements with no opposing lights and with an opposing light varied in intensity (from 0.25 to 2.00 ft.-c) at a three-degree angle, or 2) with angle varied from one through five degrees and intensity at one ft.-c, and 3) differential discrimination of colored objects with and without opposing light (angle of three degrees, intensity one ft.-c). Data from 43 Ss were analyzed with respect to effects of angle and intensity on acuity and color discrimination. Practical applications were discussed.

Leibowitz, M. PHOTOMETRIC SCALES AND THE DUPLICATION THEORY OF VISION. *Amer. J. Psychol.*, Oct. 1952, 65(4), 632-634. (University of Wisconsin, Madison, Wisc.).

Because of the spectral selectivity of the eye and the technical difficulties involved in energy determinations, visual data are more conveniently presented on photometric scales. The establishment of a photometric scale requires the evaluation of spectral radiant flux with respect to its visual effect. One method is to adjust the energy in isolated spectral regions to produce an equality-response when compared visually with a fixed reference field. Energy-values which produce such an equality-response define equal photometric units. When visual data obtained from a homogeneous retinal area are plotted as a function of photometric units, the curves for all wave lengths are superimposed. An alternative method for establishing a photometric scale is based upon the fact that energy-values of the isolated spectral regions which will produce an equal visual response may be predicted from the luminosity data of the eye. By multiplying the radiant flux for a given wave length by the luminosity-factor of the eye for that wave length the visual effectiveness of radiant flux can be evaluated and expressed in terms of a photometric unit. Formulae are given for this method with cautions as to its application. (HEIAS)

Leibowitz, M., Note, F.A. & Thurlow, W.R. SIMULTANEOUS CONTRAST AS A FUNCTION OF SEPARATION BETWEEN TEST AND INDUCING FIELDS. *J. exp. Psychol.*, Dec. 1953, 46(6), 453-456. (University of Wisconsin, Madison, Wisc.).

By means of a binocular matching technique the interaction between a foveal test field and an equal-sized inducing field was investigated for various separations between the 2 fields. For all separations, little or no effect is produced in the test field when the luminance of the inducing field is less than that of the test field. For inducing field luminances greater than the test field, the test field is inhibited in direct proportion, on a double log plot, to the luminance of the inducing field. The present data are consistent with the assumption that luminance differences in the fovea are exaggerated by an inhibitory mechanism. The ability of inducing fields imaged in the peripheral retina to inhibit activity in the fovea is apparently due to stray light. The relevance of the present data to constancy and other forms of retinal interaction, as well as contrast, is suggested.

Lichte, W.H. SHAPE CONSTANCY: DEPENDENCE UPON ANGLE OF ROTATION; INDIVIDUAL DIFFERENCES. *J. exp. Psychol.*, 1952, 43, 49-57. (University of Missouri)

5656
To study the influence of angle of rotation upon shape constancy, fifty subjects rotated a square plate on the vertical axis until it appeared equal in shape to a rectangle (length same as standard, five inches, width varied 4.75, 4.25, 3.75 and 3.25 inches). Each setting, angle of rotation from fronto-parallel plane, was converted into a measure of apparent width. Ratios were then computed of apparent width to actual width of variable stimulus (considered an index of constancy), and are analyzed as a function of angle of rotation. Individual differences of constancy are analyzed and discussed.

Lichte, W.H. ATTRIBUTES OF COMPLEX TONES. *J. exp. Psychol.*, June 1941, 28(6), 455-480. (Southern Methodist University, Dallas, Tex.).

A series of studies were undertaken to discover whether or not complex tones have identifiable attributes other than pitch and loudness. 3 series of complex tones, each of which demonstrated a basic type of change in quality or timbre, were selected and psychological scales determined by the method of paired comparisons for brightness, roughness and fullness. Further experiments were then made using the tone series in pitch matching and quality matching. The data on pitch matching showed that the judgments on which the scales were based did not result from differences in pitch among the complex tones. The evidence seemed to warrant the conclusion that complex tones have, in addition to pitch and loudness, at least 3 attributes: brightness, roughness, and fullness (tentative). Brightness is a function of the location on the frequency continuum of the midpoint of the energy distribution. The results of the quality matching study suggest that brightness in complex tones is not similar to that of pure tones. Roughness was present in tones containing high partials above the sixth. Fullness was a function of the relative presence of odd- and even-numbered partials. (HEIAS)

5659
To study the effect of meaningfulness in radar-scope display perception upon accuracy of aiming point identification, two groups of Ss (30 in each) were first trained, then tested on their ability to identify the aiming point on scope photographs taken during actual runs on seven targets. Two training procedures were used: 1) a "configurational method" emphasized the perceptual patterns in the scope display and gave them names of familiar objects which they resembled, and 2) a "pointer" method used simple linear relationships and gave the returns names of the objects or areas on the ground which they represented. Mean radial errors were analyzed for differences attributable to method.

5663
To determine whether factors of motivation or of practice cause audience participation to result in superior verbal learning from films, 12 groups of about 80 high school students were required to view a film and then to answer a test on its contents. The following conditions were varied: 1) inclusion of test periods between sections of the film; 2) overt (versus covert) answering of test questions; 3) knowledge of results after each test period; 4) prior announcement of postfilm test of retention. A control group underwent the test periods but did not see the film. Results, number of items correct on the retention test, were compared among the various groups.

Pfefferkorn, R.G. & Lauer, A.R. CHANGES IN POSITION OF PRESENTATION AS RELATED TO PERCEPTUAL EFFICIENCY IN STIMULUS IDENTIFICATION. Proc. Iowa Acad. Sci., 1954, 61, 406-412. (Iowa State College, Ames, Iowa).
It was hypothesized that visual perception of incomplete circles is unaffected by position of the gap. The stimulus was composed of points of light arranged to form 2 concentric rings around a central point (inner ring and center light served as fixation point); the outer ring of 8 lights was shown as an incomplete circle by omitting one light and the gap thus formed was varied in position around the circle. 20 Ss each received 50 trials of the various patterns at exposures of .017 sec. Responses consisted of indicating any perceived missing light and marking its position on a prepared chart. Analysis of the results suggested that there are individual differences in perceptual efficiency and that perceptual efficiency of a gapped circular pattern varies as a function of the position of the gap. The upper portion of the pattern was perceived accurately most consistently. Certain possible operational characteristics of the closure phenomenon are suggested. (NEIAS)

Siddall, G.J. & Molding, D.H. ERRORS OF AIM AND EXTENT IN MANUAL POINT-TO-POINT MOVEMENT. Rep. 63, Jan. 1956, 16pp. Clothing & Stores Experimental Establishment, Ministry of Supply, London, England.

Many experiments have been performed to study the relations between such variables as speed, accuracy and amplitude of manual point-to-point movements, but little work has been reported comparing the magnitudes of different types of error when such movements are carried out at a high rate. It is suggested that this could have importance for the future design of displays and controls for certain types of equipment. A comparison was made of the magnitude of errors of aim with errors of extent in simple discrete movements carried out at a high rate and in different directions relative to the position of the S. 40 Ss were required to draw 4 lines in succession from a starting point to a target as fast as possible. A lower limit to the speed was set by demonstration and brief training. 4 directions of movement were compared; left to right; right to left; outwards from the front of the body and inwards towards the body. Errors in extent and deviations to left and right of the target were recorded as was the duration per 4 movements. Errors of extent were significantly greater than errors of aim. Constant errors of extent were overshoots and constant errors of aim were deviations to the right of the target. There were no significant differences in accuracy between the 4 directions of movement. Duration of left-to-right movements was significantly less than movements in the other 3 directions. Speed and accuracy were negatively correlated.

Baker, H.D. SOME DIRECT COMPARISONS BETWEEN LIGHT AND DARK ADAPTATION. J. opt. soc. Amer., Oct. 1955, 45(10), 839-844. (Office of Naval Research, Florida State University, Tallahassee, Fla.).

Both the absolute threshold and the difference threshold appear to be limited by photochemical conditions in the visual receptor during dark adaptation, and after complete light adaptation to any luminance level. During light adaptation the absolute threshold reflects photochemical conditions but the difference threshold does not. It is suggested that this is because the difference threshold is affected by the near-maximum response of the visual receptor during early light adaptation. Experiments which test this idea are reported.

Christman, R.J. FIGURAL AFTER-EFFECTS UTILIZING APPARENT MOVEMENT AS INSPECTION-FIGURE. Amer. J. Psychol., Jan. 1953, 66(1), 66-72. (West Virginia University, Morgantown, W. Va.).

An experiment was conducted to test the hypothesis that a greater figural after effect (FAE) would result if satiation were produced by apparent movement than if it were presented by a motionless inspection object. 5 conditions of satiation (1 min. fixation upon central point) were used: a) control, with fixation point and no pattern, b) a stationary pattern of 2 bars, c) alternation of the 2 bars to produce flicker, d) a stationary pattern of one large bar, and e) alternation of the 2 bars to produce apparent motion. FAE was measured by comparison with a 1-sec. exposure of a test pattern of 2 bars on either side of center at intervals of 4 sec. for 10 times. 75 Ss were used. Judgments of equal, left square higher, and right square higher were analyzed for effect of the 5 conditions. The condition in which movement appeared (condition e) produced an after-effect greater than other conditions at high levels of confidence. (HEIAS)

Christman, R.J. SHIFTS IN PITCH AS A FUNCTION OF PROLONGED STIMULATION WITH PURE TONES. Amer. J. Psychol., Sept. 1954, 67(3), 484-491. (USAF Rome Air Development Center, Rome, N.Y.).

In 2 experiments shifts in the pitch of a standard tone of 600~ were found following monaural stimulation (satiation) with pure tone of 450-800~ and of 1- or 2-min. duration. The pitch of the standard was lowered by satiating tones of higher frequency and raised by satiating tones of lower frequency, the effect being somewhat greater in the former case than in the latter. The magnitude of the effect varied directly with the duration of the satiating tones and inversely with the time between satiation and testing. The results of the experiments can be explained in terms of the Kohler-Wallach theory.

Clausen, J., Gjessvik, A. & Urdal, A. CHANGES IN GALVANIC SKIN RESISTANCE AS INDICATION OF PAIN THRESHOLD. J. gen. Psychol., 1953, 49, 261-271. (Psychology Dept., University of Oslo, Oslo, Norway).

To determine whether GSR could be used as an indicator of pain threshold (radiant heat), both were measured on the volar surface of the left lower arm on 2 groups of Ss (20 males and 20 females). The first received instruction as to sequence of sensations to be expected, but reported "Now" at reached threshold; at a later day the threshold was determined by using verbal report after each stimulus. The other group received no instruction of the sequence but reported after each stimulus. The data analysis indicated that while most of the stimuli resulted in a decrease of GSR, a pronounced decrease occurred at the pain threshold in the majority of Ss. The various forms of report had no effect on threshold level although instruction caused the critical resistance change to appear at a lower level than when no instructions were given. When the pain threshold was determined twice, the second threshold was lowered. (HEIAS)

Clausen, J. & King, M.E. DETERMINATION OF THE PAIN THRESHOLD ON UNTRAINED SUBJECTS. *J. Psychol.*, 1950, 30, 299-306. (Tulane University, New Orleans, La.).

An attempt has been made to formulate a standardized method of instrumentation and procedure for the measurement of pain threshold by the Hardy, Wolff, Goodell technique, with particular stress on applications to the untrained S. It has been found that temporal factors, conducted heat, distraction, reporting method, and area of the body stimulated all are directly influencing factors in the thresholds obtained; and that other conditions, such as age and educational level, probably also contribute to the variance obtained with this measure. Some of the additional relevant factors in the measurement of pain sensation which must be further studied have been discussed.

Clausen, J., Gjesvik, A. & Urdal, A. REPETITION EFFECT IN PAIN THRESHOLD DETERMINATION. *J. gen. Psychol.*, 1954, 51, 185-192. (University of Oslo, Oslo, Norway).

Through the utilization of the Wolff-Hardy-Goodell technique and standard procedure, pain threshold was determined on forehead, arm, and leg on 20 Ss. All 3 areas were stimulated on each of 3 testing days but the sequence was so rotated that each area was tested first in one session. When stimulated first in a session it was found that the forehead had the highest, the arm a somewhat lower, and the leg the lowest threshold. For all 3 areas the threshold was lowered significantly if it was determined immediately following the pain threshold determination of another area. There was evidence of a more pronounced effect in the case of 2 rather than one preceding stimulation. For the leg it was found that the threshold for warmth was higher than for the arm or forehead; that repetition effect occurs also for warmth sensation; and that occasionally the pain threshold was lower than threshold for warmth. It was suggested that physiological rather than psychological factors are responsible for the repetition effect.

Clausen, J., Urdal, A. & Gjesvik, A. RELATION BETWEEN GALVANIC SKIN RESISTANCE AND REPETITION EFFECT IN PAIN STIMULATION. *J. gen. Psychol.*, 1955, 53, 29-36. (University of Oslo, Oslo, Norway).

12 Ss had threshold determined simultaneously with recording of galvanic skin resistance on 3 consecutive days. 3 body areas: forehead, arm, and leg, were stimulated on each of the 3 testing days, the order of stimulation so rotated that each body area was stimulated first on one of the days. In 95 out of 102 cases it was possible to determine pain threshold on the basis of the GSR record. The pain threshold as determined by GSR was compared with the pain threshold determined by verbal report. This was done for the total number of cases, and for the cases grouped according to day of recording, body area, and series position. None of these comparisons gave a statistically significant difference. The repetition effect -- previously demonstrated for the verbally determined threshold when more than one body area is stimulated in the same experiment, is thus reflected in the GSR record also. This finding is interpreted to mean that the repetition effect is caused by physiological rather than psychological processes.

Deatherage, B.H. FIGURAL AFTER EFFECTS IN STROBOSCOPIC MOVEMENT. *Amer. J. Psychol.*, June 1954, 67, 259-267. (University of Texas, Austin, Tex.).

The effect of satiation on the time between successive stimulations required for optimal stroboscopic movement was studied in 2 experiments. In the first experiment, the time for optimal movement was increased by the prolonged inspection of stroboscopic movement. This result may be deduced from Korte's law of the relation between time and distance, on the assumption that the inspection of stroboscopic movement increases resistance (functional distance) in the line of movement. In the second experiment, the effect on the time for optimal movement of satiation-produced changes in the size of the stimuli for movement was measured. An increase in apparent size increased the time and a decrease in apparent size had no significant effect, neither result being in accord with predictions made from Korte's law of the relation between intensity and time. Subsequent measurements of the relation between time and physical size contradicted Korte's law, however, and provided results directly comparable to those of the satiation experiment. In both experiments, then, stroboscopic movement was found to be similarly affected by physical and satiation-induced functional changes in selected parameters.

Fox, B.H. FIGURAL AFTER-EFFECTS: "SATIATION" AND ADAPTATION. *J. exp. Psychol.*, Nov. 1951, 42(5), 317-326. (George Washington University, Washington, D.C.).

In 2 experiments, figural after-effects (FAE) with different distances between non-symmetrical inspection (I) figures and a symmetrical test (T) figure were investigated. I figures, mounted on glass, were inspected against a bright background. A similarly mounted movable T figure was placed at different distances from the former position of the I figure with respect to a fixation cross, and adjusted to the apparent horizontal by S. 3 Ss were studied. A comparison of the first and second 5 of 10 trials per session showed that the cumulation of FAE is not universal for some experimental conditions—here a decline in effect occurred as often as an increase. In the second experiment, adaptation to the norm was removed by using a stimulus symmetrically placed with respect to the fixation mark. Smaller increments of distance between I and T figures were used. The "distance paradox" was verified in this experiment where satiation alone was acting. Indications are that the maximum FAE for present conditions occurs with separation between I and T figure boundaries of between 1/4 and 3/8 in. Smaller FAE occurred in the second experiment. (MEIAS)

Gilchrist, J.C. THE FORMATION OF SOCIAL GROUPS UNDER CONDITIONS OF SUCCESS AND FAILURE. *J. abn. & soc. Psychol.*, April 1952, 47(2), 174-187. (University of Wisconsin, Madison, Wisc.).

5686
To investigate one aspect of group formation under conditions of success and failure, 234 college students, divided into four treatment groups, were studied. Small groups of four subjects were studied as to their grouping choices (after failing or succeeding as individuals) when group action is required for further possible goal attainment. Under the guise of a test development program, various reasoning tests were used as the experimental tasks; thus an initial level of aspiration was provided for these student subjects. The frequencies of first and second task choices for the systematically varied success-failure conditions were analyzed.

Grant, D.A. THE DISCRIMINATION OF SEQUENCES IN STIMULUS EVENTS AND THE TRANSMISSION OF INFORMATION. *Amer. Psychol.*, Feb. 1954, 9(2), 62-68. (University of Wisconsin, Madison, Wisc.).

In this presidential address given at the meeting of the Midwestern Psychological Association, May 1, 1953, the author states that psychologists stand on the threshold of a new era in the analysis of behavior; that new statistical procedures and new mathematical models are ushering in changes which should revolutionize the methods of investigation in all areas of psychology. He proceeds to outline in a general way some of these new techniques and models that are now available and indicates how they have already proved useful in some of their initial applications to psychological problems. The new techniques of quantification spoken of here deal with behavior as a time series and are concerned precisely with those concepts of organization and patterning of behavior in individual cases which have been so difficult to approach using the nonothetic, cross-sectional statistical methods that have been available in the past. Jones, G. M. AIRCREW FATIGUE IN LONG RANGE MARITIME RECONNAISSANCE: 9. BODY WEIGHT CHANGES. *FFRC 907.9*, Aug. 1956, 55-58. RAP Institute of Aviation Medicine, Farnborough, Hants, England.

5690
A survey of changes in body weight of 37 aircrew (four crews) during approximately one week of high intensity flying operations was made. All men were weighed before the start and after the end of the program. A record was made of which crew each belonged to, whether he lived in the mess on the camp or outside with his family, and his crew duty. Weight changes were studied for differences which might be attributable to any one of these factors. The findings are discussed in relation to fatigue and morale of the men. Suggestions are included for some changes in procedures of food management.

Grant, D.A., Kaestner, N.F. & Schipper, L.M. AUTOCORRELATION ANALYSIS OF GROSS LEARNING SCORES. *Percept. Mot. Skills*, 1955, 2, 53-63. (University of Wisconsin, Madison, Wisc.).

5691
Autocorrelational methods are applied to gross scores of motor performance. Two groups of 24 Ss (college students) were given 90 and 450 20-sec. trials on a standard pursuit rotor. The serial correlation coefficients for learning trials at a given separation, tau, in the time series are plotted against tau for both individual and group performances. The uses of autocorrelational analysis in predicting final achievement, in classifying motor skills in terms of complexity, and in describing performance are discussed. Individual differences and the effect of level of training are discussed also.

Grings, W.W. & Rigney, J.W. A COMPARISON OF THE EFFECTS OF FOUR DISPLAY CONDITIONS ON THE DISCRIMINATION LEARNING OF SIMULATED SONAR ECHO-RETURNS. Contract Nonr 228 (02); Proj. NR 153 093, Tech. Rep. 8, Aug. 1953, 23pp. Department of Psychology, University of Southern California, Los Angeles, Calif.

5695

This study investigated the effects of four types of displays on the learning to discriminate stimulus patterns of brief duration (translations of echo-return patterns in a sonar system) that differed in the shape of the amplitude envelope. Five groups of 18 subjects were trained for 20 trials (5 discriminations per trial) to discriminate among 5 stimuli. Knowledge of results was provided by an indicator light. Information was presented to each group aurally, visually, aurally and visually simultaneously, or aurally succeeded by visual, or visually succeeded by aural. Effectiveness of the display condition is evaluated in terms of mean number of correct responses per trial during training and during a post-training test series in which no knowledge of results was provided. Harris, J.D. REMARKS ON THE DETERMINATION OF A DIFFERENTIAL THRESHOLD BY THE SO-CALLED ABX TECHNIQUE. J. acoust. Soc. Amer., July 1952, 24(4), p417. (USN Medical Research Lab., New London Submarine Base, Conn.).

In this brief note, the ABX technique for making discriminative judgments is described and some of its advantages and disadvantages are indicated. In the ABX technique the S is given 2 successive items, A and B, which differ in some respect. X is then presented, a replica of either A or B. The S is required to tell whether X is more like A or B. This procedure, suitably counterbalanced, is reliable and can be used in difficult discriminations or with complex stimuli because the S need not concern himself with what the nature is of the difference between A and B. Its limitation is that the judgmental process called for is really very involved and the S is not making a single judgment but a compound one, thus data cannot be interpreted as clearly. Evidence shows that the ABX is too complicated to yield the finest measures of sensitivity. (HEIAS)

Harris, J.D. PITCH DISCRIMINATION UNDER MASKING. Amer. J. Psychol., April 1948, 61(2), 194-204. (USN Medical Research Lab., New London Submarine Base, Conn.).

The present series of experiments opens up the field of pitch discrimination in masking, studying the differential thresholds of pitch for pure tones as a function of frequency, sensation-level, and signal-noise ratio. All stimuli are produced and controlled electronically. Discrimination is studied by the method of constant stimuli. Group-to-group comparisons are made either by noting differences between means of individual thresholds or by graphic methods. The first experiment compared discriminability at 500 cps and 800 cps, at 2 sensation-levels, 30 and 50 db, and 4 signal-noise ratios, 5, 10, and 15 db, and infinity. At all comparable sensation-levels and signal-noise ratios, thresholds at 500 cps were superior to those at 800 cps. Discriminability becomes progressively worse as the signal-noise ratio changes from infinity (no noise) to zero (in-noise threshold). The impression is reached that the introduction of masking will not change the relative characteristics of pitch-discrimination, but that the absolute magnitudes of all thresholds will be markedly altered. At a constant signal-noise ratio, discriminability does not change for the worse when the sensation-level is raised 20 db.

Heuty, G.T. PRIMARY OCULAR NYSTAGMUS AS A FUNCTION OF INTENSITY AND DURATION OF ACCELERATION. J. exp. Psychol., Sept. 1953, 46(3), 162-170. (University of Rochester, Rochester, N.Y.). (ONR)

A study was made of the extent and duration of eye movements resulting from rotation of widely varying speeds and accelerations and photographically recorded through closed lids at high magnification. Of 3 Ss selected, 1 was subjected to 5 different velocities of rotation, 180°/sec. to 12°/sec., reached by each of 6 different accelerations; the other 2 Ss served in spot-checks at critical stimulating conditions. The total amount of slow-phase eye movement was measured from the photographic records for each 2 sec. of the primary nystagmus up to the point where secondary nystagmus began. Conclusions derived were as follows: a) Intensity of acceleration was directly related to the extent of eye movements occurring in primary nystagmus but did not modify the duration of this response; b) Duration of acceleration was directly related to the duration and extent of eye movements of primary nystagmus, and to the period of recruitment of eye movements; c) Total primary nystagmic response output was directly related to total sensory input, i.e., the product of acceleration and its duration; d) Inter-individual variation was of considerable extent with the greatest variation occurring in the duration and amplitude of slow-phase movement.

Hess, E.H. 'SUBJECTIVE' COLORS: RETINAL VS. CENTRAL ORIGIN. *Amer. J. Psychol.*, April 1952, 65(2), 278-280. (University of Chicago, Chicago, Ill.).

A rather simple test of the central vs. retinal theories for the origin of subjective colors was made by fusing stereoscopically the components of a total pattern so chosen that the pattern produced subjective color while the components, taken separately, did not. Each of 5 Ss observed such patterns, 1 presented components of the pattern separately to each eye; the other presented both components to the same eye. All reported color in the latter case but not in the first. The writer feels that these results cast considerable doubt upon the validity of a central interpretation of subjective color and are consistent with the explanation in retinal terms.

Hirsh, I.J. BINAURAL SUMMATION--A CENTURY OF INVESTIGATION. *Psychol. Bull.*, May 1948, 45(3), 193-206. (Harvard University, Cambridge, Mass.). (OMR)

This review attempts to summarize experiments of the last 100 yrs. that have revealed evidence for or against binaural summation. The discussion is organized around 2 topics; binaural summation of loudness and binaural summation at threshold. The experiments reported reveal a considerable amount of evidence on the interaction of the 2 ears of the human organism. A sound is heard more easily and, once heard, sounds louder when an observer uses 2 ears than when he uses only one. More than that, the difference in loudness between a tone heard monaurally and one heard binaurally varies with intensity. The difference between the binaural and monaural thresholds varies as a function of the frequency of the tonal stimulus and as a function of the level of a background noise against which stimuli are presented. Explanations which have been deduced by analogy to mechanical or electrical systems have seemed inadequate in the light of subsequent data. It remains to future experimentation to bring to light the parameters which determine interaural summation at threshold and interaural summation of loudness.

Hirsh, I.J. BINAURAL SUMMATION AND INTERAURAL INHIBITION AS A FUNCTION OF THE LEVEL OF MASKING NOISE. *Amer. J. Psychol.*, April 1948, 61, 205-213. (Rep. PNR 47, OMR, Harvard University, Cambridge, Mass.).

The difference between the binaural and the equated monaural thresholds for 3 pure tones and speech, as a function of the level of a white masking noise, has been investigated. It was found the binaural summation was maximal in the quiet and decreased as the level of the masking noise increased. For lower frequencies and for speech, not only does this binaural summation decrease to zero, but it also becomes negative. The binaural threshold is shown to be higher than the monaural threshold, indicating some kind of interaural inhibition. For listening to at least certain stimuli in the presence of loud thermal noise, 2 ears are not better than one.

Hirsh, I.J. & Bowman, W.D. MASKING OF SPEECH BY BANDS OF NOISE. *J. acoust. soc. Amer.*, Nov. 1953, 25(6), 1175-1180. (Central Institute for the Deaf, St. Louis, Mo.).

The threshold of intelligibility for 2-syllable (spondee) words was measured in the presence of different levels of masking noise. 12 different bands were used, one (20 to 6600 cps) approximating a white noise and each of the other 11 containing a band of frequencies corresponding to a pitch interval of 250 mels. The absolute thresholds for these bands were also measured to permit transformation of the noise level from an absolute scale to a scale of sensation level. The results show linear relations between the masked threshold and noise level for white noise and for bands of noise between 394 and 1420 cps. For noise bands above 1420 cps this masking function is accelerated, while the 2 bands below 394 cps yield sigmoid masking functions. Of the bands used, the most effective contained frequencies between 670 and 1000 cps. The signal-to-noise ratio at threshold for this band was about -25 db while for bands above or below it became gradually smaller than -25 db, reaching a minimum of -60 db for the highest and lowest bands. White noise was more effective than any band, giving a threshold S/N ratio of -15 db.

Hirsh, I.J., Reynolds, Elizabeth G. & Joseph, M. INTELLIGIBILITY OF DIFFERENT SPEECH MATERIALS. *J. acoust. soc. Amer.*, July 1954, 26(4), 530-538. (Central Institute for the Deaf, St. Louis, Mo.).

Articulation scores for nonsense syllables and for monosyllabic, disyllabic, and polysyllabic words were obtained as a function of the cut-off frequency of low-pass and high-pass filters and also as a function of signal-to-noise ratio at different noise levels. Results indicate that eliminating all frequencies above or below 1600 cps does not impair the intelligibility of words seriously. The intelligibility of a word is a direct function of the number of syllables in the word and monosyllabic words are more intelligible than nonsense syllables. The relation between the intelligibilities of each word type and nonsense syllables is not the same when the system is impaired by filtering as it is when the system is impaired by noise. The implications of the lack of consistency from one experiment to the other for the generality of the concept of articulation index is discussed.

Hirsh, I.J. PSYCHOPHYSICS OF HEARING. *Acta Oto-Laryngol.*, 1950, 40(5-6), 273-282. (Psychological Lab., Harvard University, Cambridge, Mass.).

The way in which the psychophysicist has attacked the problems of hearing and the use of psychophysics by the specialist in hearing problems are discussed. The psychophysicist is said to be interested in the relations between certain measurable aspects of the response of individuals to auditory stimuli that seem to give rise to these responses. The contributions of Fechner's psychophysical methods and systematic approach to psychophysical problems are discussed along with recent advances in both control and measurement. 2 basic measures--absolute threshold for pure tones and threshold of intelligibility for English speech--are said to be well enough established so that there are norms with which to compare similar measures made on patients in clinical work. Other relations, such as the difference limen, masking, maximum articulation score, and loudness, have been well enough established for norms but not placed in the clinical testing program. The author feels that the clinician should make himself aware of the work done on the psychophysics of hearing and he should also put psychophysical method to work, not only to make his present kinds of audiometric tests more reliable, but also to expand his own view of the relations between hearing and its pathologies and the kind of stimuli that evoke specific behavioral response in his patient's repertoire.

Imus, H.A. INDUSTRIAL OPHTHALMOLOGY: COMPARISON OF ORTHO-RATER WITH CLINICAL OPHTHALMIC EXAMINATIONS. *Transact. Amer. Acad. Ophthalmol. Otolaryngol.*, Sept.-Oct. 1950, 69-71. (USN School of Aviation Medicine, Pensacola, Fla.).

In order to compare the results of testing vision with the Ortho-Rater and clinical ophthalmic methods, a test-retest experiment was conducted with 100 Ss obtained from the officer, cadet, and enlisted personnel of the Naval Air Training Bases, Pensacola, Florida. The same examiner tested each S with standard clinical devices and with the Ortho-Rater, 1/2 being tested first clinically and the other half on the Ortho-Rater. Standard procedures were used and the retest was conducted without either examiner or the Ss having knowledge of results of the first test. In general, the visual tests of the Ortho-Rater are as reliable as the clinical tests. Heterophoria for distant vision and depth perception measurements were more reliable on the Ortho-Rater: vertical phoria at near vision measures were equal; far visual acuity and near lateral phoria clinical measurements were a bit more reliable. The correlation between the Howard-Dolman test and the test of depth perception of the Ortho-Rater is too low to be considered satisfactory. This may be due in part to the lower reliability of the Howard-Dolman test.

Kiesse, F.H., Peterson, B.H. & Grant, D.A. MULTIPLE RESPONSE TRANSFER AS A FUNCTION OF SUPPLEMENTARY TRAINING WITH VERBAL SCHEMATIC AIDS. Contract AF-33(039) 23294, AFPRC IN 55 34, Oct. 1955, 10pp. USAF Personnel and Training Research Center, Lackland AFB, Tex. (University of Wisconsin, Madison, Wisc.). (Reprinted from *J. exp. Psychol.*, Nov. 1954, 49(5), 381-390).

5716

To test the hypothesis that verbal conceptualization would facilitate transfer of training from one method of coding on a display to another when the data coded (range, azimuth, and elevation of a simulated target) are the same, a task was developed which required the making of a three-component stick response to a stimulus pattern presented on an oscilloscope. Mechanically-instructed groups were told what responses to make to change the pattern's location and character in a prescribed way, whereas the conceptually trained group were told that the patterns represented aircraft in different positions. Two different types of display were used. The 80 subjects were run in a trifactorial design--display, instructions, and transfer.

Luce, R.D. CONNECTIVITY AND GENERALIZED CLIQUES IN SOCIOMETRIC GROUP STRUCTURE. *Psychometrika*, June 1950, 15(2), 169-190. (Massachusetts Institute of Technology, Cambridge, Mass.).

By using the concepts of antimetry and n-chain it is possible to define and to investigate some properties of connectivity in a sociometric group. It is shown that the number of elements in a group, the number of antimetries, and the degree of connectivity must satisfy certain inequalities. Using the ideas of connectivity, a generalized concept of clique, called an n-clique, is introduced. n-cliques are shown to have a very close relationship to the existence of cliques in an artificial structure defined on the same set of elements, thus permitting the determination of n-cliques by means of the same simple matrix procedures used to obtain the clique structures. The presence of 2 or more m-cliques, where m is the number of elements in the group, is proved to mean an almost complete splitting of the group.

Hann, C.W. AN ANALYSIS OF THE OCULOGYRAL EFFECT. *J. aviat. Med.*, June 1957, 28, 246-253. (Psychology Dept., Tulane University, New Orleans, La.).

In a recent series of articles, Hayne has suggested that, within the limits of the linearity of the vestibular system, the duration of the subjective effects arising from the stimulation of the semicircular canals is proportional to the angular velocity. He arrives at a formula for the duration of the first effect of the form $Y = ae^x$. The application of this formula to the data of nystagmus in pigeons by Hower and the oculogyral effect obtained by Clark and Graybiel gives a good fit to the exponential curve. In this study an attempt was made to apply Hayne's formula to the first effects during and after rotation in the oculogyral illusion. The curve of the data derived from the total first effects appeared sigmoidal, but a good fit to Hayne's exponential curve was obtained at velocities up to 20 rpm when the formula was applied to the gross visual effects--described in this article as the "picket fence" phase of the first effect. Analysis of the results indicates that the total first effect of the oculogyral illusion is made up of 2 components. One of these is produced by the rapid oscillations of the cupula due to its inertia during and following rotation, and the other by the finer movements of the cupula induced by the inertia of the endolymph of the semicircular canals.

5731
Mann, C.W. VISUAL FACTORS IN THE PERCEPTION OF VERTICALITY. *J. exp. Psychol.*, Dec. 1952, 44(6) 460-464. (Tulane University, New Orleans, La.).

The experiment was designed to test the hypothesis states by Gibson to the effect that the error in the perception of the vertical under consistent visual-proprioceptive stimulation will be less than that made under discrepant conditions. Consistent visual-proprioceptive conditions occur when the vertical lines of the retinal field are parallel to the direction of the gravitational vertical; discrepant conditions are produced when these directions are not parallel. 9 Ss were tested in 15 experimental conditions of room and body tilt. In each condition S was required to set a target rod in alignment with the gravitational vertical. An analysis of the average and constant errors gives support to Gibson's hypothesis. Comparing the results of this experiment with those of a previous experiment by Boring, one concludes that when visual stimulation is increased to the point at which S can identify himself with the visual frame-work, there is conflict between the visual stimulation produced by the frame-work and the proprioceptive stimulation produced by the gravitational force acting on the statocysts. The hypothesis offered by Gibson needs a qualifying statement to the effect that in the judgment of the vertical, reliance will be placed upon the proprioceptive stimulus variables until the visual factors in the visual-proprioceptive variables become sufficiently effective to offer conflict with the proprioceptive variables. When this happens, a compromise judgment will be made, the judgment lying somewhere between the inclination of the visual field and the gravitational vertical.

Mann, C.W. SUBJECTIVE EFFECTS OF DIFFERENT ROTATIONAL VELOCITIES. Contract N7onr 434, T.O. 1, Proj. Design. NR 143 455, Proj. NM 001 063.01.24, March 1952, 5pp. *USN School of Aviation Medicine*, Pensacola Air Station, Fla.

Mayne's formula for the duration of the first subjective effect following stimulation of the semicircular canals is of the form $Y = ae^{-kx}$. An attempt was made to apply Mayne's formula to the first effects of the oculogyral illusion during and after rotation. A good fit was obtained to Mayne's exponential curve up to velocities of 20 rpm. for the gross visual effects. The analysis indicated that the total first effect of the oculogyral illusion is made up of 2 components: 1. Rapid oscillations of the cupula and finer movements of the cupula induced by the inertia of the endolymph of the semicircular canals.

Mann, C.W., Berthelot-Berry, N.H. & Dauterive, H.J., Jr. THE PERCEPTION OF THE VERTICAL: I. VISUAL AND NON-LABYRINTHINE CUES. *J. exp. Psychol.*, Aug. 1949, 39(4), 538-547. (Tulane University, New Orleans, La.).

The precision of judgment of the postural vertical from lateral tilt positions in the absence of visual cues is of the order of 0.08° with a standard deviation of 1.1°. The precision of judgment is significantly decreased when the nonlabyrinthine proprioceptive cues are modified by the introduction of a well padded seat. There is a marked tendency for the mean error of judgment to be in the direction of lateral tilt. The precision of the judgment of the visual vertical when the individual is seated in a vertical position is of the order of 0.3° with a standard deviation of 2.6°; of the visual horizontal, of the order of 0.4° with a standard deviation of 2.9°. These values are significantly increased when the judgment is made in a position of lateral tilt. The visual target, when placed in positions deviating not more than 15° from the horizontal, does not significantly affect the judgment of the postural vertical.

Mann, C.W. & Boring, R.O. THE ROLE OF INSTRUCTION IN EXPERIMENTAL SPACE PERCEPTION. *J. exp. Psychol.*, Jan. 1953, 45(1), 44-48. (Tulane University, New Orleans, La.).

To test the effect of instructions upon the perception of the gravitational vertical, two groups of subjects were required to set a target rod to the gravitational vertical against a visual framework under various conditions of lateral inclination (30 degrees L, 0 degrees, and 30 degrees R). While one group was made aware of the correct criterion of judgment, the other group was simply told to set the target to the vertical. The results are discussed in terms of differences between the groups in accuracy and variability of judgments as a function of pre-experimental training in the proper criterion of performance.

Mann, C.W., Guedry, F.E. & Ray, J.T. POST-ROTATIONAL PERCEPTION OF APPARENT BODILY ROTATION. *J. exp. Psychol.*, Feb. 1951, 41(2), 114-120. (Tulane University, New Orleans, La.).

This investigation was designed to determine the relative contributions of the visual and postural factors to the post-rotational effects of the oculogyral phenomenon. Comparisons were made of the post-rotational effects produced under conditions of a) no visual stimulus, b) continuous visual stimulus, and c) flickering visual stimulus. 3 sophisticated Ss were used in the investigation. The equipment consisted of a Link Trainer modified to rotate at 20 rpm. Reports by the Ss of the cessation of post-rotational apparent movement under all conditions yielded subjective measures of the duration of the first effect of the oculogyral phenomenon. The duration of the first effect under conditions A, no visual stimulus, and B, continuous visual stimulus, were of the same order. A Phi phenomenon was experienced by observers at the commencement of the first effect. It was of variable duration for each observer, but in each case was of lesser duration than the total visual first effect. It is concluded that the perceptual nature of the first effect of the oculogyral illusion is a result of 2 components: a) a visual component which produces the rapid Phi phenomenon, probably a corollary of nystagmic eye movements, and b) a postural component which contributes the smooth unidirectional apparent motion characteristic of the first effect. It is proposed to designate the postural component the "postural negative aftereffect."

Benjamin, P.H. THE EFFECT OF PAIN ON PERFORMANCE. *MADG-MA-5612*, Proj. NM 001:103 301, Rep. 10, Sept. 1956, 19pp. U.S.N. Aviation Medical Acceleration Laboratory, *MADG*, Johnsville, Penn.

5739

To study the effect of pain on performance, 26 subjects each serving as his own control were used. Pain was produced by: 1) pressure headgear yielding mild pressure pain of one dol or less; 2) pressure cuff yielding deep aching pain of two to three dols; and 3) ice water immersion yielding cold pain up to four dols. Performance tests were composed of mental test items, memory items, time perception, muscular coordination, reaction time and work (bicycle ergometer). All subjects performed each test once with and once without each of the pain producing stimuli. Differences in performance for experimental and control conditions were analyzed. The findings are discussed and interpreted in light of the present state of knowledge in this area.

Mystrom, C.O. S. G. R. A. J. A. PERFORMANCE ON A KEY PRESSING TASK AS A FUNCTION OF THE ANGULAR CORRESPONDENCE BETWEEN STIMULUS AND RESPONSE ELEMENTS. *PERCEPT. MOT. SKILLS*, 1955, 5, 113-125. (University of Delaware, Newark, Del.; University of Wisconsin, Madison, Wisc.).

groups of 25 Ss per group performed a key-pressing task which differed between groups in that the stimulus light display took angular orientation relative to a fixed horizontal set of keys of 0°, 45°, 90°, 135°, and 180° counter-clockwise. Orthogonally to this independent variable, half the Ss matched 2-light patterns, the other half matched 4-light patterns. After 9 blocks of 25 2- or 4-light matches, each S was shifted to 4- or 2-light patterns, respectively. It was found that: a) There was a significant difference in the effects on performance due to the stimulus light orientation variable; b) 2-light patterns were matched significantly faster than 4-light patterns, with an overall advantage of 1.10 sec. per pattern on the average; c) The number-of-lights-per-pattern interacted with the stimulus light orientation effect on performance during the first 9 blocks of patterns, in that a somewhat different relationship existed between pattern-matching time and stimulus light orientation depending on whether 2-light or 4-light patterns were employed; d) Greater positive transfer effects were apparent in transferring from 4-light to 2-light patterns than in transferring from 2-light to 4-light patterns; e) Although initially the degrading effect of angular orientation was greater for the 4-light patterns than for the 2-light patterns, after training the angular effect was equal.

Passey, G.E. THE PERCEPTION OF THE VERTICAL. IV. ADJUSTMENT TO THE VERTICAL WITH NORMAL AND TILTED VISUAL FRAMES OF REFERENCE. *J. exp. Psychol.*, Dec. 1950, 40(6), 738-745. (ONR, Tulane University, New Orleans, La.).

5 midshipmen from the Tulane Naval ROTC unit served as Ss. They were required to adjust a chair to the vertical positions from tilted positions in the lateral plane. The chair was located in a room which could be tilted to various inclined positions in the lateral plane. Adjustments were made in the presence of a visual frame of reference consisting of the entire room set 0°, 5°, 10°, 15°, and 20° from the gravitational vertical in the right and left quadrants. 10 determinations were made for each position of room tilt. Ss always began his adjustments from a tilted position of 45°. The theory of Koffka that the accepted vertical will agree with the main lines of visual space though they may be in conflict with the postural cues was rejected under the conditions of this experiment. Adjustments in the presence of a visual frame of reference showed equal variability when the visual cues presented were in conflict with the postural cues, and when the 2 were in alignment. When adjustments were made from tilted positions in the same quadrant as the tilted room the resulting average errors and constant errors in the direction of the tilted room were greater than when adjustments were made from tilted positions in the opposite quadrant from the tilted room. With increasing amounts of tilt of the visual framework there was an increase in the size of average error of adjustment and of constant error in the direction of the tilted room. Statistical treatment revealed that only the differences between conflict in postural and visual cues and no conflict were significant. Implications for the relative importance of postural and visual factors in the perception of the vertical were discussed.

Passey, C.E. & Goddy, F.E., Jr. THE PERCEPTION OF THE VERTICAL: II. ADAPTATION EFFECTS IN FOUR PLANES. *J. exp. Psychol.*, Oct. 1949, 33(5), 706-707. (Psychology Dept., Tulane University, New Orleans, La. & USN School of Aviation Medicine and Research, Pensacola Air Station, Fla.).

16 Ss were required to return a modified Link trainer to 'straight and level' flight following inclination. Inclinations were made in 4 planes passing longitudinally through the gravitational vertical and were designated as medial, left oblique, lateral, and right oblique. 20 adjustments were made in each plane during 4 experimental sessions in which each session was devoted to making determinations in one plane only. 10 adjustments were made from each direction within a plane and half of the trials in each direction were made under conditions of immediate return to the vertical after inclination while half of the trials entailed a 60-sec. delay before readjustment was allowed. When either absolute divergence from the gravitational vertical in degrees or number of errors in direction of initial inclination is considered, there is a significant adaptation effect. Delay also serves to produce significant difference in variability. There is no significant difference in performance shown in comparison of adjustments from different directions of inclination in the same plane. Adjustments in the lateral plane are made with greater accuracy than adjustments in either medial, left oblique, or right oblique. The differences are significant at the one percent level.

Stevens, K.N. A SURVEY OF BACKGROUND AND AIRCRAFT NOISE IN COMMUNITIES NEAR AIRPORTS. Tech. Note 3379, Dec. 1954, 36pp. US National Advisory Committee for Aeronautics, Washington, D.C. (Bolt Beranek and Newman, Inc., Cambridge, Mass.).

An extensive survey has been made of background and aircraft noise levels in residential communities in 8 cities having major airports. The measurements were made in areas up to a distance of 12 miles from the airports, and the areas were chosen to be under regularly used flight paths. Readings of background noise were obtained primarily in the octave bands 75 to 140, 300 to 600, and 1,200 to 2,400 cps, about 25 such spectra being taken in each area. Octave-band spectra were obtained from magnetic tape recordings of the noise of about 250 aircraft in flight, representing substantially all commercial types.

Trant, J.P., Jr. PRELIMINARY INVESTIGATION OF A STICK SHAKER AS A LIFT-MARGIN INDICATOR. Tech. Note 3351 Feb. 1955, 15pp. National Advisory Committee for Aeronautics, Washington, D.C. (Langley Aeronautical Lab., Langley Field, Va.).

An exploratory study was made to determine whether a pilot could use vibration of the control stick, in which either the amplitude or the frequency, or both, varied with lift or angle of attack, as a means of maintaining a desired lift margin below the stall. The study was made in the laboratory with several Ss, both pilots and nonpilots, by using an apparatus consisting of a control stick, a shaker, and shaker control equipment which provided varying amplitude and frequency with stick displacement. The tests consisted of having a S attempt to maintain a given frequency and amplitude of vibration by moving the stick to compensate for an arbitrary change in frequency and amplitude imposed on the system by an operator independently of the stick motion. A brief study was also made to determine the minimum change in frequency or amplitude a S could detect. The results of these tests indicated that, once established, a given flight condition could probably be maintained by sensing variation in stick vibrations at least over the period of time covered by the tests (35 sec.), provided that the allowable variations from the desired flight conditions produced changes in amplitude of vibration of about 100% or changes in frequency of about 40%, or both. In the ranges of amplitude and frequency covered in the tests, sensitivity-to-amplitude changes increased with increase in amplitude and frequency; sensitivity to frequency changes did not appear to be materially affected by amplitude.

Culbert, S.S. SYSTEMATIC ERROR IN THE ESTIMATION OF SHORT TIME INTERVALS. *J. crim. Law Criminal.*, Jan.-Feb. 1954, 45(5), 684-688. (University of Washington, Seattle, Wash.).

This report summarizes a classroom experiment on the error of estimation of short time intervals--120 sec. All students in a class were required to estimate the time interval between 2 events under 3 conditions (each at widely separated classmeetings): a) Instructor enters room, announces an experiment in which all will take part, tells students it may be embarrassing if they are not attentive, fills remaining time with other preparations, and finally slaps desk loudly. A questionnaire, including one item on estimate of time lapse was then filled out by each S; b) Instructor walks into room, lectures for 100 sec., and writes V on blackboard. This time only an estimate of time elapsed was required; c) Instructor announced that he was going to ask the students to estimate the time between 2 signals; he then talked informally during this period. In the first instance, the lowest estimate was 2 min. 46 sec., median was 8 min., highest was 20 1/2 min. In the second situation there was over-estimation but not as great, the mean was 2 min. 20 sec. And finally, the mean for (c) was 58.2 sec. with 2/3 underestimating the interval. The importance of these findings to testimony and reliability of witness report is discussed.

Culbert, S.S. DIRECTIONAL AFTER-EFFECTS FOLLOWING SYSTEMATIC DISTORTION OF THE VISUAL FIELD. *J. Psychol.*, 1954, 37, 81-93. (University of Washington, St. Louis, Mo.).

The study was concerned with the problem of how S's phenomenal horizontal would be influenced by systematic distortion of the visual field. An experiment compared the directional after-effects of 6 geometric transformations of a rectangular grid composed of 10 vertical and 10 horizontal lines, the grid being the only figure in a black visual field. Each of 36 Ss made 240 difficult judgments of whether an exposed line was slanting up or down. The scores were subjected to an analysis of variance. Very considerable individual differences between different orders of presentation indicate that perceptual after-effects bridged the inter-trial rest period of 4 min. and had slight but measurable effects on the next trial series. A detailed analysis of the overall significance of experimental treatment showed that the effect on S's phenomenal horizontal was measurable after the visual stimulus field and visual after-effects had disappeared, and that the amount of the effect was a curvilinear function of the amount of distortion. Gledstone, R. A GROUP TEST OF PALMAR SWEAT. *J. gen. Psychol.*, 1953, 48, 29-49. (School of Education, Oklahoma A. & M. College, Okla.).

A group test of palmar sweating was developed. It is cheap and simple. It was tested for its ability to discriminate between the average palmar sweat of a group when the individuals of that group were at different emotional levels. Essentially 3 different sorts of situations were used to test the validity of the test: situations which are laboratory-like, or staged, in nature; the academic examination; and certain aspects of the normal school situation. The data from all 3 of these situations indicated the validity of the test as a test of intra-individual emotionality on a group basis. Some contra-evidence was obtained, but it is both considerably overshadowed by the positive evidence and of doubtful validity due to certain experimental errors committed. Some data indicate that the test is individually diagnostic if the stress is severe enough. It is concluded that the test promises to be useful. Some variables involved remain to be more fully explored. Use of the test in the solution of psychological problems is to be discouraged at this point of the development of the test unless competent personnel have a thorough understanding of the variables involved.

Grings, W.W. THE EVALUATION OF EXPERIMENTALLY CONTROLLED CRITERIA. *Psychol. Bull.*, July 1952, 49(4), 333-338. (University of Southern California, Los Angeles, Calif.) (Diss.)

Many of the most relevant objective criteria of performance in military and industrial situations are rendered comparatively useless because of their unreliability. They are often complex and their variance is determined by a multitude of factors other than performance. This paper considers some of the problems of estimating or predicting the improvement that might be expected to result from the exercise of experimental control over selected sources of extraneous variation within the criterion. In particular, a method of randomizing the effects of a given variable with reference to individual performers is developed. (HEIAS)

Hastorf, A.H. THE INFLUENCE OF SUGGESTION ON THE RELATIONSHIP BETWEEN STIMULUS SIZE AND PERCEIVED DISTANCE. *J. Psychol.*, 1950, 29, 195-217. (Dartmouth College, Hanover, N.H.).

A study was conducted to determine whether a change in suggestion as to the nature of a stimulus would alter its apparent distance. Thus, one circular stimulus was called a ping-pong ball and later a billiard ball. 32 Ss adjusted the size of the projected stimulus so that it appeared to be the same distance as a fixed marker; at a later time they merely made localization judgments. A comparison of size settings under different suggestion shows that significant differences did occur in the direction expected. Analysis of the localization judgments supports the size setting analysis. The results were interpreted as a demonstration that, under certain conditions, the size of a stimulus can be used as a distance cue and that apparent distance depends upon assumed size of object being judged. The phenomenon of size constancy was discussed in relation to these findings. (HEIAS)

Hill, C.W. PERCEPTUAL JUDGMENT AS A FUNCTION OF MENTAL SET, ANCHORING POINT, AND METHOD OF JUDGMENT. *J. exp. Psychol.*, Nov. 1953, 46(5), 325-328. (Vanderbilt University, Nashville, Tenn.).

2 heretofore separate lines of investigation into the dimensions of perceptual judgment were integrated by examining the interacting influences of a visual anchoring point and a conflicting mental set upon the formation of a scale of perceptual judgment. The influence of the suggestion-induced set, with or without the presence of the anchoring point, was significant beyond the .1% level of confidence. A gradual increase in the influence of the anchoring point throughout the series of judgments could be accepted at the 5% level of confidence. It was concluded that: a) the influence of a mental set may be a strong determining factor in the perception and subsequent judgment of an unstructured situation; and b) the presence of an anchoring point may be of help in stabilizing the perceptions and judgments, but its influence should not be taken for granted.

Knehr, C.A. INDIVIDUAL DIFFERENCES IN SUBJECTIVE COLOR. *J. Psychol.*, 1953, 36, 289-294. (Cornell University Medical College and Hunter College, New York, N.Y.).

The experiment was designed to investigate the possible role of central activity in subjective color. A standard Benham disc rotated clockwise against a medium gray background at 12.5 revolutions per second. 25 Ss looked at the rotating disc and, after a minute or two, described what they saw, and matched the color against standard color caps. The inner band (of the Benham disc) yielded only 2 colors. Green was seen by 2 Os, while purple or blue-purple was reported by 6 Os. The second band showed a wide distribution of color matching from yellowish-green around through yellow, orange, and red, to blue-purple. The distribution of the third band was quite different with most Os reporting colors from the bluish green around to reddish orange. In the fourth band, most Os reported charcoal or other dark gray. Repeat testing on 6 Ss indicated no appreciable changes in color matching. The large individual differences in subjective color might be attributed to some aspects of central, rather than retinal, functioning. (HEIAS)

Lewis, D. THE EFFECT OF NOISE AND VIBRATION ON CERTAIN PSYCHOMOTOR RESPONSES. *Res.*, 6, Jan. 1943, 87pp. Civil Aeronautics Administration, Washington, D.C. (State University of Iowa, Iowa City, Iowa).

Experiments were undertaken to learn if there is a decrement in work under noise and vibration conditions similar to those characterizing military aircraft. In the first study, 80 male Ss performed on a Hashburn apparatus for 1 1/2 hrs under conditions of silence (control), noise of 85 and 110 db, vibration 4 to 6 mils, and a combination of the 2 noise levels and vibration. The second study used 36 Ss over a 4 1/2 hr work period. Effects of noise and vibration, respectively, on heart rate, breathing, tilt perception, brain waves, and hearing acuity were studied in addition to work performance on the perceptual motor task. Exposure to loud noise for as much as one hour raised the threshold for hearing somewhat and there was an indication that breathing rate was accelerated during some of the experimental conditions. On the whole, however, the results were negative in the sense that they revealed no consistently significant differences between reactions when noise, vibration, or both were present and when these supposedly disturbing factors were absent. The experimental design did not permit a detailed examination of changes in attitudes and feelings and of possible increases in effort required to maintain "efficiency" under such conditions. Miller, G.A. & Frick, F.C. STATISTICAL BEHAVIORISTICS AND SEQUENCES OF RESPONSES. *Psychol. Rev.*, Nov. 1949, 56(6), 311-324. (Harvard University).

5786
This paper is concerned with procedures that can be used to analyze serial dependencies in chains of responses. An approach to experimentation in modern psychology, called "statistical behavioristics", is set forth. Within this area lie the problems that involve sequences of response or courses of action. Methods of approximate representation of the course of action are discussed and an index of behavioral stereotypy (predictability) is defined. An experimental illustration of the procedures is given using data on multiple-choice behavior.

Bean, E.S., Davenport, E.W., & Harsh, C.M. AIR STATION CONTROL TOWER SURVEY. *NEL/Rep.* 707, Aug. 1956, 28pp. U.S. Navy Electronics Laboratory, San Diego, Calif.

5787
To make a human factors evaluation of air-traffic control towers, 4 military and two civil installations were studied by visits of a survey team or by mailed questionnaire. Data obtained from all towers related to problems of air traffic, control tower operating procedures, communications, equipment in the cab, tower structure and cab environment, and personnel. Numerous recommendations are made for improvement in these areas and the desirability of standardization is discussed.

Scopino, J.A., Gartner, W.B., Manning, F.E. & Older, H.J. STUDY OF THE PRESENT STATUS OF TRAINING AIDS AND DEVICES IN THE ARMY TRANSPORTATION COMPANY OFFICERS' COURSE. Contract Nonr 1927(00), NAVTRADEVEN Proj. 20 F 16, Tech. Rep. 1927 02 1, June 1956, 65pp. USN Training Device Center, Port Washington, Long Island, N.Y.

A study was undertaken in order to determine the optimum utilization of the current training aids and devices being used in the Transportation Company Officers' Course at the Transportation School, Ft. Eustis, Va. Most of the aids in use were two-dimensional graphics, films, and models; with few exceptions, complex training devices were not employed. Data were obtained from various sources such as vault files, interviews with instructors, evaluation forms, student surveys, and instructors' opinions. The major findings can be summarized as follows: Of the 150 training aids surveyed 78 were judged satisfactory in their present form, 54 were satisfactory if modified, and 18 were unsatisfactory. The most common weakness of the aids was their lack of attention value. Specific recommendations are presented for modification of existing aids, substitutions for the unsatisfactory aids, and optimum utilization of all training aids. (HEIAS)

Moore, F.A. & Riopelle, A.J. THE EFFECT OF VARYING THE INTENSITY AND THE DURATION OF PRE-EXPOSURE UPON SUBSEQUENT DARK ADAPTATION IN THE HUMAN EYE. ALCOHOL, PHARMACOL. PSYCHOL., Feb. 1953, 46(1), 49-52. (University of Wisconsin, Madison, Wisc.; Emory University, Atlanta, Ga.).

The recovery of dark adaptation was measured following all the combinations of intensities and durations of pre-exposure for 4 intensities (66, 66.4, and 6.64 m.L.) and 4 durations (500, 50, 5, and 0.5 sec.). The measuring instrument was a Nachts-Spieler adaptometer, and threshold tests were made for a parafoveal region, 3° visual angle in extent, centered 7° from the fovea on the nasal portion of the right retina. The pre-exposure stimulus was white from the threshold-exposure stimulus was violet. All pre-exposure and test measurements were made through a 2-mm. artificial pupil. The authors served as experimenters and Ss, and each went through all 16 combinations of intensities and durations 3 times. The raw data were recorded in log micromicrolamberts. The values used in the analysis of the results were the arithmetic means of the 3 sets of logarithmic threshold values. The chief results were as follows: a) As pre-exposure intensity is increased (at constant duration) or duration is extended (at constant intensity), the initial threshold rises and the recovery of dark adaptation is retarded. When the pre-exposure intensity is increased by a given factor, the initial threshold value is raised more than if the duration is increased by the same factor. b) There is a marked variation in the values of the threshold at which color is last seen in the test stimulus; following lower intensities of pre-exposure, colored stimuli are seen at lower threshold values than at higher intensities. c) When the reciprocity relationship of pre-exposure for the different values of intensity and time for which $I \times t = C$ is investigated, it is found that there is little or no difference in the course of dark adaptation following degrees of pre-exposure equal to 3,320 m.L.-sec. and below. For higher degrees of pre-exposure, 33,200 and 332,000 m.L.-sec. marked differences are found; the higher the degree, the greater the difference. R 15

Travers, R.M.W., Marron, J.E., & Post, A.J. SOME CONDITIONS AFFECTING QUALITY, CONSISTENCY, AND PREDICTABILITY OF PERFORMANCE IN SOLVING COMPLEX PROBLEMS. Proj. 7703, Task 77071 and 77073, Res. Rep. AFTRC-TN-55-27, Sept. 1955, 86pp. Personnel Research Laboratory, AFTRC, Lackland AFB, San Antonio, Tex.

5791

This report is a preliminary study of determinants of behavior in solving problems in complex situations. As a first step, theories of problem solving were reviewed for ones concerning the psychological variables that might be related to the problem. Four administrative-type problems were developed in which the quality of solution could be reliably scored and were administered at Lackland Air Force Base without attempt to introduce incentives. Analysis of the scores led to further testing of groups with and without threat (instructions that test results might affect their future) and ratings on basis of anxiety levels. Results were related to scores on certain tests from Airman Classification Battery. Implications of the findings for further research are discussed. T. R 24

Weiss, E.C. THE EFFECTS OF MAGNIFICATION ON VISION IN RELATION TO ORDNANCE OPTICS. Proj. TBI-1000-10, Rep. 4, Nov. 1955, 21pp. Aberdeen Proving Ground, Ordnance Corps, Research and Development Division.

5799

To evaluate the effectiveness of magnification as a visual aid for Ordnance optics, field studies were conducted, under desert conditions, to test the hypothesis that, at specified ranges, visual acuity improves with increased magnification while depth perception performance is independent of magnification. Twenty subjects located the gap in a Landolt ring at 100 yards and made judgments of depth for two tombstone shaped targets at 200, 400, 800, and 1600 yards with binoculars having 1, 6, 7, and 10 x magnification. The data are handled by analysis of variance, the results discussed, and certain recommendations with respect to binoculars and future research are outlined.

Thetford, P.E. & Cuedry, F.E. THE POSTURAL VERTICAL IN UNILATERALLY LAMINECTOMIZED INDIVIDUALS. Contract W60nr 434, T.O. 1, Proj. Designation NA 143 455, Proj. NA 001 063 01 26, Rep. 26, June 1952, 6pp. USN School of Aviation Medicine, Pensacola Air Station, Fla.

5 female human Ss with only one functioning labyrinth were tilted 20 degrees right and left under conditions of delay (45 seconds) and no delay in the tilted position. Displacement of the postural vertical in direction of the injured side was not exhibited by these Ss. The results indicate that Ss respond to delay about the same as normal Ss. Adaptation to tilt was not specific to the healthy side.

DEVELOPMENT OF NOISE SUPPRESSORS FOR SPEECH
COMMUNICATION SYSTEMS. Contract AF 28(089)-
208, Interim Engng. Rep. 4, Jan. 1951, 6pp.
Air Materiel Command, Watson Laboratories,
Red Bank, N.J.

5800
This is an interim engineering report on the develop-
ment of noise suppression methods to be used in systems
transmitting speech. Progress to date on an experimental
model of a noise suppressor is reported. Changes in the
compressor circuit and problems encountered in equalli-
zing expander channels due to temperature sensitivity and
differences between circuits are discussed. Some signal-
to-noise measurements are included to compare a wide-
band expander with a 30-channel expander.

Vandenberg, J.O. THE FACTS ABOUT HUMAN ENGINEERING: AN IMPORTANT NEW MANAGEMENT TECHNIQUE.
Advanced Management, Nov. 1953, 18(11), 25-27. (Pittsford Arsenal, Dover, N.J.).

In the past 10 years the term "human engineering" has been applied to a new area of psy-
chological endeavor. This area of work is still so new that it not only lacks definition of
boundaries but many psychologists are relatively unfamiliar with what their fellows are
attempting to do. This paper has, therefore, both an historical and definitive purpose. It
traces briefly the history of human engineering and presents a definition which seems appro-
priate to its preferred, current usage.

Hoser, H.M. & Dreher, J.J. RESEARCH ON THE LANGUAGE OF VOICE PROCEDURES. A COMPARISON OF
UNITED STATES - UNITED KINGDOM AND INTERNATIONAL CIVIL AVIATION ORGANIZATION PHONETIC ALPHAB-
BETS. Contract AF 19(600) 316, AF Proj. 519, Rep. 3, Part 11, June 1953, 64pp. Ohio State
University, Research Foundation, Columbus, Ohio

An experimental comparison was made of 2 phonetic alphabets--United States - United King-
dom (US-UK) and International Civil Aviation Organization (ICAO). Articulation tests using
a representative panel of foreign and American speakers and heard by an equivalent panel of
listeners trained in both alphabets and the foreign accents of the speakers were administered.
Under signal to noise ratios (S/N) ranging from 0 to -16 db. Analysis of articulation scores
and confusability scores for each alphabet shows the ICAO to be superior at all S/N levels
above zero, yielding fewer errors and confusions. A rating scale for preference, given to
166 Ss of mixed nationalities before and after training on the 2 alphabets, showed that train-
ing reduces any initial preference for either alphabet. A further test of response tenden-
cies favoring the use of one alphabet over the other showed the ICAO to be favored by the Ss
who took part in the articulation tests. Therefore, revisions in the ICAO alphabet were sug-
gested (on basis of item analysis and also further testing) to improve its original frame-
work. Changes recommended were to change COCOA to CHARLIE, NETNO to MIKE, UNION to UNIFORM,
and EXTRA to X-RAY. (HEIAS)

Ellis, D.S., Montgomery, V. & Underwood, B.J. REMINI-
SCENCE IN A MANIPULATIVE TASK AS A FUNCTION OF WORK-
SURFACE HEIGHT, PREREPT PRACTICE, AND INTERPOLATED REST.
J. exp. Psychol., Dec. 1952, 44(6), 420-427. (Iowa
State College, Iowa City, Iowa).

5807
This experiment tests reminiscence in a manipulative
motor task as a function of work-surface height, prerept
practice, and interpolated rest. One hundred and eighty
subjects were presented with the Minnesota Rate of
Manipulation Test under various conditions of three
variables: (a) work-surface height: 3 in. below and 8 in.
above S's elbow height; (b) 2, 8, and 16 min. of massed
prerept practice; and (c) 2 min., 10 min., and 24 hr.
rest periods. The results discuss the effects of these
variables upon reminiscence (defined as difference
between postrest performance and extrapolated linear
curve of the mean performance).

Platzter, H.L. A NON-LINEAR APPROACH TO HUMAN TRACKING. Contract Nonr 1571(00), Proj. NR 145
099, Interim Tech. Rep. 1 2490 1, Dec. 1955, 32pp. Office of Naval Research, Washington, D.C.
& Physiological Psychology Branch, The Franklin Institute, Philadelphia, Penn.

The phase plane has been used to study response characteristics of the human operator
in tracking problems. This study has revealed strong evidence of non-linear behavior. The
phase-plane can be used as a tracking display, and since it presents more information than
a conventional display, improved performance should be observed. This was found to be the
case, especially when the phase-plane display had an optimum-switching line marked on it.
The disadvantage of the phase-plane display is that it is 2-dimensional. The θ -display was
developed to overcome this disadvantage. The θ -display contains most of the information
contained in the phase-plane display including its optimum switching properties, and has the
advantage of being one-dimensional. Finally, the sampled θ -display was used to study the
essential role played by velocity information in tracking.

TRAINING METHOD. *J. appl. Psychol.*, Dec. 1948, 23(6),
420-436. (Division of Education & Applied Psychology,
Purdue University, Lafayette, Ind.).

5808

This report describes the development of a method of analyzing the hand-foot coordination movements involved in the operation of a contact disc cutting machine. Movement analysis as a training device is examined by comparing new operators trained with this method against previous experienced operators, and against new operators not trained in this method. Finally, data are offered on the effects of this method upon old experienced operators. Results are discussed in terms of comparative quality and quantity of production evidenced by the various groups of operators.

Jesty, L.C. & Phelps, N.R. THE EVALUATION OF PICTURE QUALITY WITH SPECIAL REFERENCE TO TELEVISION SYSTEMS. PART II. *Marconi Rev.*, 1951, 14(103), 25-35.

5815

To evaluate the picture quality of various reproducing systems—television, still and motion picture photography—(see 5816), four parameters (brightness, resolution, contrast, and viewing distance) were varied and their effects on visibility in reproduction determined. The experimental results were analyzed in this paper with respect to system performance. Interactions of resolving power, brightness characteristic, and signal/noise (graininess) were discussed. A method of applying the type of data obtained in these experiments to the determination of television standards was illustrated. Further research needs were indicated.

Imus, H.A. MANUAL FOR USE IN THE SELECTION OF FIRE CONTROLMEN (STEREOSCOPIC RANGEFINDER OPERATORS). Contract OCMsr 1171, Proj. N-114, OSRD Rep. 4050, Memo. 8, Aug. 1944, 52pp. Office of Scientific Research & Development, NSRD, Applied Psychology Panel, Washington, D.C. (University of Wisconsin, Madison, Wisc.).

This report consists of a manual for use in the selection and classification of Naval personnel for training as stereoscopic rangefinder operators, FC (O). It includes the directions for the organization, equipment and procedure of a testing unit in a Naval Training Center or Naval Receiving Ship. Detailed instructions for the administration of the various tests and for the reporting of the results are presented also. The selection procedure consists of a preliminary elimination by the Selection Office of the Training Center of those men who do not meet certain qualifications on the General Classification, Reading and Mechanical Aptitude Tests. Only men who meet these qualifications and are under 30 are sent to the Vision Testing Center FC (O), where tests for visual acuity and heterophoria at far vision are administered first. The men who meet the specified qualifications are tested then for stereoscopic acuity and their interpupillary distances are measured.

5819

Flexman, R.E. & Smith, J.F. A METHOD FOR PHOTOGRAPHIC RECORDING OF FLIGHT PERFORMANCE IN 3-PLACE T-6G AIRCRAFT. Research Note Pilot: 511, Proj. 21 08 004, March 1951, 2pp. USAF Human Resources Research Center, Goddard AFB, San Angelo, Tex.

A method of obtaining a photographic record of the instrument indications in the rear cockpit in the T-6 aircraft during flight was devised. The requirements met included frequency of recording (often enough to show any significant changes), simplicity of operation, establishment of operating procedures and methods for evaluating the photographic records. A detailed account of the camera installation is included. (HEIAS)

5820

Imus, H.A. & Brogden, W.J. DISTRIBUTIONS OF MEASURES OF INTERPUPILLARY DISTANCE. Contract OCMsr 815, Proj. PDRC 759, OSRD Rep. 1341, Rep. 1, March 1943, 6pp. Office of Scientific Research and Development, NSRD, Brown University, Providence, R.I.

This report was prepared because of request from the National Bureau of Standards and the Frankford Arsenal (see letters in appendix) for data on distributions of measures of interpupillary distances. Measures of interpupillary distance are presented in both tabular and graphic form for 6553 white soldiers and 127 negro soldiers examined at the Stereoscopic Testing Center, Fort Eustis, Va., during the period from June 1, 1942 to February 1, 1943. The distribution for the white population has a mean of 64.65 mm., a median of 64.15 mm., a range of 52-77 mm., and a standard deviation of 2.73 mm. The distribution for the negro population has a mean of 68.18 mm., a median of 67.78 mm., a range from 61-76 mm., and a standard deviation of 3.22 mm. The average interpupillary distance of the negro population is reliably larger than that of the white population, as indicated by a critical ratio of 12.17. The 2 distributions may be subject to a sampling error at the shorter measures of interpupillary distance, since no soldiers less than 5'6" in height were examined.

Hill, H.E., Kornetsky, C.H., Flanary, H.G. & Wikler, A. EFFECTS OF ANXIETY AND MORPHINE ON DISCRIMINATION OF INTENSITIES OF PAINFUL STIMULI. J. Clin. Invest., May 1952, 31(5), 473-480. (National Institute of Mental Health, Addiction Research Center, Public Health Service Hospital, Lexington, Ky.).

The effects of subcutaneous injections of 15 mg. of morphine on the ability of Ss (post-addicts) to judge the intensity of painful electric shock stimuli were studied under 2 conditions: a) formal, proceeding with the experiment without familiarizing the Ss with the potentially fear-inspiring experimental situation; b) informal, preceding the experiment with reassurance, demonstration and explanation designed to allay the Ss' anxiety. In both groups 6 consecutive series of 9 stimuli were delivered in each experiment, and the Ss were required to state whether each stimulus was "stronger" or weaker than a standard stimulus. The strength of each stimulus was controlled on the basis of the power (wattage) value delivered to the S. It is concluded that a) under conditions which promote anxiety or fear of pain, Ss tend to overestimate the intensities of painful stimuli; b) morphine reduces such anxiety; c) under conditions in which anxiety is largely eliminated, little if any overestimation of the intensities of painful stimuli occurs; d) morphine does not affect the ability of Ss to accurately estimate the intensities of painful stimuli when anxiety is dissipated; and e) anxiety, particularly that which is associated with anticipation of pain, is one important variable which must be controlled in experimental investigations of problems related to pain and analgesia.

Forbes, T.W. DRIVER CHARACTERISTICS AND HIGHWAY OPERATION. Traffic Engineering, Nov. 1953, 24, 3pp. (National Research Council, Committee on Highway Safety Research, Washington, D.C.).

A growing interest among highway traffic engineers as well as among other traffic groups in driver characteristics, habits, and behavior in relation to highway characteristics is discussed in this paper. Following presentation of human factors information that could improve the design of a specific faulty intersection, these topics are discussed: importance of the unfamiliar driver, highway improvements which cause human factor accidents, human factors on freeways; and one possible cause of rear-end collisions. The writer points out that much human factor information is available and lists some sources for such information. In conclusion the need for more human factor research in traffic studies is discussed. (HCIAS)

Forbes, T.W. & Reiss, R.J. 35-MILLIMETER AIRPHOTOS FOR THE STUDY OF DRIVER BEHAVIOR. Highway Res. Board Bull., 1952, 60, 59-66. (Institute of Transportation & Traffic Engineering, University of California, Los Angeles, Calif.).

Aerial pictures of highway traffic were obtained using a reasonably priced, 35-mm movie camera modified for the purpose. Satisfactory definition was obtained by projecting the pictures at a magnification up to 40 diameters with a 2- by 2-in.-film slide projector. The use of such a camera will allow 1,200 exposures without reloading, thus making it possible to follow driver behavior on the highway without excessive cost for film. Pictures taken from a light airplane at between 3,500 and 4,000 ft. obtained information on driver behavior which would be very difficult to obtain in any other way. Somewhat greater altitude could have been used to advantage. Rental of a light plane is not excessive in cost, relatively speaking. Further work is necessary on aiming and sighting mechanism for obtaining vertical pictures while following the curvature of highways, and a special intervalometer must be developed for the modified camera. The ordinary aerial-mapping technique of taking photos in straight and level flight is not satisfactory for the study of driver behavior if cost is to be held within the range of most university and traffic research organizations. Acquaintance with the usual problems of air photography and some practice on the part of the pilot in maintaining a track vertically over the highway will be necessary even when these devices are available. However, the method has been shown to be both feasible and promising for the study of driving behavior on the highways. A new type of traffic sample is provided by the sweeping characteristic of the pictures.

Fattu, M.A. & Mech, E.V. THE EFFECT OF SET ON PERFORMANCE IN A "TROUBLE SHOOTING" SITUATION. J. appl. Psychol., 1953, 37, 214-217. (Institute of Educational Research, Indiana University).

5835
Three groups of 18 college students solved six trouble-shooting problems before and after an interpolated period in which group 1 read magazines, group 2 received a lecture on the nomenclature and functioning of gear trains, and group 3 received a lecture on systematic methods in trouble-shooting. The problem apparatus consisted of a pair of complex gear trains. Differences between the experimental groups are analyzed with respect to the proportion of correct solutions reached before and after the interpolated period, and the length of time taken for each trial.

Erickson, D. & Lendis, C. THE EFFECT OF INTENSITY, LIGHT-DARK RATIO, AND AGE ON THE FLICKER-FUSION THRESHOLD. *Amer. J. Psychol.*, July 1952, 55(3), 375-388. (Columbia University, New York, N.Y.).

We have determined the flicker-fusion threshold at 6 levels of apparent brightness (frequency-intensity contours) for 7 trained Os, making 12 determinations daily at each brightness for 6 to 10 days with a stroboscopes and for 5 days with an episcope. The stroboscopes provided a fixed flash duration of 20 msec. throughout the frequency-range used, which resulted in a dark period that varied between 95.90 and 99.96% of the stimulus cycle. The episcope provided a flash cycle with equal light and dark periods as frequency varied. For each of the 6 levels of brightness, the average CFF for all Os was higher with the stroboscopes than with the episcope. In 36 of the 42 comparisons the difference was statistically significant. The 5 younger Os (age 22-26 yr.) had significantly higher CFFs than the 2 older Os (age 50-54 yr.) over the middle range of intensity with the stroboscopes and the upper middle range with the episcope. Variability (SD) of CFF bore a regular increasing relationship to increasing apparent brightness for the entire group of Os. This relationship was not systematically related to age. Variability which is often designated as the effect of practice was shown during the first 3 or 4 days with the stroboscopes. We attribute this to a process of establishing a subjective standard of discrimination at the higher levels of brightness. The difference in frequency-intensity contours between the younger and older Os is partly due to shifts in the effective brightness, but to a much larger extent to a lengthened restoration-period in the functioning of the visual mechanism with increasing age. The difference in frequency-intensity contours between the stroboscopes and episcope is due to the difference in the duration of the dark period in each flash-cycle of the 2 apparatus.

Ellis, D.S. SPEED OF MANIPULATIVE PERFORMANCE AS A FUNCTION OF WORK-SURFACE HEIGHT. *J. appl. Psychol.*, Aug. 1951, 35(4), 289-296. (Iowa State College, Cedar Rapids, Iowa).

An experiment was performed to determine the relationship between work-surface height and speed of manipulative performance of a simple block-turning task. Ss were 48 male college students who performed the task at 6 levels of work-surface height, ranging from a minimum average height of 25.9 in. to a maximum average height of 52.7 in. A Latin-square experimental design was used, in which each S worked at each work-surface height for a 3-minute trial. Analysis of the data yielded the following results: a) Statistically significant variations in speed of manipulative performance were associated with variations in work-surface height. Maximum performance occurred at an average height of 42.0 in., which corresponds to a setting approximately 3 in. below the elbow. Significantly slower performance occurred at higher work-surface heights than at lower heights. b) Significant variations in feelings and locus of muscular strain are associated with variations in work-surface height. An interpretation of the obtained results is offered on the assumption that muscular tension is the variable intervening between work-surface height and performance. The applicability of the construct of reactive inhibition to the data is also noted, and an experiment is suggested to test an hypothesis stemming from the use of this construct. While the results are considered as having only minor immediate practical value for problems of industrial equipment design, they are viewed as indicating that work-surface height is an equipment design variable which is worthy of further investigation.

Eckstrand, G.A. & Wickens, D.D. TRANSFER OF PERCEPTUAL SET. *J. exp. Psychol.*, 1954, 47(4), 274-278. (USAF Aero Medical Lab., Wright-Patterson AFB, Ohio).

5840
This experiment tests the influence of perceptual sets produced by pre-training upon later learning. In the pre-training tasks the S learned to respond to either the form or color dimension of visual stimuli. This was followed by a standard task in which both dimensions were relevant. In the test task, the relevant pre-training dimension was either absent or present for the various groups tested. The learning measure employed was number of responses to reach a criterion of ten consecutive correct responses.

Eckstrand, G.A. STUDIES IN CUE UTILIZATION BEHAVIOR. PART I. THE INFLUENCE OF A RELEVANT BUT "UNUSED" CUE IN TRAINING UPON TRANSFER IN A POSITIVE TRANSFER SITUATION. RDO 694 44, WADC TR 52 79, April 1952, 19pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

5841
This experiment is concerned with the influence of unintentional secondary cues in a training device or simulator upon the learning of primary cues which must be relied upon in the operational situation. In a situation in which Ss pressed one of four reaction keys in response to stimuli in which form, letter, and color were cue dimensions, Ss first learned, on the basis of a secondary cue, a task also containing a primary cue. They were then forced to perform the task on the basis of the primary cue alone, their performance being compared with Ss not experiencing the primary cue during learning.

Eckstrand, G.A. & Morgan, R.L. THE INFLUENCE OF TRAINING ON THE TACTUAL DISCRIMINABILITY OF KNOB SHAPES. Proj. 7182 71513; WADC TR 56 8; Jan. 1956, 16pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

5842

To determine the effects of training on tactual discrimination, three matched groups of 20 Ss were required to discriminate tactually among four knob shapes. After a two-sec. visual presentation of a knob shape, the S grasped an unseen knob attached to the top of a lever and judged it same or different from the shape just presented. A buzzer provided knowledge of results after each of 48 discriminations. Performances (error and time scores) of the three groups, which had undergone 1) no previous training, 2) previous training in associating names with the tactually perceived knobs, or 3) previous experience in feeling the knobs only, are compared.

Egan, J.P., Clarke, F.R. & Carterette, E.C. ON A THEORY OF THE TRANSMISSION AND CONFIRMATION OF MESSAGES IN NOISE. Contract AF 18(600) 571, Tech. Rep. AFSCRC TN 55 67, Oct. 1955, 49pp. USAF Air Research & Development Command, Bolling AFB, Washington, D.C. (Indiana University, Bloomington, Ind.).

In a series of experimental studies the severe restrictions imposed upon the communication process by an articulation test were slightly relaxed by increasing the number of events in the communication sequence. This report presents some of the theoretical considerations that have grown out of this research. A communication event refers to the transmission of a message from a talker (source) to a listener (receiver) followed by the return of a message (correct or incorrect) from receiver to source for confirmation. The relation between source and receiver, serving successively as talker and listener, is asymmetric. Since source knows the original message, he must accept or reject the message sent back to him according to some criterion level. Various types of communication events arise depending upon whether or not the receiver correctly hears the message and whether or not the source confirms the message sent back to him. The various probabilities associated with these types of communication events are defined. The behavior of the source and the relations between the 2 conditional probabilities associated with a correct and with an incorrect confirmation are discussed. A simple mathematical model is presented describing the process of sending the same message over and over again until source confirms it. A theorem is established for a wide class of relations between the conditional probability of a correct confirmation and of an incorrect confirmation. (HEIAS)

Egan, J.P. PERSTIMULATORY FATIGUE AS MEASURED BY HETEROPHONIC LOUDNESS BALANCES. *J. acoust. soc. Amer.*, Jan. 1955, 27(1), 111-120. (USAF Air Research and Development Command & Hearing Communication Lab., Psychology Dept., Indiana University, Bloomington, Ind.).

Perstimulatory fatigue is the decrease in loudness of a steady auditory stimulus during its presentation. In the past it has been measured by requiring a simultaneous dichotic loudness balance between 2 pure tones of the same frequency, one in each ear. Under these conditions the listener hears a single phantom sound whose localization depends upon the relative intensities of the 2 tones. The present investigation shows that the process of localizing the sound image in making the loudness balance is not critical to the occurrence of perstimulatory fatigue. 2 principal conditions were compared. In the first, the frequency of the comparison stimulus was the same as that of the fatiguing stimulus. In the second, the comparison and fatiguing stimuli differed sufficiently in frequency so that the listener always heard 2 pure tones which he could correctly localize in the 2 ears. It is concluded that the amount of perstimulatory fatigue is very nearly the same under these 2 conditions. In the early phases of the present research it was suspected that the loudness balances were influenced by absolute judgments of loudness. A procedure is developed which precludes the formation of a single absolute standard of loudness. This method results in greater measured fatigue than the usual procedure.

Egan, J.P. & Meyer, D.R. CHANGES IN PITCH OF TONES OF LOW FREQUENCY AS A FUNCTION OF THE PATTERN OF EXCITATION PRODUCED BY A BAND OF NOISE. *J. acoust. soc. Amer.*, Nov. 1950, 22(6), 827-833. (University of Wisconsin, Madison, Wisc.).

The excitation pattern of a tone is markedly altered by a masking stimulus. It should be expected that the pitch of the masked tone, as well as its threshold and its loudness, would be affected. In the present investigation the effect of a narrow band of noise (90 cps wide, centered at 410 cps.) upon the pitch of pure tones of low frequency was measured in a series of experiments. Ss matched the pitch of a tone heard in the presence of a band of noise to the pitch of a tone heard alone. These 2 tones, one partially masked and the other not, were presented to the S in repeated succession. The listener first matched these tones for loudness. He then adjusted the frequency of the unmasked tone until it was the same in pitch as the masked tone. The pitch change was investigated at a number of frequencies and of loudness levels. Systematic changes in pitch were observed. The presence of the noise raised the pitch of a partially masked tone whose frequency is immediately above those of the band of noise. This change in pitch occurs even though the intensity of the masked tone is greater than that of the unmasked tone. In contrast, the presence of the masking noise lowers the pitch of a tone whose frequency is just lower than those of the band of noise, but this change is largely accounted for in terms of the intensity difference required for an equal loudness match. An attempt is made to account for the changes in pitch in terms of a place theory.

Egan, J.P. & Klumpp, R.G. THE ERROR DUE TO MASKING IN THE MEASUREMENT OF AURAL HARMONICS BY THE METHOD OF BEST BEATS. *J. acoust. soc. Amer.*, May 1951, 23(3), 275-286. (University of Wisconsin, Madison, Wisc.).

The method of best beats has been employed to estimate the intensities of aural harmonics and of combination tones. It has been generally assumed that the listener hears best beats when the exploring tone produces in the cochlea a disturbance that is equal in magnitude to that of the aural harmonic or of the combination tone being measured. However, as the experiments to be reported will show, when the tone to be measured is near the absolute threshold or is partially masked, the most prominent beats will be heard when the intensity of the exploring tone exceeds that of the unknown tone. Consequently, since aural harmonics and combination tones are partially masked, their intensities will be overestimated when the method of best beats is used. The present paper concerns the magnitude of this error of overestimation. A procedure is presented by which a better estimate of the intensity of an aural harmonic or of a combination tone may be made. When the tone being measured by the method of best beats is well above threshold, the listener hears beats over a wide range of intensities of the exploring tone, and the error of overestimation is small. However, when the tone being measured is near threshold, there is a small range of audible beats, and the error of overestimation is of considerable magnitude. It is therefore possible to correct for this error by determining the range of intensities of the exploring tone over which beats are audible as well as the intensity of the exploring tone required for best beats. Application of this procedure to the measurement of a second aural harmonic is illustrated. An explanation is given of the fact that the intensity of a tone near its absolute threshold will be overestimated by use of the method of best beats. This explanation is formulated in terms of the relation of the minimum and the maximum of the envelope of the beating complex to the listener's threshold for the tones that beat.

Warren, J.M. & Egan, J.P. ON THE ACCURACY OF THE METHOD OF BEST BEATS FOR DETERMINING THE INTENSITY OF A TONE. *J. acoust. soc. Amer.*, Jan. 1951, 23(1), 111-113. (University of Wisconsin, Madison, Wisc.).

The reliability of the method of best beats for determining the intensity of a tone was determined. In all experiments the primary tone had a frequency of 400 cps and an intensity of 50 db; frequency of the secondary tone was varied from trial to trial from 1 to 2 cps (a few trials were given at 35 and 50 cps as well). The task was to listen for a "best beat" when both tones were presented and to adjust the intensity of the secondary tone until these beats were most prominent; 3 Ss were used. Mean SPL's of settings for best beats as a function of frequency show deviations of only a bit over 1 db from the 50 SPL standard. Variability in judgments was surprisingly constant for 2 Ss; the third S reversed, upon questioning, an unusual method of listening leading to a recommendation for emphasizing method to be used during the instructional period. (HEIAS)

5848

Klumpp, R.G. & Egan, J.P. ON THE CORRESPONDENCE BETWEEN THE INTENSITIES OF TWO TONES FOR BEST BEATS. *J. acoust. soc. Amer.*, Jan. 1951, 23(1), 113-114. (University of Wisconsin, Madison, Wisc.).

In this investigation the relation between the intensity of 2 tones differing by 2.5 cps was determined by the method of best beats. The 2 tones, 590 and 692.5 cps, were simultaneously presented to one ear of S who then adjusted the secondary tone to a point where the beats became most prominent. Intensities of the primary tone varied from 60 to 112 db in 6 steps; 6 Ss were used. The relation between the SPL's of the 2 tones are shown graphically; while individual differences are present, the curve is very nearly linear with a slope of less than one. (HEIAS)

Cole, E.L., McIntosh, B.B. & Grether, W.F. BRIGHTNESS LEVELS OF THREE INSTRUMENT LIGHTING SYSTEMS USED BY PILOTS FLYING AT NIGHT. Tech. Rep. 6031, Aug. 1950, 16pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

The red flood, indirect red, and ultra-violet instrument lighting systems installed in C-47 transports were investigated by several pilots during night flights. Brightness levels used by the pilots were recorded for the 3 systems under the conditions of normal night flying, night instrument (maximum), and minimum brightness necessary for safe flight. For normal conditions the lowest brightness level used occurred under red flood and the highest under indirect red. At maximum levels (night instrument condition) red flood was highest, indirect next and ultra-violet and lowest brightness. At minimum levels, indirect red was the lowest followed by ultra-violet and red flood. Indirect red was preferred by the pilots as being the most pleasant and comfortable system and the red flood system was preferred as being the most effective of the 3.

Adams, J.H., Belar, D.C., & Linn, H.A. THE RELIABILITY AND PRECISION OF THE HRC AND MARCH
AND LOMB INTERPUPILLIOMETERS. Contract OCH-
615, OCS Rep. 2087, Sept. 1943, 15pp. US Office of Scientific Research & Development, Washington, D.C. (University of
Wisconsin, Madison, Wis.).

A study of the reliability and precision of the HRC Interpupillometer and the March
and Lomb Interpupillometers was made using trained examiners. 81 Ss were measured twice on
both instruments by independent examiners. Data on the last 59 men were analyzed for reli-
ability. The analysis showed that a) the range of measures of interobserver distance ob-
tained was comparable to that of a male army population; b) there were no significant differ-
ences between mean and S.D.'s obtained on the 2 instruments; c) dispersion of differences
between test and re-test was significantly less for the HRC instrument than for the March
instrument; d) a significant proportion of measurements obtained with the HRC instrument fell within the toler-
able limits required for rangefinder operation (± 0.25 mm); e) while coefficients of reliability
for both instruments were high that for HRC instrument was higher; and f) that probable
error of measurement favors this same instrument. Therefore, it was recommended that the
HRC Interpupillometer be used in selection tests for men assigned to use binocular instru-
ments. (HEIAS)

UN Air Test Center. COMPARATIVE STUDY OF PILOT FATIGUE RESULTING FROM EXTENDED INSTRUMENT
FLIGHT USING THE STRAIGHT AND BAYLISH INSTRUMENT PANELS. FINAL REPORT. Proj. ATL 801,
Oct. 1939, 44pp. UN Air Test Center, Patuxent River, Md.

In the field test, a group of 6 relatively inexperienced Naval pilots and a group of 6
relatively experienced Army pilots flew a P-51A through 1 hour flight using the Air panel
and 1 hour flight using the Bayliss panel. Both flights being made under simulated instru-
ment conditions. At 3 set intervals during each flight they flew a carefully prescribed
flight pattern which provided a standard work-sample for comparing performance from panel
to panel. During these work-sample portions of the flights, motion photographs were made of
the instrument panel and of the pilot's eyes. Experimental controls were employed to mini-
mize variation and error due to weather, practice effects, unfamiliarity with the airplane
and task, and variations in physical condition of the Ss. No statistically significant
differences in "goodness of flight" scores were found; that is, neither panel is superior
to the other with respect to inducing superior "goodness of flight", as measured by the
grading technique here employed. In fact, it is indicated that a relatively slight amount
of practice has more influence on "goodness of flight" than does an exchange of either panel
for the other. Statistically significant differences between the panels were discovered,
however, with respect to the time spent on various individual instruments. These differences
are directly attributable to differential position of a particular instrument on the 2 panels.
It is therefore indicated that a panel arrangement plays a considerable part in determining
the amount of time pilots spend on a given instrument.

Yaglom, C.P., & Kimball, D. PREVENTION OF
HEAT CASUALTIES AT MARINE CORPS TRAINING
CENTERS. Contract NS-61-07665, Final Rep.,
May 1956, 13pp. NSR, Harvard University.

5862
To develop a rational program for the control of heat
casualties in military training centers, studies were
conducted at three East Coast Marine Corps Training
centers during the summer of 1955. Meteorological observa-
tions (temperature, radiation, humidity, wind) were re-
corded and composite heat indices studied in relation to
heat loads (evaporative sweat loss measurements), heat
stress (changes in heart rate and body temperature), and
peak loads versus long-training hours for four squads
(44 men) during a six-week training period. Incidence of
heat casualties was studied in selected groups of basic
and advanced trainees, using the infirmary logs of camps,
and tolerance limits for work determined in the heat.
Recommendations are included for a program to prevent
heat casualties. T. G. R 4

Licklider, J.C.R. THE INTELLIGIBILITY OF AMPLITUDE-DICHOTOMIZED, TIME-QUANTIZED SPEECH WAVES. *Acoustics Lab., MIT, 1956, 44(6), 870-873.* (Massachusetts Institute of Technology, Cambridge, Mass.).

This paper describes a way of reducing the normally very complicated speech wave to simple geometric form without destroying intelligibility. Reports the results of articulation tests of the simplified speech, and gives two illustrations of things that can be done more simply with the simplified than with the normal wave. Both methods of simplification involve dichotomization of the amplitude scale and then quantization of the time scale. The first step is achieved by subjecting the speech wave to infinite peak clipping. The second by generating a rectangular wave whose switchings from one amplitude level to the other are related to the switchings of the clipped speech wave by one or the other of 2 rules. One of the rules yields marginal intelligibility with quantized 0.2 millisecond in length; the other requires slightly shorter quanta. The relative merits of the 2 methods are accounted for by an elementary application of information theory. Autocorrelation functions, which are especially easy to compute for the simplified waves, are shown.

5866
Morris, J.D. NORMAL HEARING AND ITS RELATION TO ACUITY. *Laryngoscope, Nov. 1954, 64(11), 528-557.* (USC Medical Research Lab., New London, Conn.).

The history is briefly reviewed of how American "Normal Hearing" came to be standardized. It was shown that the standard could be specified in terms of sound pressure level in the ear canal as well as in a brass coupler as at present. The discrepancy usually cited as excessive between hearing norms as collected by large clinical surveys and by laboratory studies is shown to be sharply reduced when the quite correct comparisons are made. Nevertheless, an appreciable discrepancy, though not exceeding 8 db, exists. It is reasoned that the clinical-laboratory discrepancy is not due to selection of Ss, nor of familiarity of Ss with psychophysical judgments, but resides in features of the clinical situation which are correctable. A laboratory standard for audiometer "Normal Hearing" is proposed which would more nearly correctly describe the status of an individual's hearing ability in comparison with young, healthy ears, and which would tend at the same time to have a salutary effect upon audiometric practice.

Licklider, J.C.R. A DUPLEX THEORY OF PITCH PERCEPTION. *Experientia, 1951, 7(4), 128-133.* (Massachusetts Institute of Technology, Cambridge, Mass.).

The essence of the duplex theory of pitch perception, as presented here, is that the auditory system employs two kinds of analysis--frequency and autocorrelation. The frequency analysis is performed by the cochlea and has been incorporated into the resonance-place theory of Helmholtz; the autocorrelational analysis, carried out entirely in the time domain, is performed by the neural part of the system. The latter, therefore, is an analysis not of the acoustic stimulus itself but of trains of nerve impulses into which the action of the cochlea transforms the stimulus. The neural mechanism of analysis is developed in some detail and the relations between theory and observation are discussed. The appendix gives a definition of the running autocorrelation function as used in the above argument. (MEIAS)

Licklider, J.C.R. ON THE PROCESS OF SPEECH PERCEPTION. J. Acoust. Soc. Amer., Nov. 1952, 24(6), 590-594. (Acoustics and Lincoln Labs., Massachusetts Institute of Technology, Cambridge, Mass.).

The process of speech perception is analyzed into 3 main operations: a) translation of the speech signal into form suitable for the nervous system, b) identification of discrete speech elements, and c) comprehension of meaning. The first operation appears to correspond roughly to the transformation made by the sound spectrograph. The second may be carried out by the neural equivalent of a set of matched filters. The third appears to involve a neural form of cross-correlation that exhibits some of the properties of the analogous electronic process.

Muggins, W.M. & Licklider, J.C.R. PLACE MECHANISMS OF AUDITORY FREQUENCY ANALYSIS. J. Acoust. Soc. Amer., May 1951, 23(3), 290-292. (Massachusetts Institute of Technology, Cambridge, Mass.).

One of the central problems in auditory theory is to reconcile a) the acute perception of slight changes in pitch displayed by the human listener with b) the broad tuning of his cochlear analyzing mechanism. This paper attempts to describe and to relate a number of theoretical solutions to that problem. The hypotheses involve mechanisms, both mechanical and neural, for sharpening the analysis inherent in the cochlear transformation from frequency of stimulation to locus of vibration. These mechanisms operate in the domain of place--they are place theories that supplement the classical place theory.

McCard, F. THE EFFECTS OF AUDITORY-VESTIBULAR NERVE PATHOLOGY ON THE ADJUSTIVE EYE-ROLLING REFLEX. Contract N00014-54, T.G. 1, Proj. Designation NR 143 455, Proj. NM 001 063.01.32, Jotac Project Rep. 32, June 1953, 4pp. WVA School of Aviation Medicine, Pensacola Air Station, Fla. (Psychology Dept., Tulane University, New Orleans, La.).

The method of measuring the counter-rolling reflex by the use of after-images was applied to a patient with VIII nerve pathology. Virtual absence of adjustive eye-rolling to lateral body tilts in the right quadrant; and minimal values to tilting in the left quadrant were found for the patient. The results support the contention that normal adjustive eye-rolling is dependent upon the functional integrity of the vestibular system.

Ryan, T.A., Bitterman, R.E. & Cotterell, C.L. INVESTIGATIONS OF CRITICAL FLICKER FUSION FREQUENCY (CFF). Proj. 12, Contract with Research Committee of the Illuminating Engineering Society, 1948-1950, 16pp. Cornell University, Ithaca, N.Y.

A series of experiments were conducted to investigate further the validity of the critical-fusion frequency of visual flicker (cff) as a measure of cumulative fatigue effects resulting from visual work. Studies of conditions and methods of testing were first made to establish the effects of surround brightness, adaptation, base level and rate of increase of flicker upon cff. Thereafter, a visual task of reading for a 3 1/2 hr period was performed under the following conditions: a) 3 illumination levels (2, 11, and 50 ft-l) with cff determinations made before, during, and after reading; in the same illumination as the work, 12 Ss; b) 2 levels of illumination (2 and 50 ft-l) with tests as before only now under varying conditions, 32 Ss; and c) glare light source, 10 Ss. An analysis of mean cff's and changes due to the various test conditions was made. No significant changes, whether of decrease or increase were found. It is suggested that the cff test is not sensitive to the effects of the visual conditions of reading or other tasks where the stress is not primarily of a visual nature. (MEIAS)

Vaughan, J.A., & Daniels, P. Jr. THE PHYSIOLOGY OF LOAD-CARRYING. IX. THE ENERGY COST OF SLED PULLING BY ONE MAN. Tech. Rep. EP-26, Jan. 1956, 25pp. Quartermaster Research & Development Center, Environmental Protection Unit, Attick, Mass.

5874

To establish the relationship between sled loads and energy expenditure in men pulling the load over snow surfaces, 16 conditioned men pulled gross loads varying from 53 to 196 pounds on a plastic boot-type sled at two sites in the Canadian Arctic. In one phase, walking speed ranges were varied to study effect of speed. The energy cost (analysis of expired air), pulse rate, and drag were measured and the mechanical efficiency calculated from the external work done. Snow characteristics were measured and studied in relation to energy expenditure and drag. The results are applied to maximum load conditions for such work.

Keating, C.E. 400 DITCHING SEATS. FINAL PROGRESS REPORT. Contract N00s.53 418f, Eng. Rep. 664, May 1954, 26pp. Century Engineers, Inc., Burbank, Calif.

The design and testing of an aircraft seat suitable for ditching or crash landing conditions in multi-engine long range military aircraft are described. Requirements and specifications of design are listed, preliminary designs, using 3 types of construction--nylon webbing, nylon mesh, and polyvinyl webbing, were tested both statically and dynamically. The final design is a seat fabricated of both nylon webbing and mesh with standard A4 hardware. It has harness riser attachments to overhead structure. A modified safety belt is used to help retain occupant during crash conditions. Stowage straps are provided so that seat can be folded and stowed to top of aircraft with upper attachment fittings in place providing quick accessibility.

Kesslake, D. M. FACTORS CONCERNED IN THE REGULATION OF SWEAT IN MAN. *SPAC 879*, May 1954. 25pp. Physiological Research Committee, London, England. (RAF Institute of Aviation Medicine, Farnborough, Hants, England).

5876
To test the hypothesis that sweat rate depends on the temperature of receptors situated at some depth in the skin, a series of experiments were conducted. 1) Observations were made on three Ss of skin temperatures and of sweat rates at various rates of working (walking the treadmill) in warm environments of low humidity. 2) The humidity was raised to a moderately high level, and observations were repeated. 3) The same Ss were then studied at rest in warm and very humid environments. On the basis of the findings, suggestions were made as to the factors concerned in the regulation of sweat production in man.

Lowell, C. DESIGN AND DEVELOPMENT OF THE R.A.E. DUMMY OF THE STANDARD ALBINO. *Tech. Note Rech. Exp. 176*, May 1954. 27pp. Royal Aircraft Establishment, Farnborough, Hants, England.

5880
A dummy of the standard albino, developed by the Royal Aircraft Establishment for use in dynamic and static tests, is described. It has the dimensions of the average albino, the limbs and complete man have approximately the correct weights and centers of gravity. Its weight is normally 166 pounds but can be varied if desired. The dummy can be dressed in standard aircraft clothing, equipment, and headgear. There are cavities for instruments in the head and in the upper and lower trunks. This dummy has been used in extensive seat ejection trials to test its suitability for experimental use.
