This report contains detailed specifications for the installation and use of a Broad-band Blue lighting system for a radar air traffic control center which will permit scope observers, maintenance personnel, and other individuals to work in the same room while engaged in a 24-hour-a-day operation. The essential characteristics of the system are summarized in Table 1, page 3. The varied requirements of a lighting system are stated, the relevant psychophysiological and physical facts summarized, alternative lighting systems are critically evaluated, and the results of preliminary operational suitability tests of the proposed system are given. The basic principle employed is the selective use of the visible spectrum; the shorter wave lengths from 400 to 540 mμ are utilized for room illumination (maintenance, etc.) and the longer wave lengths from 540 to 720 mμ are assigned to the scope observers. The system permits one to carry on essential maintenance operations while working next to a scope observer who can see more than a minute of trail on a conventional P-7 phosphor radar display. With minor modifications the system is applicable to other types of radar control centers.

Lambertsen, C.J. & Bascom, W. THE PERMISSIBLE LEVEL OF CARBON MONOXIDE IN INSPIRED AIR. *SIO Ref. 53*, Dec. 1953. 10pp. Scripps Institution of Oceanography, University of California, Berkeley, Calif. (University of Pennsylvania Medical School, University Park, Penn.).

The possibility that compressed air breathed by underwater swimmers may contain small amounts of CO which could be dangerous led to a series of letters in which Dr. C.J. Lambertsen, of the University of Pennsylvania Medical School, answered and discussed a series of questions on the subject. These notes, observations, and calculations are assembled in this report. In answer to the question of how much CO can the body stand without perceptible effect, data from the Bureau of Standards (1921) and Henderson (1927) are graphed to show permissible amounts of CO at sea level. An individual doing light work such as walking can breathe 0.0152 CO indefinitely with no symptoms; for conditions of rest, he can breathe 0.02% CO in air for 2 1/2 hrs without ill effect, for hard work 1/3 that length of time. The second question related permissible amounts of CO at depth. Here the degree of CO uptake by the blood depends on inspired CO concentration, time of exposure, exercise level, and ambient pressure. From Henderson's Toxicity Factor, equations were developed taking the above factors into account and, along with the Navy's "no-decompression" table, were used to develop graphs for figuring maximum allowable CO at any depth. The problem of setting a sensible standard which can be rigorously maintained to insure the safety of all concerned still remains. (HEAS)

Lindner, H.G. NONLINEAR COMMUNICATIONS SYSTEM. A MATHEMATICAL ANALYSIS OF THE EFFECT OF SPEECH CLIPPING ON THE INTELLIGENCE OF SPEECH. *Tech. Memo. R 1520*, July 1953. 34pp. USA Signal Corps Engineering Labs., Fort Monmouth, N.J.

The effect of intelligibility of infinite clipping of speech is analyzed. The approach is based on the assumption that the infinite clipping is equivalent to the action of ideal limiting. The output amplitude frequency spectrum of the ideal limiter is obtained as a function of amplitude samples in the time domain. Next, the power spectrum of directly clipped whispered speech is theoretically determined. Finally in the time domain the mathematical relation for a message function of time, which consists of an amplitude (as a function of time) and a phase (as a function of time) is first differentiated, then clipped and finally integrated. Hedderley, D. THE STATISTICAL THEORY OF DETECTION I. OPTIMUM DETECTION OF SIGNALS IN NOISE. Tech. Rep. 36, Nov. 1953, 71pp. Lincoln Lab., Massachusetts Institute of Technology, Bedford, Mass.

5881

A complete theory of detection is presented that is capable of treating general types of signals (periodic, aperiodic, and random waves) in noise of arbitrary statistical character. By proper formulation of the detection problem as a test of statistical hypotheses, the precise structure of the optimum detector is specified and minimum detectable signals can be defined uniquely when suitable decision curves are constructed. Appendices include some results of sampling theory and integral equations associated with optimum filtering.

Townsend, J.C. & Sanford, E.E. ESTIMATION OF ATTITUDE INSTRUMENT FLYING PROFICIENCY BASED ON PERFORMANCE IN A FLIGHT SIMULATOR. Proj. 400K 7710, Sept. 1954, 5pp. USAF Basic Pilot Research Lab., Goodfellow AFB, Tex.

5884

To test the feasibility of evaluating pilot performance in single place aircraft by measuring performance in a simulator, 64 pilot trainees were required to perform certain maneuvers twice in a simulator and twice in an aircraft (SKY or CFI electronic instrument flight simulator and T-6 or SKY aircraft). Performances in simulators and aircraft were evaluated according to both an objective flight check and a subjective instructor estimate. The coefficients of correlation between these performances, between simulator performances, and between aircraft performances are presented.

Townsend, J.C. STUDENT AND INSTRUCTOR OPINION OF AN EXPERIMENTAL PRIMARY PILOT TRAINING PROGRAM IN WHICH A CONTACT FLIGHT SIMULATOR WAS USED. Proj. 400K 7710, Nov. 1954, 15pp. USAF Basic Pilot Research Lab., Goodfellow AFB, Tex.

5886

This report presents the responses to a questionnaire administered to students and flight instructors who had served in an experiment evaluating the effectiveness of the Link, T-6 contact flight simulator (Type P-1) when used in an Air Force Primary Pilot Training Program. Opinions concerning the use of the contact flight simulator, as well as other aspects of training, were gathered at the end of Primary from both students and instructors and at the end of Basic from students only.

Straight, D.E. & Verdi, A.P. FLIGHT CHECK ITEMS INVENTORY T-6 PRIMARY PILOT TRAINING CONTACT MANEUVERS. Proj. 400K 7710, Task 77166, Sept. 1954, 150pp. USAF Basic Pilot Research Lab., Goodfellow AFB, Tex.

5887

This report contains an inventory of flight check items developed on the basis of an analysis of maneuvers in T-6 aircraft. Each flight check was described in terms of four indices: tolerance limits (allowable error), difficulty level, discriminative power, and reliability. Norms were based on the performances of about 200 student pilots at five levels of training and were checked against their subsequent performance through the final phase. The inventory included general rules and definitions and illustrations of each flight check during the standardization procedure and in the final categorical form. The usefulness of the inventory for the measurement of student performance and the setting of standards for training was discussed.

Solarz, A.K., Matherly, M.G., Dougherty, Dora J. & Hasler, S.G. THE EFFECT OF ATTITUDE TOWARD LINK TRAINING UPON PERFORMANCE IN THE AIRCRAFT. Contract AF 33(634) 25726, Task D; Misc. Rep. D 12, Sept. 1953, 9pp. University of Illinois, Urbana, Ill.

5888

This experiment was undertaken to investigate the effect of a positive or negative attitude toward the P-1 Link trainer upon transfer of training to the T-6 aircraft. An attitude scale was devised to measure attitude toward the P-1 Link. In one experimental group of four Ss a positive attitude toward the Link trainer was induced, and in a similar group a negative attitude. A control group practiced only on the T-6 aircraft. Performance was measured in both the Link and T-6 in terms of trials to reach criterion on a flight sequence.

Vanderbilt, J.N., & Bone, D.F. DEVELOPMENT OF FIELD SLEEPING GEAR. Proj. 7-82-11-0014, Rep. 13 Tentage & Equipage Series, Aug. 1956, 28pp. Textile, Clothing & Footwear Division, Quartermaster Research & Development Center, Watik, Mass.

5889

This report presents the results of a series of observations on the performance of standard and experimental sleeping gear. Insulation measurements were made in the laboratory utilizing the "dipper" and "hot-plate" techniques yielding insulation requirements for various ambient temperatures in CLO values. Various materials and design changes were evaluated in terms of increased insulation. In addition several experimental bags were evaluated by having 20 subjects sleep in them for five days each in a Climate Chamber at 35 degrees Fahrenheit. An analysis of the functional features necessary for adequate field sleeping gear is included and specific areas for further development are suggested.

McIntosh, B.B., Hilton, J.L. & Cole, E.L. PILOT PERFORMANCE DURING EXTENDED PERIODS OF INSTRUMENT FLIGHT. AF Tech. Rep. 6725, May 1952, 47pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

The purpose of this investigation was to collect exploratory data on pilot performance during extended instrument flights. Each of 3 pilots flew a C-47 aircraft for 10, 15 and 17 hours respectively. Equipment installed in the aircraft permitted recording of a) amount of time flight indicators were kept within tolerance limits, and b) continuous variation of flight indicators and control positions. Pilots' introspections and observations by a safety pilot were also obtained after each flight. To supplement the above measures, addition, illusion, and reaction comprehension tests were given before, during and after the 10 hour flight, pilot reaction time to a signal light was taken during the 15 hour flight and an alertness indicator was operated during the 17 hour flight. The time within tolerance results indicate that the pilots kept the flight indicators within the specified tolerance limits for both precision maneuvers and straight and level flight as well after 10, 15 and 17 hours of instrument flight as they did during the first hours of these flights. The results of the graphic records also gave indications that performance, as measured, was not a function of time, since no decrement appeared between the first and last portions of the flight.

Martin, W.B. & Johnson, E.E. AN OPTIMUM RANGE OF SEAT POSITIONS AS DETERMINED BY EXERTION OF PRESSURE UPON A FOOT PEDAL. Proj. AMRL 6 95 20 001, Rep. 86, June 1952, 3pp. USA Medical Research Laboratory, Medical Research & Development Board, Fort Knox, Ky.

The object of this study was to determine an optimum range of seat positions for exertion of pressure upon a foot pedal. Tests on 166 men with anthropometric measurements representative of Army male personnel in general revealed that: a) for the positions in which the most pressure was exerted (25% of total positions tested) the mean vertical adjustment of the pedal was 2.4 in. above the seat and the mean horizontal adjustment from seat to pedal was 33.2 in. b) The mean vertical adjustment for the position at which most foot pressure could be applied was 3.5% of the average body height ($SD = 2.7\%$) and the mean horizontal adjustment was 47.5% of the average body height ($SD = 2.3\%$). c) In generalizing for the average height of Army male personnel (58.4 in.) the position at which the greatest pressure could be exerted upon a foot pedal would require a vertical distance from seat to pedal of 2.4 in. plus or minus 0.3 in., and a horizontal distance of 32.5 in. plus or minus 4.25 in.

Middleton, R.H., & Comfort, Elizabeth. A-20 EXPERIMENTAL CONTINUOUS-FLOW OXYGEN MASK. Rep. WEDP-696-107M, Jan. 1952, 2pp. WADC, Wright-Patterson AFB, Ohio.

5896

To evaluate an experimental continuous-flow oxygen mask, three subjects were selected arbitrarily on the basis of face size to represent the three standard sizes, small, medium and large. The mask was worn under conditions of rest and mild exercise, in which the resting pulmonary ventilation was doubled, in the low-pressure chamber at simulated altitudes of 20,000, 25,000, and 30,000 feet. Minimal oxygen flows designated in the A-9-A oxygen regulator were used. Air samples, obtained from the mask at altitude, were analyzed for nitrogen content at ground level. No evaluation was made for long-term comfort or probable life expectancy. Recommendations are included.

Lowless, H.E. HUMAN TRACKING IN THE FOUR QUADRANTS OF A CIRCULAR SCALE. FPRC 835, May 1953, 14pp. Medical Research Council, Flying Personnel Research Committee, Cambridge, England.

In a compensatory tracking task, the subjects were required to control the pointer on a circular scale by means of a control knob placed vertically below it. 4 targets were used; the top, bottom, left-hand and right-hand cardinal points of the scale. Two control display connections were used: a) "Direct drive," when a clockwise rotation of the control knob caused the pointer to rotate in a clockwise direction. b) "Reversed drive," when a clockwise rotation of the control knob caused the pointer to rotate in a counter-clockwise direction. Each subject was tested on 4 different targets in succession, the drive remaining the same. It was found that the sequence in which the targets were presented greatly influenced the scores, so that these transfer effects tended to obscure any inherent merits which a target might have.

Lipold, O.C.J. & Boyler, P.F.B. THE DESIGN OF LOAD CARRYING EQUIPMENT FOR THE SOLDIER IN BATTLE. Rep. 11/50, Oct. 1950, 58pp. USA Operations Research Group, Department of the Scientific Adviser to the Army Council, Washington, D.C.

The Physiological principles concerned in load-carrying into battle are explained. Experimental procedures are outlined which may be used in the testing of equipment produced in the future and which were used to enable the deductions to be made. The equipment which was used for load-carrying in the experiments is described and criticised and suggestions are made as to how it may be improved. The military requirements of and for carrying equipment in the Army are considered and it is urged that the whole problem of design of clothing, fighting order, marching order and equipment for portage is co-ordinated before the design of any one of these proceeds further. It is concluded that: a) Carriage of loads on the hips is preferable to other methods; b) Less muscular effort is required to carry loads when these are close to the body and disposed in a balanced fashion.

Light, R.S. THE INVESTIGATION OF CANOPY-OFF COCKPIT BUFFETING IN THE B-47 AIRPLANE. Contract W32 038 ac 22413, March 1952, 72pp. Boeing Airplane Company, Seattle, Wash.

This report describes the test and resulting changes to the B-47 Airplane configuration which were necessary to produce a satisfactory cockpit for high speed flight with the canopy and/or the navigator's hatch removed. The investigation was required because early flight tests of the canopy-off configuration showed buffeting in the cockpit so severe that crew members found themselves on the verge of unconsciousness and unable to perform the operations necessary for emergency seat ejection. The critical buffeting occurred at 430 mph IAS, which is below the ejection seat design IAS of 450 mph. The buffeting was alleviated by the addition of a turtledeck aft of the copilot and a copilot's windshield as shown on Page 2. Flight tests proved this configuration to be satisfactory under all canopy and/or hatch off conditions up to an IAS of 525 mph. The fix was obtained by wind tunnel tests on a detailed model of the B-47 nose and cockpit. The reduction in oscillatory pressure intensity obtained in the wind tunnel by changing the cockpit configuration is shown graphically. It was recommended that the cockpit revisions described in this report be incorporated on all B-47 Airplanes having ejection seats.

Lazo, J. HUMAN ENGINEERING INVESTIGATION OF INTERIOR LIGHTING OF NAVAL AIRCRAFT. I. COLORING FOR SINGLE SEAT AIRCRAFT COCKPITS. TED EL 52004, Rep. XG T 216, April 1954, 13pp. USN Air Material Center, Aeromedical Equipment Lab., Philadelphia, Penn.

This is a study of the color requirements for the various surfaces in single seat naval aircraft. 11 pilots participated in the flight evaluation of variously painted aircraft interiors. It was felt that the use of higher reflective paints would be advantageous, if paints are neutral, and contrast is provided for such items as control knobs. (NEIAS)

5905

Lauer, H.K. FLOODLIGHTING OF AIRCRAFT INSTRUMENTS. Rep. 119, June 1952, 14pp. Grimes Manufacturing Co., Urbana, Ohio.

The basic illumination problem and installation restrictions and principles for floodlighting aircraft instruments have been discussed and a smaller floodlighting fixture has been made available. The advantages of floodlighting have been enumerated and the fallacy of a single "standard" fixture has been pointed out. Desirable improvements in instrument design from the illumination and viewing aspect have been presented. If such improvements are made it would appear desirable to seriously consider an extensive investigation on the design of a minimum number of floodlighting fixtures which could provide adequate lighting of most aircraft instrument panels.

Katchmar, L. INDICATORS OF BEHAVIOR DECREMENT. REVIEW OF THE LITERATURE ON REACTION TIME. Proj. DA 47 007 MD 222, Tech. Rep. 5, March 1952, 10pp. USA Medical Research & Development Command, Office of the Surgeon General, Washington, D.C. (Psychology Dept., University of Maryland, College Park, Md.).

5910

Kendall, K. FILM PRODUCTION PRINCIPLES. Information Bull., Fall 1952, 3(3), 73-92. (National Film Board of Canada, Ottawa, Quebec, Canada).

5912

A review of the literature on reaction time is presented. First, the theoretical background is covered, some of the representative types of apparatus for measuring reaction time are described, and finally the general findings on the factors which have been found to influence reaction time (age and sex differences, intensity, size and duration of stimulus, number of categories, distraction, practice, incentives, fatigue and loss of sleep) are covered.

T. R 58

5910

This paper summarizes the results of several research projects that were carried out under the Instructional Film Research Program and that sought to measure the effectiveness of training films. Among the topics discussed are "learning accelerators" in films (e.g., audience participation, level of verbalization), variables that determine the effectiveness of informational and attitude-changing films, the role of music, and certain important "functional factors" (e.g., viewing angle of the screen). The paper also includes a brief evaluation of the research. Some general principles suggested by the research (e.g., specificity of effect of the film, relative effectiveness of visual versus auditory components of films) are enumerated.

5911

Katchmar, L.T. INDICATORS OF BEHAVIOR DECREMENT: AN EXPLORATORY INVESTIGATION IN THE USE OF SELF-PACED TESTS AS INDICATORS OF BEHAVIOR DECREMENT. Proj. DA 49 007 MD 222 (G.I. 19 52), Tech. Rep. 15, May 1953, 43pp. Dept. of Psychology, University of Maryland, College Park, Md.

5911

In a study of the utilization of self-paced tests as indicators of behavior decrement, 18 Ss were required to react to stimulus numbers under three sets of incentive instructions (i.e., general operational, knowledge of results, and praise and reproof instructions) and three different time periods (1.5, 10, 20, and 30 min.). The results are presented and discussed in terms of the relative effect of each type of incentive instruction and the duration of time period on the performance reflected in two types of self-paced reaction time tests.

5913
Katchmar, L. INDICATORS OF BEHAVIOR DECREMENT: THE EFFECTS OF STRESS, ANXIETY AND EGO INVOLVEMENT ON "SHIFT" TASK PERFORMANCE. Proj. DA 49 007 MD 222 (G.I. 19 52), Tech. Rep. 22, Dec. 1953, 57pp. USA Medical Research & Development Command, Office of the Surgeon General, Washington, D.C. (Psychology Dept., University of Maryland, College Park, Md.).

This study is an investigation of the effects of psychological stress on level of aspiration and performance on a highly repetitive task which requires a shifting between 2 well-practiced tasks. The performance test used was the Woodworth-Wells form naming and substitution test. 3 variables were used: level of anxiety, ego-involvement, and failure stress. 54 Ss were selected on the basis of high and low anxiety scores as measured by the Taylor Manifest Anxiety Index. High anxiety Ss showed poorer performance and failure stress showed increase in failure stress. The relationship between performance and failure stress showed increasing levels of failure stress. The ego-involvement instructions did not differentially affect the performance of Ss. (HEIAS)

Dougherty, Dora J., Hasler, S.G. & Matheny, W.G. COMPARISONS OF FLIGHT TASKS PERFORMED IN THE T-6 AIRCRAFT AND P-1 TRAINER. Contract AF 33(038) 25726, Memo. Rep. D 15, Sept. 1953, 20pp. University of Illinois, Urbana, Ill.

5924

This investigation dealt with the relationship between fidelity of simulation and transfer of training for the P-1 trainer and T-6 aircraft, a case in which transfer is high. Patterns of control movements in the T-6 aircraft were compared with those in the P-1 trainer flown through the same maneuvers. Photographic records were made of instrument panel dial readings, including indicators of elevator, aileron, and rudder movements. Comparisons were made of identical performances by skilled instrument pilots on straight and level flight, straight climbs, and level turns.

5926

Day, R.M. EFFECT ON A DIFFICULT COORDINATION OF THE FREQUENCY OF SIGNALS. *FPAC 815*, Jan. 1953, 7pp. Flying Personnel Research Committee, London, England. (Psychology Dept., University of Bristol, England).

The purpose of this experiment was to determine what effect the frequency of signals had on the control of a fugitive spot. Subjects were required to direct, by moving hand and foot controls, a fugitive spot of light into one of 4 positions in accordance with changes in the source of signals. Simultaneously they were required to extinguish 2 lights using a left-hand response, each light requiring a different direction of movement. Results show that: a) Increasing the frequency of signals from 4 successively but irregularly functioning source: resulted in significant increases in "error" scores made in controlling the fugitive spot, but did not affect the other part of the task. b) The order of a sequence of 4 signal frequencies over 4 trials had no effect on the scores made.

Chalmers, E.L. MONOCULAR AND BINOCULAR CUES IN THE PERCEPTION OF SIZE AND DISTANCE. *Amer. J. Psychol.*, July 1952, *LXX*, 415-423. (Princeton University, Princeton, N.J.).

5929

To investigate primary monocular and binocular cues in the perception of size and distance, a testing situation was provided such that only illuminated triangles (comparison and standard) could be seen. Eight standard triangles, sized to subtend a visual angle of 45 min. at distances varying between 10 and 120 ft., were judged for size by adjusting the variable comparison triangle (positioned at 10 or 120 ft.) to apparent equality; monocular and binocular judgments were made by five observers. The data are analyzed as functions of size and distance for monocular and binocular vision and interpreted with respect to the importance of the cues available.

5930

Chalmers, E.L. THE ROLE OF BRIGHTNESS IN PRIMARY SIZE-DISTANCE PERCEPTION. *Amer. J. Psychol.*, 1953, *66*, 584-592. (Princeton University).

5930

To investigate the role of brightness in primary size-distance perception, an experimental situation was arranged so that secondary cues were eliminated (see 5929). The observer, using monocular or binocular vision, indicated when the size of a comparison object was the same apparent size as a standard object (seven sizes such that each subtended a constant visual angle at its respective distance--10 to 120 ft.). Brightness of the stimulus objects was 25 ft.-L for half the judgments and 0.025 ft.-L for the other half. Analysis is with respect to effects of decreased brightness and physiological explanation is advanced.

Cassel, R.N. EVALUATING INSTRUCTOR TRAINING. *Information Bull.*, Fall 1952, *3*(3), 25-32. (USAF Training Analysis & Development Div., Parks AFB, Calif.).

5931

This article describes an experimental approach to Air Force instructor training evaluation in which final grades of instructor students are compared with a predicted grade based on the student's Technical Specialty Aptitude Score. The discrepancy between predicted and actual achievement is presumed to be a measure of motivation to learn and credit for the presence of motivation is attributed to the teacher. A discrepancy greater than one standard deviation is presumed to be atypical and of concern to training supervisors.

Butler, R.G., Bamford, H.E., Kautz, R.K. & Ornstein, G.M. CLUSTER ANALYSIS OF PILOT PROFICIENCY MEASURES: IV. THE INSTRUMENT FLIGHT CHECK BATTERY. *Staff Res. Memo.*, Proj. 400K 7710, Task 77166, Dec. 1954, 9pp. Basic Pilot Research Lab., USAF Air Research and Development Command, Goodfellow AFB, San Angelo, Tex.

Objective measures of instrument flight proficiency gathered on 179 subjects of an experimental Primary Pilot Training Program were cluster analyzed. The number of sub-measures originally gathered was 204. This number was reduced to 77 by the introduction, successively, of criteria of relevance, difficulty, and generality. Based upon the 77 remaining items 5 clusters and 23 residuals were produced in the reduction. Attempts to identify the obtained clusters met with no success.

Bamford, H.E. & Butler, R.G. CLUSTER ANALYSIS OF PILOT PROFICIENCY MEASURES: III. A METHOD OF COMPOSING CLUSTERS FOR A TAYLOR CLUSTER ANALYSIS. *Staff Research Memo.*, Proj. 400K 7710, Jan. 1954, 7pp. USAF Personnel & Training Research Center, ARDC, Goodfellow AFB, San Angelo, Tex.

This paper explains step-by-step, the mechanics of a method of composing or searching for clusters of congruent measures for further use in cluster analysis. Two measures are said to be congruent if the ratio between the correlations of the two measures with any third measure is equal to a constant.

5934

This paper is one of a series concerned with the analysis of the pilot's task into a set of measurable component clusters as a step toward an explanatory theory of pilot behavior. This paper presents the logical foundations of the cluster analysis technique to be employed in these studies. A set of definitions and conditions are listed, the general formula for the correlation of sums is derived, and the necessary formal theorems are developed.

Alexander, I.E. & O'Brien, T.F., Jr. HIGH TONE STIMULATION AND HEARING LOSS. Proceedings National Acad. Sci., Sept. 1954, 40(9):848-852. (Princeton University, Princeton, N.J. & Yale University Medical School, New Haven, Conn.).

Specific and localized cochlear lesions were produced in the ears of guinea pigs by use of an intense high-frequency tone (5,000 cycles). Loss in sensitivity for tones between 200 and 10,000 cycles was measured immediately after the injury and after a period of 5 weeks or more. It was found that hearing loss was uniform and severe for tones between 500 and 5,000 cycles, least severe for the lowest tones, and most severe for tones higher in frequency than the injury-producing tone. The results are discussed with regard to cochlear localization and pitch perception.

USA Medical Nutrition Laboratory. THE EFFECT OF VITAMIN SUPPLEMENTATION ON PHYSICAL PERFORMANCE OF SOLDIERS RESIDING IN A COLD ENVIRONMENT. Rep. 115, Sept. 1953, 99pp. Army Medical Nutrition Lab., Department of the Army, Chicago, Ill.

Under the conditions of this experiment supplementation of an adequate diet with large amounts of ascorbic acid and B-complex vitamins in men subjected to the stresses of high physical activity, residence in a cold environment and, during the latter part of the experiment, caloric deficit, did not result in significantly better physical performance than that of unsupplemented men. Vitamin supplementation of the type used in this study resulted in a reduction in the fall in rectal temperature on exposure to cold. A caloric deficit of 1200 Calories per day for 22 days did not lead to detectable impairment of physical performance. The present study indicates that the current army minimal allowances of water soluble vitamins are capable of supporting good physical performance under the conditions of this study. An ascorbic acid intake of about 60 mg per day (control group) resulted in whole blood ascorbic acid levels of 0.3 to 1.2 mg% with a mean value of 0.7 mg%.

Flanagan, J.C. SITUATIONAL PERFORMANCE TESTS (A SYMPOSIUM). Pers. Psychol., Winter 1954, 1(4), 461-497. (American Institute for Research, Pittsburgh, Penn.).

This article is an adaptation by its several authors of the proceedings of a symposium on Situational Performance Tests presented at the meetings of the American Psychological Association in Cleveland, Ohio, September 7, 1953. The approach is to the measurement of non-intellectual aspects of human performance--not what the man can do but what he does or will do in the future--by means of standard samples of behavior. This type of test is described, reasons for using the tests are discussed, and some specific examples of their use are presented. These examples include leadership evaluation, small group performance measurement, and evaluation of clinical psychologists. (HEIAS)

Henderson, R.L. REMOTE ACTION POTENTIALS AT THE MOMENT OF RESPONSE IN A SIMPLE REACTION-TIME SITUATION. J. exp. Psychol., Oct. 1955, 44(4), 238-241. (University of Missouri, Columbia, Mo.)

Action potential measurements were taken from a non-participating body member of a group of 20 Ss responding in a simple reaction-time situation to a visual stimulus. The reaction time was found to decline steadily over a period of 6 successive practice days of 100 trials each. The action potential during the foreperiod and at the moment of the response was found to decline during the first 4 days of practice, then to rise on days 5 and 6. Although the terminal rise in action potential was not statistically significant, a tentative hypothesis was advanced which explains the rise in terms of increased general tension arising from increased motivation to improve as the asymptote of learning is reached. 5945

To develop a general methodology for description and analysis of the behavior of task-oriented groups or teams, an exploratory study was made. The activity of Navy teams was recorded and analyzed in terms of communication structure: input (signals or stimuli that elicit behavior); process (behavior carried out); and output (signals or stimuli resulting from process). Fourteen descriptive variables and measures were derived, with computational procedures for ten, and applied to the following Navy teams: 1) anti-aircraft gunnery; 2) combat information center, airplot and surface plot; 3) flight deck operations, landing and take-off and catapult; and 4) ship control. The computation and interpretation of the descriptive variables for each team are described. Implications for development of procedures for team training are discussed. (T.G. 1)

Walker, E.L. INVESTIGATION OF VISUAL FACTORS CONTRIBUTING TO NIGHT AIRCRAFT ACCIDENTS, WITH SPECIAL REFERENCE TO METHODS OF LIGHTING PLANES. Proj. X 498 (AV 265 P), Rep. 1, July 1945, 16pp. USN Air Training Bases, Corpus Christi, Tex.

The results of an extensive investigation by questionnaire and statistical analysis of aircraft accidents, it was determined that the most important difficulties experienced by pilots while flying at night were: a) confusion of plane lights with ground lights and stars; b) inability to judge position, attitude, distance and speed of other planes; c) disorientation and vertigo due to or related to auto-kinesis. A 40-inch plexiglass bar 1 in. in diameter was placed upon the upper and lower surfaces of each wing tip and illuminated at each end with the appropriate colored light. An amber colored light was added to the tip of each horizontal stabilizer. Brightness control and a blinker with speed control were added. Motion pictures were taken of the design with and without the blinker in operation. The experimental plane was flown to a number of rendezvous with other planes the pilots of which were asked to rate standard lights, experimental lights on steady and experimental lights blinking. The experimental lights were preferred with blinking and brightness controlled to fit different flight operations. (HEIAS)

Whitfield, T.C.D. THE EFFECT UPON THE MINIMUM VISUAL ANGLE OF DET OF FOCUS BLURRING. *TPRC 873, March 1954, 2pp. Flying Personnel Research Committee, London, England. (RAF Institute of Aviation Medicine, Farnborough, England).*

This experiment was undertaken to assess the extent of reduction in pick up range which could be attributed to the involuntary accommodation known as "day myopia". This involuntary accommodation occurs during visual search of an empty visual field. A cycloplegic was employed to fix accommodation and to enable known amounts of out of focus blurring of a collimated test object to be produced by the interposition of suitable spectacle lenses before the eyes. The test object consisted of a number of dots 0.5 mm. in diameter. It was always presented at infinity and its angular size was varied by employing collimated lenses of various focal lengths with the test object always being at the focal point of the lens. Some of the results were that: a) when the S was accurately focussed on the test object at 0 dioptres +0.25 dioptres of blurring could be tolerated; b) when there was more than +0.25 dioptres of blurring the test object size had to be increased to be visible. A conclusion reached was that detection of a target aircraft by a pilot is greatly facilitated by the existence of stimuli at infinity, e.g. clouds in the background. (HE145)

Weitz, J. EFFECT OF SHAPE AND COLOR CODING OF AIRPLANE CONTROLS ON SPEED AND ACCURACY OF PERFORMANCE. Proj. 335, Rep. 1, Dec. 1944, 6pp. *USAF School of Aviation Medicine, Randolph Field, Tex.*

The maximum forces which could be applied in the vertical direction (up and down) and in a horizontal arc were measured for 37 men in several prone position situations. Much greater forces could be applied to horizontal rotation than to the lifting or depressing movements. Averaging all bed positions the means were 114 lbs. for the "up" movement, 130 lbs. for the "down", and 269 and 250 lbs., respectively, for right and left rotation. When instructed to apply to a given dimension of control movement "as much pressure as you can and still keep enough reserve so that you feel you could retain control over the other movements, and be prepared to make emergency adjustments as would be necessary in the flying situation," these pilots applied about 50% of their maximum forces to the controls. Altering the elevation of the bed and its horizontal distance from the control handles influenced the forces which could be applied.

Tomdorff, J. & Brogan, F.A. SHORT-DURATION AUDITORY FATIGUE AFTER WHITE-NOISE STIMULATION. Proj. 21 1203 0001, Rep. 3, Feb. 1953, 14pp. *USAF School of Aviation Medicine, Randolph Field, Tex.*

A method is described for routine testing of short-duration auditory fatigue. From the results on normal-hearing Ss, it was found that the combination of white-noise stimulation and click probes may yield the most information for differentiation of Ss as to threshold shift, retrain pattern, and an aftereffect which may either overshoot or consist of a secondary drop. This method is intended for use in a follow-up study to determine whether or not there is a correlation between reversible auditory fatigue and permanent noise-induced hearing loss. The method may then be used to predict susceptibility to noise.

Tomdorff, J. & Brogan, F.A. PROCEDURE IN NOISE AUDIOMETRY. Proj. 21 27 001, Rep. 3, March 1952, 10pp. *USAF School of Aviation Medicine, Randolph Field, Tex.*

After construction and assembly of suitable equipment a procedure of routine noise audiometry was developed. Pure tone (250-4000 cycles) and speech (spondaic and monosyllabic) tests were conducted in the presence of calibrated white noise, ranging from "quiet" up to 100 db in steps of 10 db. The speech tests are interrelated in such a way that the results of the spondaic test serves as a reference level for conduction of the monosyllabic word test. In this way a characteristic articulation pattern (percent articulation vs. noise) is obtained. The shape of this pattern is explained. Advantages of noise audiometry are discussed.

Yonck, J. ADDITIVE EFFICIENCY OF THE HAD-OF-HEARING IN NOISE. Proj. 21 27 081, Rep. 8, Sept. 1952, 17pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Pure-tone and speech tests were conducted for 66 Ss with unilateral or bilateral partial deafness. The material was classed in 7 groups displaying characteristic types of hearing loss. Articulation was tested by the intensity step-up method which permits estimation of the maximum level of articulation. Maximum levels were observed to decline with increasing noise in many cases of perceptive deafness. The speech threshold and the maximum articulation level were utilized to derive the "Social Adequacy Index for Hearing". The relative speech impairment with regard to the pure-tone perception was expressed by a ratio between the speech loss and that for pure-tones. The hearing efficiency of impaired ears in noise does not always follow the pattern established for normal-hearing ears. This fact cannot be predicted on the basis of audiometric tests taken in quiet. Although the findings presented in this report are not backed by sufficient experience to warrant establishment of standards in exact numerical values, they are considered as evidence of general trends.

Yonck, J. COMBINED EFFECT OF NOISE AND HYPNIA UPON THE AUDITORY THRESHOLD. Proj. 21 1203 0001, Rep. 1, March 1953, 9pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The combined effect of hypnia and noise upon the auditory threshold of human Ss was evaluated during and after noise exposure. Although the effect of both agents is similar as to temporary threshold impairment and subsequent improvement, hypnia was shown to act beyond the cochlear level (i.e., upon the central part of the auditory system) while noise is known to affect the organ of Corti directly. This finding aids in comprehending the pattern of masking curves of impaired ears. Incomplete recession was used as a descriptive term; it is now explained as a phenomenon of true nerve-type deafness.

Strickland, B.A., Nelson, G.L. & Adler, H. EFFECTS OF DRAMAMINE ON AIRSICKNESS. Proj. 21 32 007, Rep. 1, Feb. 1951, 14pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A series of tests were conducted to investigate the usefulness of Dramamine (8-dimethyl-10-phenyl-10H-5-chloro-5H-benzothiazepine) as a preventative of motion sickness. Conditions included simulation of turbulent conditions in aircraft and swing tests. Dramamine proved to be a moderately good preventative of airsickness (216 Ss tested) reducing the sickness rate to 20.7% in contrast to 55.6% for Ss receiving placebo. In 20 susceptible Ss, the drug appeared to be no more effective than a placebo in preventing swing sickness. In comparison of two drugs (Dramamine and hyoscine hydrobromide) the latter was superior to the former in preventing experimentally induced airsickness. Of 205 Ss receiving Dramamine (100 mg) 8.7% experienced undesirable side effects; with hyoscine hydrobromide (0.55 mg) the only side effect in 88 Ss was mouth dryness. In 30 Ss, Dramamine did not adversely affect performance on complex coordination test nor RT. Incidence of sickness as influenced by time interval between last meal and flight was not affected by use of Dramamine. (HEIAS)

Smith, M.H., Jr. & Haire, M. THE PROFICIENCY OF GRADUATE BASIC GUNNERS DURING TEN SUCCESSIVE GUN CAMERA MISSIONS. Proj. 344, Rep. 1, Jan. 1945, 23pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

5969

This experiment determined the change in flexible gunnery proficiency resulting from a series of ten gun camera missions. Two groups of 16 graduate gunners, trained in gunnery school on the Martin turret and the Sperry lower ball turret, were given ten successive missions of six pursuit curve attacks on which they used Sperry upper turrets and Martin upper turrets. Mean errors for each mission, measured in mils, were presented. The reliability of gun camera mission scores was estimated by rank order correlations between odd and even numbered attacks within groups of missions and between groups of missions in order to determine how many missions were required to obtain scores sufficiently stable to be used as a measure of proficiency.

5972 Schmidt, Ingeborg. STUDY OF EFFECT OF ILLUMINATION ON INTERPRETATION OF PSEUDO-ISOTHERMATIC PLATES. Special Report, May 1951, 8pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Pseudo-isochromatic plates were studied in artificial daylight of different intensity and different color temperature. A variation of illumination between 25 and 100 foot-candles affected only deuteranomalous subjects, the error percentage slightly decreasing with more illumination. The color temperature of the illuminating light affected the number of errors made by both normals and color defectives. As the color temperature was increased, normals increased slightly in error percentage; deuteranomalous subjects distinctly, and tritanopes less noticeably. Protanomalous and protanopic persons did not change their average error score. Only artificial daylight with standardized color temperature and intensity would be used to obtain comparable results in pseudo-isochromatic plate tests.

5973

Edwards, R.F. VENTILATION IN SUBJECTS DURING THE SWING TEST. Proj. 333, Rep. 1, May 1945. 6pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A study of ventilation rates and respiratory rates and patterns during exposure to the Swing Test for motion sickness was conducted using 35 Ss. Findings were: a) Ventilation rates are almost invariably elevated in Ss during the Swing test; b) Increase in ventilation rate tends to be greater in individuals suffering from symptoms of motion sickness than in individuals unaffected by the swing test; c) There is poor correlation in this group of Ss between the increase in ventilation rate and subjective complaint of symptoms which may be attributed to acupnia; d) With one exception, every S studied tended to synchronize his respiratory movements in rhythm with the motion of the swing; e) Overventilation is not considered to be of importance in the etiology of swing sickness; f) Several Ss exhibiting the greatest increases in ventilation rates during the swing test admitted they were apprehensive and excited during the test. It is recommended that ventilation rates along with pulse rates and blood pressures be studied on aviation cadets during their initial flights.

Rowland, Louise S. SELECTION OF COLOR VISION TESTS FOR THE ARMY AIR FORCES: A REVIEW OF STUDIES MADE AT THE AAF SCHOOL OF AVIATION MEDICINE. Proj. 333, Rep. 1, June 1945. 14pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A summary is presented of investigations on the selection of color vision tests for the Army Air Forces which were conducted during the period between June 1942 and June 1945. It had been found that the existing color vision requirements were completely arbitrary; therefore a "job analysis" was made to determine the type of color discrimination required of the various aircrew personnel. It was found that the color discriminations fell into two categories: a) those in which the colors differed markedly in chromaticity, but subjectively were difficult to discriminate because of low intensity, small visual angle, or both (colored light signals, colored reflecting surfaces for daytime signals, and colors used in coding equipment); b) those in which the colors were of low purity and differed only slightly in dominant wavelength, but were of fairly high brightness and large area (colors of the terrain, colored maps, and map colors). These facts were kept in mind in the selection of a battery of color vision tests. A number of available tests were investigated (American Optical Company Pseudo-Isochromatic Charts, SAM Anemoloscope Test, Farnsworth 100-hue Test, Canadian Lanterns, Color Threshold Lantern, etc.) and where indicated modifications were made. In addition, certain new tests were developed (Terrain Test). Tests of the anemoloscope type and those employing pseudo-isochromatic charts were felt to best meet requirements, therefore extensive studies on reliability and validity were conducted leading to a test battery consisting of screening tests and of quantitative tests for further testing when indicated. (HEIAS)

Rowland, Louise S. & Fry, J.H. SELECTION OF COLOR VISION TEST PLATES. II. SELECTION OF 18 PLATE TEST. Proj. 362, Rep. 2, July 1945. 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

An investigation was conducted of the relative efficiency of the various plates of the American Optical Company Pseudo-Isochromatic Charts in separating normal color vision from color-deficient Ss. The test was given to 273 Ss, who were first classified as normal or color-deficient by other means; 200 were classified normal and 73 color-deficient. An analysis of error scores yielding percentages for each group of passing and failing scores was made. A single index for rating the charts in accordance to relative diagnostic efficiency was applied and 18 charts were selected for further testing. (HEIAS)

5976

Rowland, Louise S. & Heagan, F.V. FREQUENCY OF COLOR DEFICIENCY AMONG AIR CORPS CADETS. Proj. 314, Rep. 1, Aug. 1944. 5pp. USAF School of Aviation Medicine, Randolph Field, Tex.

3 different groups of air cadets, who had previously been classified as having normal color vision, were tested either with the SAM Anemoloscope or with the Robb's test for color deficiency. Any who failed the initial test were given the abridged American Optical Company test; 695 men were tested in all. The purpose of these tests was to determine whether the low rate of rejection for color deficiency (about 3%) by Aviation Cadet Boards in comparison with the frequency in the general population (about 8%) was due to failure to detect color deficiency, and if so, to study the causes of such failure. It was found that color deficiency frequently passes undetected in classification examinations. Possible causes for this situation were thought to be a) use of yellow artificial light rather than daylight illumination; b) use of only a few charts from the complete tests and poor selection of those chosen; and c) previous coaching of applicants. The abridged version of the American Optical Company charts was found to be more successful than the standard test in detecting the deficiency in those who have been coached, probably because only one chart is presented at a time and they are shown in an unfamiliar order. (HEIAS)

Rowland, Louise S. AN EVALUATION OF THE ISCC TEST FOR COLOR DEFICIENCY IN THE SELECTION OF AIR FORCE PERSONNEL. Proj. 54, Rep. 1, May 1942. 5pp. USAF School of Aviation Medicine, Randolph Field, Tex.

An evaluation of the Inter-Society Color Council (ISCC) Test for color deficiency was made in terms of its usefulness in selection of Air Force personnel. 5 Ss (color-deficient on the Ishihara charts) were given 2 or 3 successive tests; 6 normal Ss were tested once. It was concluded upon the basis of analysis of scores that this test was not reliable enough to obtain an estimate of degree of color deficiency from a single test nor was it entirely reliable in detecting color deficiencies. (HEIAS)

Rowland, Louise S. & McDonald, P.R. AN ABRIDGED EDITION OF THE AMERICAN OPTICAL COMPANY PSEUDO-ISOTHERMIC PLATES FOR TESTING COLOR PERCEPTION: COMPARISON WITH OTHER SCREENING TESTS. Proj. 68, Rep. 3, 14 p 1945, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A comparison was made of the American Optical Company (A.O.), the Robbin, and the SAM lantern tests as to their efficiency as dichotomous tests for distinguishing normal from deficient color perception. 495 Ss were tested. Any one of the 3 tests of color vision investigated in this study gives a reliable differentiation between normal and deficient color perception in a high percentage of cases. A definite diagnosis of normal color vision can be made by the abridged A.O. test if 2 or less errors are made, and a definite diagnosis of color deficiency if 6 or more errors are made. The relatively few individuals making 3 to 5 errors may have either normal color vision or a slight defect. It may be possible to eliminate the occasional equivocal findings on the abridged A.O. test by modification of a few of the less satisfactory charts in the series. An analysis of the comparative diagnostic efficiency of the individual charts is described in a following report.

5509

Rowland, Louise S. AN ABRIDGED EDITION OF THE AMERICAN OPTICAL COMPANY PSEUDO-ISOTHERMIC PLATES FOR TESTING COLOR PERCEPTION. Proj. 68, Rep. 2, Oct. 1942, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

In the first report on this project an abridged version of the American Optical Company Pseudo-Isometric Plates for Testing Color Perception was presented. This study compares these data with data from the same Ss on the complete version and with the SAM lantern test. Error scores of 81 Ss who read incorrectly one or more charts of the standard version and for the same Ss on the 17 plates of the abridged version are shown graphically. Both error distributions show a division into 3 groups with the abridged version presenting more definite evidence of separation. The same group of Ss made the fewest errors on both tests and also passed the lantern test. Therefore, a recommendation is made that consideration be given to the advisability of substituting the abridged for the complete American Optical Test as the basic test for color perception. (MEIAS)

Rowland, Louise S. & McDonald, P.R. SELECTION AND VALIDATION OF TESTS FOR COLOR VISION--THE RECOGNITION OF PYROTECHNIC SIGNALS BY NORMAL AND COLOR DEFICIENT SUBJECTS. Proj. 137, Rep. 6, Nov. 1943, 6pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A series of tests were conducted to obtain information as to the ability of both normal and color deficient Ss to identify pyrotechnic signals under night time conditions. A total of 140 Ss, 51 normal and 89 color-deficient, were tested with various signal configurations, color combinations, and instructions; 5 color vision tests for red-green deficiency were administered and test scores compared with performance scores. The conclusions were that pyrotechnic signals (red, green, and yellow) fired at night from a plane at a distance of 6 mi. and altitude of 5000 ft. were not always identified correctly by Ss with normal color vision. About 7% of color deficient Ss made as few errors as normals. Under the same conditions but using only red and green signals, all the normal and about 1/2 the color-deficient Ss identified them correctly. It was therefore recommended that yellow be eliminated in pyrotechnics. The Color Threshold Lantern and a modified RCN Lantern provided a most reliable basis for selection of color deficiencies. (MEIAS)

5581

Rowland, Louise S. SELECTION AND VALIDATION OF TESTS FOR COLOR VISION--THE COLOR THRESHOLD LANTERN AS A QUANTITATIVE TEST FOR RED-GREEN COLOR DEFICIENCY. Proj. 137, Rep. 5, Oct. 1943, 7pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The Threshold Lantern Test, described in this report, was devised as a means of rating individuals with red-green color deficiency in terms of their ability to distinguish colored lights of low intensity. Details of design, testing procedure, and method of scoring are given. The test results from 200 normal and 209 color-deficient Ss are presented. Test-retest correlation of 43 color-deficient Ss is +0.80. 95% of the normal and 12% of the color-deficient Ss make scores of 60 or better. Scores of the remaining 88% color-deficient Ss range from 59 to 9. Comparison of the scores on this test to scores from tests measuring other aspects of color discrimination shows that there is some relation between them. (MEIAS)

Rowland, Louise S. SELECTION AND VALIDATION OF TESTS FOR COLOR VISION: A COMPARISON OF TWO LANTERN TESTS FOR RED-GREEN DEFICIENCY, THE COLOR THRESHOLD LANTERN AND A MODIFICATION OF THE RCN (ROYAL CANADIAN NAVY) LANTERN. Proj. 137, Rep. 4, Oct. 1943, 6pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A comparison of 2 lantern tests for red-green deficiency in recognition of colored lights was made: the Color Threshold Lantern and a modification of the Royal Canadian Navy (RCN) Lantern. The RCN Lantern Test was given to 185 Ss (63 normals and 122 red-green color-deficient) once and to 44 color-deficient Ss twice. The scores were analyzed and compared with data from a previous similar study with the Color Threshold Lantern. It was found that a scoring procedure using only certain errors characteristic of the color-deficient Ss must be used thus eliminating from scoring color confusions made with equal frequency by both groups on the modified RCN Lantern. Compared with results from the Color Threshold Lantern, the RCN Lantern predicted performance on signal identification less well. Test-retest reliabilities of 0.62 for the RCN Lantern and 0.80 for the Threshold Lantern were used. (MEIAS)

Rowland, Louise S. FURTHER STUDIES WITH A SIMPLE ANOMALOSCOPE FOR DETECTING RED-GREEN COLOR DEFICIENCIES. Proj. 137, Rep. 3, Sept. 1943, 4pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A comparison was made of the relative merits of a simple anomaloscope and an abridged version of the American Optical Company Pseudo-Isoschromatic Charts (Abridged A.O. Test) for detecting red-green color deficiencies. Conclusions and recommendations were: a) Of 60 Ss who pass the abridged A.O. test, 39 also pass the anomaloscope test; of 233 who fail the former, 231 also fail the latter. b) The 3% or so of color deficient individuals with a mild defect, detected by the abridged A.O. test but not by the anomaloscope, can be considered "color safe" for all color discriminations required of air crew personnel at the present time including the identification of pyrotechnic signals. c) Both tests are, therefore, satisfactory as rapid screening tests for red-green color deficiency although neither one gives an adequate measure of the degree of defect. In order to determine whether an individual with impairment of color vision nevertheless has adequate color perception for certain tasks, an adjunct quantitative test must be used. d) The average time required to give the 2 tests is about the same. There is no possibility that Ss could be coached to pass the anomaloscope test. The possibility of coaching Ss to pass the abridged A.O. test may, however, become a problem in the future.

5584
Rowland, Louise S. A SIMPLE ANOMALOSCOPE FOR DETECTING AND CLASSIFYING RED-GREEN COLOR DEFICIENCIES. Proj. 137, Rep. 2, July 1943, 6pp. USAF School of Aviation Medicine, Randolph Field, Tex.

An investigation was made of the value of an anomaloscope in detecting color deficiency and in estimating the degree of defect. Conclusions and recommendations were: a) This test detects 97% of Ss who fail the abridged American Optical Company and the Rabkin pseudo-isochromatic tests. b) About 1/4 of those who fail the test show a more marked defect than the other 3/4. c) The test is not recommended as a quantitative test of color vision in its present form.

Rise, H.W. & Ripple, P.H. VISUAL PROBLEMS OF PILOT IN PRONE POSITION. Proj. 21 24 011, Rep. 1, Aug. 1951, 8pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

5586
To investigate visual problems imposed by the prone position in flight, ten Ss were required to look in the direction of the horizon for one hour while in the prone position bed with head portion adjusted to angles of 15, 20, 25, and 30 degrees of elevated gaze. Measurements were made of muscle balance and ability to maintain elevated binocular gaze. Records were taken of all subjective phenomena. Lateral limits of binocular vision were measured for 30 Ss immediately after assuming the prone position. The results are discussed in relation to effective visual performance of the pilot in flight. Recommendations are included.

Rowland, Louise S. SELECTION AND VALIDATION OF TESTS FOR COLOR VISION. A TEST FOR ABILITY TO DISTINGUISH TERRAIN COLORS. Proj. 137, Rep. 1, May 1943, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A "terrain" test was devised to simulate the color discriminations that might be involved in the choice of fields for aircraft emergency landing. A series of 20 colored discs forming a graded series varying by small steps from a yellowish-red to green to a slightly bluish-green was constructed. The S's task was to arrange the discs in the proper order between red at one end and green at the other within a 2-1/2 min. period. This test and the Threshold Color Lantern test was given to 51 Ss with normal color vision and to 62 color-deficient Ss. It was concluded that the Terrain Test could distinguish 3 degrees of ability to distinguish differences in color simulating those of nature; that ability to make these discriminations is not closely related to ability to identify signal lights (Lantern Test); and that color-deficient Ss do as well as color-normal on the task in the Terrain Test.

Ripple, P.H. APPRAISAL OF THE CONSOLIDATED NIGHT VISION TESTER. Proj. 21 02 088, Feb. 1949, 6pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The Consolidated Night Vision Tester meets some but not all of the criteria for a good night vision test. Its chief assets are: a) Ability to test 8 Ss simultaneously. b) Radium plaque illumination which keeps the machine easily standardized and makes its light source durable. c) Relative freedom from mechanical difficulties in the test itself (this is not true of its scoring mechanism). Its chief disadvantages are: a) Unevenness of illumination of the testing field because of a definite bright spot in the center of the testing field. b) Lack of specifications for tracing cloth used as a diffusion screen. c) Unavailability and high cost of the switchboard used for scoring. The fact that it does not score automatically, but requires the presence of an extra technician, is also considered a serious disadvantage. d) Lack of a prescribed "random setting" routine. The average examiner's random settings show preference for certain positions. e) Metal light baffles have no tactile identification marker, and are therefore difficult to use in the dark. f) The radium activated paint used is sensitive to exposure to light. g) Abnormal distribution of test scores with a marked tendency for piling up at the difficult end of the test.

Raid, J.B., Kaplan, S.J. & Melching, V.N. A METHOD FOR ANALYSIS OF CROSS BEHAVIOR. Proj. 21 3501 0003, Rep. 10, June 1955, 18pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A method of data collection is described that permits presentation of results in a form suitable for purposes of analysis and quantitative comparisons when error scores are lacking or are insufficient for meaningful interpretation of results. The examples demonstrating its use were selected from an investigation that involved observations of infrahuman primates undergoing exposure to ionizing radiation under conditions that precluded the scoring of successes and errors in accomplishment of any discrete task. The technique is not restricted to such investigations but is equally suitable for investigations involving humans or any other type of organism and could be adapted to evaluating behavioral effects of therapy, etc. It could also be used when discrete trials are used but "extraneous" activity is of as great or greater import in interpreting results as the usual error scores. Payne, R.B., Moore, E.W. & Bethrum, J.L. THE EFFECTS OF CERTAIN MOTION SICKNESS PREVENTIVES UPON PSYCHOLOGICAL EFFICIENCY. Proj. 21 32 019, Rep. 1, Aug. 1952, 23pp. USAF School of Aviation Medicine, Randolph Field, Tex.

In order to assess the psychological risks which might be incurred by aircrew personnel through their use of certain motion sickness preventives, a comprehensive battery of psychological tests was administered to a large population of volunteer airmen under 5 conditions of medication (placebo, benadryl-hyoscine, benadryl, dramamine, and hyoscine). The tests were carefully selected in terms of the degree to which they were known to measure abilities relevant to the performance of pilot and navigator duties. The drugs exerted uniformly the most pronounced effects upon those psychological functions which are highly implicit, such as visual imagery, ideation, mental set, and judgment. They exerted uniformly the least pronounced effects upon those functions which are more explicit, such as perceptual-motor and spatial decision activities. Since this distinction corresponds in a general way with the principal psychological distinction between the duties of the pilot and those of the navigator, it was suspected and demonstrated that the drugs impaired those abilities which account for navigation proficiency variance more severely than they impaired those which account for pilot proficiency variance.

Ogden, F.W. EVALUATION OF EAR PLUG EFFECTIVENESS. PRELIMINARY REPORT. Proj. 257, Rep. 1, April 1944, 5pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The results of this evaluation of ear plug effectiveness are as follows: a) cotton plugs attenuate low pure tone frequencies slightly (5 db) and the high frequencies markedly (20-35 db). The use of water soluble jelly increases the attenuation of pure tones throughout all frequencies. The Sepco and S.M.R. Ear Protectors attenuate the low pure tone frequencies (20 db) and the high (40 db). The N.D.R.C. Ear Warden attenuates the low pure tone frequencies (20 db) and peaks twice in the higher frequencies (30-35 db). Intelligibility for words accompanied by approximately 100-110 db of synthetic aircraft noise was not diminished by the use of any of the ear plugs. (MEIAS)

Ogden, F.W. EFFECT OF GUNFIRE NOISE UPON AUDITORY ACUITY FOR PURE TONES. Proj. 315, Rep. 1, Sept. 1944, 6pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The purpose of this study was to determine whether the audiometric curves of individuals who have been repeatedly exposed to the noise of gunfire differ markedly from those of a comparable group of Ss who have had little exposure to gunfire. It was concluded that: a) The noise of gunfire does produce a definite loss of hearing for high tones (2048-11584 cps) among gunnery instructors; b) Among the 7 groups of instructors examined, the Air Specialists showed the least amount of hearing loss; c) The instructors on the shotgun ranges showed the greatest amount of hearing loss; d) A major portion of the temporary high tone hearing loss which is present immediately after exposure to the noise of gunfire is recovered in the subsequent 24 to 48 hrs.

5994

Ogden, F.W. EARPLUG PROTECTION AGAINST NOISE AND CONCUSSION OF GUNFIRE. Proj. 326, Rep. 1, Nov. 1944, 8pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The object of this report was to determine by a field test the amount of hearing protection afforded by several types of readily available ear plugs against the noise of gunfire. Significant high tone (2896-11584 cps) hearing losses (3-9 db) were produced in the average audiograms of a group of students who almost never wore ear protection during a six weeks course in flexible gunnery (Charts 1 and 2). The groups of students who wore one of 5 types of ear plugs (Sepco Ear Protectors, NDRC V 51R Ear Wardens, cotton twists, lubricated cotton twists, lubricated cotton rolls) incurred, with one minor exception, non-significant average hearing losses during the course (Charts 1 and 2). The results of questionnaires which were filled out by the subjects suggest that lubricated cotton rolls were the most comfortable ear plugs, that the NDRC V 51R Ear Wardens gave the most subjective protection against gunfire noise, and that the NDRC V 51R Ear Wardens were more durable than the Sepco Ear Protectors.

Melton, A.W. FLEXIBLE GUNNERY PROFICIENCY ON THE GUN CAMERA MISSION AS EFFECTED BY PRACTICE ON THE SPERRY SPOTLIGHT TRAINER (E-8, MODIFIED) AND THE PANORAMIC GUNNERY TRAINER, MARK II. Proj. 321, Rep. 1, Oct. 1944, 25pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

5995

This is an experimental study of the effect of practice in flexible gunnery training on proficiency as tested in gun camera missions. Sixteen Sperry upper turret gunners were tested on three gun camera missions both before and after two weeks of intensive training on the Sperry Spotlight Trainer; the Panoramic Gunnery Trainer was used for 16 Martin upper turret gunners. Performance is reported in terms of tracking and framing errors for Sperry gunners, circled error and percent hits for Martin gunners, as well as reliability measures of these scores. The reliability measures are analyzed to provide a satisfactory gun camera criterion of flexible gunner proficiency.

McDonough, F.E. AIRSICKNESS IN NAVIGATION TRAINING. Proj. 165, Rep. 1, July 1943, 14pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

5996

This article presents the results of a follow-up study of airsickness and airsickness elimination in 380 navigation cadets, who were administered the swing test for motion susceptibility during their pre-flight training. The results of the study are discussed in terms of the incidence of airsickness and the elimination rate, the type and frequency of symptoms, symptom duration, the relation of motion sickness other than airsickness to swing sickness, factors related to production of airsickness, and so forth.

5997 McDonough, F.E. THE USE OF DRUGS IN THE TREATMENT OF AIRSICKNESS. Proj. 194, Rep. 1, July 1944, 7pp. USAF School of Aviation Medicine, Randolph Field, Tex.

184 air cadets were given doses of motion sickness preventive, U.S. Army Development Type 2116k318049c, 22703. These cadets were chosen because they had become sick more than 3 times. The drug was administered orally 30 mins. prior to takeoff. Each S was checked before taking the drug and after the flight for visual acuity, near vision, accommodation and phorias. They were questioned after the flight concerning symptoms of airsickness. If accommodation did not drop more than 1.0 diopters it was disregarded as being within the limits of error of the test. If it dropped 1.5-2.0 diopters it was termed a mild side reaction. A drop of 2.0-3.0 was termed a moderate reaction and a drop of more than 3 was considered a severe reaction. Visual acuity remained the same after taking the drug and after the flight for all but 1 cadet. Near vision varied from normal only when accommodation was severely impaired. Phorias present prior to taking the drug were not exaggerated and sometimes lessened. The drug was effective when airsickness was the result of sensitivity to motion and ineffective when it was due to psychological reasons. It seemed to eliminate motion sickness for more than one flight and its effect often lasted through subsequent flights without medication.

Matthews, J.L. AN INVESTIGATION OF CERTAIN ASPECTS OF COLOR VISION. Proj. 168, Rep. 1, Aug. 1943, 12pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

5999

To investigate the color differentiations required of various air crew personnel in the performance of their duties (1943), interviews were conducted with 19 officers experienced in various theaters of operation in World War II. Pyrotechnics, distress signals, recognition signals, smoke signals, lights for various purposes, panels, flags, and other markings, colored markings of bombs, and camouflage are analyzed in terms of colors used, day or night visibility, and the responsibility of each member of the crew—pilots, bombardiers, navigators, and observers.

6000 Baker, C.H. BIASING ATTENTION TO VISUAL DISPLAYS DURING A VIGILANCE TASK. A SUMMARY REPORT. APRU 277/56, Oct. 1956, 10pp. Applied Psychological Research Unit, Medical Research Council, Cambridge, England.

When searching a PPI type of display with a sweep-line rotating at 6 rpm subjects pay relatively little attention to the peripheral and central regions of the display. In a considerable degree, visual attention can be biased towards the periphery of the display (the result being earlier "early" warning) by use of the green-light or the box-sweep technique. When pips appear on an average of one every 2 minutes, there is no deteriorating in visual performance over a period of an hour when the box-sweep is employed, though there is with the green light. Thus the evidence from these studies is that a box-sweep is superior, considered from either the proportion of peripheral pips detected or deterioration of performance in time, to any of the other techniques investigated, including the conventional one. It is suggested that a box-sweep should be developed and compared with a conventional sweep-line in a field trial under operational conditions. The development too, of a device to inject artificial pips onto the CRT at fairly regular intervals, would, it is believed, greatly reduce the penalty paid due to reduced vigilance late in the watch period.

Lazarus, R.S. & Erikson, C.W. EFFECTS OF FAILURE STRESS UPON SKILLED PERFORMANCE. J. exp. Psychol., Feb. 1952, 43(2), 100-105. (Johns Hopkins University, Baltimore, Md.).

The effects of a failure threat upon the performance of college students on an extended version of the Wechsler-Bellevue digit-symbol subtest were studied. The main results were: a) A significant increase in inter-individual variability in test performance occurred in the stress group; b) An increase in the number of errors made under stress was compensated for to some extent by an increase in speed. Speed scores accounted for 92% of the variance in total scores; c) Students with high grade point averages showed a tendency to improve their performance under stress. Students with poor academic standing did more poorly and were much more variable.

Lazarus, R.S., Deese, J. & Osler, Sonia F. THE EFFECTS OF PSYCHOLOGICAL STRESS UPON PERFORMANCE. Psychol. Bull., July 1952, 49(4), 293-317. (Johns Hopkins University, Baltimore, Md.).

A critical discussion of work in the field of psychological stress and its effect upon performance is presented. The concept of stress is defined as a secondary concept, built upon the relationship between a primary concept, motivation, and the situation in which motivated behavior appears. Stress is said to occur when a particular situation threatens the attainment of some goal and the actual responses of the individual will depend partly upon the kinds of mechanisms that have been previously established. Various experimental techniques that have been used for producing stress are discussed and evaluated under 2 main headings: stress induced through failure and stress induced by the task itself. A review of the kinds of performance which have been studied under stress includes verbal performance, perceptual-motor performance, components of performance, qualitative changes in performance, personality correlates, and performance under stress as a predictor. Some of the theoretical implications of the work on stress and skilled performance are discussed with their implications for future research. (MEIAS)

Jerger, J.F., Lightfoot, C. & Carhart, R. SOME EFFECTS OF SHORT-HIGH-LEVEL SOUNDS UPON AUDITORY THRESHOLD. Proj. 21 1203 0001, Rep. 9, April 1955, 8pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The threshold shift for 3,000 and 4,000 cps. pure tones was measured at intervals of 60, 140, 500, 1,025, and 3,025 msec. following the termination of a 2-sec., 111-db blast of either a 2,000 cps pure tone or thermal noise. Results suggest that threshold shifts measured at intervals greater than 400 msec. following termination of the blast hold more promise as indices of noise susceptibility than threshold shifts measured at intervals less than 400 msec.

Jerger, J.F. THE INFLUENCE OF STIMULUS DURATION ON THE PURE-TONE THRESHOLD DURING RECOVERY FROM AUDITORY FATIGUE. Rep. 55-19, June 1955, 8pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The time-intensity relationship for threshold during the course of recovery from auditory fatigue was investigated by exposing 12 normal ears to thermal noise at an overall SPL of 110 db for 2 minutes, then studying the resultant shift in the threshold for short tones of 3 durations (500, 50, and 5 msec.). 30 sec. after the termination of the noise, the pre-exposure intensity differential among these 3 short-tone durations was markedly reduced. As postexposure time increased, the decline in the degree of temporary hearing loss was accompanied by a gradual return to the pre-exposure time-intensity relationship.

Hughes, H.M. DISCRIMINATORY ANALYSIS. III. DISCRIMINATORY OF ACCIDENT PRONE INDIVIDUALS. Contract AF 41(128) 8, Proj. 21 49 004, Rep. 3, Oct. 1950, 43pp. USAF School of Aviation Medicine, Randolph Field, Tex. (University of California, Berkeley, Calif.).

The mathematical statistical problem of the discrimination of accident prone individuals is presented with many illustrative examples from industrial and Air Force literature. The arguments in the literature for proneness are criticized and the need for better mathematical models of proneness is pointed out.

Humes, D. THE INTELLIGIBILITY OF SPOKEN MESSAGES. Amer. J. Psychol., July 1932, 65(3), 460-465. (USAF Wright Air Development Center, Aero-Medical Lab., Ohio).

This note presents a quantitative formulation of data from a previously reported experiment on the relative intelligibility of sentences suggesting activities liked and disliked by the responding Ss. All sentences were 3 words, following a set rhythmic pattern, and were requests to execute some activity. A sentence was counted correct only if all 3 words were transcribed correctly when heard in noise; therefore, the intelligibility of the least intelligible word was presumed to be the limiting factor. A correlation was computed between the frequency of correct transcription of the sentences to the Thorndike-Lorge frequency of occurrence of the least frequent word in each sentence and found to be +0.68 and after correction for gerunds and plurals, +0.77. A relationship of this extent allows the inference that sentence intelligibility can be predicted with considerable accuracy from the average word-probability of the least probable word in the sentence and that desirability and familiarity are not operating in this particular situation. Highland, R.W. A CONSIDERATION OF SOME PERTINENT PROBLEMS RELATIVE TO RADAR MECHANIC TRAINING RESEARCH. Res. Tech. Note 51 9, Nov. 1951, 19pp. USAF Human Resources Research Center, Lackland AFB, Tex.

This report is concerned with the problem of generalized versus specialized radar mechanic training. Some problems in conducting research in this area are considered. Current basic radar mechanic training is described and possible variations in content and organization of such training are considered. Problems in selecting criteria for evaluating training methods are also discussed.

Hemingway, A. & Green, E.L. INCIDENCE OF AIRSICKNESS IN CADETS DURING THEIR FIRST TEN FLIGHTS. Proj. 170, Rep. 3, Jan. 1943, 7pp. USAF School of Aviation Medicine, Brooks AFB, Tex.

This article reports an attempt to determine the amount of airsickness in early flight training and to develop a selection procedure suitable for eliminating individuals chronically susceptible to airsickness. The records of airsickness of 2689 aviation students was analyzed statistically. The results are presented and discussed in terms of the degree of incidence of airsickness evidenced during each of ten hours of flight and in terms of the observed differences among individual cadets as indicative of differences in motion sickness susceptibility.

Hemingway, A. & Smith, P.K. EFFECT OF U.S. ARMY DEVELOPMENT TYPE MOTION SICKNESS PREVENTIVE ON SWING SICKNESS. Proj. 198, Rep. 1, Nov. 1943, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

To determine the effectiveness of a U.S. Army Motion Sickness Preventive (barbiturate, atropine, and ipecacine, hydrobromide), 19 susceptible Ss were given either drug or placebo on 2 successive trials on the swing test. Capsules were given 2 hrs. before tests. The Preventive was found to be partially successful in preventing swing sickness. (MEIAS)

6013
Hemingway, A. ADAPTATION TO FLYING MOTION BY AIRSICK AVIATION STUDENTS. Proj. 170, Rep. 4, Dec. 1943, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

198-airsick aviation students who had completed 10 hours of dual instruction in college training detachments were given a motion sickness swing test and a survey was made of the incidence of airsickness. It was found that there was a progressive decrease in the incidence of airsickness during the training period of this group. 84% were sick on the first flight and 10.5% on the last flight. In order to separate the chronic airsick from those who become adapted to flying motion, it is recommended that information on airsickness be obtained by an airsickness record from the instructor in the College Training Detachment.

Hemingway, A. & Smith, P.K. EFFECT OF BARBITAL ON SWING SICKNESS. Proj. 104, Rep. 1, Jan. 1943, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

To determine whether sodium barbitol in 5 grain doses is effective in preventing swing sickness, only Ss who became definitely ill during a 20 min. swing were studied. One group were given the drug and another a placebo, in alternating procedures on 2 further trials each separated by 3 days. It was found that sodium barbitol in the above doses was no more effective in preventing sickness than was a placebo. (MEIAS)

Harvey, A. MOVING SICKNESS HISTORY AND RESULTS OF THE SING TEST OF ONE HUNDRED AND SEVEN (107) AIRSICK BLANKETS FROM FLIGHT TRAINING. Proj. 170, Rep. 2, Sept. 1953, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

107 individuals who were disqualified because of airsickness in flight training were given the S.A.M. sing test and a survey was made of the history of motion sickness. 81 of these were given a psychiatric examination. The incidence of sing sickness was 50.4% in this group with 65.4% vomiting during the sing test and 27% having mild symptoms. The incidence of other types of motion sickness as determined by questioning was as follows: 18.7% were seasick; 33.7% reported carsickness; 9.4% took sickness; 39.2% sickness on amusement park devices; and 63.4% sickness on either boat, car, train, or amusement park devices. In a control group of 348 individuals who stated that they had never been airsick and who were given the sing test and questioned concerning motion sickness history, the incidence of other types of motion sickness were significantly lower.

Quilliam, V., Jr., & Wechsberg, P. PHYSIOLOGICAL EFFECTS OF MECHANICAL VIBRATION. Proj. 21-1203 6002 Jan. 1953, 16pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Small groups of rats subjected to mechanical vibration under controlled conditions of duration, intensity, and frequency showed alterations of vascular tone as expressed in terms of delayed rearming of vibrated extremities after standard chilling. Frequencies of 3.62 and 7.230 cycles per min. and an acceleration amplitude of 8 to 9 g units were used. Rearming times increased progressively with exposure time of as much as 1,000 hours, returned to normal values after a 30-day rest period, and increased again during a second period of exposure. Alterations of vascular tone appeared earlier in rats exposed to the higher frequency. Abnormal per capillaries were observed after prolonged vibration. Preliminary experiments showed that low oxygen tension approximates vibration-induced vascular disturbances.

Green, E.L. SELECTION OF COLOR VISION TEST PLATES: I. CRITERIA. Proj. 362, Rep. 1, July 1955, 11pp. USAF School of Aviation Medicine, Randolph Field, Tex.

An index of the diagnostic efficiency of each plate in a color vision test may be obtained from knowledge of the rates of misclassification of normal and color deficient Ss for each plate. The index is a function of the sum and of the difference of the rates of misclassification, which may be weighted equally or unequally, depending upon policy. Tests composed of several plates separate the color deficient from the normal with an efficiency which depends upon the efficiency of the individual plates and upon the number of plates in the test. The distribution of errors among normal and color deficient Ss depends upon the manner in which the 2 rates of misclassification have been balanced in the computation of the index of efficiency. It is recommended that tests composed of plates selected in the proposed manner be used only as screening tests.

Bell, B., Wells, J.G. & Clark, R.T., Jr. IN-FLIGHT STUDIES OF HYPERVENTILATION. Rep. 56-69, June 1956, 9pp. USAF School of Aviation Medicine, Air University, Randolph AFB, Tex.

6019

To investigate hyperventilation as a possible cause of unexplained jet aircraft accidents, fourteen aviation cadets (ranked in upper third of class) served as subjects for laboratory and in-flight studies, and 12 additional cadets were used for in-flight studies only. In the laboratory, psychomotor performance was tested before during and after passively induced hyperventilation. Individual patterns of reactions were established and essential respiratory data gathered. In the flight tests spot samples of mixed expired air were collected during various maneuvers and alveolar carbon dioxide tensions were estimated. The limitations of the methodology are discussed.

This report presents information on four investigations of visual phenomena (perception of three-dimensional form, Miller-Lyer illusions, visual thresholds, and brightness discrimination) conducted in various parts of Europe during 1956.

6020. Cline, P.A. THE EFFECT OF RETINAL ILLUMINATION ON VISUAL PERCEPTION OF SPACE. I. EXPERIMENTAL STUDIES RELATED TO A SPECIAL TYPE OF ANISOKONIA. Proj. 21-31 011, Rep. 1, March 1951, 28pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Analysis is made of a special type of anisokonia (unequal imagery in the 2 eyes) due to differences in the retinal illumination; the state of refraction or in the retinal threshold of brightness. The spatial distortion and angular disparity between the correlated boundaries of real and apparent patterns increase as the differences in retinal illumination, refraction, and sensitivity to light increase. The threshold amplitude of depth discrimination remains constant. It is recommended that methods be standardized to cover depth discrimination, anisokonia due to overall magnification (type 1) and anisokonia due to differences in retinal illumination of retinal sensitivity to light (type 11).

Johnson, H.J. DIFFERENTIAL EFFECTS OF NOISE AND FATIGUE ON A COUNTER COUNTING TASK. Proj. 21 32 014, Rep. 5, Oct. 1956, 20pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio.

6022

To compare performance under the combined stress of noise and fatigue, a complex counting task was performed by fourteen subjects. Three two-hour sessions were used--a training session followed, in counter-balanced order, by experimental (working in quiet--77.5 decibels--one half hour followed by 1 1/2 hours in noise--111.5 decibels) and control (working in quiet). Training and control sessions were both in presence of a 77.5 decibel masking noise. Several analyses of the data--percent correct responses for half hours of work--were performed: (1) using statistical control of individual differences; (2) of performance during experimental and control conditions; and (3) of performance in first half hour of both conditions.

Chinn, H.I. EFFECTIVENESS OF VARIOUS DRUGS IN PREVENTION OF AIRSICKNESS. II. COMPARISON OF HYOSCINE WITH BENADRYL-HYOSCINE MIXTURE DURING NAVIGATION TRAINING FLIGHTS. Proj. 21 32 014, Rep. 2, Dec. 1950, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The incidence of nausea and vomiting among cadets undergoing actual navigator training flights was compared after they had received the following medications: a) placebo; b) hyoscine hydrobromide, 0.65 mg.; c) hyoscine hydrobromide, 0.33 mg.; Benadryl, 25 mg. No S receiving the hyoscine-Benadryl mixture vomited or became severely nauseated, whereas 7.3% receiving hyoscine alone and 16.7% receiving placebo were affected in this fashion. Among those who had been airsick at some previous time, the incidence of severe nausea and vomiting was: Benadryl-hyoscine mixture - 0%, hyoscine alone - 9.0%, placebo - 20.6%. The incidence of drowsiness was the same for all groups. Dry mouth was high in both the hyoscine and mixture groups. The occurrence of blurred vision, nervousness, excessive fatigue and headaches was lower in the mixture group than in the hyoscine group. The mixture of 25 mg. Benadryl and 0.33 mg. hyoscine is as effective as 0.65 mg. hyoscine hydrobromide alone with a significant decrease in the side effects of the latter medication.

Chinn, H.I., Noell, W.K. & Smith, P.K. PROPHYLAXIS OF MOTION SICKNESS: EVALUATION OF SOME DRUGS IN SEASICKNESS. Proj. 21 32 014, Rep. 4, Oct. 1950, 20pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The object of this study was to determine whether antihistamine efficacy of a drug is related to antihistamine action, to compare a series of antihistamines with a known preventive of motion sickness, and to effect a rapid screening of potential preventives for subsequent testing in the airplane. Hyoscine, Benadryl, Dramamine, Artane and Perazil were all markedly effective in decreasing the incidence of seasickness of normal, unselected soldiers during a transatlantic crossing aboard a U.S. Army Transport. Theophorin and Neomergan were ineffective. Among known motion sick susceptibles, Theophorin showed a slight protective action although less marked than hyoscine, Dramamine or Benadryl. Hyoscine and Dramamine were tested therapeutically and found not to be significantly effective. A lower, but nevertheless significant, incidence of relief was afforded with placebos alone.

Chinn, H.I., Handford, S.W., Cone, T.E. & Smith, P.K. THE EFFECTIVENESS OF VARIOUS DRUGS FOR THE PROPHYLAXIS OF SEASICKNESS. Proj. 21 32 014, Rep. 6, March 1952, 6pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Lergigan, Trimeton, Benadryl-scopolamine mixture, and Wellcome Preparation No. 47-83 all provided approximately equal protection against seasickness. No preparation was significantly superior to that of diphenhydramine although the observed percentage of protection afforded by Lergigan was slightly greater. No protection was given by the antihistaminic Diatrin or by the antispasmodics M-290 and Prantal. Slight protection, not significant at the 1% level, was obtained with Scopodex alone or with a mixture of Benadryl and Scopodex. Side effects were minimal in all cases except among those persons receiving the Scopodex. When 2.0 mg. doses of the latter were given three times daily, hallucinations, an increased incidence of nightmares, dry mouth, blurred vision, and ringing in the ears was observed. When 1.0 mg. was given combined with 25 mg. of Benadryl, there were no hallucinations but the incidence of nightmares, dry mouth, and blurred vision was still increased. There was an inverse relation between the incidence of vomiting and the age of the S.

Chinn, N.I. & Hiltch, L.J. EFFECTIVENESS OF VARIOUS DRUGS IN PREVENTION OF AIRSICKNESS. VII. EVALUATION OF PHENERGAN AND TRIMETON. Proj. 21 32 014, Rep. 7, Aug. 1952, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The following preparations were tested during simulated aircraft turbulence: a) placebo; b) Lergigan, 25 mg.; c) Phenergan, 25 mg.; and d) Trimeton, 25 mg. All 3 drugs reduced significantly the incidence of vomiting below that in the placebo group. Phenergan exhibited the greatest protection. Side effects with each drug were slight, an increase in drowsiness being the most apparent effect. The possibility that the effectiveness of Lergigan is due to an admixture with Phenergan is discussed.

Buettner, K. EFFECTS OF EXTREME HEAT ON MAN. II. ANALYSIS OF TEMPERATURE CHANGES CAUSED BY DIFFERENT KINDS OF HEAT APPLICATION TO THE SKIN. Proj. 21-26-002, Rep. 2, Nov. 1951, 10pp. USAF School of Aviation Medicine, Randolph Field, Tex.

6029

This report concerns a mathematical analysis of the temperature changes in the skin when subjected to different applications of heat. These changes are subject to the physical laws of heat conduction and heat transfer. Calculations show the temperature increase upon applications of non-penetrating constant heat, penetrating radiant heat, Newtonian and contact heat, and heating through a protective layer. Causation of burns is subject to the law of rate processes and can be predicted from temperature curves.

Buettner, K. EFFECTS OF EXTREME HEAT ON MAN. III. SURFACE TEMPERATURE, PAIN, AND HEAT CONDUCTIVITY OF LIVING SKIN IN EXPERIMENTS WITH RADIANT HEAT. Proj. 21 26 002, Rep. 3, Nov. 1951, 9pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Irradiation of human skin with strong infrared heat produced pain within 2 to 60 secs., depending on radiation intensity and initial skin temperature. Peripheral blood flow and wetness of the skin do not influence temperature or pre-pain time for higher intensities. Pain threshold temperature is 44.8°C. and the pain receiver depth 0.1 mm. Heat conductivity of the upper skin can be derived from data given. Pre-cooling the skin seems to offer effective protection against over-heating.

Berger, C., Mahneke, A. & Mortensen, O. ELECTRONIC FLICKER APPARATUS WITH AUTOMATIC-FREQUENCY VARIATION. J. opt. soc. Amer., April 1955, 45(4), 307-308. (Instituto de Ciencias Fisiologicas, Montevideo, Uruguay).

An electronic apparatus is described which delivers light flashes with intensity, light-dark ratio, and frequency as independent variables. The flash rate is varied automatically, and is proportional to the voltage on the control grid of the charging pentode. The control voltage is taken from a highly isolated condenser through a cathode follower with very low grid current. When the condenser is charged or discharged by a constant current, the control voltage, and hence the frequency, will change proportionally with time. The rate of frequency change is determined by the magnitude of the current, and can be started or reversed either manually or by a saw-tooth voltage. This automatic and variable frequency variation makes it possible to keep the conditions more constant from measurement to measurement for each rate of frequency change, and to compare the effect of varying speed of frequency variation as well as of the duration of series of exposures (prethreshold exposure time) upon FFF (flicker fusion frequency) with significant precision. These factors are important for the standardization of FFF determinations.

Gibson, J.J., Olum, P. & Rosenblatt, F. PARALLAX AND PERSPECTIVE DURING AIRCRAFT LANDINGS. Amer. J. Psychol., Sept. 1955, 68, 372-385. (USAF Personnel and Training Research Center, Lackland AFB, San Antonio, Tex. & Cornell University, Ithaca, N.Y.).

The accepted formulation of monocular motion parallax as a cue to distance is shown to be insufficient, particularly when applied to the problem of locomotion relative to a surface such as the earth. A more general description of the parallax phenomenon is given under the name 'motion perspective.' The latter holds for a O's movement along any line parallel or inclined to any extended surface, which includes the case of aircraft landings. A mathematical analysis of motion perspective is presented in terms of the optical flow-pattern reflected from a surface to an eye. It is shown that the variables of this flow-pattern are specific not only to the 'depth' of the surface but also to the movement of an O. Assuming that these variables are stimuli for perception, they can determine not only the experience of a stable tridimensional world, but provide a basis for the judgments required for the control of locomotion in that world.

Berger, C. A COMPARISON, UNDER DIFFERENT DEGREES OF BRIGHTNESS, OF MINIMUM VISUAL DISTANCES OF TWO LUMINOUS POINTS AND OF A BROKEN CIRCLE. *Amer. J. Psychol.*, 1942, 55, 354-370. (Cornell University)

6034

To compare, under different degrees of brightness, the minimum visible distances between two points and between the arms of a broken circle, both self-luminous on a black background, the author tested the left, right, and both eyes of three subjects. Average minimum visual angles and standard deviations in seconds of arc of the just visible distance are given for both test objects, each viewing condition, and at brightnesses from 17.5 to 1476.8 lux. The results are discussed with reference to the retinal processes involved.

6036 Berger, C. ILLUMINATION OF SURROUNDING FIELD AND FLICKER-FUSION FREQUENCY WITH FOVEAL IMAGES OF DIFFERENT SIZES. *Acta Physiologica Scand.*, 1954, 20, 161-170. (University of Copenhagen, Copenhagen, Denmark).

The influence of surround illumination upon flicker-fusion frequency (FFF) is investigated with different fields and illumination intensities, surrounding images of various sizes in the light-adapted human fovea. In addition, the effect is studied of several steady (non-flickering) illumination intensities, superimposed upon the flicker-areas on a black background. A superimposed steady illumination diminishes FFF, more with small than with large areas, proportionally to its intensity. It can be concluded, that stray light plays no significant role whatever in the surround effects reported here. The illumination of an immediately adjacent white field does not affect FFF, when very large or very small foveal areas are tested. Maximal surround effects for areas around 1° in diameter consist in a rapid increase (75%) of FFF with increasing surround illumination up to ratio 1 and a progressive decrease of FFF to its initial value and below, when surround illumination is increased beyond test-illumination. Both, facilitation as well as inhibition decrease with increase of foveal image-size, inhibition disappearing with test-areas around 10' and facilitation around 200' diameters. FFF increases with increased illumination of the white part of a mixed black and white surround for all areas between 0.9' and 25' in diameter up to surround-illuminations 38 times the test-illumination. Surround effects upon FFF are attributed to an interaction of different functional units (receptive fields), of single receptors within receptive fields of the fovea, and to an increased contrast-sensitivity. Berger, C. THE INFLUENCE OF STROKEWIDTH UPON THE LEGIBILITY (THRESHOLD OF RECOGNITION) OF SOME NARROW NUMERALS OF VARYING HEIGHT. *Acta Ophthalmologica*, 1952, XXX(IV), 409-420. (University of Copenhagen, Copenhagen, Denmark).

6037

To study the influence of stroke width and height upon legibility (threshold of recognition) of narrow numerals, seven Ss made threshold judgments viewing the test-object monocularly with a light adapted eye at 58 and 28 ft. Test numerals were 0 and 5 of constant width (1.0 mm), varied heights (from 2.5 to 8.5 mm) and two stroke widths (0.25 and 0.1 mm). Distance between eye of observer and test objects was the measure of legibility. The data were analyzed as functions of height and stroke width. Discussion was in terms of limiting factors and of theoretical significance of the results. T. G. I. R 21

Bates, Grace E. & Neyman, Jerzy. DISCRIMINATORY ANALYSIS. VIII. CONTRIBUTION TO THE THEORY OF ACCIDENT PRONENESS. PART 11. TRUE OR FALSE CONTAGION. *Proj. 21 49 004*, Rep. 9, Dec. 1951, 35pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The paper deals with the distribution of the numbers X_1, X_2, \dots, X_n of accidents in successive periods of observation, as implied by the Poisson contagious time-effect scheme, generalized to include the possibility of accidents being fatal. Given that the individual survives at least first periods of observation, the distribution of X_1, X_2, \dots, X_n is multivariate binomial. This distribution can coincide with the similar distribution implied by the no-contagion-no-time-effect mixture model of Greenwood-Yule-Newhall only in a most exceptional case. Thus, at least in principle, the presence of contagion and/or of time effect may be subject to statistical tests. R 5

Ammons, Carol H. & Metz, J. CENTRAL AND PERIPHERAL FACTORS IN THE PHI PHENOMENON. *J. exp. Psychol.*, Nov. 1951, 52(5), 327-332. (Tulane University, New Orleans, La.).

It was the purpose of this experiment to investigate the relative role of central and peripheral factors in the perception of phi movement. 22 Ss observed phi under each of 4 conditions. These conditions were designed to allow comparison of movement using monocular and binocular stimulation of the same and different cerebral hemispheres. Phi movement was reported in all conditions of observation, but the greatest number of reports of uncomplicated phi movement occurred with monocular stimulation. Although phi was perceived with binocular stimulation, reports were more variable and there was more fluctuation and variety in kinds of motion perceived. It was also found that when stimulation was of the same cerebral hemisphere, phi tended to be judged as moving a shorter distance than when different hemispheres were stimulated, even though the time and distance between stimuli were constant. It is concluded that retinal or at least subcortical factors are important in the perception of phi and it would seem that a homogeneous brain-field theory is too general and oversimplified to account for the present findings.

Ammons, R.B. LEARNING THEORY AND MOTOR SKILLS. ca. 1948, Spp. *University of Louisville, Louisville, Ky.*

6044

This paper reports two experiments concerned with rotary pursuit performance. The first experiment tested learning theory predictions of the parallel development of permanent and temporary work decrement. Subjects (104) were tested for 20 min. following 90 min. practice in which half the group had massed practice of 10 min. work and 10 min. rest, while half had distributed practice cycles of one min. work, two min. rest. The second experiment employed 192 Ss in tests of bilateral transfer of proficiency, warm-up decrement, and temporary work decrement in order to determine whether these phenomena involve central processes. Mean performance data are presented as percent of total possible stylus-target circuit completion time.

Balle, S. CORRELATION OF STATIC AND PHYSICAL ENDURANCE. I. A TEST OF PHYSICAL PERFORMANCE BASED ON THE CARDIOVASCULAR AND RESPIRATORY RESPONSE TO GRADUALLY INCREASED WORK. Proj. 21 32 OG, Rep. 1, April 1952, 14pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Physical exercise on the treadmill was used to determine the reactions of pulse rate, pulse pressure, pulmonary ventilation, and gas exchange to gradually increased work. The speed of the treadmill was kept constant and the angle was raised from minute to minute. The initial work load and the additional steps were kept small enough to allow for functional adaptations. The test was carried on until a pulse frequency of 180 was reached. In general that was the point of an individual's "optimal work capacity." When work was continued beyond that point a decrease in pulse pressure indicated cardiovascular inadequacy; the oxygen uptake dropped, the respiratory exchange ratio exceeded 1.0, and the ventilation equivalent for oxygen increased out of proportion. Test criteria were duration of the test in minutes and/or the performed work in meterkilograms at the cut-off point. The test proved satisfactory in the evaluation of physical performance influenced by conditioning or deconditioning.

Blotzer, P., Krumm, R.L., Krus, D.H. & Stark, D.E. ACCIDENT CAUSATION. Sept. 1954, 318pp. Pennsylvania Turnpike Joint Safety Research Group, Penn.

The present report summarizes the results of the combined efforts of 4 organizations, during an 18 month period, to analyze accident causation on the Pennsylvania Turnpike. The first chapter discusses the environmental conditions under which most accidents occurred, the factors which precipitated the accidents, how the vehicle was involved, and the severity of the injuries resulting. Chapter 2 analyzes in more detail human and vehicular factors related to turnpike accidents, while Chapter 3 does the same for environmental factors. Appendices provide details of various field surveys and a selective review of the literature.

Brown, J.S., Buel, J. & Helton, A.W. DEVELOPMENT AND EVALUATION OF THE S.A.M. DISCRIMINATION REACTION TIME TEST. (CP6110), MODEL 8. Proj. 470, Rep. 1, March 1946, 19pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The S.A.M. Discrimination Reaction Time Test was designed to measure the speed with which individuals make differential manual responses to visual stimulus patterns differing from one another with respect to the spatial arrangement of their component parts. The test required that the S react by pushing 1 of 4 toggle switches in response to the lighting of a red and green signal lamp. The time taken to operate the correct switch on each trial is accumulated on an electric clock and constitutes the test score. The report includes procedures for operation and maintenance and summaries of representative distribution, reliability, and validity statistics. (HEIAS)

USA Board Number 3. STUDY OF INTENDED USES OF THE RUCKSACK. Proj. NR 2724, DA Proj. 7 82 01 002, July 1956, 32pp. USA Board Number 3, Fort Benning, Ga.

6054

To re-examine intended uses of the rucksack to determine whether additional guidance to the developer is necessary, Department of Army publications were reviewed to determine existing doctrine guiding the use of the rucksack. Further study was made of reports of rucksack projects, tests of individual load-carrying equipment, and of standard and experimental rucksacks in order to determine the capabilities and limitations of the equipment. The military characteristics for the rucksack were reviewed and analyzed to determine the extent of guidance furnished the developer. Recommendations were included.

Carmichael, L. READING AND VISUAL WORK: A CONTRIBUTION TO THE TECHNIQUE OF EXPERIMENTATION ON HUMAN FATIGUE. Trans. N.Y. Acad. Sci., Dec. 1951, Series II, 14(2), 94-96. (Smithsonian Institution, Washington, D.C.).

This paper evaluates certain aspects of an elaborate study on reading and visual fatigue. In these experiments all eye movements made during each reading period of 6 hr. were electrically recorded. 40 Ss read for 2 such periods material presented as books and as projected micro-film pages. The 2 books were Adam Smith's "Wealth of Nations", Vol. II and Richard Blackmore's "Lorna Doone." Ss were paid for the task and were required to take comprehension tests over the material. Samples of work used for statistical analysis were chosen in an objective way only after the full records were complete. An analysis of all possible changes in the motor pattern of the eyes failed to reveal any significant decrement with any of the materials used. This finding was accounted for on the basis of continuous, high motivation; other relevant studies were cited. Practical implications in industry, education, and psychiatry are indicated. (HEIAS)

Adams, J.A. AN EVALUATION OF TEST ITEMS
MEASURING MOTOR ABILITIES. Proj. 7700,
Task 77010, AFTRC-TX-58-55, May 1956,
22pp. Skill Components Research Laboratory,
AFTRC, Lackland AFB, Tex.

6055
To test the hypothesis that for certain simple per-
formance criteria, a test composed of simple motor test
items would predict as well as complex motor
ability tests and thus could replace them in a classifica-
tion battery, 46 test items were developed to span a
wide range of motor abilities. The major ability classi-
fications were represented: (1) dexterity and manipula-
tive, and (2) gross muscular strength and coordination.
The relative predictive value of three test items, as
compared with four complex psychomotor tests and the Air-
crew Classification Battery, was studied using the fol-
lowing criteria: (1) success in primary pilot training,
and (2) success in reciprocal engine mechanics, hydraulic
mechanics, and aircraft electrician technical schools
for airman. T. R. 16

Crook, M.N. STUDIES IN THE LEGIBILITY OF NUMERALS. Feb. 1950; 20pp. US Armed Forces Vision
Committee Meeting. (Tufts University, Medford, Mass.).

This is a report, given at the Feb. 1950 Armed Forces Vision Committee meeting, concern-
ing a number of studies on the legibility of numerals conducted at the Tufts Institute for
Applied Experimental Psychology. Among the legibility factors investigated were type size,
brightness, and vibration. Factors of digit design were also studied. Emphasis was placed
not so much on the level of phrases and thought units, as in previous studies, but on the
level of numeral reading wherein each character must be separately identified. The data
indicate that: a) if the results of the numeral reading is compared to what is known about
the reading of verbal material, it appears that in the numeral reading task any factor can
be varied over an even wider range without affecting performance than in the verbal reading
b) there exists a kind of performance limit. In other words, for a given work situation in
which information on brightness, type size, and relative vibratory movement between the eyes
and the visual field is available, it seems safe to assume that performance relative to the
maximum will probably be no better, and may easily be worse, depending on whether other
adverse conditions are present, than indicated by the experimental results. Recommendations
are made for changes in configurational design of numerals for military use. (NEIAS)

Crook, M.N., Hanson, J.A. & Mulfleck, J.W. THE LEGI-
BILITY OF TYPE AS A FUNCTION OF REFLECTANCE OF BACK-
GROUND UNDER LOW ILLUMINATION. Contract W33.038 AC
14559, RDO 694 15; WADC TR 52 85, June 1952, 16pp.
USAF Wright Air Development Center, Wright-Patterson
AFB, Ohio. (Tufts University, Medford, Mass.).

6058
To study various factors in legibility of type
such as might be used on aeronautical charts, 12 Ss
performed a letter cross-out test printed in six- and
eight-point type on three papers (reflectances of
0.87, 0.49, and 0.26). Simulated red cockpit illu-
mination was used covering the range from 0.014 to
0.129 ft.-c. Speed and accuracy scores were analyzed
as functions of illumination level, reflectance of
background, and type size. The specific application
of the data to chart design is made in subsequent
papers.

Daniels, F. Jr. CONTACT COOLING OF THE HAND AT -20° F. Proj. 7-64-12-004, Tech. Rep. LP 22,
Jan. 1956, 21pp. Environmental Protection Div., Quartermaster Research and Development Com-
mand, Natick, Mass.

Cooling curves were obtained at 1) points on the hand and fingers of 3 men with bare hands
exposed at -20° F. Measurements were made with hand exposed to air, grasping iron and alumin-
um pipes covered with an expanded plastic material, and grasping the bare iron pipes. The
general shape of cooling curves in air and in contact with the insulated pipes was an initial
rapid drop, followed by a lower fall which was practically a straight line during the period
of measurement. Some of the points of contact with bare metal plunged in a straight line to
below the freezing point of water. The favored position of the third finger in having slower
cooling than the other fingers was apparent. The small finger was particularly vulnerable
to rapid cooling. The importance of insulating metal equipment in the cold is discussed
such insulation is in many instances more feasible than trying to maintain dexterity by in-
sulating the hand.

Davis, R.C., Buchwald, A.M. & Frankmann, R.W. AUTONOMIC AND MUSCULAR RESPONSES, AND THEIR
RELATION TO SIMPLE STIMULI. Psychol. Monographs, 1955, 69(20), 1-71. (Indiana University,
Bloomington, Ind.).

This monograph reports a series of experiments on the somatic responses to external sti-
muli when there is no external movement required of the S. Recordings were made of numerous
features of cardiovascular, respiratory, dermal, and skeletal-muscle responses. Topics in-
vestigated were: a) the interrelation of various cardiovascular response measures; b) the
stimulus effect of blood-pressure measuring techniques; c) the effect of stimulus repetition
upon the various response elements and their interrelation; d) the responses as functions of
auditory stimulus intensity; e) the nature of responses to a variety of cutaneous stimuli.
The direction and temporal course of the response was ascertained for each response element
in each situation and the response magnitude was related to the stimulus condition. In gen-
eral, the results indicated that there are a number of different but overlapping response
systems whose differential action is related to the stimulus and whose characteristics can be
modified by stimulus repetition.

Gibbons, T.B., Phillips, I.A., Budensiek, R.K. & Gilbertson, J.R. AGE, HEIGHT, AND WEIGHT OF 2173 MEN ENTERING RECRUIT TRAINING DURING 1952 AT THE U.S. NAVAL TRAINING CENTER, GREAT LAKES, ILL. Proj. Rep. NM 003 044.01.01, June 1953, 18pp. Naval Medical Research Unit 4, USN Training Center, Great Lakes, Ill.

Observations were made on 2173 men entering the Recruit Training Program during 1952 at the U.S. Naval Training Center, Great Lakes, Illinois. Data were collected as to age, height, and weight of these men, and it was possible to correlate the 3. The average recruit entering training was 19 years old, 5'8 1/2" tall, and weighed 152.4 pounds. Body weights represented, on the average, 105.4 percent of the standard weight for height and age as given in the Medico-Accurial Report of 1912. The recruits studied ranged in age from 17 through 25 years, in height from 5' to 6' 6", and in weight from 105 to 258 pounds. Relative body weights were from 74 to 157 percent. Comparison of these figures is made with previous information obtained on former draft registrants, Army inductees, and Army septeens. In general the 1952 Navy recruits were slightly taller and heavier, the difference being small but significant. Cf. 6053

Gibbons, T.B., Phillips, I.A., Budensiek, R.K. & Gilbertson, J.R. CHANGES IN BODY WEIGHT DURING RECRUIT TRAINING AT THE U.S. NAVAL TRAINING CENTER, GREAT LAKES, ILL. Proj. Rep. NM 003 044.01.01, June 1953, 18pp. Naval Medical Research Unit 4, USN Training Center, Great Lakes, Ill.

A representative sample of young men entering the Recruit Training Program during 1952 at the U.S. Naval Training Center, Great Lakes, Illinois, was studied in terms of age, height, and weight at the beginning and again at the end of their training. The purpose of the study was to evaluate the nutritional effects of the training program. Data describing the men entering training program were presented in another report. The present report deals with the changes in these measurements which occurred during recruit training. Data was complete on 2173 men entering training, and of these 2116 completed training with their original company in the prescribed time. During training, more recruits gained weight than lost, and about 1/3 maintained a constant weight throughout the period. Closer scrutiny of weight behavior revealed that weight gain was most likely to occur in younger men and in underweight men. Weight losses usually occurred in overweight recruits especially if over 20 years of age. A seasonal variation in weight behavior existed, with a tendency towards losing weight in the spring and summer and gaining weight in the fall and winter. The nutritional status of the great majority of men appeared to be improved during recruit training. Cf. 6061

Frick, B.C., Green, E.L. & Fry, J.H. THE AAF SAM COLOR CODE TEST (COLCODE). A PERFORMANCE TEST OF COLOR DISCRIMINATION ABILITY. Proj. 415, Rep. 1, Sept. 1945, 17pp. USAF School of Aviation Medicine, Randolph Field, Tex.

A performance test known as the AAF SAM Color Code Test (COLCODE) has been devised to score the ability of the color deficient individual to use colors as required in AAF aircraft maintenance. The reliability coefficient of the AAF SAM Color Code Test is 0.94. It is sufficiently accurate to score the subject's position within the group. The test will score the ability to name colors and to use a mimeographed identification card in aircraft maintenance. The test will score the ability to use the master color identification chart in aircraft maintenance. The test will score the overall ability of a subject to perform color identifications as required in aircraft maintenance. The ability to identify colors and to use the master identification chart is decreased by lower levels of illumination. The ability to identify colors is decreased by lowered clarity of the colors. The AAF SAM Color Code Test (COLCODE) does not correlate well with the AAF SAM Color Threshold Test. "Safe" or "unsafe" subjects selected for work with colors in aircraft maintenance should not be judged on the basis of their AAF SAM Color Threshold Test scores.

Gottsdanker, R.M. PREDICTION-MOTION WITH AND WITHOUT VISION. Amer. J. Psychol., Oct. 1952, 65(4), 533-543. (University of California, Santa Barbara, Calif.)

15 Ss were each given the task of continuing to track a target after it had disappeared from view. Under one condition of continuation S kept his eyes open, and under another condition his eyes were closed. From the results it was concluded that: a) Basically the same mechanisms of prediction operate in visual and non-visual continuation motion, as shown by the same relative rates of continuation under the 2 conditions and by the correlations between conditions; b) Non-visual continuation tended to be less accurate and consistent than that with vision; c) Individual differences were highly consistent; d) A positive bias of non-visual continuation found was attributed to an error of central tendency; e) Ss reported the use of kinesthetic, visual, and cutaneous cues, usually in combination. Vision seemed to have been utilized even by those Ss who denied its influence; f) About half of the Ss did not perceive the acceleration of the target. Only one-fourth showed complete appreciation of acceleration. No effect on performance was found to result from awareness of acceleration. (HEIAS)

6069

Gottsdanker, R.M. THE ACCURACY OF PREDICTION MOTION. J. exp. Psychol., Jan. 1952, 43(1), 26-36. (University of California, Santa Barbara, Calif.)

Ss tracked targets with an apparatus which moved sheets of paper upon which curves were printed. Ss were asked to continue tracking after the target disappeared in the manner in which he would predict the motion of an airplane which has flown behind a cloud. The following results and conclusions were reached: a) mean rate of continuation of a constant rate deviated only about 1% from the required rate; b) mean average error of prediction motion was 11% of the required rate; c) prediction of a positively accelerated motion is at a lower rate than the terminal guided rate; prediction of negatively accelerated motion is at a rate higher than the terminal guided rate; d) individual differences in measures of prediction motion were reliable; e) repeated exposure to the same segment of an accelerated pattern did not cause Ss to learn to extend the acceleration; f) differences in prediction motion could not be predicted from differences in the previous guided motion; g) correlation between measure of prediction motion and tracking proficiency was negligible; h) the tendency of gunners to lag on approaching targets and to lead on receding ones is in accord with the present findings on accelerated targets. (HEIAS)

6070

Gottsdanker, R.M. THE CONTINUATION OF TAPPING SEQUENCES. J. Psychol., 1954, 32, 123-132. (University of California, Santa Barbara, Calif.)

Ss were instructed to synchronize key tapping movements with regular sequences of discrete sounds and to continue their tapping after each series ended. The continuation responses were analyzed and results were compared with those of earlier studies in which Ss were required to maintain continuous unidirectional lateral motion. It was concluded that: a) Repeated discrete movements may be maintained at a constant rate much more accurately and consistently than may continuous motion. b) Acceleration is incorporated into continuation behavior more often in the tapping situation than in the lateral motion situation, but not necessarily in an exact and consistent manner. c) There was no evidence that the smoothing found for continuous movement occurs when Ss attempt to maintain the final tapping rate of an accelerated pattern. d) Individual differences in the rate at which a tapping sequence is continued are consistent as indicated by a reliability estimate of .84 for 6 6-sec. trials.

R 6

6071

Gottsdanker, R.M. A FURTHER STUDY OF PREDICTION MOTION. Amer. J. Psychol., Sept. 1955, 68(3), 432-437. (University of California, Santa Barbara, Calif.)

Adult human Ss were given the task of predictively continuing the tracking of a target which had been made to disappear from view. A pattern of constant rate and a positively accelerated pattern were included within each of 3 ranges of target movement. In addition, an ordinary tracking task was given to provide a criterion of skill. The following results were obtained: a) Previous results, showing the smoothing of accelerated patterns, relatively high accuracy on patterns of constant rate, and consistent individual differences, were corroborated. b) For targets with similar patterns of acceleration, the ratio of continuative rate to terminal rate was fairly constant. c) Relative accuracy increased slightly as the rate of the movement of the target increased. d) No measure of prediction motion provided a satisfactory forecast of skill in tracking. The facts argue for a new approach to the problem.

Haire, M. & Smith, M.H. THE RELATIONSHIP BETWEEN B-29 GUNNERY PROFICIENCY AND CERTAIN PRO-
POSED SELECTION TESTS. Proj. 476, Rep. 1, June 1946, 14pp. USAF School of Aviation Medicine,
Randolph Field, Tex.

In order to investigate the validity of the AAF Classification Battery for the selection
of B-29 Gunners, carefully controlled gun camera missions were given to a group of candidate
gunners who had previously taken the classification tests as cadets. The reliability of
the criterion missions in this experiment was somewhat higher than that reported in previous
projects. The average intermission r runs from .16 to .32 while the average intra-mission
 r runs from .40 to .60. The validities of the psychomotor tests are encouragingly high.
The optimal weighting of psychomotor tests on this sample yields an r of .34. Addition
of the paper and pencil tests raises this figure to .38. The Pedestal Sight Manipulation
Test (CM8248) was given its first long run try-out in this experiment. Unfortunately,
techniques for maintaining the calibration were inadequate at the time, and the resulting
unreliability seriously attenuated the test's validity. However, it is thought that the
test still has considerable promise for gunnery selection.

6074
Peterson, G.E. & Barney, H.L. CONTROL METHODS USED IN A STUDY OF THE VOWELS. Monograph
1982, ca. 1953. Bell Telephone System, New York, N.Y.

Relationships between a listener's identification of a spoken vowel and its properties
as revealed from acoustic measurement of its sound wave have been a subject of study by
many investigators. Both the utterance and the identification of a vowel depend upon the
language and dialectal backgrounds and the vocal and auditory characteristics of the in-
dividuals concerned. The purpose of this paper is to discuss some of the control methods
that have been used in the evaluation of these effects in a vowel study program. The plan
of the study, calibration of recording and measuring equipment, and methods for checking
the performance of both speakers and listeners are described. The methods are illustrated
from results of tests involving some 76 speakers and 70 listeners. (AEIAS)

6075
Hemingway, A. MOTION SICKNESS AMONG AIR CREW PERSONNEL. Proj. 126, Rep. 1, March 1943, 6pp.
USAF School of Aviation Medicine, Randolph Field, Tex.

The purpose of the study was to establish the incidence of air-sickness and determine
whether there was any relation between it and sea, car, and train sickness. Sickness
on 1 or more occasions was reported by 14.1% of the men questioned. Vomiting on 1 or more
occasions from airsickness was reported by 9.1% of the men. A lower percentage of pilots
reported airsickness than did other aircrew members, 9.0% of the pilots reporting airsickness,
half of whom said they had vomited. A history of sea, car, or train sickness was reported
by 53 men, 8.6% of the men questioned. 30.2% of the 53 men reporting sea, car, or train
sickness said they had been airsick. There is a definite correlation between a history of
airsickness and a history of sea, car, and train sickness. It is recommended that a new
questionnaire with a more precise definition of airsickness be given to a large group of
aircrew personnel.

Holland, J.G., & Henson, Jean B. TRANSFER
OF TRAINING BETWEEN QUICKENED AND UNQUICKENED
TRACKING SYSTEMS. Proj. NR 592-010, Rep. 4703,
Feb. 1956, 7pp. NRL, Engineering Psychology
Branch, Washington, D.C.

6076
To determine the direction and extent of transfer of
training for subjects trained on either a quickened or
unquickened tracking system with subsequent shift to the
other system, four groups of six subjects were used.
Two groups were trained on each system; one group prac-
ticed for 140 40-second trials, the other for 260 40-
second trials. After training each group was switched to
the system with which it was naive. Transfer of
training was evaluated by comparing the performance
during this initial test period with the first training
session of the two groups originally trained on the sys-
tem in question. The findings are discussed in relation
to learning theory and to practical operational pro-
cedures.

Lobron, C.H. ESTIMATE OF EYE LEVEL TO FLOOR DISTANCE FOR TANKERS; HUMAN ENGINEERING REPORT 4. Proj. TBI 1000, Rep. S 4030, May 1954, 5pp. USA Frankford Arsenal, Philadelphia, Penn.

Information and recommendations were requested regarding the distance from the floor to the eye level of an average tanker (standing with shoes) for use in the design of tank optics. Since no anthropometric data on a direct measure of eye level to floor were available, the distance was computed from data on stature, eye height, eye level from seat, etc. 4 different sets of data from different populations were used. The desired measurement was computed for each set of data in order to check and substantiate the solutions. The various solutions were a) for 1000 air cadets, eye level to floor (no heels) $M = 64.2"$, $S.D. = 1.9$; b) for 4000 enlisted men (with heels) $M = 64.7"$, $S.D. = 2.4$; c) for 84,000 inductees (no heels) $M = 64.1"$, $S.D. = 2.4$; d) for 17,000 Army separablees (with heels) $M = 64.5"$, $S.D. = 2.5$. On the basis of various considerations of group size and similarity of group to Army personnel the last figures were recommended. (HEIAS)

Lobron, C.H. & Hedberg, R.D. THE MAXIMUM TORQUE A MAN CAN APPLY TO A 1-1/8" KNOB. HUMAN ENGINEERING REPORT 5. Proj. TBI 1000, Rep. S 4065, June 1954, 7pp. USA Frankford Arsenal, Philadelphia, Penn.

Measurements of the amount of turning force a man could apply to a knob with a diameter of 1-1/8 in. were made on 33 male Ss. The Ss were selected to conform to a normal distribution. The average maximal force that could be exerted in turning the knob clockwise with thumb and forefinger and while in a standing position was 19.4 lb., $S.D. = 4.5$ lb. From a practical standpoint then, 84% of a comparable male population can be expected to exert a turning force of 14.7 lb. or more; 98% can exert 10.4 lb. or more on this knob. (HEIAS)

Loucks, R.B. AN EVALUATION OF VARIOUS PSYCHOLOGICAL PERFORMANCE TESTS FOR ALTITUDE CHAMBER RESEARCH. Proj. 202, Rep. 1, Aug. 1944, 26pp. USAF School of Aviation Medicine, Randolph Field, Tex.

An experimental technique has been developed by means of which decrements in psychological performance due to a simulated altitude of 15,000 feet can be detected within a single experimental session. The technique eliminates the extensive preliminary training which has commonly been employed in previous studies. A comparison was made of 4 psychomotor pursuit tests, differing in complexity, at 18,000 feet simulated altitude. One test registered a deterioration in performance in 90% of the group. The next best test showed a decrement in only 56% of the Ss. Test-retest measurements on a battery of tests indicate that the ground level performance is consistent but that the amount of impairment an individual exhibits as the result of anoxia at one test session cannot be used to predict the amount of impairment at the next session. Therefore individual decremental scores cannot be used for classification. The decrement in group performance, however, is highly significant and predictable.

Matthews, J.L. PHYSICAL STANDARDS FOR SELECTION OF RADAR OPERATORS. Proj. 167, Rep. 1, July 1943, 5pp. USAF School of Aviation Medicine, Randolph Field, Tex.

An investigation of the operation of the various types of air-borne and ground control Radar installations was made. An analysis of the operational requirements of operators of the equipment is presented. Ocular fatigue following Radar operation is attributable to accommodative asthenopia, convergence insufficiency, and flicker, of which accommodative asthenopia is considered the most important. Recommendations for the revision of physical standards for Radio Observers "I," "C," and "V" and ground control operators are made.

6082

McDonald, P.R. THE RELIABILITY OF THE AAF NIGHT VISION TESTER. Proj. 199, Rep. 1, Nov. 1943, 2pp. USAF School of Aviation Medicine, Randolph Field, Tex.

In the course of various studies on night vision, it was found that candidates tested on the AAF Night Vision Tester showed considerable improvement in performance on retests. In order to investigate this improvement of performance, 85 Ss were given 4 tests on the AAF Night Vision Tester. The correlation between the scores obtained on the second and fourth tests is 0.797 which shows the high reliability of the second test. The practice effect is greatest between the first and second tests, there being little improvement on subsequent tests.

Moeller, G., Fooks, G., Sperling, H.G. & Farnsworth, D., et al. EVALUATION OF OPTICAL FILTERS FOR SPECIAL MILITARY PURPOSES. I. DARK ADAPTATION AND THE NEAR ULTRAVIOLET. II. EVALUATION OF AN EXPERIMENTAL AIR-SEA RESCUE GOGGLE. FINAL TECHNICAL REPORT. Contract Monr 1276 (00), Proj. NR 142 082, Feb. 1956, 23pp. Office of Naval Research, Washington, D.C. (Connecticut College, New London, Conn.).

This report describes 2 series of studies conducted as cooperative enterprises of the Psychology Department, Connecticut College and the Medical Research Laboratory, U.S. Naval Submarine Base, New London, Connecticut. The 2 studies reported first were concerned with the effects of exposure to the near ultraviolet upon subsequent dark adaptation. Those studies failed to confirm reports by others that exposure to the near ultraviolet affects dark adaptation deleteriously. The third experiment reported here was designed to evaluate an experimental air-sea rescue goggle. The evidence indicates that the goggles will not improve visual performance in detection of small targets against a water background relative to such performance without any visual aid.

Hemingway, A. EFFECT OF VASANO ON SWING SICKNESS. Rep. 153, March 1943, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

To study the effect of Vasano, a mixture of hyoscine and hyoscyamine, on swing sickness, 20 susceptible Ss were given 2 trials on the swing test. Those who received Vasano on the first trial received a placebo on the second and vice versa; the drug was given 2 hrs. before swinging. The assessment of sickness incidence showed that Vasano was not significantly more effective than a placebo in preventing swing sickness. (HEIAS)

Hemingway, A. INCIDENCE OF SWING SICKNESS IN FIGHT CATEGORIES OF ARMY PERSONNEL. Rep. 180, July 1943, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The incidence of swing sickness in 1625 individuals concerned with various phases of aviation is given. The individuals tested have been divided into groups according to history of airsickness, flying interest, and experience. Group I includes those who have had airsickness; Group II, those who have had flying experience or who intend to fly; and Group III, enlisted men on ground duty only. These groups have been divided into 8 sub-groups. The incidence of swing sickness is significantly higher in those groups having a history of airsickness.

6086

McDonough, F.E. AIRSICKNESS DURING AN AIRBORNE INFANTRY MANEUVER. Rep. 102, Nov. 1942, 4pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Airsickness was studied among the personnel of an infantry division (10,070 Ss) during its participation in air landing training, October, 1942. Distance of flights varied from 130 to 150 mi. at altitudes of under 2000 ft. 97 men, as simulated casualties, were prone throughout the flights. The officer in charge of the flights submitted a report of the degree of severity of airsickness from mild to severe (unable to carry on duties at termination). An analysis of the data showed the incidence of sickness to be 3.4% for seated men and none at all for the prone men. A further study was carried out on another group of men by means of direct questionnaire to the men. Of these, 9.8% out of 688 total, reported airsickness symptoms. The difference between these 2 figures is explained by the data gathering procedure. Only 3% of the individuals with airsickness were unable to carry on their duties. Conditions of flight related to airsickness were found to be "roughness" of flight, long flights, cool or warm cabin rather than a comfortable one, and presence of odors; the first condition was the most important. Newcomb, T.M. AN APPROACH TO THE STUDY OF COMMUNICATIVE ACTS. Psychol. Rev., Nov. 1953, 60(6), 393-404. (University of Michigan, Ann Arbor, Mich.).

Communicative acts, like other molar behaviors, may be viewed as outcomes of changes in organism-environment relationships, actual and/or anticipated. Communicative acts are distinctive in that they may be aroused by and may result in changes anywhere within the system of relations between 2 or more communicators and the objects of their communication. It seems likely that the dynamics of such a system are such that from an adequate understanding of its properties at a given moment there can be predicted both the likelihood of occurrence of a given act of communication and the nature of changes in those properties which will result from that act. Some of the most significant of group properties are those which, hypothetically, vary with intragroup communicative acts. It should therefore be rewarding to discover whether support for the present hypotheses, as apparently provided by the scattered evidence now available, can be confirmed in more systematic ways. If so, there are promising possibilities of investigating the phenomena of social interaction by viewing them as events within communication systems.

North, W.J. EFFECT OF CLIMB TECHNIQUE ON JET-TRANSPORT NOISE. Tech. Note 3582, Jan. 1956, 19pp. Lewis Flight Propulsion Lab., National Advisory Committee for Aeronautics, Cleveland, Ohio.

A theoretical investigation of jet-transport climb technique was made to determine the effect of variations in engine thrust and airspeed on sound pressure levels heard by a ground observer. Reduced noise levels will be obtained when climbing on the steepest flight path consistent with minimum safe airspeed. Additional noise reduction may be obtained by throttling the engine; however, the additional benefit accompanying permissible thrust reduction is small.

Peterson, G.E. DESIGN OF VISIBLE SPEECH DEVICES. J. acoust. soc. Amer., May 1954, 26(3), 406-413. (Speech Research Lab., University of Michigan, Ann Arbor, Mich.).

This paper describes a number of the parameter relationships which must be considered in the design of certain types of visible speech devices. Possible designs have been outlined for an instantaneous cathode-ray speech translator; and for continuous linear and logarithmic sound spectrographs. System parameter values have been selected which should afford good quality pattern portrayals. In all of the systems described there exist major mechanical or circuit design problems. In this manner the present writing illustrates the nature of the difficulties which are to be encountered in the design of speech display equipment. It also explains perhaps why such an instrument as a practical logarithmic spectrograph has not as yet been constructed.

Peterson, G.E. APPLICATIONS OF INFORMATION THEORY TO RESEARCH IN EXPERIMENTAL PHONETICS. J. Speech Dis., June 1952, 17, 175-188, Bell Telephone System Mono. 2135. (Bell Telephone Laboratories, Inc., Murray Hill, N.J.).

This discussion describes the major steps required in the design of voice operated devices and shows in a general way how information theory applies to these problems. The general nature and purpose of the work that has been done in experimental phonetics is described and new objectives in extracting the phonetic content from speech by automatic means are discussed. The mathematical concept of information is then considered along with the fundamental research problems in the automatic control of devices by means of speech.

 Peterson, G.E. SYSTEMATIC RESEARCH IN EXPERIMENTAL PHONETICS: 2. THE EVALUATION OF SPEECH SOUNDS. In Speech Hearing Disorders, June 1954, 1972, 152-168. University of Michigan, Ann Arbor, Mich.).

The author's comments very briefly upon the general nature of the speech communication processes, and emphasizes some of the major problems which yet obtain in their description—a description which the speech scientist seeks to make quantitative. The task is the operational description of the speech processes in the various speech situations, conversation, and the arts. At the present time attention is directed primarily at the elementary communication situations with emphasis on normal speech. The motor-architectural and the acoustico-ventrory transformations of speech processes are discussed in light of what is known; speech communication theory is outlined; and statistics of the acoustical signal are summarized.

 Peterson, G.E. & Naisbeck, G. THE MEASUREMENT OF NOISE WITH THE SOUND SPECTROGRAPH. Monograph 2135, 1953, 20pp. Bell Telephone System, Murray Hill, N.J.

The sound spectrograph principle may be employed in the quantitative measurement of noise. Measurements may be made with the conventional amplitude section circuit in which, in the customary use of the sound spectrograph, each section provides observation during a few millisecond intervals of the signal time. A long integrating time circuit for the amplitude sectioner has been developed which provides integration over a period of as much as one or two seconds of signal time. The amplitude sectioning circuit of the sound spectrograph may be employed to determine the relationship between the level of a pure tone and the power-per-cycle of noise. Measurements were made for various types of amplitude analysis with the sound spectrograph. A study was made of the degree to which the section displays conform to the computed values of noise level.

 Peterson, M.V. & Birdsall, T.G. THE THEORY OF SIGNAL DETECTABILITY. PART I. THE GENERAL THEORY. PART II. APPLICATIONS WITH GAUSSIAN NOISE. Contract DA 36-039-sc-15358, Proj. M970, Tech. Rep. 13, June 1953, 89pp. Signal Corps, Department of the Army, Washington, D.C. (University of Michigan, Ann Arbor, Mich.).

The several statistical approaches to the problem of signal detectability which have appeared in the literature are shown to be essentially equivalent. A general theory based on likelihood ratio embraces the criterion approach, for either restricted false alarm probability or minimum weighted error type optimum, and the a posteriori probability approach. Receiver reliability is shown to be a function of the distribution functions of likelihood ratio. The existence and uniqueness of solutions for the various approaches is proved under general hypothesis. The full power of the theory of signal detectability can be applied to detection in Gaussian noise, and several general results are given. 6 special cases are considered, and the expressions for likelihood ratio are derived. The resulting optimum receivers are evaluated by the distribution functions of the likelihood ratio. In 2 of the special cases studied, the uncertainty of the signal ensemble can be varied, throwing some light on the effect of uncertainty on probability of detection.

 Ripple, P.H. & Sells, S.B. THE USAF SAM OPHTHALMIC ERGOGRAPH. EFFECTS OF ACCOMMODATION-CONVERGENCE EXERCISE. Proj. 21 24 005, Rep. 2, July 1950, 11pp. USAF School of Aviation Medicine, Randolph AFB, Tex.

A group of 19 healthy males (aged 17 to 27, median age 19) was given a series of accommodation-convergence exercises (primarily accommodative) on an ophthalmic ergograph. Each S received from 4 to 6 1/2 hr. exercises consisting of accommodating and converging intermittently at a target moving toward the S. Measurements for the 92 observations were performed prior, during and after the exercise with reference to the effects in accommodation and muscle balance. 3 phenomena were noted: a) increase in amplitude of accommodation in the individual eyes, but not necessarily in both eyes, b) a shift to esophoria, c) an increase in the amplitude of convergence, d) a slight loss in divergence. The authors recommend that muscle balance be taken at the near point and a minimum amount of exophoria (around 2 diopters) and an adequate amount of prism divergence (about 15 diopters) should be required to eliminate asthenopic individuals. Schmidt, Ingeborg. COMPARATIVE EVALUATION OF THE NEW LONDON NAVY LANTERN FOR TESTING COLOR PERCEPTION. Proj. 21-29 009, Aug. 1951, 10pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Of 500 S's (435 normals and 65 color defectives) investigated, some, established as "normal" by other testing methods, failed the Navy Lantern Test and others, established as color defective by other testing methods, were able to pass. The test was compared to several others and the results were not very significant. The test-retest reliability of the Navy Lantern, in relation to color defectives, proved satisfactory. The following observations were made: The two samples of the Navy Lantern did not show marked differences. The test result was affected by the subject's adaptation to the light. Repeating the test revealed a learning effect in normals and those moderately defective. Two general types of errors could be distinguished: a) misinterpretation of white and calling green "white"; b) misinterpretation of red and calling green "red", "yellow" or "orange". (HEIAS)

Lorge, I., Tuckman, J., Aikman, L., Spiegel, J. et al. THE ADEQUACY OF WRITTEN REPORTS IN PROBLEM SOLVING BY TEAMS AND BY INDIVIDUALS. J. soc. Psychol., 1956, 43, 65-74. AFPTC TN 56-100, July 1956, AFPTC, Lackland AFB, San Antonio, Tex. (Teachers College, Columbia University, New York, N.Y.).

6107

To estimate the bias in written reports of problem solving, 31 five-man teams and ten individuals (ROTC cadets) were asked to solve a problem which required formulating a plan to get a five-man group across a mined road, using materials such as beams, ropes, etc., without discharging a mine. Two trained observers recorded the behavior and statements. Each team prepared a written report, as did each individual. The observer's records and the solvers' reports were content analyzed and assigned a Quality Point Score, based on the aggregate scoring weights for various components. The observers' records were used as a criterion of problem-solving effectiveness and compared with the written reports. Implications of the findings are discussed.

Smith, G.M. THE EFFECT OF PROLONGED MILD ANOXIA ON SLEEPINESS, IRRITABILITY, BOREDOM, AND OTHER SUBJECTIVE CONDITIONS. J. gen. Psychol., 1946, 25, 239-250. (Psychology Dept., College of the City of New York, N.Y.).

16 male college students, with a median age of 18 yrs., 4 mos., were asked to rate themselves with respect to 10 different subjective conditions at 5 different periods during a continuous 8 hour session in a nitrogen dilution chamber in which an altitude of approximately 10,000 ft. was simulated. The same procedure was followed during an 8 hour control run. The conditions rated were sleepiness, fatigue, boredom, attention, irritability, headache, elation-depression, motivation, coordination, and general feeling of well-being. Although the results for the altitude and control runs varied from one condition to another, there was on the average a pronounced trend on the altitude run in the direction of poorer adjustment from the first period, 1 1/4 hrs. after admission to the chamber, through the 4th period which occurred after an exposure of 6 1/4 hrs. The differences between the mean ratings for the control and altitude runs were in every case reliable at the points of maximum divergence which occurred most frequently at the 4th rating period. There was in general a marked end-spurt between the 4th and 5th period when the Ss were aware that their ordeal was nearly over.

Smith, G.M. THE EFFECT OF PROLONGED MILD ANOXIA ON SPEECH INTELLIGIBILITY. J. appl. Psychol., June 1946, 30(3), 255-264. (College of the City of New York, New York, N.Y.).

Using the method and materials employed in an earlier study in collaboration with C.P. Seltz, 12 Ss were tested for their ability to perceive standard speech sounds at 4 periods during an 8-hour exposure to the mild anoxia encountered at an altitude of approximately 10,000 ft., simulated in a nitrogen dilution chamber. The decrement in speech intelligibility at altitude was very slight and unreliable at the 3/4 hr. period; it was nearly reliable at the 2 1/4 hr. and 4 3/4 hr. periods; but there was a marked lessening of the altitude effect at the last period, 6 3/4 hrs. after entering the chamber. The Ss' ability to overcome the mild deterioration in performance exhibited in the middle of the run in an "end-spurt" suggests that the apparent loss of efficiency at the altitude and sound level employed is primarily due to subjective factors such as wandering attention and boredom.

R 3

6110. Smith, G.M. THE DIFFERENTIAL EFFECT OF PROLONGED MILD ANOXIA ON SENSORY AND SENSORY-MOTOR REACTIONS AND ON SUCH SUBJECTIVE STATES AS SLEEPINESS, IRRITABILITY AND BOREDOM. J. gen. Psychol., 1948, 28, 3-14. (Psychology Dept., City College of New York, New York, N.Y.).

At intervals during an 8-hour exposure to an altitude of 10,000 ft. (simulated in a nitrogen dilution chamber), and also during a control run, 16 male college students were given tests of visual, auditory, and sensory-motor efficiency and were asked to rate themselves on 10 subjective conditions, including sleepiness, irritability, and boredom. The detailed results for 3 of these measures, previously reported in separate journals, are here summarized together with some new material, and the differential reactions to prolonged mild anoxia are discussed. Taken as a whole, the results indicate a moderate but progressive loss of efficiency and a generally poorer emotional adjustment as the exposure to the relatively low altitude is prolonged.

6111

Smith, G.M. & Seitz, C.P. SPEECH INTELLIGIBILITY UNDER VARIOUS DEGREES OF ANOXIA. J. appl. Psychol., April 1946, 30(2), 182-191. (College of the City of New York, N.Y.).

Under standard conditions speech intelligibility is shown to decrease with increasing altitude. If the original sound level is low the decrement in articulation is large, discrete word intelligibility falls precipitately and speech rapidly becomes unintelligible. The effects of anoxia are minimal if sea level articulation is high. (As was pointed out in our earlier paper, this will be the case when the sound level is high; a superior communication system is employed; personnel are trained in speech production and in listening under noisy and distracting conditions; and when "filling in" is made easy by familiarity with the type of message transmitted.) The fact that 67% of the subjects (8 of 12) showed a decrement in performance at 13,600 ft. suggests the importance of using oxygen equipment on long flights even at low altitude.

Smith, G.M., Seitz, C.P. & Clark, K.B. VARIATIONS IN THE ANGIOSCOTOMA IN RESPONSE TO PROLONGED MILD ANOXIA. J. Aviat. Med., Dec. 1946, 17(5), 590-595. (College of the City of New York, N.Y.).

The peripheral blind area (angioscotoma) of 15 subjects was tested 5 times during a 7.5 hour exposure to an altitude of 10,000 feet, simulated in a nitrogen dilution chamber. A progressive and statistically significant increase in the size of the scotoma was observed, which became most marked at the end of 7.5 hours. The results are in contrast with the negative data obtained when psychomotor performance is measured. It is pointed out that when extraneous motivational factors are eliminated or minimized (and this is probably true of a visual task), an anoxic effect may become progressively evident with prolonged exposure to even a moderate altitude.

6118

To study the feasibility of simulating sled-pulling by applying posterior drag through a harness to men walking on a treadmill, a laboratory study was conducted. After a one-week training period, twelve men performed the activity at two rates (2 1/2 and 3 1/2 miles per hour) with a drag of 17.5 pounds while wearing cotton fatigue suits; five men also performed wearing arctic clothing. Metabolic costs and pulse rates were measured during latter part of exercise. The data were analyzed and compared with similar data obtained from walking the treadmill, and walking carrying a load (44 pounds) and for actual sled-pulling in the field. The use of this method for establishing baseline values for sled pulling studies in the field is discussed.

6120 White, C.E. REPORT ON EFFECT OF INCREASED ATMOSPHERIC PRESSURE UPON HEARING. Proj. NM 002 014.06.03, Memo Rep. 55 7, Dec. 1955, 6pp. USN Medical Research Lab., New London, Conn.

Under conditions simulating increased atmospheric pressures encountered by a diver submerged to a depth of 200 feet, with a signal-to-noise ratio between 15 and 20 decibels, the decrease in listening sensitivity as measured by articulation scoring methods is 25.8 per cent. This loss is obtained when using monosyllabic, phonetically-balanced word lists.

6121 White, C.E. REPORT ON EFFECT OF INCREASED ATMOSPHERIC PRESSURES UPON INTELLIGIBILITY OF SPOKEN WORDS. Proj. NM 002 014.06.04, Memo Rep. 55 8, Dec. 1955, 8pp. USN Medical Research Lab., New London, Conn.

For male Ss exposed to a change in pressure from atmospheric to 103 psi, absolute, the decrease in articulation scoring is determined to be 24.7 per cent. This decreased scoring is obtained under signal-to-noise ratios of 30 db. and while using phonetically-balanced monosyllabic word lists.

Martin, E.F., & Henry, J.P. EVALUATION OF THE ANTI-G SUIT. Memo Rep. MCREXD-689-2C, Rep. 8, July 1948, 18pp. WADC, Aero-Medical Laboratory, Dayton, Ohio.

ATI 38691.

Returned.

6123

This memo report compares the effectiveness of three anti-G suits (Type G-3A standard, Type G-4A experimental, and Type G-5, the Capstan modification of the Lamport Pneumatic principle) in maintaining cerebral blood pressure. Three trained subjects with and without each anti-g suit were run on the human centrifuge at accelerations of 1, 2.5, 3.5, and 5g both "normally" and using the M-1 maneuver (forced expiration against a partially closed glottis). G-tolerance under the three suit conditions, in terms of visual symptoms, direct radial artery pressures, and arterio-venous oxygen are presented and discussed.

Proctor, H., & Weiner, H. THE CHARACTERISTICS OF PERFORMANCE ON A COMPENSATORY FOOT CONTROLLED TRACKING DEVICE. Proj. DA-49-007-MD-222 (O.I. 19-52), Tech. Rep. 27, Aug. 1954, 23pp. Medical Research and Development Division, University of Maryland.

6124

To investigate factors affecting performance on a foot-controlled compensatory tracking device (Balaflex) a series of experiments were performed. The learning process was examined (25 subjects for ten-minute period; four subjects for nine additional periods of six minutes). A correlational analysis was made of the relationship between Balaflex performance (24 subjects) and standing, tapping, coordination, age, weight, and height. The effect of different visual conditions (normal, central binocular, central monocular, and "quarter" (25 percent) binocular) upon Balaflex performance (20 subjects) was examined. The findings are discussed in terms of motor and perceptual skills necessary for efficient performance on the Balaflex and are related to studies investigating factors in motor performance. T. G. Katchmar, L.T. A STUDY OF DIRECTION OF RESPONSE ERRORS IN A HORIZONTAL DISPLAY-CONTROL PATTERN. Proj. DA-49-007-MD-222 (O.I. 19-52), Tech. Rep. 26, Aug. 1954, 17pp. University of Maryland, College Park, Md.

6125

To investigate the effects of certain display-control variables on response accuracy in a perceptual motor task, 36 subjects were tested. The task was to identify (verbally or by pressing a corresponding key) the position of light flashes occurring on a horizontal display of lights (five, nine, or eleven). Distances between the lights were varied (three, five, and seven inches); lights were presented in random order every 0.6 seconds. Error data (total number, direction, and magnitude) were analyzed for differences due to number of stimuli, distance between stimuli and type of response. The results are discussed in terms of desirable display-control relationships.

Whittenburg, J.A. A STUDY OF THREE MEASURES OF PERCEPTUAL EFFICIENCY DURING SUSTAINED VIGILANCE. Proj. DA-49-007-MD-222 (O.I. 19-52), Tech. Rep. 14, Feb. 1953, 38pp. USA Medical Research and Development Board, University of Maryland, College Park, Maryland.

12 female and 15 male Ss were each given the "Hickworth Clock Test" for a 2 hour period. Mean scores for both male and female subjects showed a significant decrease in perceptual efficiency after the first half hour as measured by errors of omission. During the last hour, the female subjects made significantly fewer errors of omission than the male subjects. Errors of omission proved to be a relatively reliable measure for the male subjects but not for the female subjects. The measure involving errors of commission was of little value since contributions to this measure were made by very few subjects. The majority of subjects either did not exhibit any error of commission over the 2 hour period or only a very few. It was concluded that perceptual efficiency, as measured by errors of omission and response time, may serve as useful measures of behavior decrement under conditions of sustained vigilance.

Bowen, J.H. THE RELATIONSHIP BETWEEN STRENUOUS WORK AND SLEEP PRIVATION AND PURSUIT TRACKING LATENCY. Proj. DA-49-007-MD-222 (O.I. 19-52), Tech. Rep. 13, ca. 1952, 20pp. USA Medical Research & Development Board, University of Maryland, College Park, Md.

6129

To determine the effects of strenuous work and sleep deprivation upon pursuit tracking latency, 48 subjects were assigned at random to one of six experimental conditions. Three groups were deprived of a night's sleep and then had a normal night's rest. Further subdivision was based on bicycle riding (20 miles per hour) as follows: no riding, riding for five minutes, or riding for ten minutes. The task was to follow a line which deviated at right angles to its previous course and returned at intervals of 3/8, 5/8, 1 1/4, and 1 1/2 seconds. Tracings were analyzed for two reaction times (deviation and return). The data were studied by analysis of variance techniques for changes due to sleep deprivation, to exercise, and to size of deviation.

Whittenburg, J.A. THE EFFECTS OF GENERAL ACTIVITY AND EXTENDED DIURNAL VARIATION ON OLFACTORY SENSITIVITY. Proj. DA-49-007-MD-222 (O.I. 19-52), Tech. Rep. 11, Aug. 1952, 16pp. Army Medical Research and Development Board, University of Maryland.

6130

To determine whether or not olfactory sensitivity would provide a sensitive and reliable indicator of general systemic fatigue, two investigations were performed. (1) The effects of general activity (stair climbing) were measured on five untrained subjects. Threshold measures were taken twice on two days (morning and afternoon) with and without exercise by means of the "stream" technique. Food intake, diurnal variation and smoking were controlled. (2) The effect of diurnal variation on threshold measures was determined on five untrained subjects. Measurements by the "blast" technique were taken early in the morning and late in the evening of same day. Food intake and smoking were controlled. The data were analyzed for differences due to the experimental variables and for consistency of results. T.I.R 14

Lybrand, W.A. AN EXPLORATORY INVESTIGATION OF TASKS OF PERCEPTUAL ORGANIZATION AS POTENTIAL INDICATORS OF BEHAVIOR DECREMENT. Proj. DA-49-007-MD-222 (O.I. 19-52), Tech. Rep. 10, July 1952, 26pp. Army Medical Research and Development Board, University of Maryland.

6131

To explore the relationship of perceptual organization to bodily conditions assumed to induce general systemic fatigue, measures were taken on three tasks of perceptual organization: Kohs Block Design, Perception of Hidden Figures, and the Muller-Lyer Illusion. Twelve subjects were assigned to each of four conditions: at rest, after a five-mile march carrying a back-pack, after missing a night's sleep, and after missing a night's sleep and a five-mile march carrying a back-pack. The effects of the experimental conditions were studied by analysis of covariance techniques (Kohs Block Design and Perception of Hidden Figures) and by analysis of variance techniques (Muller-Lyer Illusion). Discussion is related to the usefulness of these tasks as indicators of behavior decrement.

Ross, S. REPORT ON "SYMPOSIUM OF FATIGUE" OF THE ERGONOMICS RESEARCH SOCIETY, HELD 24-27 MARCH 1952 AT THE COLLEGE OF AERONAUTICS, CRAWFORD, ENGLAND. Proj. DA-49-007-MD-222 (O.I. 19-52), Tech. Rep. 9, April 1952, 21pp. Army Medical Research and Development Board, University of Maryland.

6132

This paper reports brief summaries of individual papers given at a symposium on fatigue of the Ergonomics Research Society in England. The various studies represent physiological and psychological frames of reference. Both laboratory and field investigations in industrial situations are reported. In addition, several papers on methodology and apparatus are included.

6133

Katchmar, L.T., Whittenburg, J.A., & Weiss, E.C. REVIEW OF THE LITERATURE ON MENTAL WORK AND SUSTAINED VIGILANCE. Proj. DA-49-007-MD-222 (O.I. 19-52), Tech. Rep. 8, March 1952, 12pp. Army Medical Research and Development Board, University of Maryland.

6133

This report presents a critical review of the literature on mental work and sustained vigilance (attention). The main emphasis is placed on the methodology employed and studies related to behavior decrement. The problem of definitions is treated followed by review of mental work and factors of sleep deprivation, blocks and errors, and muscular tension. Experimental studies on attention are grouped under three headings: adequacy of attention, secondary changes, and breaking strain.

Hussman, T.A. A CRITICAL EVALUATION OF FOUR INDICATORS OF BEHAVIOR DECREMENT. Proj. DA-49-007-MD-222 (O.I. 19-52), Tech. Rep. 12, Aug. 1952, 23pp. Army Medical Research and Development Board, University of Maryland.

6138

To determine the usefulness of four variables (steadiness, blind steadiness, critical flicker frequency thresholds, and tapping) as indicators of behavior decrement, an experiment was designed utilizing a collegiate boxing situation to produce fatigue and anxiety. Twelve experienced and twelve novice boxers were tested at rest, after heavy exercise, before fighting, and after fighting. Each subject was tested on all four variables three times for each condition. Analysis of variance techniques were used to test the changes in each variable as a function of fatigue and of anxiety. Each variable was evaluated for its reliability and potential as a predictor.

Hauty, G.T. & Mendt, G.R. STUDIES OF VESTIBULAR FUNCTION: I. THE DURATION OF PRIMARY NYSTAGMUS AS A FUNCTION OF SPEED OF ROTATION AND OF ACCELERATION. J. Psychol., 1953, 26, 143-151. (University of Rochester, Rochester, N.Y.).

In the first part of the experiment each of 3 Ss was stimulated 6 times by acceleration to or from each of 5 speeds of rotation (11, 22, 45, 90, and 180°/sec.), with duration of acceleration constant at about 1/2 sec. In the second part of the experiment the same Ss were stimulated 6 times by each of 5 rates of acceleration to or from a speed in each case of 180°/sec. The rates were such that the speed of 180°/sec. was reached in 0.5, 5, 30, 85, and 165 secs. Duration of the primary nystagmus was determined by the method of ocular movement of a fixation object. In the first part of the experiment it was found that the duration of nystagmus was probably constant, unaffected by the amount of work done on the ear. Speeds of 11, 22, 45, 90, and 180°/sec. produced primary nystagmus with mean durations of 28, 25, 27, 28, and 27 secs. respectively. On the other hand, in the second part of the experiment when the period of acceleration was lengthened, the primary nystagmus was also lengthened. With a fixed speed of 180°/sec. reached or stopped in various times, the duration of primary nystagmus was: accel. 0.5 secs., 27 sec. of nystagmus; accel. 5 secs., 29 sec. of nystagmus; accel. 30 secs., 48 sec. of nystagmus; accel. 85 secs., 87 sec. of nystagmus; accel. 165 secs., 164 sec. of nystagmus. With the 2 longest accelerations the data indicated that the primary nystagmus sometimes ended and was replaced by the secondary inverse nystagmus while S was still being accelerated. Arguments are presented to show that the results are incompatible with attributing the duration of nystagmus to the duration of deviation of the cupula.

Gee, A.H., Stevens, M.R. & DeAngelis, F. ODOR CONTROL FOR AIR EVACUATION AIRCRAFT. Contract AF 18(600) 146, S.E.O. 698 29, Tech. Rep. 6565, Part 4, Sept. 1952, 78pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

This is the 4th formal report on work intended to find ways to suppress malodors from wounds of patients on air evacuation aircraft, without interfering with detection of alarm odors indicative of mechanical trouble or overheating. In this phase of the investigation, malodor, odor-control agent, and alarm odor were commingled in a dynamic air flow system equipped with sniff ports for appraising the resulting mixtures. Ozone was found to have a definite cancelling effect, selective for malodor, and not interfering appreciably with the alarm odors. The amounts needed, however, present a problem in practical application from the standpoint of tolerable levels of ozone. One aldehyde, 3,5,5 trimethyl hexaldehyde, was investigated extensively, as an example of a volatile organic compound of the masking type. It was found to suppress malodor, but only when used in large amounts. These amounts, from toxicological studies, may have an unfavorable effect on personnel.

6151

Gee, A.H., Ellner, P.D. & Stevens, M.R. CONTROL OF ODOR IN EVACUATION AIRCRAFT. Contract AF 18(600) 146, S.E.O. 698 29, Tech. Rep. 6565, Part 3, May 1952, 40pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

This is a continuation and extension of work intended to find methods or materials for suppressing malodors on evacuation aircraft, without interfering with the detection of alarm odors indicative of mechanical trouble or overheating. 2 kinds of agents have been found more promising than any hitherto investigated for the purpose: Ozone from small generators has been found capable of reducing high level of malodor, which can be virtually eliminated under laboratory conditions. The action of the ozone is selective so that alarm odors can still be detected, save under extreme conditions. The results are considered sufficiently promising to warrant investigation of the problem of practical application. 2 aldehydes also have been found useful for odor control, both of them superior to heptaldehyde. Heptaldehyde was one of the more promising of a series of essential oils, aldehydes and related materials previously investigated. One of the aldehydes, 3, 5, 5 tri methyl hexanal, is believed worth further investigation.

Olsenski, K.W., Pohoski, A. & Olastula, K.W. LIMITING DIMENSIONS OF COCKPIT FRAMING BASED ON THE GEOMETRY OF BINOCULAR VIEW. Class 629.13.012.3, Rep. 2095, Nov. 1945, 52pp. Royal Aircraft Establishment, Farnborough, England.

This investigation originated from an old query by H.A.P. connected with the effect of the widths of windscreen frames on visibility. Only provisional and unproved quantities were given in the answer. After a few years' interval, the subject has been developed further and the results are issued in this report. Its importance is chiefly confined to operational aircraft, but it may also be useful for civil aircraft. A blind "spot", (the space entirely lost to view behind a given non-transparent object) is smaller when looking with both eyes than when looking with one only. If the obstruction is small or narrow--such as the various components of the windscreen framing--blind spots may disappear altogether when both eyes are used, although an appreciable interfering effect remains, since parts of the distant background are visible to one eye only. This report gives general outlines and a number of limiting dimensions for designing cockpit frames so that blind spots are avoided as far as reasonably possible when looking out of an aircraft with both eyes. An approximate photographic method is suggested for measuring the overall forward field of binocular view from a given aircraft and for locating blind spots.

Packer, D.H. & Lock, C. THE BRIGHTNESS AND POLARIZATION OF THE DAYLIGHT SKY AT ALTITUDES OF 18,000 TO 38,000 FEET ABOVE SEA LEVEL--AND APPENDIX. Rep. 3713, July 1950, 59pp. USN Research Lab., Washington, D.C.

The brightness and polarization of the daylight sky over Arizona and southern California were measured from B-29 aircraft while flying at altitudes of 18,000, 27,500, 34,000, and 38,000 feet above sea level. Comparison of the results with the Tousey-Hulburt theory of sky brightness showed that the theory agreed fairly well with the experimental data for all altitudes of observation, for all points in the sky more than 30° from the horizon and for scattering angles greater than about 40° from the sun, when an atmospheric attenuation coefficient of 0.017/km was assumed. The values of sky brightness observed at scattering angles within 30° of the sun indicated that large scattering particles were present in the atmosphere overhead at all altitudes of observation, including 38,000 feet. The measured values of sky brightness and polarization are presented graphically, plotted as functions of the angle between the sun and the observed point in the sky.

Henneman, R.H., Reid, L.S. & Long, E.R. THE INFLUENCE OF CATEGORICAL CUEING ON THE IDENTIFICATION OF VISUALLY DISTORTED WORDS SELECTED FROM A LOGICALLY ORGANIZED POPULATION. THE SEVENTH OF A SERIES OF REPORTS ON "SET" AS A DETERMINER OF PERCEPTUAL RESPONSES. Contract W33(038)-ac-21269, Proj. 7192, Tech. Rep. 54-362, April 1955, 16pp. WADC, Aero Medical Laboratory, Dayton, Ohio.

6161
To investigate the role of perceptual set in aiding recognition of visually distorted words drawn from a logically organized population when subjects were familiar with word categories and the specific words, 90 subjects were required to identify distorted (two per cent identification level) words. Cueing was provided by presenting subjects with the names of the categories containing the word before, after, or both before and after stimulus presentation; degree of setting was varied by progressively reducing the size of category, hence number of stimulus words; familiarization was varied by two types of training prior to identification. The number of correct identifications was studied by analysis of variance for effects of categorical restriction, temporal position of cueing, and familiarity. T. I. R 9 111 - 668

6163
Lee, W.A., & Preitag, M. THE CONCEPT OF RESPONSE RESTRICTION APPLIED TO DIAL READING. THE EIGHTH OF A SERIES OF REPORTS ON "SET" AS A DETERMINER OF PERCEPTUAL RESPONSES. Contract W33(038)-ac-21269, Proj. 7192, Tech. Rep. 54-364, April 1955, 13pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio.

6163
To investigate the effectiveness of setting cues as an aid to accuracy of dial-reading performed simultaneously with a competing visual-motor task, forty subjects were required to respond to randomly flashing lights (two per second) by pressing the appropriate key with the right hand; the left hand operated keys to indicate a dial pointer (in any one of four dials) in a "critical" zone. Differential cueing for the dial-monitoring was varied by using seven combinations of sense channel (vision, audition) and degree of cuing. Percentages of correct detections were studied due to degree of cuing and sense channel used. The quality of performance on the secondary task was also assessed.
T. R 9

6164
Long, E.R., & Garvey, W.D. THE ROLE OF SETTING CUES IN REDUCING THE SIMULTANEOUS LOCATION AND IDENTIFICATION AMBIGUITY OF LETTER PATTERNS. THE FIFTH OF A SERIES OF REPORTS ON "SET" AS A DETERMINER OF PERCEPTUAL RESPONSES. Contract W33(038)-ac-21269, Proj. 7192, Tech. Rep. 54-289, April 1955, 19pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio.

6164
To investigate some aspects of the action of perceptual set as an aid to identification of ambiguous visual stimuli, multiple (four) letter patterns were employed to provide such a condition. Subjects (72) were required to select and identify a single critical letter under different degrees of location restriction (red mark for visual denotation of four, three, two or one of the letters) and three difficulty levels of figural contour distortion. Temporal position of figure cuing was varied by having one-half the subjects view undistorted letters both before and after stimulus presentation and the other half only after presentation. The data (frequencies of correct identifications) were studied by analysis of variance for effects of the experimental variables. T. I. R 6

6165
Long, E.R. & Garvey, W.D. THE INFLUENCE OF SENSORY CHANNEL OF CUEING ON THE IDENTIFICATION OF AURALLY PRESENTED DISTORTED WORDS. SIXTH OF A SERIES OF REPORTS ON "SET" AS A DETERMINER OF PERCEPTUAL RESPONSES. Contract W33(038) AC 21269, Proj. 7192, Tech. Rep. 54 361, April 1955, 22pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

6165
To study the nature and operation of perceptual set as an aid in identifying distorted auditory stimuli, subjects (90) were required to identify distorted spondaic words as heard through earphones. Cueing consisted of presenting the subjects with four non-distorted words, one of which was the same as the distorted stimulus. Auditory cues or visual cues or a combination of both were presented before or after or both before and after (nine combinations) stimulus presentation. Frequencies of correct word identification (recall) for all combinations of conditions were studied by analysis of variance for differences due to cuing, to sense channel used for cuing and to temporal position of cuing. The findings are related to those from visual studies.

Air Transport Association of America. RECOMMENDATIONS FOR SAFE CONTROL OF EXPANDING AIR TRAFFIC. PART 1. Feb. 1947, 84pp. Air Transport Association of America, Air Navigation Traffic Control Group, Washington 6, D.C.

ATI 44622.

6166

In anticipation of increasing different aircraft traffic control problems, the present report presents analysis and recommendations intended to guide appropriate individuals and agencies in establishing priorities and evaluation procedures designed to achieve maximum improvement in air traffic control operations. Some of the topics discussed involve operational requirements pertaining to pilot and air control displays, operational flight patterns, proposals for electronic system integration, etc.

ATI 65393.

6167

To assess the usefulness of X-band airborne radar in providing anti-collision information, appropriate installations and test flights were undertaken. The obtained findings are reviewed and conclusions drawn on the adequacy of such radar in avoiding collisions with terrain, other aircraft, and weather disturbances and the degree of pilot's attention required to use the developed equipment. Engineering design recommendations are also included.

Wagner, H.G. REPORT ON STUDY OF RED LIGHTING REQUIREMENTS FOR THE COCKPITS OF NAVAL AIRCRAFT. Rep. TED NMA 31410, March 1947, 6pp. Naval Air Experimental Station, USN Air Material Center, Philadelphia, Penn.

A series of scan and pick up times of targets was made on a number of dark adapted observers exposed to different levels of indirect red panel illumination. At levels of illumination required to read instruments, the time required to pick up targets outside an aircraft under night sky conditions is lengthened steadily with increasing levels of indirect red illumination inside the cockpit. There was no evidence in this study of a beneficial effect to dark adaptation at useful levels of red illumination to the instruments.

Noble, Rosalie. HUMAN ENGINEERING INVESTIGATION OF AIRCRAFT COCKPIT VISUAL DISPLAY: DIAL DESIGN FOR MACH-AIR-SPEED INDICATOR. Rep. NMA AE 7047.5, Top. Rep. XG T-237, Dec. 1954, 4pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

This report includes drawings and proposed specification requirements for the dials and pointers for 2 Mach-air-speed indicators. Various proposals of dial presentations of air speed and Mach number were considered for possible exploitation in the design of an indicator which fulfills the service need (850 knot airspeed and Mach number) and meets the requirements demanded with respect to readability, accuracy, and acceptability. In addition to a review of diagrammed and photographed proposals, interviews and discussions with pilots and personnel familiar with the use and design of aircraft instruments were held. The proposals and recommendations presented are believed to be in line with the present state of engineering design developments. (HETAD)

Noble, Rosalie & Mandelson, E.S. AFTER-BURNER NOISE MEASUREMENTS IN GROUND ENGINE RUN-UPS. Rep. TED NMA AE 6513.1, WH 001062.05.08, Feb. 1954, 27pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

4 sets of measurements of F-94B aircraft afterburner noise were made with determinations of overall SPL's and frequency distributions. The following generalizations of the sonic spectra can be drawn from the observed data: a) The variability of the calculated overall sound pressure level was greater from test to test than within a single day. From data accumulated at 12 locations, standard deviation of the calculated overall sound pressure levels obtained during all the tests ranged from 1.4 to 6.48 db, whereas in a single day the range of the standard deviation was from .68 to 4.08 db. b) The variation of the frequency pattern at a particular location on any single day was sufficiently small for generalizations on the characteristics of the various spectra to be made. Comparisons among the tests showed variation to the extent that individual descriptions of the spectra obtained during each test had to be given. c) The higher sound intensities of the noise emanating from jet engine powered aircraft with afterburners is concentrated toward the rear and exhaust regions of the aircraft. On a semi-circle about the center of the tailpipe opening with the engine at rest, the overall sound level gradually becomes higher from the forward area about the aircraft to the rear regions. The most intense noises are measurable along bearings of slightly over 135°.

 Noble, Rosalie. HUMAN ENGINEERING INVESTIGATION OF AIRCRAFT COCKPIT VISUAL DISPLAY: FUEL QUANTITY PRESENTATION. Rep. TED NAM AE-7047.7; Rep. XG-T-243, Feb. 1955, Spp. Naval Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

6175
 To present an optimum-type display for fuel quantity information on multi- and single-tank aircraft, several dial presentations were considered. Particular attention was given to the need for both qualitative and quantitative information with minimal use of panel space. Two presentations of a single-tank indicator and four of multi-tank indicators are shown. These designs are discussed and specific recommendations are made.

 Mendelson, E.S., Noble, Rosalie, & Tiller, P.R. COMPARISON OF STANDARD AND EXPERIMENTAL EAR PLUGS. Proj. NM 001 062.05, Rep. 3 & Rep. TED NAM AE 6513.1, Nov. 1955, Spp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

Comparative measurements have been carried out of the shifts in auditory threshold for each ear of 11 laboratory subjects using standard ear plugs (V-51R, Ear Wardens) and experimental ear plugs (Dunbar-Knight Hearing Guards). The results are consonant with previous theoretical and empirical analyses on similar devices. The V-51R plugs provide more effective sound attenuation, particularly in the low frequency range where afterburner powered jet engines generate their most intense noise. As compared with other commercial ear plugs of similar acoustic design, the experimental plugs are likely to be more effective for noise exclusion. They appear worthy of consideration in principle for use by personnel who must maintain headset communications in extremely noisy environments, i.e. in instances where maximum sound attenuation may be undesirable.

 Lowery, E.A. & Brown, F.R. INSTRUMENT LIGHTING--INVESTIGATIONS OF ULTRAVIOLET REFLECTIONS. PART III. A STUDY OF DARK ADAPTATION DURING OBSERVATION OF AN ULTRAVIOLET ACTIVATED AIRCRAFT INSTRUMENT PANEL. Rep. TED NAM 31334, Part 3, April 1950, 8pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

Measurements of dark adaptation thresholds while viewing an aircraft cockpit instrument panel illuminated with ultraviolet flood lights were obtained on 2 trained subjects. These data are compared to thresholds attained by the same subjects during a similar period in darkness. It is concluded that dark adaptation is impaired while viewing the test panel and for each subject the mean impairment is constant during observations of the panel. For one subject the mean impairment of dark adaptation while viewing the test panel was approximately 0.40 log units (micro-micro-lamberts). The mean impairment of dark adaptation for the other subject was approximately 0.20 log units (micro-micro-lamberts).

 Lowery, E.A. SHIELDING DEVICE FOR PROTECTION OF LANDING SIGNAL OFFICER'S EYES AGAINST ULTRAVIOLET LIGHT. Rep. TED NAM AE 25790, Sept. 1949, 8pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

The eyes of Landing Signal Officers must be protected from the radiation coming from the ultra-violet lamps used for activating the fluorescent strips of his garment during night carrier operations. A shield meeting the stated requirements, designated the MAES LSO eye shield, has been designed, fabricated, and evaluated. It is constructed of rubber laminated on an aluminum ribbing and is provided with elastic straps for positioning against the face. Satisfactory evaluations have been conducted under conditions of operational use.

6180
 Lazo, J. & Brown, F.R. INSTRUMENT LIGHTING INVESTIGATIONS OF ULTRA-VIOLET REFLECTIONS. PART II. MEASUREMENTS OF ULTRA-VIOLET ENERGY IN AIRCRAFT COCKPITS EQUIPPED WITH FLUORESCENT INSTRUMENT LIGHTING. Rep. TED NAM 31334, Part 2, Feb. 1950, 30pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

An Ultra-Violet Radiometer Assembly has been designed and constructed to measure average radiant flux densities over the spectral range of 312 to 399 millimicrons. This instrument has been used to measure the energy at the pilot's eye position in cockpits of naval aircraft equipped with ultra-violet floodlighting of fluorescent instrument markings. The energy so measured is largely attributable to reflections on the instrument panel, adjoining consoles and windscreens, and, in some cases, to direct radiation from the lamps. 10 naval aircraft (JH, SHB, K40, SHJ, BTD, PB4, P61-W, JD, PBY, PBH) equipped with ultra-violet instrument floodlighting fixtures (360 BL lamps), were investigated. One commercial aircraft, a Martin 2-0-2, equipped with a cold cathode ultra-violet floodlighting installation was also studied. In addition to the measurements of radiant flux density, the related brightnesses of the fluorescent instrument markings on the aircraft panel were determined. These measurements supplement data previously reported on the amount of visible light reaching the pilot's eye position in similar aircraft. An analysis of the measurements and observations indicate that ultra-violet radiations and reflections can be minimized by improved positioning of the ultra-violet sources, by better shielding over the instrument panel and by uniform use of a standard fluorescent paint on the instrument markings.

Lazo, J. & Brown, F.R. COLOR, SIZE AND SHAPES OF AIRCRAFT INSTRUMENT DIAL MARKINGS. PART II. DESIGN FOR THE TURN AND BANK INDICATOR ADAPTED TO RED INSTRUMENT LIGHTING SHIELDS. Rep. TED NAM EL 618, Top. Rep. XG T 145, Oct. 1950, 5pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

A modification of the standard aircraft turn and bank indicator dial face for use with indirect red lighting is the subject of this report. The lighting system was designed for individual illumination of the aircraft instruments to be accomplished by shields placed on the front of the instrument and containing lamps in red plastic housings which are located to top left and top right. This lighting method proved to be inadequate for the directional balance indications in the turn and bank indicator. The modifications to the dial face were a) reversal of brightness relationships of directional balance indicator elements; and b) forward inclination of dial face portion above the inclinometer to allow light to fall over the inclinometer ball. (HEIAS)

6182

Lazo, J. THE DEVELOPMENT OF INSPECTION METHODS AND CRITERIA FOR OPTICAL DISTORTION IN COCKPIT ENCLOSURES. PART III. DETAILS OF A PROPOSED METHOD FOR INSPECTING AIRCRAFT TRANSPARENCIES FOR VISUALLY OBJECTIONABLE DISTORTION. Rep. TED NAM AE 4405, Top. Rep. XG T 225, Sept. 1954, 7pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

A study was made of methods for the inspection of aircraft transparencies for visually objectionable distortion. The details of such an inspection method are presented in this report. Laboratory and analytical studies, with their results and conclusions, form the basis for the method; however, since previous reports have been published on these studies no data are given here. The inspection method includes criteria related to the severity of localized distortion as well as the extent of the area over which distortion is exhibited. A listing is made of considerations which should be included in individual determinations of acceptability standards. (HEIAS)

Lazo, J. HUMAN ENGINEERING INVESTIGATIONS OF THE INTERIOR LIGHTING OF NAVAL AIRCRAFT. PART III. RECOMMENDATIONS FOR STANDARD ELECTRICAL AND ELECTRONIC CONTROL KNOB FOR AIRCRAFT. Rep. TED NAM EL 52004, Rep. XG T 258, July 1955, 5pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

This report discusses and recommends a series of knobs for adoption as standard electrical and electronic control knobs in aircraft cockpits. Previous reports had designated 3 classes of control knob shapes relating to control function on the basis of their manipulative and position-monitoring characteristics: a) round for spinning or twirling where orientation is not major source of information; b) bar for both spinning and twirling and step-function controls for which tactual and visual monitoring is desired; and c) pointer for those step function controls requiring considerable force for manipulation and where tactual monitoring is major source of information. 2 sizes of knob series (3 large and 3 small) incorporating features found desirable in previous study are proposed herein with detailed drawings presented in appendix. (HEIAS)

Lazo, J. HUMAN ENGINEERING INVESTIGATION OF INTERIOR LIGHTING OF NAVAL AIRCRAFT. PART II. LIGHT-CONDUCTED HANDLES FOR TOGGLE SWITCHES. Rep. TED NAM EL 52004, Top. Rep. XG T 219, May, 1954, 3pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

An investigation was conducted of the possible utility of light-conducting toggle switch handles to be used in conjunction with aircraft control panel plastic lighting plates. An installation of 3 toggle switches: (a) standard, with metal, non-light-conducting handle; b) plastic encased handle presenting 4 bright circular lines around switch handle with another at top; and c) same plastic encasement sanded to provide a "glowing" effect) was observed under both day and night illumination. The frosted-finish plastic encased switch handle was most visible under both illumination conditions. (HEIAS)

Lazo, J. LIGHTING REQUIREMENTS FOR COCKPITS AND COMPARTMENTS OF NAVAL AIRCRAFT. PART II. INVESTIGATION OF SUPPLEMENTARY FLOODLIGHTING FOR PANELS EMPLOYING INDIVIDUAL INSTRUMENT LIGHTING FIXTURES. Rep. TED NAM EL 619, Rep. XG T 178, June 1952, 5pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

2 alternative systems for aircraft instrument panel lighting were investigated by means of laboratory tests and pilot preference study. The 2 systems were red individual instrument fixture lighting only and red floodlighting in combination with the individual lighting. 7 Ss made comparative observations following 15 min. dark adaptation as illumination from individual lighting fixtures varied from .02 ft-L to 1.15 ft-L. At each setting various intensities of red floodlighting were added for additional observations (range upward from .020 ft-c). The addition of red floodlighting did not appear to improve the lighting display. In order to affect noticeably the brightness contrast between instrument dial faces and panel areas, rather high intensities of floodlighting (0.10 ft-c) had to be used; this was found to be deleterious to dark adaptation. It was the unanimous opinion of the pilots that the individual instrument fixture lighting method was excellent; there was no desire expressed for additional lighting. (HEIAS)

6185

Lewis, J. EXTERIOR COLOR SCHEMES FOR AIRCRAFT TO PROVIDE MAXIMUM VISIBILITY. INVESTIGATION OF COLOR SCHEMES TO IMPROVE PROPELLER NOTICEABILITY. Rep. TED NAM 42-296, Rep. NO T-213, May 1954, 4pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

Studies were conducted of propeller warning schemes incorporating contrasting colors. The conclusions and recommendations are as follows: a) Propeller noticeability can be significantly improved by properly selected paint schemes. b) The color scheme offering the best possible noticeability improvement is one in which maximum brightness and color contrast with the background are separately provided by 2 colors, one providing the brightness contrast with the background and the other providing color contrast with the background. c) Brightness contrast is of greater significance in propeller noticeability than color contrast. d) The employment of high brightness color bands on the rear surface of propellers is undesirable. However, on such surfaces the use of low brightness, high chroma color bands such as bright red, AN color 319, will afford noticeability qualities without producing objectionable glare to the pilot in flight. e) The color scheme for the front surface of the propeller found to be most effective in this study and recommended for naval aircraft application is one employing a 6" band of specular white paint, AN 511, at the propeller tip followed by a 6" band of bright red, AN 319, then another 6" band of specular white, followed by a band of black paint, AN 534, to within 6" of the propeller hub and the remaining 6" bright red.

Crumley, L.W. A STUDY OF THE REQUIREMENTS FOR LETTERS, SYMBOLS, AND MARKINGS TO BE USED ON TRANSLUMINATED AIRCRAFT CONTROL PANELS. PART VI. A SURVEY OF PILOT PREFERENCES FOR SPECIAL ATTENTION PLATE MARKINGS. Rep. TED NAM 41 602, Part 6, Sept. 1951, 15pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

An opinion survey has been conducted among a group of naval pilots and other flying personnel familiar with flight problems to determine their preference among 12 alternative designs for surrounds suitable for use with transluminated special attention plates in aircraft cockpits. The results of the survey indicate that a satisfactory special attention plate design employs a minimal light flux and configuration of lines in such a manner that the area surrounding the panel attracts the pilot's attention when it falls in his field of vision, isolates the legend from the immediate surround and from the balance of the control panel, and directs the pilot's attention from the attracting surround to the legend. It was indicated that the elements of an unsatisfactory panel were mainly excessive light flux, configurations, and devices that tend to direct the pilot's attention away from the legend, and surrounding material that encroaches on and renders the legend less legible. Since no satisfactory simple method of surround markings was found suitable for both day floodlighting and night translumination use, a panel design is recommended which gives a somewhat different appearance by day than by night.

Deese, J. THE ABILITY OF UNTRAINED OBSERVERS TO MATCH VISUAL FORMS THAT ARE SLIGHTLY DISPARATE IN CONTOUR. Contract AP 33(Q38)-22642, WADC Tech. Rep. 56-570, Oct. 1956, 13pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio. (The Johns Hopkins University).

6189

This is a study of the ability of observers to match slightly disparate imaginary contours defined by three points each. Utilizing a method of overlay, 22 subjects were required to match 100 pairs of contours. The discrepancy of location of the centers of mass was determined for each subject on each trial. The results are presented and discussed in terms of the mean error (i.e., discrepancy) for all subjects and the degree of individual differences. An examination of forms conducive to high circular error suggests an hypothesis concerning the relation between shape discrepancy and magnitude of circular error.

6190 Smith, O.W., & Sherlock, Louise I. MEMORY FOR TRANSLATORY MOTION. II. A NEW EXPLANATION OF THE VELOCITY TRANSDUCTION PHENOMENON. Contract NMR 401(14), Sept. 1956, 12pp. DHB, Cornell University.

To study various aspects of transitory motion (perceived velocity), a series of investigations were conducted. The aspect of memory for transitory motion is studied by comparing the matches made by Ss (20) when viewing successively standard and variable motion fields (Halpern pattern of one centimeter squares) with matches made to the immediate memory of the constant velocity of the standard. Tests of the differences between means and variances of the two conditions were made. The velocity transduction phenomenon (that enlargement of the moving field must be accompanied by proportional increase in stimulus velocity for phenomenal velocity to be judged identical) is investigated in relation to the frequency at which moving objects leave the field by comparing judgments of apparent velocity with judgments of frequency.

Brown, F.R. & Lowery, E.A. A STUDY OF THE REQUIREMENTS FOR LETTERS, NUMBERS AND MARKINGS TO BE USED ON TRANS-ILLUMINATED AIRCRAFT CONTROL PANELS. PART II. A SURVEY OF PILOT PREFERENCES FOR MARKINGS FOR RHEOSTAT CONTROLS. Rep. TED NAM EL 609, Part 2, Feb. 1950, 13pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

An opinion survey has been conducted among a group of experienced Naval pilots to determine their preference among 12 alternative methods of marking the rheostat intensity controls found on transilluminated control panels in aircraft cockpits. The results of the survey indicate a strong preference for a marking of simple design utilizing lines of uniform stroke width. The other elements of a satisfactory marking are: verbal references to function and limits; conformity with standard directions, i.e., clockwise movement to increase intensity; interpretability of marking from any viewing angle or partial view; and combination of direction indicator with purpose designation, i.e., "Brighter" instead of "high." An unsatisfactory marking would have elements with these features: wide or non-uniform stroke widths; complex or subtle designations; too great dependence on non-verbal references; non-standard direction of rotation; and poor interpretability from a partial view.

Brown, F.R., Grumley, L.H. & Aisher, D. THE DEVELOPMENT OF INSPECTION METHODS AND CRITERIA FOR OPTICAL DISTORTION IN COCKPIT ENCLOSURES. PART I. A STUDY OF INSPECTION METHODS FOR OPTICAL DISTORTION IN AIRCRAFT TRANSPARENCIES. Rep. TED NAM AE 4405, Part 1, May 1954, 18pp. USN Air Material Center, Philadelphia, Penn.

A study has been made to determine the most practicable method which will reliably reveal the visually significant variations in optical distortion in aircraft transparencies. The study has included a determination of the characteristics of the variations of deviation in transparencies which are most influential in rendering the transparencies objectionable to pilots. Double aperture photography of a grid screen (11 x 11 squares) is proposed as the simplest and most reliable test to detect such variations of deviation. The proposed method requires that the picture be taken from a position closely approximating the position of the pilot's eyes in the cockpit in order to maintain geometric equivalence of the optical factors. A tentative specification for the method of evaluating the photographs is proposed for validation of the basic technique. The method, the results of which correlate highly with pilot preference of tested windshields, considers as most significant the area of extent of distortion. It is recommended that the proposed method be validated and evaluated in a production situation.

Brown, F.R. A STUDY OF THE LEGIBILITY OF TRANS-ILLUMINATED MARKINGS IN AIRCRAFT COCKPITS. Rep. TED NAM EL 600, Part 2, Feb. 1949, 33pp. USN Air Material Center, Philadelphia, Penn.

6195

To determine principles governing legibility of red trans-illuminated Grow Chart letters (block-type capitals) under conditions simulating those encountered in reading such markings on cockpit consoles, 75-Ss performed an oral reading task in the dark at a distance of 28 inches. The variables were: 1) letter size (5 to 15 min. of visual angle), brightness of trans-illumination (24 to 80 microlamberts), and level of background floodlighting (11 by 10⁻² to 110 by 10⁻² ft.-c). Differences in error scores for conditions varied are analyzed for their significance in aircraft console lighting.

Brower, J.A. & Orlansky, J. PRELIMINARY REPORT ON INVESTIGATION OF EXTERIOR LIGHTING EQUIPMENT. PART I. Rep. TED NAM 31333, Aug. 1945, 5pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

Recommendations for what is considered to be the most effective system of aircraft lighting for night rendezvous and join-up, which can be effected with slight modifications of conventional exterior lights are presented. 5 lights are required: a) 2 running lights on the wing tips (port wing red, starboard green); b) one white tail light; c) 2 section lights (top light a frosted white, bottom one a red, green, amber, blue, or white according to task force). Both steady and flashing lights are to be used at 3 brightness settings. Directions for rendezvous and formation flight are given. This represents a preliminary report. (MEIAS)

6197

Blasdel, Irene C. & Lazo, J. STUDY OF EXTERIOR LIGHTING FOR NAVY AIRPLANES. REPORT VI. NIGHT FLIGHT TESTS OF EXPERIMENTAL EXTERIOR LIGHTING SYSTEMS ON MILITARY AIRCRAFT. Rep. TED NAM 31333, Rep. 6, June 1949, 39pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

Extensive flight tests have been conducted using experienced pilots observing SNJ aircraft equipped with standard and experimental methods of exterior lighting. The installations used on these aircraft and some of the flight tests have been previously reported, however this report summarizes all work accomplished to the present time. As a result of all considerations of the problems encountered in night flying, it is now possible to formulate some definite conclusions concerning illumination for night operation of aircraft. Inasmuch as flashing of lights eliminates most of the confusion of aircraft lights with stars and ground lights, this method is suitable for taxi and solo cross-country flying. When planes are in formation, however, flashing causes confusion and disorientation to pilots of the formation, so that dim steady lights are required. The formation is distinctive against backgrounds of stars and ground lights when viewed from other aircraft because of the quantity of lights apparent during approach. When section lights are coded for signalling purposes, it is essential that all other lights on the aircraft be steady so that no confusion arises in the code. Recommended patterns are included.

Blasdel, Irene C. & Lazo, J. STUDY OF EXTERIOR LIGHTING FOR NAVY AIRPLANES. REPORT V. THE INSTALLATION OF LIGHTS ON THE TRAILING EDGE OF WINGS FOR LOW LEVEL ILLUMINATION OF AIRCRAFT. Rep. TED NAM 31333 & Rep. 5, May 1949, 10pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

The report deals with the method in which 4 linear lights have been mounted on the trailing edges of the wings of an SNJ aircraft to produce low level illumination for night formation flying. This method of installation was effected by mounting fixture AN3091-3, within a surface covered by sanded acrylic plastic to produce linear illumination at the trailing edge wing tip and directly inboard from the wing tip on the fuselage. This type of installation interferes in no way with the flight characteristics of the SNJ aircraft used in this evaluation because it is integral with the contour of the aircraft. This is aerodynamically satisfactory for high speed aircraft and has the added distinct advantage of producing linear light rather than the illumination by point sources found in the present formation lights. Although the glowing lines of light produced are small in area, they furnish a comfortable visual reference and aid the pilot in maintaining position during night formation flying. The strip of light on the wing tip indicates any change in attitude of the wings, while the inboard strip, parallel to the line of normal flight of the aircraft, produces an immediate reference for climb and dive, and is useful for cross-under procedures. These linear formation lights are color coded to conform with international practice for navigation lights. The port wing strip is red, starboard wing green and both inboard lights are amber. All lights are equated in brightness and are operated at a sufficiently low level to be visible only within 700 feet. The results of night flight evaluations on SNJ aircraft equipped with these and other experimental methods of exterior lighting will be the subject of subsequent reports.

Blasdel, Irene C. STUDY OF EXTERIOR LIGHTING FOR NAVY AIRPLANES. PART VII. FIELD OBSERVATION BY COMPOSITE SQUADRON FOUR. Rep. TED NAM 31333, Rep. 7, Topical Rep. FG T 119, July 1949, 7pp. USN Air Material Center, Naval Air Experimental Station, Philadelphia, Penn.

35 pilots attached to Composite Squadron Four (VC-4), observed experimental lighting installations on the SNJ-6 aircraft. Opinions obtained by use of a rating-scale questionnaire showed that the pilots strongly favored the flashing system of lights recommended for solo cross country flights, but preferred the wing tip running lights to remain steady for taxi. The use of coded section lights for rendezvous and join-up was also endorsed with consideration on invited to the use of amber filters on these lights in place of the clear glass presently used. Primary attention of the observers was directed toward methods of lighting for formation flying and the pilots strongly favored linear wing trailing edge light to replace the present standard formation lights. In conjunction with these lights, the linear tail light was preferred by 28 of the pilots over the use of floodlights on the vertical tail surface preferred by the other 7.

Atisher, D., & Lazo, J. A STUDY OF THE REQUIREMENTS FOR BACKGROUND LIGHTING OF AIRCRAFT INSTRUMENTS AND LUCITE ILLUMINATED CONSOLES. PART III. INVESTIGATIONS IN THE FLOODLIGHTING OF TRANSLUMINATED COCKPIT DISPLAYS. Rep. TED-NAM EL-600, Part 3, Oct. 1951, 14pp. USN, Air Materiel Center, Naval Air Experimental Station, Philadelphia, Penn.

A study was made of the desirability of floodlighting in conjunction with translumination of cockpit-type dial instruments and of control panels. In one phase of the present study a series of tests was conducted utilizing a special dial reader. Error scores were obtained of 4 selected subjects reading red transluminated dial markings in a series of several brightnesses, with no floodlighting and with several levels of floodlighting. Opinions of subjects on the desirability of the various illuminating conditions were noted. Reading performance in these test situations did not improve significantly above 0.04 foot lamberts of translumination on the markings. The addition of floodlighting with translumination at this level resulted in a subjectively more comfortable reading situation even though errors in reading did not show significant differences. In a second phase of this study, 15 experienced pilots, while seated in a cockpit mock-up selected the combination of red translumination and red floodlighting which they would prefer for night flying. From the data obtained, it is concluded that a fixed level of supplementary floodlighting should be used with any selected level of indirect lighting in the cockpit lighting installation. This floodlighting level would serve to provide the pilot with better cockpit orientation and visual comfort. In addition, 2 other floodlighting levels are proposed to satisfy the pilot lighting needs when translumination has failed and when the pilot is not dark adapted. These 3 levels are recommended for the "dim," "medium," and "bright" positions of the 3-position selector switch.

Alkon, E.G. COMBINED-ENVIRONMENTAL STRESSES AND MANUAL DEXTERITY. Proj. 6 95 20 001, Rep. 225, March 1956, 18pp. AHRL, Research and Development Division, Fort Knox, Kentucky.

Much of the field maintenance work performed by Army personnel is done under conditions of environmental stress. The sources of these stresses are varied and the precise tasks numerous. The purpose of this research was to develop a task representative of the field maintenance problem and then investigate the effects of 3 stress sources on efficiency at this task. A test-retest reliability measure indicated that the task used was a highly reliable measure of mechanical dexterity. Technical dexterity was significantly depressed by stresses of low temperature, intense sound and low illumination. The effects of temperature and noise stresses on kinesthetic judgment (muscular control) were significant and appeared to be cumulative; while low illumination had no apparent influence on kinesthetic judgment and the detrimental effects remained constant. A reliable measure of motor skills can be obtained with a task which closely simulates line maintenance conditions. A number of representative environmental stresses act to decrease both speed and accuracy. Length of exposure, as well as intensity, is an important determinant of behavior changes under stress.

Adams, J.A. PSYCHOMOTOR PERFORMANCE AS A FUNCTION OF INTERTRIAL REST INTERVAL. Proj. 509 020 0009, AFPTC TR 54 60, Nov. 1954, 3pp. USAF Personnel & Training Research Center, Lackland AFB, Tex. (Reprinted from: J. exp. Psychol., Aug. 1954, 43(2), 131-133).

6201

To evaluate psychomotor performance as a function of intertrial rest interval, 446 basic airmen trainees were given 150 30-sec. trials on the Potary Pursuit Test. Divided into five groups, each group had one of the following intertrial intervals: 0, 3, 10, 20, or 30 sec. The results are discussed in terms of the relation between time on target and intertrial interval as reflected in performance curves for all groups, the rate of approach to asymptote, and the nature of the asymptote level.

Adams, J.A. THE EFFECT OF PACING ON THE LEARNING OF A PSYCHOMOTOR RESPONSE. Proj. 509 020 0009, AFPTC TR 54 32, Aug. 1954, 5pp. USAF Personnel & Training Research Center, Lackland AFB, Tex. (Reprinted from: J. exp. Psychol., Feb. 1954, 47(2), 101-105).

6202

To evaluate the effect of degrees of pacing on the learning of a motor response, 295 basic airmen trainees were presented with the four-unit Complex Coordination Test. While four groups of Ss practiced the tasks under different pacing intervals, one group was permitted to pace itself. The results are discussed in terms of differences among the groups in mean performance level and performance trends. The implications of pacing as a learning variable are evaluated.

Attneave, F. PERCEPTION OF PLACE IN A CIRCULAR FIELD. Amer. J. Psychol., March 1955, 68(1), 69-82. (Lackland AFB, Texas). (AFPTC TR 55 44).

64 Os (airman basic trainees) were required to reproduce, from immediate memory, the positions of single points presented on a homogeneous circular screen in the frontal plane. Half the Os were given points on the left side of the screen, the other half points on the right; all were presented with points on the vertical midline. A total of 9) different positions within the circle were thus explored. It is clear that 0 utilized center-in landmarks which were entirely subjective; namely, the vertical and horizontal diameters of the screen. This conclusion is based upon the fact that both VE and CF were related to distance from the implicit "cross-hairs" much as they were related to distance from the physically present border of the circle. The effects which both objective and subjective landmarks had on error were these: a) Variable errors (i.e., the interquartile range of responses), taken along an axis oriented toward a given landmark, tended to decrease in the vicinity of the landmark. This effect was to be expected on the basis of Weber's law. b) Constant errors were consistently directed away from nearby landmarks. Accordingly, points were displaced toward the middle of the quadrant within which they were presented. Possible generalizations of the results are suggested.

Bahrlick, H.P., Bennett, W.F., & Fitts, P.M. ACCURACY OF POSITIONING RESPONSES AS A FUNCTION OF SPRING LOADING IN A CONTROL. J. exp. Psychol., June 1955, 49(6), 437-444. (Ohio Wesleyan University, Delaware, Ohio). (AFTRC TR 55-317).

This study investigated accuracy of positioning a horizontal arm control as a function of changes in the torque-displacement relation of the control. It was found that positioning errors were smallest when the ratio of relative torque change to displacement is largest, particularly if the absolute change of torque with displacement is also large. It is concluded that control forces opposing a movement can provide useful cues in learning to execute different amplitudes of movement, and that their usefulness depends upon the relative and absolute torque change per unit of control motion.

Psychol., Aug. 1954, 48(2), 134-142).

6207
To evaluate the effect of task difficulty, amount of practice, and reversal of controls following errors on one control, 213 Ss were given four variations of a following pursuit task. Differences between the tasks depended upon changes in relations between control movements and movements of the object to be kept on target. Following varying amounts of practice on an initial task one of the variations was presented. Results are discussed in terms of the role of task difficulty in transfer of learning, the kind and amount of transfer obtained, the effect of shifting from one control to another, and the proactive effects of practice.

This is a report of the development and evaluation of an experimental measure of student motivation. With motivation defined as the intensity of the Air Force student's efforts to attain set goals in technical training, an observer check list of classroom behavior was developed on the basis of instructors' observations of students with high and low motivation. Correlation of the ultimate measure with grades and aptitude scores as well as suggestions for possible applications of this check list are discussed.

Clausen, J. VISUAL SENSATIONS (PHOSPHENES) PRODUCED BY AC-SINE WAVE STIMULATION. Elmsl. Munksgaard, Copenhagen, Denmark, 1955, 101pp. (New York State Psychiatric Institute, N.Y.).

This study reports a series of experiments bearing on the characteristics and determinants of AC sine wave electrically induced phosphenes, both as unique investigations and as they relate to previous findings of other investigators. A low frequency sine wave generator was used as the electrical source of stimulation throughout a frequency range of 5 to 70 cps. Electrodes were placed as near to the eye as possible, one on the skin of the forehead and the other on the skin of the lower right temple area of the S. The method of limits was used for determining thresholds in both peripheral and central visual fields. Under standard test conditions, the S looked at a white wall which reflected light of a surface luminance of 3.2 ml and a standard stimulus duration of 1 sec. 10 trained Ss were included in the series. Some of the findings from 14 main experiments are as follows: a) Thresholds for peripheral phosphenes were found to require a regular increase in intensity (measured in microamperes) as the frequency of alternation was increased between 20 and 70 cps. Only one break was found in this relationship around 35 cps; b) Central or foveal phosphene frequency-intensity relationship for colored test patches also gave straight functions without additional breaks; c) Qualitative differences between peripheral and central phosphenes were found and described. Other findings related to adaptation, difference limits for flicker rate, flicker fusion, and effects of hyperventilation are given.

Coleman, P.D., & Krauskopf, J. THE INFLUENCE OF HIGH INTENSITY NOISE ON VISUAL THRESHOLDS. Proj. 6 95 20 001, Rep. 222, Feb. 1956, 26pp. APRL, Research and Development Division, Fort Knox, Kentucky.

Using the psychophysical method of limits, thresholds for 3 visual stimuli were determined during noise and quiet conditions. Noise intensities were varied between 110 decibels (db) (re. .0002 dynes/cm²) and 140 db. The suggestions of other investigators that noise may affect visual function by "rattling" the eyeballs, causing nystagmic eye movements or "overflow" in the central nervous system, were investigated by choosing the visual stimuli to be such that if one of these mechanisms were operating noise might be expected to have a differential effect on the thresholds for the stimuli. It was found that noise had no general effect on visual thresholds at any of the intensities used in the present experiment. No differential effect of noise on the thresholds for the 3 visual stimuli used was demonstrated. There were consistent individual differences in visual threshold changes during noise. Absence of any demonstrable general effect of noise was due to cancellation of opposite effects in individuals. A possible factor contributing to these individual differences was investigated by showing the subjects spurious curves, purported to represent their performance during previous sessions. Subject's performance did seem to be influenced by the fake curves, although statistical significance was not demonstrated.

Fleishman, E.A. PERCEPTION OF BODY POSITION IN THE ABSENCE OF VISUAL CUES. J. exp. Psychol., 1953, 45(4), 261-270. (Human Resources Research Center, Lackland AFB, Texas).

2 experiments investigated the influence of certain factors on accuracy of adjustment to an upright position in the absence of a visual frame of reference. The Ss were subjected to displacement magnitudes of 15°, 20° and 25° in a lateral plane, and displacement speeds of 4°, 5° and 6° per second in a tilting-chair arrangement. Direction of tilt varied from trial to trial in a randomly determined sequence. In Exp. I S's head position was not held fixed, while in Exp. II S's head position was fixed so that its medial plane approximated the gravitational vertical. The results indicate: a) Greater precision of adjustment to the upright position results when the head position is fixed than when the head position is not fixed; b) Similarly, smaller constant error of adjustment results when the head position is held fixed, although constant error is in the direction of initial displacement under both conditions; c) When head position is fixed as well as when head position is not fixed, greater precision of adjustment results as speed of displacement increases, and as magnitude of displacement decreases; d) Under both conditions, greater precision of adjustment results when direction of displacement is to the left than when direction of displacement is to the right; e) Sequence of trials with respect to direction of initial displacement seems to be an important variable in over-all error; f) Magnitude and speed of displacement are important determiners of precision of adjustment at various stages of practice; g) Individual Ss show a high degree of consistency in precision of adjustment at various stages of practice. The findings are related to previous work and questions raised by the present study are discussed

Fleishman, E.A., & Hempel, W.E. A FACTOR ANALYSIS OF DEXTERITY TESTS. Personnel Psychol., 1954, 7(1), 15-32. (Human Resources Research Center, Lackland AFB, Texas).

This study represents an exploratory investigation into the nature of factors contributing to manipulative performance. A battery of 15 widely used printed and apparatus dexterity tests was administered and subjected to a factor analysis. The results present evidence against the concept of "manual dexterity" as a unitary ability. 5 factors were identified to account for performance in the range of tasks investigated. These were named Finger Dexterity, Manual Dexterity, Wrist-finger Speed, Aiming, and Positioning. The results are discussed with respect to the factor composition of the individual tests, the utility of certain printed tests in measuring the factors identified, and possible test improvements.

Hempel, Prof. 7703, Task 77084, Rep. AFPTRC TR 54 34, Aug. 1954, 15pp. USAF Personnel &

6219

This is a factorial study concerned with the organization of abilities in certain areas of motor skills. Primary attention was given to areas of gross muscular proficiency and fine manipulative performance. The analysis is based on the intercorrelations among 46 tests of 3 general types: a) manipulative apparatus tests, b) printed tests, and c) gross physical performance tests. 15 factors were identified to account for performance on the tests with the results indicating that abilities in the 2 areas are quite independent. General categories of abilities in gross motor performance were strength, flexibility, balance, gross body coordination, and energy mobilization; for manipulative abilities were found manual dexterity, finger dexterity, arm-hand steadiness, and aiming. In addition, an independent non-verbal reasoning factor was identified in the printed tests. (HEIAS)

6221

This study was designed to analyze compensatory tracking behavior in terms of lead-lag errors. Six Ss were required to perform a compensatory tracking task under six experimental conditions varying velocity and acceleration of course input and amount of practice. Performance by Ss was compared with that of a mechanism defined mathematically as the simplest mechanism that may be substituted for a human operator. The results are presented in terms of a comparison between operator and mechanism performance. The analogy between operator and mechanism is discussed in detail.

6231 Krauskopf, J. & Coleman, P.D. THE EFFECT OF NOISE ON EYE MOVEMENTS. Proj. 6 95 20 001, Rep. 218, Feb. 1956, 8pp. USA Medical Research Lab., Research and Development Div., Fort Knox, Ky.

Integrated records of horizontal eye movements indicated that there were larger eye movements when the S was stimulated bilaterally with 137 db (re. threshold) random noise than in the absence of noise. Monocular stimulation with noise of the same intensity failed to produce a significant change in the records. Analysis of recordings of horizontal eye movements failed to reveal an increase in either the low frequency movements or the slow drifts of fixation. It would seem that the increase in total movement in the binocular situation is due to an increase in the small amplitude high frequency movements. No direct check on these movements was made. This increase in movement probably was not visually effective. It was suggested that immersion of the S in a noise field or a more intense noise might produce an effective increase in eye movements.

6241 Scher, S.H. ESTIMATED DECELERATION OF AIRPLANE NOSE SECTION JETTISONED AT VARIOUS ALTITUDES AND AIRSPEEDS. Rep. RM 150K09, Jan. 1951, 39pp. National Advisory Committee for Aeronautics, Langley Aeronautical Lab., Langley AFB, Va.

Calculations have been made to determine the deceleration at any time after jettisoning of an airplane nose-section design typical of those which have been proposed as escape devices for high-speed airplanes. The decelerations were determined by two methods, one utilizing successive approximations requiring graphical integration and the other giving reasonable close approximations by direct computation. Decelerations were obtained for the nose section for Mach numbers ranging up to 3.0 and altitudes ranging up to 120,000 feet, and for assumed nose weights of 750 pounds, 1000 pounds, and 1500 pounds. Drag coefficients of the nose at both 0° angle of attack (with stabilizing fins) and 90° angle of attack (without fins) at the various Mach numbers were estimated with the aid of available experimental drag data for spheres and circular cylinders and for bodies of revolution generally similar in configuration to the nose section. For the 1000-pound nose, estimations based on comparison of the calculated deceleration with such data as are available concerning man's ability to withstand decelerations indicates that, when the nose is stabilized with fins, the deceleration to which a pilot would be subjected would be tolerable for practically all the conditions investigated. For the unstabilized nose, which turns to an angle of attack of approximately 90° when jettisoned, it is indicated that the pilot would be subjected to cumulative deceleration-time effects which the available data indicate may be intolerable after the nose is jettisoned at Mach numbers greater than 0.95 at 30,000 feet, 1.6 at 60,000 feet, or 3.0 at 85,000 feet.

6239 Reveson, S.L., & Schultz, F.W. MEASUREMENT OF TEMPERATURES IN VARIOUS ORDNANCE EQUIPMENT UNDER THE DESERT ENVIRONMENT. TR 1000 13, Tech. Memo 14, Feb. 1956, 24pp. Human Engineering Laboratory, Aberdeen Proving Ground, Md.

The data contained in this report were collected during summer desert tests at Yuma Test Station, Yuma, Arizona. They were collected to give some idea of the temperatures encountered by the operator of Ordnance equipment under desert conditions. It should be noted that the ambient temperatures encountered did not appear to be extreme. In most cases they ranged between 90°F. and 105°F. and only in 3 or 4 cases did the ambient exceed 105°F. These temperatures are considered low for desert testing. The general conclusions that can be drawn from these data, from the human engineering viewpoint, are: a) Critically high temperatures appear to be predominantly caused by solar radiation; b) The problem of high temperatures on Ordnance equipment under desert conditions appears to be quite crucial. With most equipment, operators are working in temperatures within the pain range for the bare skin; c) The addition of both engine and transmission heat to the solar radiation effects in vehicles produce high temperatures at the man-machine links; d) In the artillery and ammunition area, firing obviously produces high barrel temperatures. However, this was not the concern of this survey, since the barrels are not normally handled directly by the operators; e) Further study should be performed in order to determine the effect of these temperatures on the efficiency of the man-machine system. Attention should also be given to the problem from the design point of view.

6243 Sutter, E.L., Tomson, J.C. & Ornstein, G.N. THE LIGHT PLANE AS A PRE-PRIMARY SELECTION AND TRAINING DEVICE: II. ANALYSIS OF TRAINING DATA. Proj. 7710, Task 77170, AFPTC TR 54 35, Aug. 1954, 22pp. USAF Basic Pilot Research Lab., Goodfellow AFB, Tex.

6243 To evaluate the effectiveness of the light plane as a training device, a study was conducted in which a group of 120 students (pilot), matched with a control group on the basis of Stanine scores, received 25 hours of light plane training during six weeks of Pre-Flight training. Flight checks were administered to the two groups at five subsequent stages of training, and differences in performance were evaluated statistically. Outlines of the courses of instruction administered to the experimental group are presented.

Williams, J.A.C. HEAT STRESS REST ALLOWANCES IN TIME STUDY: FURTHER CONSIDERATIONS. Rep. CA/PE/5, ca. 1955, 6pp. College of Aeronautics, Cranfield, England.

This note compares 2 physiological indices of heat stress for use in allocating rest periods when men work in hot conditions: a) the predicted sweat flow (P4SR); and b) the Belding and Hatch Index (BHI), which is based on heat gained by the body from various sources and the evaporative cooling capacity of the body. Values of P4SR and BHI were calculated for various arbitrary working conditions on body data providing comparable Ss. Discrepancies occurring between the 2 indices did occur, however values of both for the various arbitrary conditions bear a very close correspondence. In all practical cases of hot working conditions, it is recommended that a first approach should be to reduce the stress-raising conditions and that the use of either index should be useful for this. The evidence suggests that values of BHI of 30-40 and P4SR of .7 be taken as the upper limit for young acclimatised men working continuously on tasks requiring vigilance; with older men these values might have to be reduced. With hot work not requiring vigilance these values could be raised. The values are relevant to continued immersion in a constant hot environment.

Otis, A.B. & McKerrow, C.B. THE OXYGEN COST OF HYPER-VENTILATION. Rep. 56 28, May 1956, 10pp. USAF School of Aviation Medicine, Randolph AFB, Tex.

6247

To measure the oxygen costs of breathing at ventilations ranging from the maximal possible down to 100 liters per minute, measurements were made on five normal male subjects and two patients with tuberculosis and obstructive emphysema. The method used is described and its validity and accuracy of measurement estimated. The obtained measurements are compared with predictions from theoretical considerations and previous more limited measurements. The construction of a low resistance valve for hyperventilation is described in the appendix.

Wolfe, F.J. PHASE V (ALL WEATHER) TESTING OF F-94B AIRCRAFT. Proj. S 207 16, Tech. Rep. 6556, Sept. 1951, 17pp. Flight Test Div., Wright-Patterson AFB, Ohio.

Flight tests were conducted on an F-94B aircraft at Wright-Patterson Air Force Base, to evaluate the aircraft for all-weather flying conditions. All flying was accomplished by personnel of the All-Weather section, Flight Test Division. Data were gathered on operation of the aircraft from take-off to landing, under simulated and actual weather conditions, to determine the feasibility of instrument flight and to recommend instrument flight techniques to be incorporated in the Handbook of Flight Operating Instructions. The aircraft was found to be satisfactory for all-weather operations with restrictions imposed by heavy precipitation or severe icing.

6249

Melton, A.W. APPARATUS TESTS. REPORT 4. (RESTRICTED SUPPLEMENT). ca. 1947, 44pp. USA Aviation Psychology Program, Fort Rucker, Ala. (Ohio State University, Columbus, Ohio).

A number of different tests involving the timing of hand and foot control movements in order to control the movements of a steel ball in one or two dimensions were developed and experimentally employed at Psychological Research Unit No. 2. For the most part these tests were employed in Experimental Psychomotor Batteries which were administered to preflight students, many of whom never reached pilot training. As a consequence, the data on a number of the tests are scanty. Furthermore, the low validity of the pilot standing among samples of those preflight students who were sent to pilot training suggests that the graduation-elimination criterion was not equivalent to that which had been employed earlier in the Aviation Psychology Program. Nevertheless, the available data may be taken to indicate that simple timing reaction tests which involve the control of the movement of a steel ball in only one dimension lack validity for the selection of successful pilot trainees, and that the complication of the task, in its motor aspect, does not lead to greater validity of the test unless additional tasks, involving division of attention, are incorporated. Thus the Complex Timing Reaction Test (CM508A) seems to have no greater validity than the Timing Reaction Test (CM504A2, B1, B2) and the Rudder Timing Reaction Test (CM504D); whereas, the Complex Timing Reaction Test With Throttle Control (CM509A) and the Complex Timing Reaction Test With Memory for Procedures (CM511A) appear to have sufficiently high validity in small samples to warrant further intensive investigation.

Guedry, F.E. AGE AS A VARIABLE IN POST ROTATIONAL PHENOMENA. Contract N7onr 434, Proj. NM 001 065.01.19, Joint Proj. Rep. 19, Nov. 1950, 4pp. USN School of Aviation Medicine, Pensacola Air Station, Fla.

The present experiment indicates that age may be a variable which should be controlled in experiments dealing with vestibular stimulation. The use of t tests to evaluate the data may be questionable on the basis of the large age-range of Group II. This large age range, however, would only increase variability and hence decrease the 'significance' of differences if age is a factor, or, on the other hand, if age is not a factor such a criticism would not be applicable. A more extensive investigation controlling age and other possible variables is contemplated.

Queddy, F.E., Ray, J.T. & Niven, J.I. THE INFLUENCE OF VISUAL ORIENTATION ON APPARENT BODILY ROTATION FOLLOWING ACTUAL ROTATION. Contract N70nr 434, Proj. NM 001 063.01.23, Joint Proj. R25. 23 Jan. 1952. 5pp. USN School of Aviation Medicine, Pensacola Air Station, Fla.

Feelings of apparent bodily rotation are very similar in their general characteristics to the ecological illusion. This "postural component" can be reported independently of the visual illusion. 3 experienced observers were required to report it under two conditions of rotary acceleration and deceleration, identical except that in one there was interpolated a 5 sec. period of general room illumination following deceleration. All observers reported the first effect and the beginning of the second effect in the totally dark condition, but feelings of apparent bodily rotation were inhibited by the visual orientation afforded during illumination of the room. Duration of the first effect was significantly reduced for all observers; time to the beginning of the second effect was reduced for two observers, while the second effect was completely abolished for the third.

Miller, J.G. INTEGRATION OF BIOLOGICAL AND SOCIAL DETERMINANTS OF STRESS REACTIONS. FINAL REPORT. Contract DA 49 007 MD 575, Aug. 1955. 4pp. University of Chicago, Chicago, Ill.

A theoretical formulation of various classes and categories of homeostatic behavior has previously been completed. Following this formulation, 6 classes of behavior were distinguished, and an experimental design developed to measure performance in each class. Work to date has consisted of the construction and standardization of the various items of apparatus, films, and paper and pencil tests necessary for this design to be carried out. The construction phase is essentially complete, with the exception of one piece of apparatus. Standardization is in progress. Results obtained with the one item on which sufficient work has been carried out are summarized, and are presented more fully in an attached paper. Further work will consist primarily of standardization prior to detailed study of performance in each of these 6 classes of behavior under both stress and non-stress conditions.

Gagge, A.P. MAN'S RESPONSE TO TEMPERATURE EXTREMES. AG 20/P10, June 1955, 82-91. Report from: "Proceedings of the Fifth Agard General Assembly. The Canadian Agard Conference 10-17 June 1955." Advisory Group for Aeronautical Research and Development, NATO, Paris, France (USAF Air Research & Development Command, Andrews AFB, Washington, D.C.).

Man maintains a constant internal temperature of 37°C (98.6°F) for comfort and health. Responses to hot and cold environments are discussed in terms of physical units: MET (heat production unit), CLO (unit of thermal insulation), EVAP (unit of cooling). Man's time tolerance to excessive heat is inversely proportional to the rate of rise of mean body temperature as measured by rectal temperature. An All Weather immersion waterproof flying suit with a thermal insulating value of about 3 CLO has been developed. By means of this suit cockpit tolerance time becomes greatly extended. The use of air ventilation on the flying suit insures the full cooling effectiveness of the sweating mechanism of the skin. (HEIAS)

6260 Cohen, J. EYE-DOMINANCE. *Amer. J. Psychol.*, Oct. 1952, 65(4), 634-636. (Antioch College, Yellow Springs, Ohio).

43 Ss with normal visual acuity were tested for eye-dominance by the method of retinal rivalry. The stimulus-materials were oblique lines of opposite slope and pairs of three and four letter words. With the oblique lines, 44% of the Ss showed 'no' dominance, 32% right eye dominant, and 24% left eye dominant. With the words, 26% showed 'no' dominance, 37% right eye dominant, and 37% left eye dominant. Sensory dominance varies with the stimulus-pattern. It is more pronounced for words than for lines, since there were more Ss in the 'no dominance' category for lines and the range of dominance was three times greater for words than for lines. The correlation between measures of dominance for the verbal materials and oblique lines ($r=0.47$) is not high but is significant at the 1-% level of confidence. It may be that the greater dominance for verbal materials is a result of reading practice. Eye-fixations during reading are so rapid and fleeting that both eyes may not always be able to fixate at the same place. The resultant double images may be resolved by characteristically relying on one eye for constant information while reading.

6261 Schipper, L.M., Versace, J., Kraft, C.L., & McGuire, J.C. HUMAN ENGINEERING ASPECTS OF RADAR AIR TRAFFIC CONTROL: IV. A COMPARISON OF SECTOR AND IN-LINE CONTROL PROCEDURES. Contract AF 33(616)-3612, Proj. 7192, Tech. Rep. 56-69, Sept. 1956, 27pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio. (Ohio State University).

6262 To investigate the relative efficiency of two types of two-man control procedures (In-Line and Sector Control), two novice controllers varied alternately with a highly-skilled controller under two conditions of heavy traffic flow (one aircraft per sixty or one per ninety seconds). A return-to-base mission of 25 jet aircraft of bomber and fighter types was simulated using the OBU Air Traffic Control Simulator. Efficiency measures (control time, delay building fuel consumption, deviation from runway extension at OCA gate) and safety measures (absence of conflicts between two aircraft) were analyzed for differences due to systems, Controllers, Rates of Entry and their interactions. Implications of the findings for aircraft control systems are discussed.

6268 Buskirk, E.R., Kreider, H., Brabbie, R., Morone, N., et al. CALORIC INTAKE AND ENERGY EXPENDITURE IN A SUB-ARCTIC ENVIRONMENT. Tech. Rep. EP 33, March 1956, 34pp. Environmental Protection Div., USA Quartermaster Research and Development Center, Mettich, Miss.

Caloric intake and caloric expenditure were studied in 8 men during 10 days of pre-bivouac, 12 days of bivouac, and 8 days of post-bivouac. Fort Churchill, Manitoba, Canada, was the test site. Mean ambient temperatures for the 3 periods were -25°C (-13°F), -31°C (-23°F), and -26°C (-15°F) respectively. Caloric intake averaged approximately 3600 Cal/man/day for the entire study. The men consumed 3,613, 3,644, and 3,472 Calories respectively during the pre-bivouac, bivouac and post-bivouac periods. Since a weight loss of 1.9 kg occurred during the bivouac period, an estimated correction of caloric requirement for this weight loss would increase it to 4,260 Cal/man/day. Dietary composition did not change during the 3 periods of the experiment. The percentage of the total energy of the average food consumed during all periods was 13.8% from protein, 38.5% from fat, and 47.7% from carbohydrate. Energy expended during outdoor activities involving progression across the snow cover at 2.27 mph was found to average approximately 7 Cal/min or 221 Cal/m/hr. Thus the men averaged 1,500 Cal/man/day for outdoor activity. Variations were noted in energy expenditure between skiing, snowshoeing and walking over the same snow cover. Snowshoeing was the most economical in this group of men. A comparison was made between studies of caloric intake in northern latitude areas. It appears that food consumption calculated by the inventory method, using standard food tables, has led to exceptionally high estimates of caloric consumption. Furthermore, it is impossible to interpret the findings of most previous studies because the daily activity level was never clearly established.

Smith, H.A. INTELLIGENCE AS A FACTOR IN THE LEARNING WHICH RESULTS FROM THE USE OF EDUCATIONAL SOUND MOTION PICTURES. *J. educ. Res.*, Dec. 1952, 45(5), 243-251. (University of Nebraska, Lincoln, Neb.).

To evaluate the role of individual intelligence in the learning which results from the use of such audio-visual aids as educational sound motion pictures, two types of achievement tests and an intelligence test administered to a large high school population (exposed to a program utilizing motion pictures) served as a basis for comparison between levels of intelligence and achievement. The results are discussed in terms of the correlation between gain in knowledge of a particular area and the level of intelligence of the student.

Smith, J.G. INFLUENCE OF FATHER, EXPRESSED HOSTILITY, AND STIMULUS CHARACTERISTICS ON VERBAL LEARNING AND RECOGNITION. *J. Educ. Res.*, June 1954, 47(4), 475-493. (State University of Iowa, Iowa City, Iowa).

6272

The influence of expressed hostility, experimentally induced failure, and certain characteristics of verbal stimuli on verbal learning and on visual recognition was assessed. The subjects, 112 students previously selected as hostile or non-hostile, were required to learn two lists of paired adjectives and to recognize 30 words presented tachistoscopically. The verbal stimuli had been judged to have neutral or hostile connotations. Half the subjects were given "failure" instructions designed to elicit hostility. The dependence of number of correct responses in the learning trials and of recognition times for "hostile" and "neutral" stimuli on the experimental variables is evaluated statistically.

6275 HENRY, F.M. INCREASE IN SPEED OF RESPONSE BY MOTIVATION AND BY TRANSFER OF MOTIVATED IMPROVEMENT. *Psych. Bull.*, 1951, 47(2), 219-228. (University of California, Berkeley, Calif.).

6275

An apparatus was designed for the purpose of measuring simple reaction time (finger press), speed of a coordinated movement (snatching a ball), and speed of a less complicated movement (treadle-press). An adjustable electronic delay circuit provided for administering a mild electric shock for slow responses. Visual stimuli were used. The simple reaction time of 10 Ss shocked in their slow responses improved 9.4%, while a control group of 10 remained constant. The treadle-press speed of 10 Ss improved 11.5% when motivated by shock, compared with no change in a control group. In the ball-snatch coordination, the speed of 5 Ss improved 17.1% when shocked, compared with a 3.1% improvement in the controls. In another series of experiments, a control group practiced a coordinated movement, shifted to practice with a simpler movement, and was then retested on the original coordination. A comparable experimental group did the same, except that electric shock was administered for slow responses during the practice on the simpler intermediate movement. This experimental design permitted the measurement of transfer effects. The first experiment of this series, using the ball-snatch for the coordinated movement and the finger press for the simple movement, showed a 6% gain due to transfer in the motivated group of 5 Ss compared with a 2% gain in the controls. Using the treadle-press as the simpler movement, the 10 Ss of a new motivated group exhibited a transfer effect of 12%, compared with no significant effect in the controls. In a similar experiment in which the intermediate treadle-press practice utilized an auditory stimulus, involving an interstimulus transfer of the motivated improvement, 10 Ss showed a transfer of 7.4% while the controls failed to exhibit any significant transfer.

Dornier, Dora E. & Soupe, J.L. PROFICIENCY OF Q-24 RADAR MECHANICS: IV. AN ANALYSIS OF CHECKING RESPONSES IN TROUBLE SHOOTING ON TAB TEST PROBLEMS. Contract AF 33(038) 13236, Proj. 7709, Task 77151, AFPC TR 34 53, Nov. 1954, 15pp. USAF Armament Systems Personnel Research Lab., Lowry AFB, Colo. (Educational Testing Service, Princeton, N.J. & University of Illinois, Urbana, Ill.).

6290
By using the Tab Test (a means of evaluating the proficiency of locating radar equipment malfunction) with 77 Q-24 radar mechanics of four known proficiency levels, an analysis is made of the number and kind of responses used by mechanics in trouble-shooting radar equipment. The results are discussed in terms of the manner in which more proficient trouble-shooters differ from less proficient trouble-shooters in their attempts to isolate malfunctions.

Ellis, D.S. & Lesiw, W. MEASUREMENT OF SKILLS ON THE TI-A TRAINER. Proj. 7708, Task 77142, ASPRL TM 55 10, March 1955, 9pp. USAF Armament Systems Personnel Research Lab., Lowry AFB, Colo.

6291
This article presents an analysis and evaluation of the skills involved in the TI-A trainer, an electronic device simulating the task of the A-5 fire control system operator (B-36 and B-47 tail defense). It is used both as a trainer and a performance measurement device. The primary tasks discussed are target selection, lock-on, and firing, with an analysis of the skills required by each task used to evaluate the trainer. In addition a comparison of the skills involved under training and performance evaluation conditions is presented with some comment on the generalizability of this article's analysis to other radar gunnery tasks.

Farber, I.E. & Spence, K.W. RELATION OF STIMULUS INTENSITY, PRACTICE, ANXIETY, AND SEX TO SIMPLE RT AND TEMPORAL GENERALIZATION. Contract N90NR 93802, Proj. NR 154 107, Tech. Rep. 4, June 1955, 42pp. State University of Iowa, Iowa City, Iowa.

6292
To investigate the effects of stimulus intensity, practice, sex, and manifest anxiety upon simple reaction time, 40 male and 40 female Ss representing five levels of anxiety (as defined by Taylor Anxiety Scale) were given a training series in which stimuli (electric shock and vibrating sponge) were presented at regular 12 sec. intervals. Following this they were given a temporal generalization series (irregular intervals varying between three and 24 sec.). The results are discussed in terms of the effect of stimulus intensity, practice, sex, and manifest anxiety upon reaction time in both the training and temporal generalization series.

Hahan, T. HUMAN JUDGMENT: CAN THE CLASSROOM IMPROVE IT? J. educ. Res., Nov. 1955, XLIX(3), 161-169.

This article presents a discussion of the literature and the author's philosophical and methodological conclusions concerning the problem of the permissive group classroom as a technique to help an individual group classroom as a technique to help an individual gain insight into a problem and into his attitude toward the problem and consequently share in a more objective solution to the problem. Suggestions are offered with regard to possible techniques to be utilized in the evaluation of the change in attitude towards self and others which is implied in this orientation toward the classroom learning situation.

Tinker, M.A. & Paterson, D.G. THE EFFECT OF TYPOGRAPHICAL VARIATIONS UPON EYE MOVEMENT IN READING. J. educ. Res., 1955, 49, 171-184. (University of Minnesota, Minneapolis, Minn.).

In a series of nine experiments designed to study the effect of typographical variations upon eye movements in reading, eye movements were photographed while reading under conditions of optimal and nonoptimal typographical arrangements. The variations investigated included such factors as line width, size of type, type faces, type form, white vs. black print, etc. The results are discussed in terms of the oculomotor patterns (as measured by fixation frequency, words per fixation, regression frequency, etc.) which occurred under the various conditions of typographical arrangement.

USA Southwestern Signal Corps Training Center. TRAINING EVALUATION AND RESEARCH PROGRAMS. PART IV. TRAINING RESEARCH PROGRAMS: INSTRUCTOR-STUDENT CONTACT IN TEACHING BY TELEVISION. July 1953, 12p. USA Southwestern Signal Corps Training Center, Camp San Luis Obispo, Calif.

6295
This study was concerned with student-instructor intercommunication during television lectures. Three experiments are described in which there was 1) no intercommunication between three classes and an instructor who lectured to a studio class; 2) intercommunication by means of ultra-short wave transmitters and receivers between instructor and outlying classes; and 3) same as (2), but with no studio class. Recommendations are made on the basis of scores obtained by outlying and studio classes on posttests and of comments by office observers and students.

George Washington University. TRAINING METHODS RESEARCH. ANNUAL PROGRESS REPORT. Contract DA 44 109 Q4 650, Proj. 095 30 000, Dec. 1954, 40pp. Human Resources Research Office, George Washington University, Washington, D.C.

6299:

This report summarizes various studies on methods of training. Among the studies on methods of training for individuals the following topics are treated: map reading, training in rifle firing by the "whole" method, the relation of manifest anxiety to rifle marksmanship, night firing, retention of skills. Among the studies on training for military groups, the following topics are treated: tactical training of rifle squads, reconnaissance patrol training (information reporting and land navigation), training in electronic and fire control maintenance, the effectiveness of television as a training medium.

Ritchie, M.L. & Muckler, F.A. RETROACTION AS A FUNCTION OF DISCRIMINATION AND MOTOR VARIABLES. Contract AF 33 (038) 23726, Proj. 7706, Task 77122, AFPMR TN 55 80, Dec. 1955, 7pp. *USAF Personnel Training & Research Center*, Lackland AFB, Tex. (University of Illinois, Urbana, Ill.). (Reprinted from: *J. exp. Psychol.*, Dec. 1954, 48(6), 409-415).

6301

Retraction effects in a psychomotor task are studied as a function of the nature of the interpolated task, amount of original learning, and amount of interpolated learning. A two-stage analysis in which psychomotor performance is analyzed into discrimination and motor stages is discussed and utilized in the interpretation of results. Apparatus was developed which allowed separate analysis of these stages. Results are presented in the form of statistical evaluation of error and time scores for discrimination and motor stages of the task for each experimental variable. The implications for retraction theory and verbal learning are considered.

Saupe, J.L. AN ANALYSIS OF TROUBLE-SHOOTING BEHAVIOR OF RADIO MECHANIC TRAINEES. Contract AF 33(038) 13236, Proj. 7709, Task 77151, AFPMR TN 55 47, Nov. 1955, 32pp. *USAF Armament Systems Personnel Research Lab.*, Lackland AFB, Tex. (University of Illinois, Urbana, Ill.).

6302

This investigation analyzes the nature and proficiency of trouble-shooting. A written test of basic electronic knowledge and a performance test consisting of determining the malfunction in a superheterodyne radio receiver were administered to forty radio mechanic trainees. Specified overt aspects of trouble-shooting behavior were scored on an observation record for each subject. Nine hypotheses concerning successful trouble-shooting behavior were statistically evaluated; such as: relationship between knowledge and performance, errors in equipment use and general checks, etc. Implications for maintenance training programs are given.

Eppler, R.G.E. THE HUMAN PILOT: FUNDAMENTALS OF DESIGN OF PILOTED AIRCRAFT FLIGHT CONTROL SYSTEMS. VOL. III. Contract No. 51 514(c), BuAer Rep. AE 61 4, Aug. 1954, 200pp. (approx.) US Bureau of Aeronautics, Washington, D.C.

This volume is intended to serve two purposes. The first of these is to provide engineers who are responsible for the synthesis of flight control systems for piloted aircraft with a quantitative description of the characteristics of a human pilot viewed as a sensor and as an actuator. Chapter II contains experimental data concerning (1) the accuracy of the pilot's senses, (2) the maximum forces which a pilot can exert as well as the accuracy with which he can exert these forces, and (3) the pilot's reaction-time delays between stimulus and response. The second aim is twofold: (1) to present the approximate transfer functions which have been recently developed to describe human pilots engaged in simple tasks, and (2) to present the methods for simulating on an analog computer a pilot in a routine flying situation. This material is contained in Chapter III.

Groth, Hilde & Lyman, J. RATIONALE FOR THE EVALUATION OF FUNCTIONAL REGAIN IN PROSTHETIC SYSTEMS. Memo. Rep. 30, March 1956, 8pp. *Engineering Dept.*, University of California, Los Angeles, Calif.

In the engineering of prosthetic devices, additional criteria of user performance must be added to the usual specifications made in terms of structural and functional criteria such as strength of materials and dynamic characteristics. This report sets up the requirements for making such specifications. 2 general levels of user performance must be included: a) speeds and ranges of motion and force, and b) factors contributing to coordination, skill, motion control, and naturalness of motion. Measurements in the first category can be accomplished by the methods of physical anthropology and motion and time engineering using population data for normal individuals currently available. For the second category there is no systematic population data available in the upper extremity field for comparison of performance with different types of terminal devices to normal performance. An approach is suggested through which a group of everyday living activities are standardized as a battery of tests and would yield an index of amputee proficiency. The steps and procedures for obtaining a concise quantitative expression for the relationship between an individual amputee's performance and that of the normal population are considered. With such specific information the control problems most in need of design consideration can be located. (HEIAS)

Gaito, J. ELAPSED TIME CLOCKS, OPTIMUM PRESENTATION FOR: THE EFFECTS OF DIFFERENT METHODS OF PRESENTATION OF TIME INFORMATION ON LEGIBILITY. TED MAN AE 7047.6, Rep. NANC ACCL 271, May 1956, 32pp. Naval Air Experimental Station, USM Air Material Center, Philadelphia, Penn.

The present experiment is concerned with the effects on legibility of 8 types of aircraft clock designs presenting both time of day and elapsed time by means of direct reading counters and/or pointers on one or 2 instruments. Using average number of errors, variability of errors, average time to read, and variability in time to read as the major criteria of legibility, a paper and pencil test administered to experienced pilots revealed that the types presenting both kinds of time information by means of counters on one instrument were superior to the others for quantitative readings. A questionnaire and group interview indicated that the main uses of both time of day and elapsed time information were quantitative and that the pilots preferred the types that had been shown to be superior in the test.

Defence Research Board. SELECTION AND TRAINING OF OPERATORS, FIXED WIRELESS STATION. OR Rep. 4, June 1952, 22pp. Defence Research Board, Department of National Defence, Canada.

6314

The first part of this investigation concerns the selection process of fixed wireless station operators. Correlations were determined among a general aptitude test and the test battery used in selecting wireless operators. Also, the effects of previous experience in touch-typing, code typing, and code training on passing the course were determined. The second part studies the stage of training at which code typing should be introduced to obtain optimal learning speed. Stage of training was defined by rate of code reception achieved. The results compare the effectiveness of the different starting times in terms of speed and accuracy. Recommendations for selection criteria and training procedures are given.

Allport, F.H., Reimer, E.W. & Valentine, J.A. THE STRUCTURAL ENERGICS OF LEARNING: A STUDY OF THE EFFECT OF PERSONALITY-TREND AND COLLECTIVE STRUCTURES ON READING RATE IMPROVEMENT. Contract N6 onr 248 C7, July 1954, 69pp. Office of Naval Research, Washington Research Office, Washington, D.C. (Maxwell School of Syracuse University, Syracuse, N.Y.).

6315

This study tests several hypotheses, each with reading rate as the dependent variable, with respect to learning, based on F.H. Allport's Structural Energies Formula. The procedure involved selection of 47 subjects enrolled in a reading improvement course, securing measures necessary for the correlation techniques, and computation of the rank-difference and product-moment correlation coefficients. All hypotheses were tested by determination of correlations between reading rate improvement and the independent variables consisting of aspects of personality trend and collective structures as defined in Event-Structure Theory. This theory is described and its application in further research discussed.

Goldman, M., Horwitz, M., & Lee, P.J. ALTERNATIVE CLASSROOM STANDARDS CONCERNING MANAGEMENT OF HOSTILITY AND EFFECTS ON STUDENT LEARNING. Contract N6 ori-07144, 1955, 23pp. ONR, Group Psychology Branch, (University of Illinois, College of Education, Bureau of Educational Research).

6316

Student hostility toward the teacher as a function of the social environment of the classroom was studied in terms of tension systems. Freshman ROTC students were organized into classroom groups. The procedure consisted of inducing hostility toward the teacher; then varying forces opposing hostile action, communication, and thinking. Assuming that performance regresses with the number of hostile behaviours blocked, measures were taken of attention span, retention of learned material, and overcoming an inefficient set in problem solving. The data was statistically analyzed and interpreted in relation to the theoretical framework. The implications for the practice of teaching are discussed.

Cook, T.W. SIMILARITY AND TRANSFER. May 1954, 61pp. Defence Research Board, Department of National Defence, Canada.

6317

This paper presents and analyzes principles of similarity and transfer in relation to military training problems. The discussion is organized around the work of Osgood, Gagne, and Bartlett. The first section is an estimate of their theoretical views. Points of agreement and disagreement are presented in the second section. The topic of motor transfer and interference is considered in section three. The last two sections cover implications and suggestions for further research. T, R 53

6318
Rosenberg, N. & Nelson, W.H. TIME TO COMPLETE NAVAL AIR TRAINING: IMPLICATIONS FOR TRAINING. Contract NR 154 098 Spec. Rep. 54 14, June 1954, 15pp. Office of Naval Research, Tulane University & USN School of Aviation Medicine, Pensacola, Fla.

6318
The relationship between time-to-complete Naval Air Training and cadet success in the training program was studied. Records were selected for 47 fast, 50 slow, and 100 average cadets in terms of time-to-complete training. Data was classified into flight performance, ground performance, and leadership potentiality. The groups were compared statistically on the following: frequency and severity of accidents, frequency of board actions, unsatisfactory flight ratings during training, number of flights to complete training, flight performance ratings, and overall training score. Training cost estimates of each group were determined. Implications for flight training are considered.

6319
Poe, A.C., Maag, C.H. & Johnson, W. A STUDY OF THE EFFECT OF OMISSION OF RADIO FLIGHT TRAINING DURING STAGE D UPON LATER BASIC INSTRUMENT FLIGHT PROFICIENCY. Proj. NM 001 056.23.01, Oct. 1952, 12pp. USN School of Aviation Medicine, Pensacola Air Station, Fla.

6319
This study determined the effect of omission of radio range flights during basic instrument flight training upon later basic instrument flight proficiency. The matched group technique was used, the only training difference being omission of five radio range flights. Both groups were sub-classified for instrument proficiency. Student performance was objectively scored on a repeat basic instrument flight check, and the groups compared on the following: difference in basic instrument flight proficiency, differential effect on students of high, middle, and low proficiency, duration of differences, and effect on progress in advanced radio range instruction.

Shaycroft, Marion E. & Altman, J.W. PROCEDURES FOR EVALUATION OF JOB PERFORMANCE IN SCIENTIFIC RESEARCH, SIXTH IN A SERIES OF REPORTS DEALING WITH THE EVALUATION AND MEASUREMENT OF RESEARCH PERFORMANCE. Proj. NR 153 146, Oct. 1955, 66pp. American Institute for Research, Pittsburgh, Penn.

This report deals with the following performance evaluating procedures: a) critical incident report form, b) performance evaluation by ratings, and c) performance samples. The first 2 procedures were tried out on a large group of junior research personnel. The performance sample procedure was given a small-scale tryout. Findings were: a) the critical incident report form seems the most promising method; b) objective scores based on number of incidents reported do not seem very useful; c) in the tryout (15 cases only) the performance sample procedure did not seem to provide useful criterion measures; d) major difficulties in accurate evaluation are the variations among supervisors and among jobs, and the lack of interest on the part of the supervisors. Peters, R.W. THE EFFECT OF ACOUSTIC ENVIRONMENT UPON SPEAKER INTELLIGIBILITY. Prepared under Contract N6onr-22525, Proj. NM 001 064. 01.26, Joint Proj. Rep. 26, Aug. 1954, 7pp. Ohio State University and USN School of Aviation Medicine, Pensacola, Fla.

6322
This study was designed to evaluate the effect of acoustic environment upon speaker intelligibility. Thirty-six speakers read 12 lists from multiple-choice intelligibility tests while simultaneously hearing one of six types of acoustic signals (nonsense syllables, similar words, etc). 481 listeners in 36 panels were utilized to assess intelligibility. Double-clerification analysis of variance of the mean intelligibility value for each speaker was employed to determine the relative effects of signal conditions and speakers. The results are discussed in terms of the amount of distraction which each of the various types of acoustic environment contributes to the speaker's performance.

Carterette, E.C. PERSTIMULATORY AUDITORY FATIGUE FOR CONTINUOUS AND INTERRUPTED NOISE. *J. acoust. Soc. Amer.*, Jan. 1955, 27(1), 103-111. (Hearing & Communication Lab., Psychology Dept., Indiana University, Bloomington, Ind.).

Perstimulatory fatigue, or adaptation, is measured by a simultaneous loudness balance or median plane localization of a dichotically presented acoustic stimulus. After one ear has been stimulated for a period of time, it is usually found that the variable or comparison stimulus must be reduced below the prefatiguing intensity in order to maintain the loudness match or localization balance. 5 Gs. made median plane localizations of a continuous 100-5000 cps band-pass noise before, during and after a 7 min. fatiguing period. The fatiguing stimuli were continuous noises at 30, 60, 87, and 100 db SPL, and noises interrupted at 1, 2, 5, 9, and 12.5 ips with both burst level and noise-time fractions held constant at 90 db SPL and 0.5, respectively. It was found that: a) the time required for fatigue to reach an apparent asymptote is at least 7 mins., about twice that required for pure tones; b) the maximum fatigue increases with the intensity of the fatiguing stimulus and the function is positively accelerated; c) for a fixed intensity of fatiguing noise, the maximum fatigue for the highest rate of interruption used (12.5 ips) is less than that obtained with a continuous noise having the same over-all level (87 db).

Egan, J.P. & Thwing, E.J. FURTHER STUDIES ON PERSTIMULATORY FATIGUE. *J. acoust. Soc. Amer.*, Nov. 1955, 27(6), 1225-1226. (Hearing & Communication Lab., Psychology Dept., Indiana University, Bloomington, Ind.).

One of the puzzling characteristics of auditory adaptation is its small magnitude when measured by the alternate binaural loudness balance. The magnitude of adaptation was compared under 3 conditions of measurement using 12 Ss. The presentation of the tone, first to one ear and then the other, in repeated alternation, resulted in little measured adaptation. In a second experiment, the degree of adaptation to white noise was measured by simultaneous dichotic loudness balance using 3 conditions of phase relationships. Adaptation occurred in all 3 conditions (17 Ss). In a third experiment, 3 methods of measuring adaptation were compared using 1 experienced S. The simultaneous dichotic loudness balance, which involves judgment of both loudness and localization factors, resulted in the greatest amount of adaptation. (HEIAS)

Price, H.E. & Older, H.J. AUDITORY SIGNALS IN AIR FORCE WEAPONS SYSTEMS AND EQUIPMENT. FINAL REPORT. Contract AF 19(604) 1576, FRA Rep. 55 11, June 1956, 154pp. *Psychological Research Associates*, Washington, D.C.

This report contains the results of a survey conducted to determine: a) the present status of the use of auditory signals in Air Force weapons systems and equipment; b) the contemplated use of auditory signals in Air Force weapons systems and equipment; c) operational opinions of present and proposed auditory displays in Air Force weapons systems and equipment; d) recommendations for immediate application to auditory systems and recommendations for further research in the field of auditory displays. Information was collected using questionnaire techniques, interviews, examination of literature, and conferences. The information has been presented in such a manner that cross referencing may be done between types of auditory signals, purposes for which they are used, and weapons systems or equipment in which they are contained. Operational considerations relating to auditory signals are synthesized in a separate chapter. The final chapter contains recommendations suitable for immediate application and recommendations for further research.

Scott, D.N., Machen, G.S. & Baker, C.H. PERCEPTUAL PROBLEMS IN ESTIMATING RANGE AND BEARING FROM PPI OVERLAYS. DRML Proj. 163 134 55, DRML Rep. 163 1, Jan. 1955, 23pp. *Defense Research Medical Laboratories*, Defense Research Board, Toronto, Canada.

6328

To determine in what ways errors in telling from PPI (plan position indicator) overlays are affected by the pattern of range rings and bearing lines, a series of experiments was performed. Subjects (52) estimated the ranges of the target (pip) under conditions of: 1) varying numbers of range rings (one to 16); 2) varying degrees of visual angle subtended by whole display (from approximately five to 139 degrees); and 3) target bearing (zero to 270 degrees). Error scores were analyzed with respect to the variables used. The nature of errors in bearing estimations was explored in a final experiment.

Schaefer, K.E. & Carey, C.R. INFLUENCE OF EXPOSURE TO VARIOUS CARBON DIOXIDE CONCENTRATIONS ON FLICKER FUSION FREQUENCY AND ALPHA BLOCKING. Proj. NM 002 015.11.04, Rep. 251, Aug. 1954, 12pp. *USN Medical Research Lab.*, New London, Conn.

24 subjects were exposed to 1.5 per cent, 3.3 per cent, 5.4 per cent and 7.5 per cent CO₂ in air over periods of 15 minutes, with pre- and post-exposure periods on air of equal length. Flicker fusion frequency was measured with a Krasno-Ivy flicker photometer between the 10th and 15th minutes of the experimental periods (CO₂ and air). It was found that the flicker fusion frequency decreased with increasing CO₂ concentrations above 3.3 per cent, and the alpha blocking time increased correspondingly. Control experiments, in which the ventilation was increased to the level usually measured during inhalation of 5 per cent CO₂, while the alveolar CO₂ level was kept constant by adding small CO₂ concentrations to the inspired CO₂, showed no change in alpha blocking time. This indicates that the increase in CO₂ tension, rather than the ventilation increase, is the decisive factor in producing observed changes.

Gelinas, R.W. & Genoud, R.H. A BROAD LOOK AT THE PERFORMANCE OF INFRARED DETECTORS. P 1697, May 1959, 41pp. The Rand Corporation, Santa Monica, Calif. (The Rand Corporation, Santa Monica, Calif. & Hughes Aircraft Company, Culver City, Calif.).

The capabilities of present day infrared detectors are discussed from the viewpoint of radiant power and time. The performance limits for ideal detectors are derived, establishing a basis of comparison for real detectors. It includes the limits set by background fluctuations and by signal fluctuations. The fundamental fact is stressed that the minimum detectable power is directly related to the time taken for the detection process. The 2 methods of rating detectors, and their limitations, are discussed. The background fluctuation limits are extended through the long wave infrared region of the spectrum to the microwave region. The material presented makes it possible to arrive at a performance rating for any infrared detector, regardless of the principle of operation. (HEIAS)

Small, A.M., Jr. & Gross, N.B. INTEGRATED MUSCLE ACTION POTENTIALS IN A WEIGHT-LIFTING TASK AS A FUNCTION OF WEIGHT AND RATE OF LIFTING. J. comp. physiol. Psychol., April 1958, 51(2), 227-229. (Lehigh University, Bethlehem, Penn.).

The relation between muscle action potential (MAP) and muscle tension was investigated in a task in which the muscle lengthened and shortened. MAPs were obtained from the biceps muscles of 16 Ss while they were lifting weights of 0, 1, 2, or 4 kg. The IMAP was shown to increase as a function of both weight and rate of lifting. The IMAPs of the passive arms also tended to increase with rate and weight. It was found that the greater the strength of S, the smaller was his IMAP. The curves for the conditions of 0 and 50, though not 25, lifts per min. were nearly parallel. It is concluded that an orderly relation exists between IMAP and dynamic work. (HEIAS)

Taggart, R. USE OF THE DETECTION DIFFERENTIAL IN UNDERWATER NOISE MEASUREMENT. Rep. 371 N. 15, May 1953, 22pp. Department of the Navy, USN Bureau of Ships, Washington, D.C.

This report discusses the possible usefulness of a single-number representation of the relative detectability of ship noise in the presence of sea noise. This number, termed "Detection Differential," shows the relationship of any foreign noise to the ambient sea noise associated with sea state zero. Methods for calculating this factor are described.

Hall, A.L. SOME EFFECTS OF RAPID DECOMPRESSION TO 43,000 FEET ON HUMAN SUBJECTS: INCIDENCE AND SEVERITY OF AEREBULLOSIS (AEROEMBOLISM) IN A SUBJECT REPEATEDLY EXPOSED TO TERMINAL ALTITUDES BETWEEN 35,000 and 43,000 FEET. Res. Proj. NM 001 101 103, Rep. 1, Dec. 1955, 12pp. USN School of Aviation Medicine, Pensacola Air Station, Fla.

A human subject was exposed to simulated altitudes of 35,000 to 43,000 feet by rapid decompression for a total of 142 exposures. The man exhibited an increase both in severity and incidence of symptoms of aerobullosis (aerobolism) with repeated exposure. As the number of exposures increased, the man had to be returned to increasingly lower altitudes before symptoms disappeared. Increase in number of exposures did not decrease the time at altitude for first appearance of symptoms.

Webb, W.B. AN EXPERIMENTAL ANALYSIS OF ANTECEDENTS OF SLEEP. Proj. NM 001 109 113, Rep. 1, Feb. 1956, 12pp. USN School of Aviation Medicine, Pensacola Air Station, Fla.

3 experiments were conducted in the study of the relationship between the sleep response and systematic manipulation of past sleep experience in a given environment, time of sleep deprivation, and an irrelevant hunger drive. 2 major conclusions were drawn. In experimental conditions of these experiments the major determinants of sleep latency were within subject consistent differences in contrast to the conditions imposed on these subjects. Further observations suggested that the time to sleep may be jointly determined by the development of wakefulness tendencies as well as sleep tendencies.

Albritton, E.C. (Ed.). STANDARD VALUES IN NUTRITION AND METABOLISM. Contract AF 33(038)-2174, WADC Tech. Rep. 52-301, Dec. 1953, 380pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (George Washington University, Washington, D.C.).

The report presents tables and certain charts of data in the field of nutrition and metabolism, together with introduction, bibliography and index. Both plant and animal organisms are included. The guiding principle in selecting the material has been that it be of basic importance in its general field. The tables are arranged under the following sections: a) The Nutrients; b) Requirement of Minerals, Amino Acids or Protein, Carbohydrate, Lipids, Vitamins by Selected Animal Forms; c) the same, Selected Plant Forms; d) Daily Nutrient Allowances, Man, Laboratory and Farm Animals, other Animal Forms; e) Diets Supplying Nutrient Requirements for Animal Forms; f) Composition of Nutrient Solutions, Culture Media and Fertilizers (i.e., "diets") for Plant Forms; g) Nutrient Composition and Energy Content of Foodstuffs and Feedstuffs; h) Biological Action of each of the Nutrients in Animal and Plant Forms; i) Pathways of Metabolism of the Nutrients, Animal and Plant Forms; j) Metabolic End Products, Animal and Plant Forms; k) Tissue Oxygen Consumption and Carbon Dioxide Production, Animal and Plant Tissues; l) Energy Metabolism, Man and Laboratory and Farm Animals.

Pressesky, A.J. AUTOMATIC RECORDING HAPLOSCOPE. Contract AF33(600)8434, WADC Tech. Rep. 53-512, May 1954, 16pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (American Optical Company).

The design and construction of an automatic recording haploscope are described. The range of positions of the stimulus targets is from +10 to -2 diopters and the range of response positions is from +12.5 to -4.5 diopters. The angle of convergence has a range from +60° to -40°. Interchangeable response optometers are used. The response position may be recorded as a function of stimulus position or convergence angle.

Jarison, H.J. EFFECT OF A COMBINATION OF NOISE AND FATIGUE ON A COMPLEX COUNTING TASK. Proj. 7193, Task. 71610, WADC TN 55-360, Dec. 1955, 25pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

6340

This investigation concerns the effect of noise and fatigue on a complex counting task. Fifteen male undergraduates kept a mental count of the number of times each of three lights flashed and responded periodically in terms of the count. There were two noise levels; each present for one hour. Three two-hour sessions were given. Error frequency was analyzed in terms of the following variables: count required before a response could be made, differential flash rates, and time over the session. The performance dimensions in the counting task, and the effectiveness of this task as a stress test are discussed.

Rookway, M.R. THE EFFECT OF VARIATIONS IN CONTROL-DISPLAY DURING TRAINING ON TRANSFER TO A "HIGH" RATIO. Contract AF 18(600)-78, Tech. Rep. 55-366, Oct. 1955, 13pp. WADC, Wright-Patterson AFB, Ohio.

6342

To investigate the relationship between amount of transfer of a two-dimensional tracking skill and degree of physical similarity between training and tracking test ratios, each of three groups of subjects received training using one of three different control-display ratios. The ratios were such that one degree of control deflection produced either 3-, 9-, or 27-sixteenths inch display movement. Following training (25 trials), all groups performed with the 1:3 ratio for 25 further trials. Time-on-target scores were analyzed as a function of training on each control-display ratio, for amount of transfer on first transfer trials, and for persistence of transfer effects. Implications for design of training devices are discussed.

Christensen, J.M. THE IMPORTANCE OF CERTAIN DIAL DESIGN VARIABLES IN QUANTITATIVE INSTRUMENT READING. Proj. 7186, Tech. Rep. 55-376, Oct. 1955, 61pp. WADC, Aero Medical Laboratory, Dayton, Ohio.

6343

The design and use of instrument dials is investigated as a function of the following variables: subjects, exposure time, practice, moving pointer-moving scale, clockwise-counterclockwise scale, and point of fixation. Four dial types under two conditions of fixation were presented in a sliding mirror tachistoscope. The eight Ss knew beforehand the type of dial face to be presented in the next trial. Each variable is statistically evaluated in terms of reading error, and the relationships interpreted in relation to dial design problems. The experiment is compared to a previous experiment similar to this one with the exception that no information regarding type of dial face was presented.

Kurke, H. I. PERSONNEL VARIABLES IN THE ANALYSIS OF MAN-MACHINE SYSTEMS. Ergonomics, Aug. 1959, 2(4), 349-353. (Dunlap & Associates, Inc. Washington, D.C.).

In an experiment comparing the detectability engendered by 4 optical systems, additional data concerning certain characteristics of the Ss were collected. Analysis of the data led to the conclusion that although variations of equipment design produced significant differences in the performance of a simple psychomotor task, the personnel variables of mental ability and attitude also had significant effects. It is suggested that the design of a man-machine system should take into account both personnel and design considerations if the best human contribution to the system's effectiveness is to be achieved.

Stone, G.R. THE EFFECT OF THE DIFFERENTIAL SELECTION OF TARGET STUDY CUES UPON AIMING POINT IDENTIFICATION TEST PERFORMANCE. Proj. 7711, Rep. AFPTRC-TN-56-40, Feb. 1956, 8pp. AFPTRC, Air Research and Development Command, Mather AFB, Calif.

6348
To examine one source of human error in bomb drops, five classes of experienced aircraft observers were given an abbreviated target study correlating specific aspects of an Urban Area Analysis chart with radar scope photographs. Following the study, a test was given which required identification of the aiming point during a motion picture of the bomb run on which they had been given target study. Subjects were divided into two groups on the basis of the primary guiding cue which they used in locating the aiming point. Total performance scores and error scores were compared for group differences due to choice of cue. Hypotheses are offered to guide future research leading to reducing observer performance error.

Volters, W.D. BOMBING ACCURACY AS A FUNCTION OF THE GROUND SCHOOL PROFICIENCY STRUCTURE OF THE B-29 BOMB TEAM. Proj. 7713, Task 77219, Rep. AFPTRC-TN 56-4, Jan. 1956, 24pp. USAF Personnel & Training Research Center, Randolph AFB, Tex.

Relationships between 3 simulated radar bombing criteria (circular error, range, and deflection) and ground school grades of the 4 bomb-crew members were studied for a sample of 176 B-29 crews in combat crew training. The design permitted examination of the relationship between the proficiency (ground school grade) of each member and the bombing criteria under all possible combinations of proficiency in the remaining members. The results were consistent with the hypothesis that the aircraft commander and radar observer are directly dependent upon one another for effective expression of their respective proficiencies. The proficiency of each member correlated most highly with the bombing criteria under conditions of higher-than-average proficiency in the other member. High proficiency in the navigator appeared to compensate in some degree for lack of proficiency in the aircraft commander and radar observer, in that the navigator's proficiency appeared most highly correlated with the criteria under conditions of low proficiency in these members. The results obtained with bombardier proficiency were not sufficiently pronounced to warrant conclusive interpretation although they were generally consistent with hypotheses advanced concerning bombardier performance as a factor in the variability of bombing results.

Wolff, H.S. MODERN TECHNIQUES FOR TIME AND MOTION STUDY IN PHYSIOLOGICAL RESEARCH. *Ergonomics*, Aug. 1959, 2(4), 354-362. (Human Physiology Div., National Institute for Medical Research, Hampstead, London, England).

Conventional methods for time and motion study recording by the use of stop-watch, pencil and paper were found inadequate when army recruits were studied for a week to determine calorie balance. Methods are described for use in the field by a small and relatively untrained staff. By means of Walkie-Talkie radio sets observers can report every change of activity of Ss to a central laboratory. For group study a machine known as the multichannel integrating clock has been designed. The time spent on any activity can be calculated by reading the counters before and after the period under study. The clock can also be used for the evaluation of diary cards. Activity sampling is a method which enables one observer to study up to 12 Ss simultaneously by means of punch cards recording 11 different activities. (HEIAS)

Aracult, M.D. A COMPARISON OF TRAINING METHODS IN THE RECOGNITION OF SPATIAL PATTERNS. Proj. 7706, Task 77119, Rep. AFTRC-TN-54-27, Feb. 1956, 13pp. AFTRC, Air Research and Development Command, Lackland AFB, Texas.

6351

To compare the effectiveness of different training methods in pattern (spatial arrangement of two or more objects in a field) recognition, eleven groups of 50 subjects each were trained to recognize patterns of 16 objects arranged randomly in a circular field. For half the subjects the pattern elements were pictures of real objects and for the other half, nonsense shapes. Training (five sessions) methods were: (1) reproduction with or without a matrix, (2) answering questions about spatial elements either oral or written, (3) observation (criterion method). The criterion test consisted of selecting the learned pattern from a set of five similar ones. The percentages of correct choices on test were analyzed for differences due to meaningfulness and to training method. T. G. I. R 1

Goldstein, M. A PROFICIENCY MEASURE FOR TEMPORAL INTEGRATION OF COMPONENTS IN A PERCEPTUAL-MOTOR TASK. Proj. 7708, Task 77141, Rep. AFTRC-TN-55-35, Nov. 1955, 14pp. AFTRC, Air Research and Development Command, Lowry AFB, Colo.

6353

To evaluate a proposed proficiency measure for temporal integration of components in a perceptual-motor task, 64 subjects performed on a pedestal sight gunnery task. Three clock scores were obtained: AER (azimuth, elevation, ranging), T (triggering), and AERT; unit of practice was nine target attack flights (scores were summed); trial length was 1.170 minutes. From these figures a new score, D, was derived comparing triggering performance of subjects with expected results for a random automatic triggering device. The results were analyzed to show effects of learning and to determine reliability of the D score. It is noted that the score may be applied to other tasks than pedestal sight gunnery.

Jackson, K.F. BEHAVIOUR IN CONTROLLING A COMBINATION OF SYSTEMS. II. EFFECTS OF CHANGES IN THE VELOCITY OF DISTURBANCES. *Ergonomics*, Aug. 1959, 2(4), 363-366. (Institute of Aviation Medicine, Royal Air Force, Farnborough, Hampshire, England).

The object of the study was to determine the effect upon the pattern of operator behavior of uniform variation in the velocity of disturbances affecting a set of 4 dials. 12 Ss carried out a multiple tracking task, disturbance was provided by a set of cams rotating at 0.6, 1.0, or 2.0 cpm. An analysis of variance performed on duration and number of control movements showed that velocity affected neither the rate of working as a whole nor the components of this overall rate, namely, duration of control movements and duration of change-over movements. The duration of interruptions was similarly unaffected. In conclusion it appears that when faced with changes in the difficulty of his task due either to increased load or increased velocity of disturbance, the operator adapts his responses considerably.

6356 Colquhoun, W.P. THE EFFECT OF A SHORT REST-PAUSE ON INSPECTION EFFICIENCY. *Ergonomics*, Aug. 1959, 2(4), 367-372. (Medical Research Council, Applied Psychology Research Unit, Cambridge, England).

Little is known about the efficiency of inspectors engaged on simple checking work, or whether short rest-pauses are beneficial to performance at such tasks. An experiment was carried out to investigate these questions in the case of machine-paced work. 32 Ss inspected sets of 6 objects and had to press a key under any disc which carried a spot. The number of response failures was recorded. The results showed that, when the work was interrupted for a period of one hour, efficiency, although high on average, declined markedly after about 30 min. When a rest-pause of 5 min. was inserted at this point, performance was maintained at its initial level throughout the hour. The theoretical and practical significance of these findings is discussed.

Leslie, W. & Goldstein, M. RELATIONSHIPS BETWEEN SIZE-MATCHING TEST AND PEDESTAL SIGHT GUNNERY PERFORMANCE. Proj. 7708, AFPTRC-TN-56-29, Feb. 1956, 16pp. AFPTRC, Lackland AFB, Tex.

6357

To determine the extent to which framing the target in a pedestal gunnery task may be considered a task of perceptual recognition, 96 target diagrams similar to the pedestal sight visual display were prepared in printed test format. Subjects judged whether these diagrams represented correct or incorrect framing under power conditions (about ten minutes) and speed conditions (three minutes). After five days of test performance, practice was given in pedestal sight manipulation on a gunnery simulator followed by a final printed test. Descriptive statistics for the printed test are reported. Test scores were correlated with performance scores to establish the relationship with a detailed examination of both tasks to explain the results.

Killie, D.S. GUN-CAMERA RECORDS AS MEASURES OF PEDESTAL SIGHT GUNNERY PROFICIENCY. Proj. 7708, AFPTRC-TN-56-30, Feb. 1956, 25pp. AFPTRC, Lackland AFB, Tex.

6358

To investigate the effectiveness of ground gunnery devices in developing skill which would transfer to the aerial situation, proficiency in the air was measured from gun-camera records, filmed on aerial training missions. Prior to these missions, students were trained on one of several ground devices or on a combination of devices. A control group received no training. Film records for 139 students in a flexible gunnery course were scored for extent of error for azimuth, elevation, and range. The data were analyzed for group differences which could be attributed to ground training. The reliability of scoring methods for detecting performance differences was studied through correlational procedures. An interpretation of the findings is offered.

Adams, J.A. EFFECT OF EXPERIMENTALLY INDUCED MUSCULAR TENSION ON PSYCHOMOTOR PERFORMANCE. Proj. 509 020 0009, AFPTRC TR 54 59, Nov. 1954, 4pp. USAF Personnel & Training Research Center, Lackland AFB, Tex. (Reprinted from *J. exp. Psychol.*, Aug. 1954, 48(2), 127-130).

6360

To investigate the effect of experimentally induced muscular tension on psychomotor performance, 120 Ss kept either 10, 20, or 30 lbs. suspended by pressing stirrups to the floor during an initial practice session on the Two-Hand Matching Test. Following rest, additional practice was given without induced muscular tension. Performance was compared with a group of 40 Ss who practiced without weights throughout. The results are presented and discussed in terms of the relative effect of various degrees of tension and a condition of no tension on psychomotor performance.

6361
Wilkinson, R.T. REST PAUSES IN A TASK AFFECTED BY LACK OF SLEEP. *Ergonomics*, Aug. 1959, 2(4), 374-380. (Medical Research Council, Applied Psychology Research Unit, Cambridge, England).

12 Ss worked at the Five Choice Test for 25 min. either continuously, or with a 30-sec. rest pause at the end of each 5 min. interval. The Ss were given each version twice, once with sleep and once with no sleep the previous night. It has been confirmed that 30 hrs. loss of sleep can seriously impair performance towards the end of a 25-min. test of aerial reaction. In particular, the occurrence of gaps, or abnormally long response delays, is greatly increased. This is what happens when the test is a continuous one; when 30-sec. rest pauses were allowed every 5 min this effect of lack of sleep was found to remain unaltered, an equal though small and insignificant improvement in performance occurring under both normal and sleep-deprived conditions.

Lowless, N.E. THE EFFECT OF THE RELATIVE POSITION OF CONTROL AND DISPLAY UPON THEIR DIRECTION-OF-MOTION RELATIONSHIP. *Ergonomics*, Aug. 1959, 2(4), 382-385. (Puffels Department of Industrial Health, University of Durham, King's College, Newcastle upon Tyne, England).

The effect upon performance of the direction-of-motion relationship between a control and a display is shown to depend upon certain other features of the layout. 72 is performed a compensatory tracking task. Each group of 18 Ss used a different pointer arrangement. An analysis of variance was performed on the measures of tracking errors. When a rotary control knob is used in conjunction with a linear indicator, a clockwise movement of the control is expected to move the pointer upwards or to the right. This expectation is, however, weaker when the centre of rotation of the control is situated on the line of movement of the display than when the control is situated to the side of the line, so that the pointer moves in the same direction as the nearest part of the knob. The orientation of the display and the position of the control have no effect apart from this relationship between them.

Black, J.W. & Morrill, S.N. THE PITCH OF SIDE-TONE. *Contract N6onr 22523, Projs. NR 145 993* & NR 001 024.01.31, Rep. 31, Oct. 1954, 2pp. (USN School of Aviation Medicine, Pensacola Air Station, Fla.).

An investigation relating to the question of whether a listener and a talker hear the same pitch when both are listening to the talker's voice was conducted. 32 male experimental Ss, including 29 trained musicians, attempted to adjust the pitch of electroacoustically reproduced vowels to agree with the pitch of the same vowel currently sustained by the same S. Adjustment of pitch was achieved through altering the frequency of the voltage to the motor of the playback tape unit. Adjustments occurred at each of 4 sound pressure levels. Typically the matchings indicated that the Ss heard their own voices during vowel production as being higher in pitch than an externally generated sound of like sound pressure level and quality.

Heinonen, A.O., Karvonen, M.J. & Ruosteenoja, R. THE ENERGY EXPENDITURE OF WALKING ON SNOW AT VARIOUS DEPTHS. *Ergonomics*, Aug. 1959, 2(4), 389-394. (Institute of Occupational Health, Helsinki, Finland).

The energy expenditure of walking at natural pace on snow was determined. 7 male Ss walked 45-180 m at their natural walking pace. The energy expenditure was calculated directly from the O_2 content of the expired air. The mean depression of the feet into the snow was calculated from 20-50 measurements in each test. The results are expressed as a function of the depth of the depression of the feet into the snow. Depressions of 0, 10, 20, 30 and 40 cm gave an energy expenditure of 0.63, 1.42, 2.65, 5.72 and 8.30 cal/kg body weight per horizontal meter, respectively. The energy expenditure could be expressed as a linear function of the depression, using 2 equations, one for depressions less than and the other for those greater than 15 cm. The results are discussed.

6360 Bond, O.D. A PSYCHIATRIC ANALYSIS OF FORTY (40) SUBJECTS WHO WERE SICK BY A SWING. *Prej. 149*, Rep. 1, July 1953, 3pp. (USN School of Aviation Medicine, Randolph Field, Tex.).

To determine the incidence of psychologic factors that might predispose to swingsickness, 43 susceptible Ss were studied. 29 out of the 43 Ss gave evidence of considerable emotional maladjustment on the data collected in a very brief psychiatric examination. All but 1 of the 21 Ss who had a previous history of susceptibility to motion sickness had a history of considerable evidence of emotional maladjustment. The histories of susceptibility to motion sickness are difficult to evaluate solely on the basis of the psychologic effort of motion and in many instances point toward an emotional component in the illness. 3 Ss who had evidence of neurosis or of emotional difficulty and 1 of whom had a history of emotional difficulty did not become sick on the swing. There is evidence that an increased susceptibility to motion sickness may be a neurotic symptom, but it is clear that all those with emotional difficulty will not necessarily become sick on the swing. Because of the demonstrated evidence of emotional maladjustment in over half of those Ss, it will be well not to neglect this factor in the evaluation of future work on the etiology or treatment of motion sickness.

 Miles, W.J. THE EFFECTS OF SLEEP DEPRIVATION ON PERFORMANCE OF A COMPLEX MENTAL TASK. Proj 7153, Task 7112, Tech. Note 55 173, Sept. 1955, 13pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

Data were recorded on the performance of 6 subjects each of whom was deprived of 30 hours sleep. The task on which these subjects performed required the making of a total of 200 discrete comparisons over a period of approximately 25 minutes. 3 such performance periods were used: one at the beginning of the normal working day, a second approximately 24 hours later (no sleep having been permitted in the meantime), and a third approximately 6 hours after the second session. The performance of these subjects was compared with that of a control group of 5 subjects who performed the test 3 times but did so on 3 separate days, each session having been preceded by a presumably normal night's sleep. The statistical analysis revealed a significant difference between the 2 groups, i.e., the control group showed significantly more improvement from the second to the third sessions than did the group deprived of sleep. The general conclusion was that subjects who are suffering from loss of sleep do not show the improvement which would be expected on the basis of the performance of normal subjects when the fatigued subjects are confronted with a complex mental task which they have not as yet mastered.

 Ruffy, T.B. & Lavetta, J.T. WORK GROUP STRUCTURE, COMMUNICATION, AND GROUP PERFORMANCE. *ERGONOMICS*, 1956, 29, 105-113. (USAF Personnel & Training Research Center, Rockland AFB, San Antonio, Tex.). (AFPRC DN 55 95).

To introduce several constructs which appear to be of general utility in the measurement and analysis of communication in groups, a theoretical framework of the overall problem of group task performance is outlined. A conceptualization of: 1) the task as an observation-response matrix, and 2) personnel deployment in terms of a personnel-observation matrix and a personnel-response matrix is presented. Laboratory studies of the personnel-response matrix are summarized as illustrations. The application of the constructs and of the results to date are discussed in reference to further research.

2 experiments are discussed. They were designed for the determination of the best work method from the point of view of ergonomics. Methods for the detection of long term effects on the state of health are indicated. The economy of the work has been judged by comparison of the efforts expended and the resulting performance. The results of these measurements are also largely influenced by the personal capabilities for the performance of the particular task by each of the Ss. An analysis of this capability is given. Attention is also given to the difficulties of comparing work methods when the composition or the use made of the teams of Ss varies. If different groups of Ss are compared, each using their own work method, the groups may differ too much in general working capacity; if the same group applies different work methods, experience in using one method will be greater than with another. Adjustment of the energy expenditure to compensate for differences in pace or quality were not considered feasible.

 Evans, J.R., Crowder, G.P. & Taylor, P.F. CIRCULATORY RESPONSES TO CHANGE FROM RECLINANT TO ERECT POSTURE AS AN INDEX OF HEAT STRESS. *Ergonomics*, May 1955, 2(3), 262-273. (Applied Physiology Dept., London School of Hygiene and Tropical Medicine, London, England).

Experiments are described in which Crampton Index values, derived from measurements of blood pressure and pulse rate following on change in posture, have been related to conditions of environmental heat and to the thermal sensations of resting and working Ss. Experimental evidence is given which indicates that changes in the Crampton Index may be of value in defining individual reactions to increasing environmental heat.

 Henderson, J.G. THE ESTIMATION OF THE TRANSFER FUNCTION OF A HUMAN OPERATOR BY A CORRELATION METHOD OF ANALYSIS. *Ergonomics*, May 1955, 2(3), 274-286. (Electrical Engineering Dept., University of Birmingham, Birmingham, England).

This paper records an experiment to determine the transfer-function of a human operator, when he is acting as an element in a closed-loop control-system, by a method of analysis which is based on correlation functions. The theoretical analysis shows that under certain conditions the transfer-function of the operator can be defined by an integral equation that relates a cross-correlation function of his response to an observed 'error', to the auto-correlation function of that 'error'. It is shown how this integral equation can be solved approximately by a technique which uses an electronic analogue-computer. In this instance such a computer has been used to determine the parameters that will 'best fit' an assumed form of transfer-function to the recorded data.

 A PPI DISPLAY. Contract AF 33(638)-22642,
 Proj. 7142, Tech. Rep. 54-146, Aug. 1954,
 13pp. Aero Medical Laboratory, WADC, Wright-Patterson
 Air Force Base, Ohio.

6375
 To investigate the relationship of signal size to
 detectability on an intensity-modulated CRT (cathode-ray
 tube) display, thresholds were obtained (two observers)
 for five signal sizes (from 26 minutes, 15 seconds to
 10712 minutes, 15 seconds visual angle) at two CRT
 voltage biases (background luminance approximately 0.01
 and 2.0 millilamberts at ten degrees behind screen). De-
 tectability thresholds were measured in decibels attenua-
 tion from a fixed signal of eight volts. The data were
 studied by analysis of variance techniques for primary
 sources of variance. Graphic comparisons of the size-
 detectability function were made with data from previous
 studies. Practical implications of design engineers are
 discussed. A technique for measuring the approximate
 luminance on each display is described. T. G. R 8

 IN ABSOLUTE JUDGMENTS. Contract AF 33(638)-
 22642, Tech. Rep. 54-146, Jan. 1954, 12pp.
 Aero Medical Laboratory, WADC, Wright-Patterson
 Air Force Base, Ohio. (The Johns Hopkins University).

6377
 To account for anchor effects (accuracy with which
 one stimuli are judged) of identification data obtained
 under the method of absolute judgment, a subjective stan-
 dard hypothesis is proposed and evaluated. Two experi-
 ments were performed. (1) Two groups of subjects (five
 each) were required to judge a series of lines forming
 a circular continuum by assigning to each line a number
 (one to twenty). Groups differed in what response num-
 bers were assigned to specific lines. (2) The stimulus
 series consisted of twenty squares varying in size from
 two to forty millimeters square; methods and procedures
 were otherwise same as before. Percent correct responses
 were analyzed for anchor effects predicted by the
 hypothesis. T. G. R 9

6378
 Garbar, D.J. THE JUDGMENT OF VELOCITY AND PRECISION OF MOTION. *Ergonomics*, May 1955, 2(3),
 287-304. (Department of Scientific & Industrial Research, London, England).

Experiments are described using an interception situation and varying the amount the S is
 able to view of the progress of the object being intercepted. The results indicate that the
 Ss were able to deal with this type of situation by using a comparatively simple response
 technique. The main question which remains is the way in which the S predicts the region of
 an object once it has disappeared. Further experiments were carried out using a prediction
 situation in which the S has to press a button when he judges when a moving light which has
 disappeared has reached a specified point. The results show a systematic relationship be-
 tween the variability of the S's performance and the time the light has been invisible. The
 relationship closely approximates $V^2 = Kt^2$ where V is the variability of the S, t the time
 the light was obscured and K a constant. Divergence from this precise relationship appeared
 to be due to the use by the S of a well-established response technique. R 13

 European Productivity Agency. E.P.A. PROJECT NO. 335. "FITTING THE JOB TO THE WORKER".
Ergonomics, May 1955, 2(3), 305-329. (European Productivity Agency, Paris, France).

An international conference on ergonomics was held in March 1955 in Zurich under the
 above title. The project started in 1955 with a visit to the USA; the second phase was a
 technical seminar in Leiden in 1957. The Zurich conference discussed muscular work, work-
 place layout, display and controls, lighting, noise, climatic conditions and working rhythms.
 The papers and discussions of the Zurich conference are briefly summarized in the following
 account. At the end of the conference the employers' and trades unions' representatives pre-
 sented their conclusions about the application of ergonomics in industry. The wholehearted
 support for ergonomics expressed in the resolutions they presented clearly justifies the Euro-
 pean Productivity Agency in having undertaken this project. This report was prepared by Dr.

 Engen, T., & Levy, N. THE INFLUENCE OF STANDARDS ON PSYCHOPHYSICAL JUDGMENTS. *Percept. mot. Skills*, 1955, 2, 193-197. (Brown University, Providence, R.I.).

Experimental applications of the method of direct magnitude estimations to brightness and
 weight stimuli provided evidence that: a) a standard selected from the middle of the stimulus
 series will yield more sensitive judgments than a higher and lower standard; and b) if no
 standard is used, more sensitive discriminations will be obtained when the adaptation level
 (or geometric mean) is in the middle of the stimulus series. The interaction of central
 tendency with adaptation level may prove to have important implications for a general theory
 of psychophysical judgment.

Floyd, V.F. & Roberts, B.F. ANATOMICAL AND PHYSIOLOGICAL PRINCIPLES IN CHAIR AND TABLE DESIGN. *Ergonomics*, Nov. 1955, 2(1), 1-15. (Physiology Dept., Middlesex Hospital Medical School, London, England & Human Anatomy Dept., Oxford, England).

The paper is concerned with general principles derived from anatomical, physiological and clinical considerations in relation to dimensions of chairs and tables, from a study of the literature and the authors' own investigations the following conclusions emerge: a) The height of a chair seat should be no more than the length of the lower leg of the shortest person who will use the chair to allow the ischial tuberosities to bear the full weight of the trunk. The minimum seat depth for comfort is determined by the length of the thighs of the shorter persons using the seat. Seat width is adequately measured by trochanteric width. A substantially plane seat is preferable to one moulded to fit the backside. No horizontal struts of other obstruction should be placed between the front legs of the chair. Back rest should not restrict the movement of the spine or of the arms. A saddle-shaped backrest gives satisfactory support. Elbows should be about the level of the working plane of a table. The space between the under-surface of the table and the chair seat should be slightly greater than thigh thickness.

Nelson, R. COLOR AND SEEING. *Illus. Exper.*, June 1955, 59, 271-278. (University of Texas, Austin, Tex.).

6321

To explore variables affecting the ability of human observers to learn to recognize and identify previously unfamiliar complex visual forms, two experiments were performed. In both experiments the effect upon subsequent recognition skill of giving subjects practice in the use of irrelevant labels (letters of the alphabet) as discriminating responses before learning to associate them with a set of unfamiliar stimulus forms was systematically studied. Stimulus materials were varied on the basis of familiarity (geometric forms, portions of aerial photographs, abstract figures); responses varied in number used (from one to twelve). The data are analyzed in terms of practice effects, familiarity of material, and number of labels. The functions of verbal labeling practice are discussed. T. G. I. R 10

6322

The author presents a discussion of the relation between illumination and visual performance with specific emphasis upon the variables which may account for the prevalent variation in experimental investigations of this relationship. Suggestions are offered concerning conceptual and methodological problems reflected in the treatment of such pertinent aspects as the following: individual differences in color vision, the background effect of color, the effect of the spectral energy of light sources upon object colors, the effect of color of source on acuity (and other visual functions), and the attempt to define an optimal color for all sources of illumination. Pertinent references are included in this discussion. T. G. R 15

6382 Nelson, R. & Himelstein, P. A SHORT METHOD FOR CALCULATING THE ADAPTATION-LEVEL FOR ABSOLUTE AND COMPARATIVE RATING JUDGMENTS. *Amst. J. Psychol.*, Dec. 1955, 52(4), 631-637. (University of Texas, Austin, Tex.).

Extension of the theory of adaptation-level (AL) to include comparative as well as absolute types of judgments has enlarged the sphere of use of equations previously published for quantitatively evaluating factors that influence psychophysical and other types of judgment. Calculation of the best value of AL and of the weighting constant, k , which measures the relative contributions of the stimulus-series and of the AL in determining responses to stimuli, can be shortened considerably when using the method of least squares through the use of tabulated values of the function $Y = (0.5K + J) / (1.5K - J)$ which enters into the equation. In this article 2 examples are presented illustrating use of tabulated values of Y as a function of the judgments and of coded stimulus-values (X) to minimize the computations in solving the normal equations for the desired constants. Data obtained by the method of absolute judgment and by the method of comparative ratings were chosen for examples. (METS)

Griew, S. A STUDY OF ACCIDENTS IN RELATION TO OCCUPATION AND AGE. *Ergonomics*, Nov. 1955, 2(1), 17-23. (University of Bristol, Bristol, England).

A study is reported in which accident rate is related to age and occupation. Age distribution of observed accidents occurring during a 4-yr. period to manual workers in each of 9 jobs are compared with distributions expected on the assumption that job differences do not result in differences in fluctuations with age of accident rates. 3 significant differences between observed and expected distributions are obtained. These relate to the jobs of Electrician, Miller and Grinder, all of which are jobs in which mainly younger workers are normally employed. The median ages of those employed in 9 jobs are correlated with the extents to which accidents in the upper age groups are more or less numerous than expected. This correlation is significant, and indicates that older workers in jobs normally occupying younger workers tend to have more accidents than expected. Fluctuations in accident rates with age are concluded as being a function of the type of work studied. The results of the study are thought to reflect the difficulties of older workers in meeting the demands of certain types of work.

Cavis, D.R. HUMAN ERRORS AND TRANSPORT ACCIDENTS. *Ergonomics*, Nov. 1958, 2(1), 24-33. (Department of Medicine, University of Cambridge, Cambridge, England).

The paper discusses the part played by 3 psychological processes, here called 'the false hypothesis', 'pre-occupation' and 'emergency mechanisms', in the causation of transport accidents. The false hypothesis results from people responding to situations as they conceive them to be, and this may be very different from what they really are. Emergency mechanisms may come into play when a person is caught unawares, and may lead to excessive and inappropriate responses. Some of the experiments in which these processes have been studied in the laboratory are described. Explanations of the errors responsible for certain train collisions when the driver had passed one or more signals at danger, and for certain aircraft accidents are suggested by reference to one or other of these processes.

Grimaldi, J.T. SENSORI-MOTOR PERFORMANCE UNDER VARYING NOISE CONDITIONS. *Ergonomics*, Nov. 1958, 2(1), 31-43. (General Electric Co., New York, N.Y.).

A group of 52 Ss performed a tracking task in quiet and noisy environments. The noise was intermittent, within the frequency range of 75 to 5600 cycles and at sound levels of 70, 80, 90, and 100 db. The study was experimental, but simulated an occupational situation. Errors, response times and production (the number of turns of the stylus) were recorded. There was a tendency for more errors and less precision when working in the noisy environment. Response times were slower and the number of errors greater than when noise levels and frequencies were highest. The frequency range of 2400-4800 cycles was associated with the slowest response time and largest number of errors, both at 90 and 100 db. It appears that intermittent noise may have a reducing effect on the individual's capacity for quick and precise execution of coordinated movements. The implications for safety and certain production tasks seem obvious.

Jackson, R.F. BEHAVIOUR IN CONTROLLING A COMBINATION OF SYSTEMS. *Ergonomics*, Nov. 1958, 2(1), 52-62. (Institute of Aviation Medicine, RAF, Farnborough, Hampshire, England).

The state of a manually controlled system or combination of systems depends upon a balance between the skill of the operator and the difficulty of his task. When the difficulty of the task is varied by increasing the number of systems which have to be controlled, some change in the pattern of performance can be expected. It is possible to identify the parameters of performance which can be adjusted to meet the increasing demands of such a situation and to describe how they are related to each other and to overall performance. This analysis has been applied to a task in which the pointers of several dials which tend spontaneously to deviate have to be kept as nearly in alignment as possible, and an experiment with this task has shown ways in which Ss adapt to changes in the number of dials (and controls) involved.

Provins, K.A. ENVIRONMENTAL CONDITIONS AND DRIVING EFFICIENCY: A REVIEW. *Ergonomics*, Nov. 1958, 2(1), 97-107. (Human Anatomy Dept., University of Oxford, Oxford, England).

The paper is a review of work in the field of environmental effects on human performance with special reference to problems of driving efficiency. It is concerned principally with the effects of low and high environmental temperatures, and of air pollution by carbon monoxide, on sensori-motor performance at tasks related to driving. There are many papers and reviews dealing with the general problem of environment and occupational efficiency but relatively few concerned directly with motor vehicle driving. This is probably due to difficulties and dangers of experiments on the roads which might lead to reduction of driving efficiency and to the intrinsic difficulty of measuring driver performance. This review must be regarded therefore as a guide to the possible effects which environmental conditions may have on motor vehicle driver performance and a pointer to the need for further research more pertinent to the driving problem itself.

Loucks, R.B. MEASUREMENT OF SMOOTHNESS OF COORDINATION IN THE PERFORMANCE OF A PSYCHOMOTOR TEST. Proj. 45, Rep. 1, June 1942, 4pp. *USAF School of Aviation Medicine*, Randolph Field, Tex.

To determine whether smoothness of coordination in the performance of a psychomotor task can be measured, a simple pick-up unit was designed to be attached to a large variety of test apparatuses. An initial investigation of its usefulness was made during the performance of 2 groups of Ss (95 and 166) on the SAM Two-Hand Coordination Test. In one group, the Test was merely placed on the table; in the other it was clamped firmly to the table. Sums of jerkiness scores for 4 even-numbered trials were correlated to those for the 4 odd-numbered trials producing reliability coefficients of +.94 and +.91. Correlations between total scores for smoothness of coordination and total scores for performance on the Two-Hand Coordination Test were -.25 and -.32. The significance of these data for increasing the accuracy of pilot selection are discussed. (HEIAS)

Leuchs, R.B. ASSESSMENT OF INSTRUMENT FLYING PERFORMANCE: FURTHER METHODS FOR AUTOMATIC RECORDING OF AN AIRCRAFT'S FLIGHT PATH. Proj. 383, Sep. 2, Dec. 1945, 7pp. USAF School of Aviation Medicine, Randolph Field, Tex.

2 types of apparatus have been constructed which will plot an aircraft's flight path automatically. A technique is also described for recording the flight path at a ground station as well as in the aircraft itself. One of the 2 recording systems plots the aircraft's position independently of any special data regarding wind direction, wind velocity, and air speed. In contrast with photographic techniques, the present systems provide records which can be evaluated immediately upon termination of any particular flight maneuver. The records readily lend themselves to direct interpretation inasmuch as each tracing constitutes a scaled plotting of the aircraft's flight path on a conventional map. When desired, an elevation profile can be traced synchronously with the azimuth patterns provided by the 2 systems described in this paper.

Singleton, V.T. THE TRAINING OF SEWING-MACHINISTS. Ergonomics, Feb. 1959, 2(2), 146-152. (The British Boot, Shoe & Allied Trades Research Association, Kettering, England).

(Presented at a symposium on training.) A training scheme for sewing-machinists based on the 'progressive-part' method is described. It was tested in preliminary training courses run by the Research Association to which the author belongs, and was then spread throughout the industry by organizing a series of training courses for instructresses. These instructresses are selected by the parent firm or technical college, they are trained in the procedures of the scheme and then return to their factories or colleges to set up their own training schools. The main difficulties of this work have not been connected with the finding of successful training procedures, but with the initiation and maintenance of training schools in the industry. The problems which arise and some measures which have been devised for dealing with them are outlined.

6396

Blair, Isabel. PRACTICE AND KNOW: SOME COMMENTS ON LEARNING AND TRAINING IN INDUSTRY. Ergonomics, Feb. 1959, 2(2), 167-170. (National Institute of Industrial Psychology, London, England).

(Presented at a symposium on training.) Learning a task differs psychologically from doing it once skill is acquired. Industrial training should focus on actual learning processes and on fostering the desire to learn. Learning may be helped by directing attention to kinaesthetic experience, which in turn can convey more meaning if irrelevant differences in machine adjustments and work-place layouts are minimized. Learning depends on identification of good responses. Knowledge of success achieved tends to create a desire for more success. The skill of instructors in using these principles, with learners who vary in rate of progress, is likely to be an important influence in the effectiveness of industrial training.

Adamson, G.T. CIRCUIT TRAINING. Ergonomics, Feb. 1959, 2(2), 183-186. (Physical Education Dept., University of Leeds, Leeds, England).

(Presented at a symposium on training.) The paper describes a form of training in which there is progressive loading of the individual. The 'circuit' includes a number of exercises, usually 9 to 12, selected so as to improve general muscular condition, and circulatory and respiratory responses. The main assumption underlying this approach is that general fitness is determined by: muscular strength, the capacity to exert force against resistance; muscular endurance, the capacity for continuous performance of heavy activity making small demand on circulatory and respiratory functions; general endurance, the capacity to continue sub-maximal contractions of sufficient intensity to make demands on circulatory and respiratory functions; muscular power, the capacity to develop horsepower. Circuit training consists of the following phases: teaching, timing, training and relating in accordance with a target time. Some figures are given showing improvement in performance attained by a group of 20 university students attending training for 8 weeks on a circuit consisting of 12 exercises. R 1

Cotes, J.E. & Hinde, R. PHYSICAL TRAINING IN RELATION TO THE ENERGY EXPENDITURE OF WALKING AND TO FACTORS CONTROLLING RESPIRATION DURING EXERCISE. Ergonomics, Feb. 1959, 2(2), 195-206. (Medical Research Council, Pneumoconiosis Research Unit, Llandough Hospital, Penarth, Glamorgan, Wales).

(Presented at a symposium on training.) In 11 National Service men during their preliminary training course there was a decrease in energy expenditure and 'vertical work' done in walking at 3 1/2 mph. This is attributed to increased economy of movement since the rate of energy expended to 'work' done remained constant. The reduction in exercise ventilation on switching the inspired gas from air to oxygen also occurred over the training period, suggesting improved oxygenation of the blood in the lungs. There was no concurrent change in pulmonary diffusing capacity or ventilation equivalent. No experimental evidence was obtained to support the hypothesis that as a result of this training the body temperature rises less on exercise and that this contributes to the changes in exercise ventilation. 6409

This report is the fourth in a series of studies designed to evaluate the effects of certain drugs in preventing motion sickness. Conducted during an actual sea voyage, the study employed approximately 500 subjects who received systematic dosage of one of the following: benzadrin, pontofen, loranin, thiamine, Eli Lilly Preparation No. 01730, and placebo. The results are reported in terms of the relative incidence of seasickness as a function of type of drug, previous history of motion sickness, and age of subjects. Side effects are described and one drug emerges with positive potential as a motion sickness preventative.

Muller, E.A. TRAINING MUSCLE STRENGTH. Ergonomics, Feb. 1959, 2(2), 216-222. (Max-Planck-Institut fur Arbeitsphysiologie, Dortmund, Germany).

(Presented at a symposium on training.) The stimulus for increase in muscle strength is not fatigue but the force exerted during the job. When this force exceeds one-third of maximum strength, the maximum speed of increase in strength is reached with one single, short duration static contraction per day. The slower increase by weekly training leads to a more permanent acquisition of strength. To avoid fatigue in static work the muscles should be trained against a force about double the highest static force which occurs during the job. Inactivity lowers strength about 30% in a week, with an equally quick return to normal strength by new activity. Atrophy can be prevented by one contraction per day with a force one-fifth of maximal strength. Normal strength is maintained by contractions lying between one-fifth and one-third of maximum strength. The ability of muscles to increase maximum strength varies from muscle to muscle and from person to person. For men it is maximal at 25 years of age and half-maximal at ages 10 to 60 years. The rate of increase in men is double that of women at age 25 years and 25% higher at ages 19 and 60 years.

Harker, G.S. & Henderson, A.C. EFFECTS OF INDUCED VERTICAL IMBALANCE ON DEPTH PERCEPTION. Proj. 6 95 20 001, Rep. 201, Aug. 1955, 13pp. Research and Development Div., USA Medical Research Lab., Fort Knox, Ky.

A binocular depth judgment task was used to evaluate the effect of induced vertical imbalance on binocular vision. Zero, 1/2, and 1 prism-diopters were used in conjunction with two alternation rates, 30 and 15 alternations per half hour experimental period. The data were analyzed to show the effect of two exposure times, 15 and 30 minutes. The data of this study in conjunction with that of Ogle and Prangen indicate that the use of binocular instruments which require vertical fusional effort on the part of the observer will be most fatiguing when the observer seeks to change frequently from viewing with the instrument to viewing with the unaided eye.

Hausman, H.J. THE B-29 AVIATION MECHANIC TESTING PROGRAM IN AIR WEATHER SERVICE (MILITARY AIR TRANSPORT SERVICE). Memo. Rep. 4, March 1951, 6pp. USAF Human Resources Research Labs., Bolling AFB, Washington, D.C.

As a group, B-29 mechanics in 3 stations of the Air Weather Service seemed to be proficient, according to test results of the B-29 Oral Proficiency Examination during the period October to December, 1950. 1/2 of them scored in Groups I and II, where competent mechanics should score. Many of the remaining half need only further experience to achieve this score. Some undoubtedly should be closely examined for fitness as mechanics. Differences between stations are minor and can easily be explained by differences in the number of experienced men tested at each location. The test results should prove highly useful to squadron maintenance officers in planning assignments and training of their mechanics. Mechanics currently being schooled in the OJT program can be examined after a suitable time and their proficiency in maintaining B-29 aircraft can be determined. Mechanics who fail the examination at this time may be able to pass after more training. A continuous testing program should include retesting of mechanics who fell in Groups IV and V, or even those who are "Satisfactory" in Group III.

Head, C.V., Jr. RESEARCH PLANNING CONFERENCE ON TRAINING AND PROFICIENCY MEASUREMENT OF NAVIGATOR-BOMBARDIERS. Conf. Rep. 49 3, Sept. 1949, 24pp. USAF Human Resources Research Center, Mather AFB, Calif.

This report contains a summary of a research planning conference on training methods and proficiency measurement of navigators, bombardiers, and radar observers. A review of research results of the AAF Aviation Psychology Program was presented, existing problems were considered, and a research program was formulated. The major recommendations of the conference briefly stated are as follows: a) study the Navigator-Bombardier's job to provide an accurate definition of job behavior; b) develop criteria of performance for research use; c) investigate problems in radar scope interpretation and target identification; d) evaluate the use of training devices; e) formulate plans for instructor selection and training; f) analyze and evaluate curriculum organization and content; and g) develop measurements of proficiency maintenance. Hudson, G. AN INVESTIGATION INTO THE PROBLEM OF FOOT CASUALTIES IN THE ARMY. Rep. 9/54, Aug. 1954, 11pp. USA Operational Research Group, Department of the Scientific Adviser to the Army Council, Washington, D.C.

An assessment of the magnitude of the manpower wastage caused by foot ailments in the Army and the influence of certain variables (training, climate, Arm of Service, etc.) was made. A survey was made of all foot ailments seen on unit sick parades over a period of 4 wks. of a planned sample of some 8000 other ranks involving recruits and trained men from all Arms of Service. A smaller survey covering about 850 Malayan other ranks was also made. Overall, approximately 22% of unit strengths reported sick with foot ailments each week or about 1/4 of all sick-parade attendance. The manpower wastage was equivalent to the permanent incapacitation of some 120 men/division. No differences between Infantry and other Arms were found. Among recruits the incidence and associated manpower loss was 2 to 3 times as great as among trained men with major contributing ailments of orthopedic condition and blisters. Among trained men the most prevalent complaints involved skin conditions other than blisters. Findings on the Malaysian troops were similar. Recommendations are included. (HEIAS)

Henry, F.H. THE PREVENTION OF ALTITUDE PAIN BY PRESELECTION. J. Aviat. Med., June 1947, 18(3), 259-265a. (Medical Physics Div. & Physical Education Dept., University of California, Berkeley, Calif.).

The relation between individual differences in altitude pain susceptibility, measured by a standard test, and occurrence or absence of pain in validating exposures with altitude exercise, and denitrogenation differing from the standard test conditions was investigated in 2 experiments. a) 53 men were classified in a 38,000 ft. test with isotonic type arm exercise; 34 of these were given a validating exposure with half as much exercise and 33 were given about 2% as much work in ft. lbs. (isometric work). Correlations between test and validation averaged .59 with isotonic work and .48 with isometric work. Pre-selection by discarding the most susceptible men (75%) reduced moderate and severe pain from 65% to 25%. b) 151 men were classified by a standard preoxygenated test at 33,750 ft. With exercise 98 were then given validating exposure under the standard test conditions and 53 were given 2 preoxygenated exposures at 35,000 ft. with twice as much work. Average correlation between test scores and altitude pain occurrence was .45. It was concluded that preselection by non-preoxygenated tests using a standard exercise and altitude are effective in reducing the occurrence of altitude pain in further exposures. (HEIAS)

Moser, H.M., & Dreher, J.J. STANDARD PRO-
NUNCIATION OF THE MODIFIED ICAO ALPHABET.
Contract AP 10(600)-316, RP Proj. 519, Psp.
18, AFCE-15-54-89, Dec. 1954, 7pp. Air Force
Cambridge Research Center, Cambridge, Mass.
(Ohio State University).

6424

To assess the patterns of variation in pronunciation among certain words in the modified International Civil Aviation Organization (ICAO) alphabet with regard to relative efficiency, eight males of various nationalities were used as speakers with three groups of listeners: (1) 11 American females, (2) 75 Air Force ROTC seniors, and (3) 26 foreign nationals. Each speaker recorded his list twice and these recordings were presented to the listeners under varied signal-to-noise ratios. Analyses of variance and t-tests of error scores were computed. The results are discussed in terms of designating the specific words which warrant concern with regard to variation in pronunciation and the general role of such variation on the efficiency of all other ICAO words.

Hoss, H.L. & McDonald, P.R. THE EFFECT OF HIGH ALTITUDE ON THE CURVATURE OF THE CORNEA.
Proj. 61, Rep. 1, Oct. 1943, 5pp. USAAF School of Aviation Medicine, Randolph Field, Tex.

A study was made to determine the effect of reduced atmospheric pressure on the curvature of the cornea. 15 Ss were examined on the ophthalmometer at ground level with and without an oxygen mask. The chamber was then taken to simulated altitude of 50,000 ft; and after 50 min. at this altitude, the ophthalmometer readings were recorded again with oxygen mask in place. The results of an analysis of changes in horizontal and vertical meridians and astigmatic errors associated with wearing the mask or with a decrease in atmospheric pressure revealed slight and insignificant changes in corneal curvature. (HEIAS)

Haggard, E.A. ON THE APPLICATION OF ANALYSIS OF VARIANCE TO GSR DATA: II. SOME EFFECTS OF THE USE OF INAPPROPRIATE MEASURES. J. exp. Psychol., Dec. 1949, 39(6), 861-867. (University of Chicago, Chicago, Ill.).

The purpose of this paper is to apply 4 measures of the GSR to a given set of original data, to show that the application of the F-test to inappropriate measures results in invalid conclusions, and to attempt to account for discrepancies among the F-values in terms of the qualities of the 4 measures as they affect the F-ratio under identical experimental conditions. The GSR measures include: Resistance change, Conductance change, Log Resistance change, and Log Conductance change. Comparisons were made in terms of certain scale characteristics of the 4 measures, and in terms of the variables of Age, Sex, and PIU (words previously rated by the Ss as being 'pleasant', 'indifferent', or 'unpleasant' in emotional tone). A group of 50 boys and 50 girls were tested at 13.5 and retested at 17.5 years of age. The study is based on 2305 responses. The findings of this study justify the following conclusions: a) The 4 GSR measures examined in this study cannot be used interchangeably, since when applied independently to the same original scores, some measure yielded highly significant differences for a given comparison, whereas other did not. b) The variability among the obtained F-values arises from the scale characteristics of the 4 measures as they are applied to the original or derived scores. It may be assumed that those measures which violate the basic assumptions underlying the analysis of variance technique yield biased F-values.

O'Neill, J.J. THE EFFECTS OF EXPOSURE TO WHITE NOISE ON INDIVIDUAL TEST SCORES: LOUDNESS-BALANCE AND INTELLIGIBILITY TESTS. Prepared under Contract N6onr-22525, Proj. Designation 145-993, Proj. NM 001 064.01.29, Rep. 29, Sept. 1954, 8pp. USN School of Aviation Medicine, Pensacola, Fla.

6428

In order to determine the effects of exposure to white noise on the results of loudness-balance and speech-intelligibility tests, 16 subjects were first required to make a series of loudness-balance matches and complete half of an intelligibility test and then, after a 30-minute exposure to 100 decibels of white noise, to repeat the loudness-balance matches and complete the intelligibility test. Loudness-balance findings and intelligibility scores are treated in terms of the effects of white noise on incidence of auditory fatigue and recruitment, and the relative temporal effects on intelligibility scores.

Polegion, M.J. THE STATISTICAL CALCULATION OF SERVO SYSTEMS. Library Trans. 475, July 1954. 44pp. Royal Aircraft Establishment, Farnborough, England.

The complete book describes the application of a new statistical theory of telecommunication to the problems of servo-mechanisms. Chapter 3 is a study of relays in detail, giving the various types and uses of relays and the problems likely to be encountered in their use. A detailed study is made of the operating time constants for relays both when mounted on a stationary and a vibrating piece of apparatus. This latter has shown the necessity of using a mounting as nearly free from vibration as possible. Chapter 4 details the various mathematical properties which can be used to obtain the probability functions and various types of autocorrelators and similar machines designed to lessen the tedious mathematics which would otherwise be necessary to determine these functions.

Peters, R.M. COMPETING MESSAGES: THE EFFECT OF INTERFERING MESSAGES UPON T-C RECEPTION OF PRIMARY MESSAGES. Contract Memor 22525, Proj. Designation NR 145 908 & Proj. NR 061 064.01.27, Rep. 27, Sept. 1954, 7pp. School of Aviation Medicine, Pensacola, Fla.

6432

To evaluate the effect of interfering messages upon the reception of primary messages, 144 subjects (in 36 listening parties) heard two simultaneous and non-simultaneous messages and were required to respond to only that message designated as the primary message. Six types of message were employed (e.g., same words as primary, unrelated words, nonsense words, and so forth). The data were analyzed in terms of the mean listener reception value under each of the experimental conditions. The condition leading to maximum message interference is discussed along with the positive effect of primary message delay, with relation to the interfering message, at the reception of the primary message.

Peters, R.M. STUDIES IN EXTRA-MESSAGES: LISTENER IDENTIFICATION OF SPEAKERS' VOICES UNDER CONDITIONS OF CERTAIN RESTRICTIONS IMPOSED UPON THE VOICE SIGNAL. Contract Memor 22525, Proj. Design. 145 903, Proj. NR 061 064.01.30, Rep. 30, Oct. 1954, 9pp. School of Aviation Medicine, Pensacola Air Station, Fla.

The ability of listeners to identify a speaker by voice was studied relative to certain restrictions imposed upon the voice signal. These restrictions included: a) high-pass, low-pass and octave-band pass filtering of the voice signal, b) the altering of the relative sound pressure level of the voice signal, and c) the masking of the voice signal by noise. A decrease occurred in correct identifications of voice with increasing amounts of the signal rejected through progressive high-pass or low-pass frequency filtering. For the octave bands considered, maximum correct identification of voices occurred for the octave band of 1200 to 2400 cps. A decrease in listener identification occurred when the voice signal was presented at a relatively low signal level. Listener identification of voices decreased directly as the signal-to-noise-ratio of the masking noise was decreased in the range from a plus to a minus 8 signal-to-noise-ratio.

Polonis, Bernice W. ANALYSIS AND SUMMARY OF FOOD PREFERENCE SURVEY DATA. Contract DA 71 009 QM 19865, Proj. 7 64 15 007, Rep. 5, May 1953, 4pp. USA Quartermaster Food & Container Institute for the Armed Forces, Chicago, Ill.

6436

This report presents a survey of the findings of five food preference surveys of Armed force personnel conducted during 1950 to 1951. The discussion is centered upon the following aspects of the investigations: 1) evaluation of the food preference questionnaire and sampling methods; 2) the stability of food preference data; 3) the relation of individual background characteristics to food preference; 4) the meaning of the scale; and 5) the variation in preference by installation-sampled.

6437

Paulson, E.C. THE PRECISION OF CHOICE REACTIONS. J. exp. Psychol., Feb. 1956, 51, 93-122. (Applied Psychology Research Unit, National Research Council, Cambridge, England).

6437

To determine the relative accuracy between one-choice and two-choice reactions, 16 subjects tracked the center line on a vertically moving paper tape, moving to right one inch or to left two inches upon a corresponding auditory signal. For one-choice reactions the pattern of signals was fixed, for two-choice, random; time intervals of 2.1 and 4.2 seconds were used. A correct reaction had to satisfy a combined criterion of time and precision; errors, reaction times and speed of movement were analyzed for differences between the two types of reactions. Further analysis was made of the "catch tests" in one-choice reactions (signal after 2.1 second occurred only 50 per cent of trials) and applied to tracking behavior in one dimension. T. R 5

Sandel, T.L., Teas, D.C., Fenderson, W.E., & Jeffress, L.A. LOCALIZATION OF SOUND FROM SINGLE AND PAIRED SOURCES. J. acoust. Soc. Amer., Sept. 1955, 27, 842-852. (Contract N0bsr-52267. University of Texas).

6438

This investigation of localization of air-borne sound from single and paired sources employed five subjects throughout three experiments. Three six-inch speakers placed 40 degrees to left, 40 degrees to right and directly at front of subject were used with a fourth moveable speaker to indicate direction of signal source. In the first experiment a single speaker at a time was used; in the second, pairs of speakers were used in phase; and in the third, pairs in phase opposition were employed. Approximately 50 judgments were made by each subject in each experiment. Predicted locations are compared with subjects' responses. The results are discussed in terms of tone localization at various frequencies as a function of interaural time differences and

111 - 708 Intensity differences at the two ears. T. G. T. R 6

Sargent, F., Sergeant, Virginia W., Johnson, R.E., & Stolpe, S.G. THE PHYSIOLOGICAL BASIS FOR TRAINING CONDITIONS IN SURVIVAL RATINGS. PART 1. THE EFFICIENCY OF YOUNG MEN UNDER TEMPERATE CONDITIONS. Contract AF 12(50C) 88, M50 656 81, Tech. Rep. 53 484, June 1954, 50pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

From December 1952 through June 1953, 12 students served in survival ration studies at McKinley Hospital, University of Illinois, Urbana. To establish physiological, biochemical, nutritional, and clinical judgments on the relative effects of water, calories, and ratio of protein, carbohydrates, and fat in all-purpose survival rations, numerous observations were made in recurring periods of adequate, restricted, and recovery diets with known amounts of vitamins at all times. Starvation and a 3000 calorie adequate ration represented the worst and best regimens. 20 nutrient combinations could be rank-ordered, by 19 different tests, with respect to effects on organ function and body efficiency. Below the 3000 calorie control ration, the highest score was obtained by a combination supplying unlimited water, 2500 calories per day, and a distribution of calories of 15% protein, 55% carbohydrate, and 30% fat.

Herrick, J.H. EFFECT OF EXPONENTIAL TYPE CONTROL LACS ON THE SPEED AND ACCURACY OF POSITIONING A VISUAL INDICATOR. Proj. 7182, Tech. Note 55-348, June 1955, 12pp. USAF Wright Air Development Center, Aero Medical Laboratory, Wright-Patterson AFB, Ohio.

6442

To determine the effect exponential type controller system lags have on the human operator's ability to position a visual indicator rapidly and accurately, twenty subjects repeatedly set a pointer to a fixed reference position by means of a rotatable knob. Exponential lags of 9, 40, 120, 360, and 1,000 milliseconds were introduced between control and display. Performance data (steering time, settling time, total acquisition time and excessive entries of pointer into center scoring area) were analyzed as functions of control lag. Further study was made of the extent to which the operator tended to compensate for the effect of lag. Implications for the design of such systems are discussed.

6445

This is a study of the effects of ophthalmic filters as used in protective goggles upon color vision. Four hundred subjects screened with the pseudo-isochromatic tables to include both color normal and color deficient individuals were tested on the SN color threshold tester and the Nagel anomaloscope while wearing each of 12 filters. Readings were made with and without goggles and the filters were presented in a random order. The results are discussed in terms of the relative effect of each of the filters on accuracy of color perception. In addition, the wave length, transmission curve, and spectral sensitivity are presented for each of the filters. Recommendations are offered concerning the utilization of colored protective ophthalmic filters by pilots or for general wear.

Sattzman, R.H., Jr. OPERATIONAL EVALUATION OF MODIFIED B-1A ATTITUDE INDICATOR (3-1/2 INCH SHAFT TWO-TONE). AFG-SAR/398, Sept. 1954, 2pp. USAF Air Proving Ground Command, Eglin AFB, Fla.

An operational evaluation of the Lear 3-1/2" In. Attitude Indicator was conducted by Air Proving Ground Command and the USAF Instructor School during August 1954. The indicator was installed in an airplane and evaluated by 16 different pilots during 4 night and 14 daylight flights. The presentation was found to be from a very satisfactory to superior. Compared to the J-8 indicator, there was complete agreement that this indicator was much more desirable. Although processional errors in some instances were reported to be as great as those found in the J-8, these errors were easier to compensate for accurately and quickly. The ability to make accurate pitch and bank adjustments when at steep climb and dive attitudes was particularly noted by all. (HEIAS)

Schubert, E.D. RESEARCH STUDY OF THE PSYCHO-ACOUSTIC EFFECTS OF HUMAN AND ARTIFICIAL SIDETONE. FINAL REPORT. Contract DA 36-029 ac 42562, Proj. 3 92 12 822, Signal Corps Proj. 17 152B, Oct 1954, 13pp. Lab. Procurement Office, USA Signal Corps Supply Agency, Fort Monmouth, N.J. (5650 University of Iowa, Cedar Rapids, Iowa).

This is a final summary report on 2 years of investigation of effects and possible uses of sidetone. It is a brief overall view of the experiments attempted, the reasoning behind them and the implications of the results. More detailed accounts of most of these experiments have appeared in earlier reports. In addition, 3 supplementary reports dealing with phases completed since the writing of the last quarterly report (July 20, 1954) will follow immediately. The present report points out that there are definite limits beyond which sidetone will cease to affect speaking behavior. Even the untrained speaker will choose to continue speaking without listening to his sidetone if too many changes from the normal speaking situation are introduced into any experiment on sidetone. Though we have not succeeded in measuring body-conducted sidetone directly our present belief is that it consists primarily of energy at the fundamental frequency and possibly a little of the second and third partials. Intelligible signals picked up "from the ear" when the usual airborne signal has been determined do not appear to be the signal which travels directly from vocal mechanism to the inner ear. Delayed sidetone produces some dramatic and interesting changes in speaking behavior. It represents, however, too radical a change from the normal speaking situation to be highly useful as an experimental tool either for modifying speech behavior within the normal range or for investigating the characteristics of the speaking mechanism. All these assertions are discussed in some detail in the text of the report.

Tschobert, V.R., Kneibick, J.L. & Bosch, E.R. STUDIES OF MANUAL DEXTERITY: I. METHODOLOGICAL STUDIES. Proj. 7 95 20 883C, Tech. Rep. EP 3, Nov. 1954, 38pp. USA Quartermaster Research & Development Command, Watrick, Mass.

A series of experiments were designed to isolate the requirements of practical testing procedures for the evaluation of manual dexterities afforded by Quartermaster handgear. The results obtained suggest that: a) There is no general test of manual dexterity; rather, individual tests evaluate specific dexterities. b) The effects of specific test-glove combinations are altered by practice. c) There is probably an optimal method of performing specific tasks with specific handgear items. Thus, the handgear item itself determines in part the specific dexterity measured by a test. d) Fatigue appears to alter the nature of specific dexterities measured by a test. In addition, the authors propose a methodology for evaluating handgear which is based upon the assumption of specific dexterities, and which takes into consideration other factors involved (fatigue, learning, etc.). Related problems for future experimentation are suggested.

Weiss, E.C. & Taylor, A.L. HUMAN ENGINEERING EVALUATION OF TRUCK, 1 1/4-TON, 4 x 4, M151. Proj. TEE 1000 19, Tech. Memo. 21, June 1955, 73pp. USA Human Engineering Lab., Aberdeen Proving Ground, Md.

6449

To evaluate the Army 1 1/4 ton truck, M151, in terms of its man-machine relationships and to provide some generalizations for an optimum vehicle of this class, a human engineering study was made. Specific suggestions are presented for the vehicle and its components in light of anthropometric data supplemented by use of subjects approximating the 5th and 95th percentiles actually performing a given task. Pertinent literature was reviewed and user information from operators of the currently used 1 1/4-ton equipment was obtained. Topics covered are: workspace dimensions (fixed limits, seating), controls, displays, visibility, safety and comfort, and maintenance.

Wechsler, R. & Koskoff, Y.D. EFFECT ON HUMANS OF MODERATE DOSES OF ATROPINE. Contract DA 18-108 CML 5370, MLCR 54, Jan. 1955, 7pp. USA Chemical Center, Chemical Corps Medical Labs., Md. (Montefiore Hospital Institute of Research, Pittsburgh, Penn.).

An investigation was carried out on the effects of large doses of atropine sulfate on humans and monkeys. The Ss were observed for cardiovascular, neurologic, and ELG effects in addition to changes in cerebral blood flow and cerebral metabolism. Findings from the human studies show that with the exception of increased pulse rate and occasional rise in blood pressure, there were no immediate changes observed as the result of atropine. (These Ss were at complete bed rest during the entire study.) Other changes such as pounding headaches, blurred vision, and dryness of mouth appeared 1 to 2 hours after injection of the drug and persisted for about 24 hr. This is a preliminary report on a long-term study.

Crannell, C.W. & Christensen, J.M. EXPANSION OF THE VISUAL FORM FIELD BY PERIMETER TRAINING. Contract AF 18(600)-25, Proj. 7186, WADC Tech. Rep. 55 368, Oct. 1955, 32pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Miami University, Coral Gables, Fla. & Aero Medical Lab., USAF WADC, Wright-Patterson AFB, Ohio).

This is the second in a series of experiments designed to examine the possibility of increasing the size of the visual form field by specialized training. The present investigation was concerned with the effect of various amounts of perimetric training on the visual form field. 5 groups were used: a control group which received no training, and 4 groups which received, respectively, 10, 20, 30 and 40 1/2 hour sessions of training. As in a previous experiment, there was considerable improvement in ability to identify familiar stimuli presented farther and farther from the foveal area, but no evidence of transfer to other stimuli.

Allist, E.A. MWP, ENGINEERING ASPECTS OF AIR TRAFFIC CONTROL SYSTEMS. (Contract AF 33(616) 43, Proj. 2138, Rep. 15, Final Quarterly Report, June 1954, Rep. 2244, Wright Air Development Center, Wright-Patterson AFB, Ohio. (Ohio State University Research Foundation, Columbus, Ohio).

6458
This report is a general summary of a research program in human engineering aspects of air traffic control systems. Included are brief statements of each study completed (purpose, description of methodology, results of results) with references to publications in which complete reports can be found. Areas covered by these experiments were: display of radar information for air traffic control, visibility and lighting, man's capacity as a monitor, information-processing capacities of the human operator, systems research and evaluation, design and development of research equipment.

US Advisory Panel on Personnel and Training Research. SYMPOSIUM ON ELECTRONICS MAINTENANCE. RPT 702/4, Aug. 1955, 21pp. US Research & Development Board, Department of Defense, Washington, D.C.

This symposium on electronics maintenance was chiefly concerned with the personnel and training research and development contributions to the operating and training programs sustained under trouble shooting and maintenance. The first session pertained to the analysis of job activities and contained 5 papers on field research, operator role in maintenance, evaluation of various job analysis methods and specific methods of forecasting maintenance job requirements. Session II, on selection and classification of personnel, presented 3 papers on this topic. Session III, proficiency measurement, described performance tests for various electronics specialties and the development of proficiency measures for technicians and guided missiles, 4 papers. Session IV, effectiveness of training in maintenance activities, contained 3 papers of various approaches to evaluation of training effectiveness, to training for trouble shooting, and on the relationship between operational effectiveness and maintenance minimization and training. Session V, maintenance organization (and teams), presented 2 papers--dimensions of team performance and team training problems and studies in the organization of maintenance. A final session was held to discuss next steps in research and development in this field. (HEIAS)

Southwest Research Institute. DESCRIPTION OF ROTARY PURSUIT TEST MODEL C. Contract AF 18(600) 605, Proj. 7701, Task 77029, Nov. 1954, 23pp. USAF Technical & Training Research Center, Skill Components Research Lab., Lackland AFB, Tex. & Southwest Research Institute, San Antonio, Tex.

This report describes the Rotary Pursuit Test which is used to measure ability of an individual to follow accurately by the "free-hand" method the movement of an object moving rapidly in a repeated curved path. The S is required to follow the contact point of a stylus in contact with the target. The score is based on total time that the stylus has been in contact with target for 5 test trials, each of 10 sec. Test periods of 10 sec. are given between test trials with 20 sec. between groups. The sequence of events during test administration are enumerated with the test and control units described in detail. Photographs and schematic wiring diagrams are included. (HEIAS)

6459
Anderson, C.H., Baker, R.E., Crippen, D.S., McKnight, F.S., et al. EVALUATION OF A TRAFFIC CONTROL MONITOR FOR USE WITH THE PRECISION APPROACH RADAR. Proj. 11 709, Rep. 150, Feb. 1953, 26pp. US Civil Aeronautics Administration, Technical Development & Evaluation Center, Indianapolis, Ind.

This report describes the operational and technical evaluation of an air traffic control aid called the PAR-Traffic Control Monitor. The equipment was designed to monitor aircraft making precision radar approaches and to perform the coordination function between the PAR controller and the departure controller. The equipment is also designed to act as a monitor of the control instructions issued by the PAR controller and to sound an alarm if less than minimum separation develops between aircraft on approaches. The PAR-Traffic Control Monitor includes direct-reading meter indications of the distance from touchdown, the point at which the airplane touches the ground, and of the ground speed of landing aircraft. It also includes means of actuating a no-take-off warning alarm when aircraft on approach reaches a preset minimum distance from touchdown. The overtaking warning alarm is actuated when aircraft on approach have less than minimum separation from other aircraft. Misfunctioning of the equipment is indicated by a no-video alarm. In the evaluation of the monitor, use was made of both actual and simulated aircraft targets. The results of the evaluation tests indicate that the PAR-Traffic Control Monitor in its present form considerably increases the work load of the PAR controller and is not sufficiently reliable to be used in the control of air traffic.

6457
USAF Air Weather Service. THE MILITARY GRID REFERENCE SYSTEM. Tech. Rep. 105-122, Oct. 1954, 12pp. USAF Military Air Transport Service, Air Weather Service, Washington, D.C.

The Military Grid Reference System (MGR) is a method for locating a point on the earth's surface to several of many degrees of accuracy. The MGR for a point consists of a) the grid zone designation--a combination of letters and numbers; b) an identification of the 100,000 meter square in which the point is located; and c) the grid coordinates of the point expressed, in numbers, to the desired degree of accuracy. This manual gives a description of each of these 3 portions of the MGR and contains a section showing how they are combined. (HEIAS)

Atkinson, C.J. RESEARCH STUDY OF THE PSEUDO-ACOUSTIC EFFECTS OF HUMAN AND ARTIFICIAL SIDETONE. SECOND QUARTERLY REPORT. Contract DA 36 639 sc 42552, DA Proj. 3 59 12 022, SC Proj. 17 1328, Jan.-March 1953, 10pp. Department of the Army, Signal Corps Supply Agency, Fort Monmouth, N.J. (State University of Iowa, Iowa City, Iowa).

This technical report covers work done at the State University of Iowa during the period Jan. 1, 1953 to March 31, 1953, on the Sidetone Project, Signal Corps Contract DA 36 639 sc 42552. Three tasks are under active prosecution at present: a.) the procurement and construction of equipment; b.) search of the literature; and c.) determination of natural sidetone paths. These tasks are at various stages of completion, and this report indicates their present status and probable direction.

Baker, P.T. THE EFFECTS OF A HOT-DRY CLIMATE ON CAGES MORPHOLOGY. Rep. 197, Jan. 1953, 21pp. US Department of the Army, Office of the Quartermaster General, Quartermaster Climatic Research Lab., Lawrence, Mass.

This study attempts to discover and assess some of the body structure adaptations that took place when 83 Army personnel were placed in the hot-dry desert near Yuma Test Station, Arizona, for a 2-1/2 month period. Measurements were made on the men just prior to their departure for the Yuma Test Station and for each week during their stay there, and finally upon their return. Analyses of the data show that some amount of circumference and fat was lost in most individuals. There were different amounts and patterns of loss according to racial group and original amount of fat. There was more loss in the extremities than in the torso. It was not conclusively proved that the heat encountered in the desert environment was responsible for the changes found, but it might be assumed that the change from a temperate to a hot-dry climate was at least a contributory factor in a multiple causation. The analysis by type of activity showed that the kind of work done was probably not an important factor in loss. (NEIAS)

6468
Baldwin Company. DEVELOPMENT OF AN OXYGEN WARNING-SIGNAL GENERATOR. FINAL REPORT. Contract AF 33(038) 23313, Rep. AFAC 4, Nov. 1953, 25pp. The Baldwin Company, Cincinnati, Ohio.

A warning-signal generator was developed for operation directly into the headset circuit of the AN/AIC 10 Intercommunication Set. Special attention was directed toward making the tone loud, attention-arresting, and unlike other sounds normally heard by flying personnel. Although intended primarily for use with an oxygen-failure indicator, it will also provide a mixing facility for other separate warning signals.

Balke, B., Grillo, G.P., Konecni, E.B., & Luft, U.C. GAS EXCHANGE AND CARDIOVASCULAR FUNCTIONS AT REST AND IN EXERCISE UNDER THE EFFECTS OF EXTRINSIC AND INTRINSIC FATIGUE FACTORS. A. WORK CAPACITY AFTER BLOOD DONATION AND AFTER EXPOSURE TO PROLONGED, MILD HYPOXIA. Proj. 21-1201 0014, Rep. 1, July 1953, 14pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Work capacity was determined during exercise on the treadmill; heart rate, blood pressure and respiratory gas exchange in response to an increasing work load were used as criteria of performance. Optimal work capacity can be defined objectively in this procedure as the highest work load at which an individual is able to balance the immediate oxygen requirement by exerting circulatory and respiratory functions to capacity. Experiments on the after-effects of blood donation (500 cc.) were carried out on 14 subjects at different intervals after venesection. Within one hour after blood donation the reduction in optimal work capacity was statistically very significant as compared to repeated controls made previously. Test results obtained 48 and 72 hours after blood loss were not significantly different from the normal. Determinations on the 8th and 10th day after blood donation revealed an improvement in work capacity which was statistically significant. After an exposure of 3 1/2 hours to a simulated altitude of 16,000 feet in a low-pressure chamber the same criteria of performance indicated a decrease in work capacity on the borderline of statistical significance. Differences in the behavior of circulatory and respiratory functions under the influence of the 2 fatigue factors employed in this study are revealed and discussed.

6472
Bengoechea, J.R. FLIGHT NOISE LEVEL SURVEY OF RB-57A AIRCRAFT. Task T04P 307L, Tech. Note WCLS-55 1, Jan. 1955, 15pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

A flight and ground noise level survey of the RB-57A airplane was conducted at Wright-Patterson Air Force Base, Ohio on 23 August 1954 and 14 September 1954. The subject survey was conducted in accordance with request contained in suborder from WCLSY-5 dated 14 April 1954, subject, "Cockpit Noise Level". Results of this test indicate that the noise level in the Navigator/bombardier location may be excessive at top airspeed. It is further indicated that additional soundproofing is required to bring sound level in the frequency bands above 600 cps to the desired handbook limits.

 Bilger, R.C. INTELLIGIBILITY OF FIELD TELEPHONE VOICE COMMUNICATIONS THROUGH RESPIRATORS. Contract DA 38 108 ONL 4037, Rep. 10, Nov. 1954, 14pp. Voice Communication Lab., Purdue University, Lafayette, Ind.

6473
 To investigate the relative intelligibility characteristics of three Army respirators (M-9 Standard, M-9 with Voice-mitter, M2-HM1-6 Optical) with respect to telephonic transmission of speech signals, a standardized multiple-choice intelligibility test was used. Two talkers read the word lists through a chest microphone under each of the three mask conditions and a no-mask condition. The listeners heard the voice signals through headphones with in-line noise for all conditions. The intelligibility scores (words accurately heard) were studied by analysis of variance techniques for differences due to transmitters. Findings are discussed in relation to data from previous experiments on these respirators.

 Bogan, J.W., & Barnett, W.E. APPLICATION OF QUEUEING THEORY TO CONGESTION PROBLEMS OF FORWARD AREA COMMUNICATION SYSTEMS. Contract DA 42-025-aa-150, DA Proj. DA 3-92-71-0C1, 30 Proj. 1023, Rep. 57-E-3, Dec. 1954, 83pp.
 Keller, Raymond and Brown, T.C., State College, Penn.

6477
 Queueing theory is the application of the probability theory to problems of congestion, such as congestion of messages on a communication link. The theory is explained and discussed and the simple queueing problem having exponential call lengths, Poisson arrivals, and ordered queueing is worked out in detail for purposes of illustration. This problem, however, does not apply to the communications of a small military organization or a forward area. In the appendixes will be found further examples using various sets of assumptions which have been worked out in the course of developing more realistic models.

 Bilodeau, Ima McD., & Bilodeau, E.A. SOME EFFECTS OF WORK LOADING IN A REPETITIVE MOTOR TASK. J. Exp. Psychol., Dec. 1954, 455-467. (USAF Skill Components Research Lab., Air Force Personnel & Training Research Center, Lackland AFB, Tex.).
 A studies used a simple cranking device with basic trainee assigned to investigate the question of the extent to which the inhibition accrued in a self-paced task varies with work loading. Experiments I and II, holding pre- and posttest loading constant, provided evidence that recovery in rate of responding is independent of work loading across manipulation of duration of pretest work, duration of interpolated rest, and ordinal number of the recovery. The data provided no unambiguous answer to the question of how much, if at all, work loading affects the amount of work inhibition accrued in a self-paced task. In Exp. III and IV the inhibitory effects of 2 loadings were studied by comparing SS shifted from the heavier to the lighter loading with control SS who worked against the lighter loading throughout. In Exp. III the variable was the duration of interpolated rest given after a constant period of pretest cranking, and in Exp. IV the variable was the duration of cranking preceding an instantaneous shift. In general, though not in every case, the post-shift performance of control groups was superior to the performance of groups shifted from the heavy to the light loading. The data thus suggest that a greater amount of work inhibition was accrued in work against the heavier loading, though alternative explanations may be offered to account for the postshift differences. Postshift differences, however, were slight; performance depending more upon present than past work loading; the different rates of responding for heavy and light loadings seemed, thus, to some extent to compensate for the difference in the work required per unit response.

6478
 Bolt, R.H. AIRCRAFT NOISE AND ITS RELATION TO MAN. Report from "Annual Flight Propulsion Meeting, Institute of the Aeronautical Sciences, March 1954, Cleveland, Ohio", March 1954, 26pp. Institute of the Aeronautical Sciences, Cleveland, Ohio. (Massachusetts Institute of Technology, Cambridge, Mass.).

The main ingredients of the aircraft noise problem are discussed in a broad way. The components of the "system", as the author sees it, are source, transmission path, receiver, and effects on receiver. These 4 components are considered in light of what is now known and then of problems that need investigation. Aircraft noise is seen as a system problem. There are possibilities of noise control on many individual parts of this system. The effectiveness of any particular control procedure should be evaluated in terms of its ultimate influence on subjective responses and the whole system designed to yield maximum acceptability at minimum total cost. Bovles, J.W. PRELIMINARY ANALYSIS OF THE THURSTONE COLOR-FORM DOMINANCE TEST. Proj. 7704, Test 77751, Tech. Rep. AFFTC TR 55-1, Nov. 1955, 5pp. Personnel Research Lab., USAF Personnel and Training Research Center, Lackland AFB, Tex.

The Thurstone Color-Form Dominance Test was administered to 8 groups of basic airmen. A series of analyses indicated that the Form score was markedly affected by seating position. This effect was more striking for some designs than for others. Test-retest reliabilities were low. With regard to the Form score, further work with group administration of the test in its present form would seem to be of doubtful value. Any relationship that Form scores might have to other behavior variables would apparently be masked by the sources of variance noted in this report and probably by other extraneous conditions that were controlled in these studies. These findings do not, of course, preclude the possibility that an individual administration of the test under carefully controlled conditions might produce significant relationships to personality variables. A vertical movement score was found to have a relatively wider range, to be less sensitive to seating position, and to be somewhat more reliable than the Form score. It appears to be more amenable to group-administered investigation than does the Form score.

Boynton, R.M. RAPID CHROMATIC ADAPTATION AND THE SENSITIVITY FUNCTIONS OF HUMAN COLOR VISION. J. Opt. Soc. Amer., March 1956, 46, 172-179. Contract Monr-668(06), ONR, University of Rochester.

6489

Bush, W.R. PUPIL LIGHT ADAPTATION AS AFFECTED BY THE SPECTRAL COMPOSITION OF THE TEST AND ADAPTING STIMULI. J. Opt. Soc. Amer., Dec. 1955, 45, 1047-1057. Contract Monr-668(05), ONR, University of Rochester.

6483

To study the sensitivity functions of human color vision, foveal, monochromatic test flashes were delivered 0.05 second after the onset of colored adapting stimuli and threshold determinations obtained by descending method of limits. Five conditions were used each on separate days: absolute threshold, red, yellow, green, and blue adaptation. Within a given session thresholds were determined at each of 29 wavelength settings from 420 to 700 millimicrons for two subjects. The data (negative log relative energy threshold values) are presented graphically. A theoretical analysis of the findings is presented and discussed in terms of color theory.

T. G. R 13

6489

To investigate foveal light adaptation as a function of wavelength, principally during the first fraction of a second, three nearly monochromatic lights (red, green, blue) equated for luminance were employed in all possible adapting stimulus-test flash combinations. The test flash was superimposed in a larger adapting field at intervals varying from -0.15 to +0.45 seconds and thresholds for three dark adapted subjects were obtained by descending method of limits. A second series of thresholds were obtained over an adaptation period of 15 minutes. Thresholds (log millilamberts) for each light were presented as functions of adapting intervals and analyzed in terms of selectivity effects of wavelength.

Brantley, J.Q. APPLICATION OF CONTINUOUS WAVE RADAR IN A POSSIBLE SOLUTION TO THE PROBLEM OF COLLISION PREVENTION IN FLIGHT. Rep. 40, Nov. 1951, 23pp. Cornell Aeronautical Laboratory, Inc., Buffalo, N.Y.

This paper develops the major requirements for a collision warning system. The necessity for detecting the presence of other objects, measuring their range, relative speed, and relative bearing is indicated and the utilization of these quantities for collision warning and avoidance is discussed. The operation of frequency modulated radar is explained and its adaptability to the fulfillment of the requirements shown. Results of an experimental program in progress at the Cornell Aeronautical Laboratory (a subsidiary corporation of Cornell University dedicated to aeronautical research and development) have also been included.

Brewer, D.A. & Wurtele, D.B. SUBMERGED AIRCRAFT POSITION INDICATOR--ORIGINAL IDEA EVALUATION. Rep. 1123, July 1955, 3pp. Central Experimental and Proving Establishment, Royal Canadian Air Force, Ottawa, Ontario, Canada.

The purpose of this project was to determine the possibility and practicability of carrying Sea Markers, fluorescent blocks Ref 33C/232 in an aircraft as a visual aid for searchers should the aircraft come down in water. Water tests were carried out using the fluorescent blocks to determine the amount of marking they would give and the length of time this marking would remain in the water. Tests were carried out by allowing the markers to sink in various depths of water ranging from 3 to 20 feet. The results obtained using the fluorescent Sea Markers Ref 33C/232 indicated it would not be suitable as an aid to search for aircraft.

Bullock, D.H., Braley, L.S. & Meyer, Susan R. RESEARCH ON MULTIPLE-CHANNEL MONITORING. Contract AF 30(602)-574, Prog. Rep. 2, Dec. 1953, 7pp. Psychology Dept., University of Buffalo, Buffalo, N.Y.

A progress report of work completed during the second quarter on multiple-channel monitoring is presented. Small scale parametric studies relating to the development of visual and auditory channels for use in simultaneous monitoring were conducted. In addition, techniques for producing auditory stimuli and for obtaining continuous recording of responses from both individual and group Ss have been developed. These visual and auditory channels are described briefly. (HEIAS)

6493

Chang, S.H., Essigmann, B.W., Phil, G.E., Stubbs, H.L., et al. VISUAL MESSAGE PRESENTATION. QUARTERLY PROGRESS REP. 17. (Contract AF 19(122)-7, Item 1, May-Aug. 1953, 46pp. Northeastern University, Boston, Mass.

Included herein are reports of progress made on the various topics under active study during the period from April 15, 1953 to July 1, 1953. General consideration is given to the tentative block diagram of a speech-analyzer component for use in a proposed speech-compression system. The general scheme employs existing techniques of speech analysis to perform the processes of segmentation and identification of discrete speech units, here defined as phonoids. Treated specifically in this connection are: a) pitch-period indication b) sampling of the clipped-speech waveform for segmentation, c) discriminatory analysis applied to fractional-power measurement for identification, and d) pertinent linguistic studies. Terminal results are reported on the intervalgram studies and on the construction of an electronic analog divider circuit.

Chiles, V.B. EXPERIMENTAL STUDIES OF PROLONGED WAKEFULNESS. Proj. 7193, Task 71612, Tech. Rep. 55 395, Dec. 1955, 16pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

2 experiments were carried out concerning the effects of prolonged wakefulness and of fatigue on performance of psychomotor and psychological tasks. The first experiment involved 4 subjects each of whom sat individually in an aircraft cockpit for 56 hours. During this time, measures of reaction time and alertness were taken, and, at the end of the experiment, 2 of the subjects flew ILS passes in a Link trainer. The reaction time and the alertness measures reflected considerable variability in the attentiveness of the subjects. The performance in the Link trainer was judged to be within the limits of acceptability. The second experiment involved the assessment of the effects of 30 hours of wakefulness with continuous work (painting a barracks) on the performance of 15 subjects on a psychological and a psychomotor task. In addition, the effects of 2 different drugs, d-amphetamine sulphate and cortisone, were compared with those of a placebo. The psychological test involved the summing of rows of figures, and the psychomotor test involved arm-hand steadiness. Each of these tests distinguished, to some extent, the 2 drug groups from the placebo group. It was concluded that the 2 drugs improve performance on the addition test, whereas they tend to decrease arm-hand steadiness as a function of time.

Chinn, H.L., Cannon, V.R., & Frantz, H.E. EFFECTIVENESS OF VARIOUS DRUGS IN PREVENTION OF AIR-SICKNESS. IX. PROTECTION OF AIRBORNE TROOPS. Proj. 21 32 014, Rep. 5, Dec. 1952, 3pp. USAF School of Aviation Medicine, Randolph Field, Tex.

Airborne soldiers received placebo and medication during 2 flights of 5 to 7 hours' duration. The incidence of vomiting for the placebo group was 6.8 percent. The following drugs given immediately prior to take-off significantly lowered the incidence of vomiting: Wellcome 47-83 (50 mg), Phenergan (25 mg), Phenergan (12.5 mg), Trimeton (25 mg), Pyrrolazote (50 mg), and scopolamine (0.65 mg). Postafene (50 mg), given 24 hours prior to take-off also afforded significant protection. None of these medications was superior to the others. The incidence of drowsiness, blurred vision, dry mouth, and fatigue was increased by some of the drugs, while dizziness, sweating, and headache were reduced. Almost 19 percent of the paratroopers became sick during a 60- to 90- minute flight prior to their jump.

Chinn, H.L., Handford, S.W., Smith, P.K., Cone, T.E., et al. FURTHER EVALUATION OF DRUGS FOR THE PREVENTION OF SEASICKNESS. Proj. 21 32 014, Rep. 10, Dec. 1952, 9pp. USAF School of Aviation Medicine, Randolph Field, Tex.

The following preparations afforded significant protection against seasickness when tested aboard Navy transports: Lergigan, Phenergan, Trimeton, Benadryl, Persidol, Pyrrolazote, Wellcome 47-83, Schering preparation 1667, Multargen, Parke-Davis S-45, Trimeton-scopolamine mixture, and Postafene. Lisergan, Probanthine, Isophenergan, Bentyll, Diparcol, Buscopan, Dramamine, Mosidal, Benthine, and Dibenzylene were ineffective. The incidence of seasickness decreases progressively with increasing age between 17 and 39. Similarly, the incidence decreased with increasing weight. Seasickness was least among those quartered amidships, increasing both fore and aft. The probable chemical identity of Phenergan and Lergigan was discussed. The relationship between chemical structure and pharmacological activity was considered.

Churchill, A.V. & Allan, D.G. EXPERIMENTAL DIAL DESIGN: DRML Proj. 164, DRML Rep. 134-1, P.C.C. Proj. 077, 94-20-27, H.R. 103, March 1955, 8pp. Defence Research Medical Labs, Toronto, Ontario, Canada.

This study is concerned with the speed and accuracy with which dials can be read when various principles of scale design are applied. The design factors tested were: black markings on a white background, and white on black; numbers inside the scale, and numbers outside the pointer tip an equal distance from the major and minor scale marks, and a different distance from the major and minor scale marks; standard scale, and staircase scale. The variables were combined to produce 16 different dials. Data were collected in terms of time and error. Analysis permits the following conclusions: a) the black on white contrast dials are read in a significantly shorter time than the white on black; b) scale marks equidistant from the pointer tip show a statistically significant advantage in reading accuracy and a slight, though not statistically significant, time advantage; c) numbers outside the scale show a significantly lower reading error when considering critical pointer positions, i.e. pointer partially obscuring numerals inside scale; d) errors of 10 or less occur more frequently in the right half of the scale, and errors of greater than 10 occur more frequently in the left half of the scale.

Clements, J.A., Johnson, R.P. & Beaton, R. COMPARISON OF VENTILATION OF A HIGH RESISTANCE-LOW COMPLIANCE PNEUMATIC SYSTEM (GAS CASUALTY MODEL) BY MOUTH-TO-MASK INSUFFLATION AND BY A PORTABLE HAND BELLOWS. Res. Rep. 290, June 1954, 19pp. Chemical Corps Medical Labs., USA Chemical Center, Md.

Normal young males can, for at least a half hour, continue the muscular effort necessary for the resuscitation by M-MI or bellows of a human nerve gas casualty manifesting extreme ventilatory hindrance. Under the circumstances of this investigation, maintenance of a competent seal of the mask to the casualty face is possible but is difficult and tiring. This study does not indicate a superiority of either M-MI or hand bellows (as modified for this comparison) with respect to ease of operation or adequacy of casualty ventilation. Further trials of these methods should be undertaken on unconscious human patients, in order to compare their ventilatory effectiveness, and especially to compare their effects on management of the upper airway.

Coakley, J.D., Fucigna, J.T., & Bishop, E.W. HUMAN ENGINEERING REVIEW OF THE RADAR SET AN/CPN-4. Contract AF 30(602)-215, Task Order .05, Rep. 55-64, Nov. 1954, 32pp. RADC, Griffiss AFB, Rome, N.Y., and Dunlap and Associates, Inc., Stamford, Conn.

6502

To evaluate a ground-controlled-approach (GCA) radar set (AN/CPN-4) and to determine needed or desirable design changes, a human engineering review was conducted of this equipment as functioning in a GCA system. A review of GCA procedures and techniques is presented in this report with a description of the CPN-4 equipment and procedures for use. The evaluation of the system includes discussion and recommendations for desirable changes in regard to (1) the load handling capability of the system, (2) the number and arrangement of scopes, (3) the design of search radar, (4) the design of precision radar, (5) the design of the communications system, (6) illumination, and (7) maintenance.

6503

This report presents the findings of a human engineering review of a surveillance radar (AN/FPS 3A) intended for use by the air defense system in either Early Warning sites or Air Defense Direction Centers. The equipment and its place in a functional system are described. The general characteristics evaluated include panel illumination, meters, alarm system for malfunctioning, off-centering procedures of the PPI display, and arrangement of PPI consoles. Appendices contain summaries of specific design features of the various components that need redesign with recommendations included.

Cohan, J. & Senders, Virginia L. FACTORS AFFECTING THE FREQUENCY OF VARIOUS FINAL DIGITS. Contract AF 18(600) 50, Proj. 7185, Tech. Rep. 55 371, Nov. 1954, 13pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

A total of 50,000 numerical responses, obtained from an experiment on the effects of repeated exposures on scale reading, was analysed to determine the effects of several experimental variables on patterns of number preferences. These variables were: exposure time, exposure number, scale graduation, and the final digit of the pointer setting. The last two variables and their interaction proved to be the most influential, but long exposure times and many repetitions of the same setting tended to reduce the amount of rounding. The results are discussed in relation to other work on number preferences, and recommendations are made concerning the design of scales and the methodology of scale reading experiments. Scales designed in accordance with established good design features are less affected by number preference patterns. Scale settings should be equalized or randomized over all the experimental conditions to keep number preference patterns from biasing research data.

Day, W.E. & Beach, Barbara R. A SURVEY OF THE RESEARCH LITERATURE COMPARING THE VISUAL AND AUDITORY PRESENTATION OF INFORMATION. Contract W33 038 AC 21269, AF TR 5921, Nov. 1950, 14pp. USAF Materiel Command, Wright-Patterson AFB, Ohio. (University of Virginia, Charlottesville, Va.).

6513

This review was oriented around two questions: 1) "Is material more easily understood when presented visually or aurally?" 2) Under what conditions and to what extent is each of the methods more efficient with respect to the comprehension of material? The findings were grouped according to the type of material presented; e.g., nonsense syllables, meaningful prose. From these data, several conclusions were drawn which point out the specific conditions under which each of the systems is superior. Implications for future communications research were outlined in five general areas: type of material, characteristics of human receiver, method of presentation, measure of intelligibility, and conditions of reception.

Cowland, Iris M. THE NUMBER OF CASUALTIES ATTRIBUTED TO THE CARELESS OPENING OF VEHICLE DOORS. Note RM/1905/INC, Feb. 1953, 7pp. Road Research Lab., Department of Scientific and Industrial Research, Harmondsworth, Middlesex, England.

An analysis of accidents during the first 6 months of 1951 shows that about 4 per cent of pedal cyclist casualties are attributed by the police to "driver negligently opening door of vehicle." No type of vehicle can be singled out as being particularly likely to be involved in this type of accident but there is some indication that certain makes of cars and goods vehicles are relatively more often involved. It is thought that about 2,000 casualties per year, including about 1,900 casualties to pedal cyclists, can be attributed to this factor. The number of casualties of this kind to pedal cyclists appears to be increasing.

Daniels, F., Jr., Vanderbie, J.H. & Winsmann, F.R. ENERGY COST OF TREADMILL WALKING COMPARED TO ROAD WALKING. Rep. 220, Aug. 1953, 10pp. Research and Development Lab., Office of the Quartermaster General, Department of the Army, Natick, Mass.

A comparison has been made between subjects walking at 3 1/2 mph on the treadmill and walking over roads and cinder tracks at the same speed. It has been found that the road or cinder track condition involves an average energy expenditure 9 to 10 percent greater than that for the treadmill. This is believed to be caused by a difference in the body mechanics while walking under these 2 different conditions. This difference must be taken into account in extrapolating climatic chamber and other treadmill data to field conditions.

Daniels, F., Jr. & Madden, R. ENERGY EXPENDITURE DURING SOME SUBARCTIC BIVOUAC ACTIVITIES. Proj. 7 64 12 004D, Tech. Rep. EP 20, April 1956, 17pp. USA Quartermaster Research and Development Center, Natick, Mass.

The energy cost for the performance of certain activities was measured at Fort Churchill, Canada. The energy costs varied from about 40 Cal/m/hr. (in sleeping bag at night) to about 325 Cal/m/hr. (simulated infantry assault), an 8 fold increase. Other activities, such as cutting snow blocks, chopping ice, pitching tents, etc., were also measured and the energy costs were in the range 200-300 Cals/m/hr. The importance of these findings to the design of Arctic clothing is discussed.

Babaglis, G.C. WINTER ARCTIC CAMOUFLAGE INVESTIGATION. Proj. 8 31 OR 004, Rep. 1234, Dec. 1952, 71pp. NSA Research and Development Lab., Fort Belvoir, Mo.

This report covers the winter Arctic camouflage investigation made to determine the visual coloration and related camouflage aspects for application to personnel clothing and related equipment to be used in winter Arctic and subarctic terrain. The investigation was conducted at Fort Churchill, Manitoba, during the period from Nov. 1950 to April 1951. The investigation was broken down into studies of three major items: overwhite fabrics (a 2-piece garment worn over the environmental clothing), colored fabrics, combination dress, personal equipment, and personnel equipment. During each of these studies, observations were made in all available terrain, weather conditions, and in all critical angles of illumination. It is recommended that: a) the overwhite uniform and raincoat cover be achromatic and have a glossless and a reflectance of 95% or more when worn over an olive drab fabric; b) a reasonable whitening compound for washing and duck personal equipment and a cleaning compound for white felt boots and mittens be developed; c) the rifle be provided with a white cover; d) personal equipment, such as skis, snowshoes, wall sleds, and other low silhouette equipment, be painted a permanent achromatic white with a minimum reflectance of 85%; e) tunings should be reversible, white on 1 side and olive drab on the other, or it should have white covers, the white being achromatic and having a reflectance of 85% - 95%; f) achromatic fluorescence be further investigated for application to overwhites; g) a white face veil, mask, or shield be developed to reduce conspicuousness of the parts head opening; h) the GQ-7 pants, with a band-down for roll and less glossiness, be used for outer garments to blend with the vegetation of the winter subarctic.

Bishop, F. & Peterson, J.L., Jr. REGENERATION OF ACCELERATIVE FORCES ACTING ON MAN IN FLIGHT AND IN THE UNDERGROUND. Proj. DA 001 052 04 01, July 1953, 225pp. NSA School of Aviation Medicine, Pensacola Air Station, Fla.

The present text endeavors to provide in a single volume most of the basic mathematics, physics, and elementary aerodynamics required for the investigation and understanding of the effects of acceleration on man. Although directed primarily to the aviation physiologist and flight surgeon, much of the material is pertinent also to the biologist engaged in studies of the effects of acceleration on animals and plants. In addition, the presentation should be intelligible to pilots and other aviation personnel who have had some grounding in physical sciences. The chapters are intended for study in their numerical order, but an idea of the overall approach may first be gained by reading the "Chapter Summaries" in conjunction with the Table of Contents. Physiologic responses in general correlate most readily with forces determined from the standpoint of an observer moving with the actual subject, rather than with force patterns calculated in terms of some stationary terrestrial reference frame, as is more usually done in ordinary mechanical studies. Chapter IV endeavors to bridge the gap between these "internal" and "external" viewpoints and to define precisely their relationship; in the past the distinction has not always been made with sufficient clarity by acceleration physiologists. The preceding chapters actually cover standard classical mechanical analysis, while in subsequent chapters the treatment is primarily from the special "physiological" viewpoint.

Bulch, J.P. & Schubert, E.D. STUDY OF BODY-CONDUCTED SIDETONE. Contract DA 36 039 SC 42562, Suppl. Rep. 6, Oct. 1954, 64pp. NSA Signal Corps, Washington, D.C. & State University of Iowa, Cedar Rapids, Iowa.

In order to study the signal which reaches the talker's ear through paths other than air during speech it is first necessary to attenuate the usual air signal. This was attempted in the study reported here by building a special "mouth-box" into which the talker spoke and a pair of "ear-boxes" to afford additional attenuation at the ears. Special materials are required to furnish adequate seals at the mouth and at the junction of the ear-box and the skull. Additional complications arise because the entire skull is vibrating to some extent during speech, and this appears to create more unwanted sound pressure under the ear-box enclosure than was anticipated. Further investigation revealed that a similar unsuspected sound pressure was present under ordinary earphone cushions during speech. Removal of this extra pressure by "cancelling" it leads to strange subjective impressions of difficulty of production of voice and unusual changes in apparent location of the source of one's own speech. The initial aim of obtaining a measure of body-conducted sidetone was pursued somewhat further by constructing a microphone probe which presents a resistive load to the ear, but the most promising means of estimating the spectrum of this signal is a non-loading capacitive pickup, currently under construction.

Drummond, R.R., & Lackey, E.E. VISIBILITY IN SOME FOREST STANDS OF THE UNITED STATES. Contract DA-44-109-ga-1019, Proj. 7-83-05-0048, Tech. Rep. XP-16, May 1955, 25pp. Quartermaster Research & Development Center, Watlik, Mass.

6520

To measure the effect of vegetation cover on continuous visibility (greatest distance to which a quiet, erect, stationary man can be kept in constant view as the observer goes away from him), 392 stands of vegetation in various parts of the United States were classified according to the nature of both primary growth and undergrowth (Kuchler's system). A standard visibility object (green cylinder simulating the dimensions of a man with military equipment) was used for making visibility determinations (in yards). Measurements were made in both summer and winter months. Data were organized and presented in tables, graphs, and maps to show limits of visibility under various conditions. Further study is recommended.

Egan, J.P., Gerjuoy, H., Shwing, E.J. CORRELATION BETWEEN ARTICULATION SCORES FOR SPEECH MASKED BY NOISE AND FOR SPEECH MASKED BY SPEECH. Contract AF 16(600)-571, Tech. Rep. AFRC-TR-56-52, May 1956, 9pp. GRO, AFRC, Bolling AFB, Washington 25, D.C. (Indiana University).

6523

To determine the degree of relationship between the ability to receive speech in a background of similar speech and in a background of noise, three experiments were performed. In each the subjects (297 in all) were given two articulation tests in a background of each type. In the first experiment, the test consisted of individual words; in the second and third, a five-word sentence test. In the last two tests, the cue for differentiating signal message from interfering speech was either differential intensity or differential quality. The data (number of correct words received) obtained for each of the abilities were compared by calculating the product-moment correlation between them.

Fisher, J.E. & Spence, K.W. MAJOR AND INTERACTIVE EFFECTS OF SEVERAL VARIABLES ON REACTION TIME. Contract AFM 5587, Proj. NR 154 117, Tech. Rep. 3, March 1955, 24pp. Office of Naval Research, Washington, D.C. (State University of Iowa, Iowa City, Iowa).

Eighty college students served as Ss in an investigation of the joint effects of manifest anxiety, experimental stress, stimulus brevity, sex, and practice on simple and complex RT. The results showed significant positive relations between speed of response and stimulus intensity, practice, and task complexity. Men were faster than women. No main effects were found for manifest anxiety or for experimentally-induced stress. There was a highly significant interaction between sex and task complexity and a marginally significant interaction involving sex, task complexity, and stress. Failure to substantiate previous findings with respect to the influence of anxiety and stress indicates the need for more information concerning the specific conditions of which their effects are a function.

Felton, W.W., Fritz, E. & Coker, G.W., Jr. COMMUNICATION MEASUREMENTS AT THE WASHINGTON NATIONAL AIRPORT FEBRUARY 1953 TO JUNE 1957. Contract CCA 26386, Tech. Rep. 1 285 2, Feb. 1957, 107pp. Air Navigation Development Co., The Franklin Institute, Philadelphia, Penn.

The main purpose of this report is to describe and analyze the use of air-ground voice communications at Washington National Airport during the measurement period. The study as a whole is intended to develop techniques for analyzing voice communications and to provide quantitative information about them. The information and the techniques may be used in two ways: to promote the best use of voice communications, to the end that assigned channels may be used more efficiently, and to guide, as required, the development of proposed systems of communications. Some of the main findings are: pilots and controllers are not able to use a single air-ground channel 100% of the time; amount of communicating time per aircraft limits the estimated maximum number of aircraft under simultaneous control per channel; the average message length is small (3.5 sec.); approx. 80% of all messages occur in conversations; message overlap is infrequent; communications in landing employ a wide variety of types of information.

5526

Fitts, P.M. & DeLongor, R.L. C-R COMPATIBILITY: CORRESPONDENCE AMONG PAIRED ELEMENTS WITHIN STIMULUS AND RESPONSE SETS. Contract AF 33(688) 10528, Proj. 77X, Task 77133, AFFWC TR 55 62, 1955, 10pp. USAF Personnel Research Center, Lackland AFB, Tex. (Ohio State University, Columbus, Ohio). (Reprinted from J. exp. Psychol., Dec. 1954, 48(5) - 483-472).

5526

This is an investigation of maximum stimulus-response compatibility for maximum rate of information as a function of the degree of agreement between stimulus and response elements with a population stereotype. One hundred Ss were given a series of stimulus-response ensembles consisting of two spatial stimulus sets and two symbolic stimulus sets. Pairing of stimuli with responses occurred in such a fashion as to provide maximum mirrored, and random stimulus-response correspondence. Results are discussed in terms of the relative performance under each of the three conditions of stimulus-response pairing.

Kolstoe, R.H., Czech, R.S. & Rozzan, G.B. ORDNANCE IFC ELECTRONICS MAINTENANCE PERSONNEL: ANALYSIS OF FIELD ACTIVITIES WITH IMPLICATIONS FOR TRAINING. Part II-T-38, Tech. Rep. 37, March 1957, 100pp. Human Resources Research Office, George Washington University, Washington, D.C.

5529

To be able to specify actual job requirements for electronic repair personnel, data were gathered from 182 officers and enlisted men from two training school programs to determine: 1) nature and frequency of tasks performed, 2) level of proficiency of the man, 3) nature and extent of on-the-job training and 4) relationship between job requirements and specific aspects of the training program. The men were compared in terms of pre-army background experience, type of job activity, number of months of field experience needed for new graduates to become satisfactory helpers, difficulty experienced in use of more complex equipment, preferred on-the-job training experience and so forth. Recommendations are made for modifications in training program.

6530

Frick, F.C. INFORMATION TRANSMISSION THROUGH THE HUMAN OPERATOR. ca. 1954, 11pp. USAF Human Factors Operations Research Lab., Belling AFB, Washington, D.C.

This report gives a generalized summary of work in progress on the development of a quantitative description of human performance that would be of use to the engineer. The use of communication theory is said to have made this task possible; thus the task of the human operator within a complex system is seen as data or information processing, and his function as transmission of information. Thus it is necessary to know something of the operator's bandwidth (informational capacity) and his characteristics as a communication channel. The author feels from his evidence that 50 bits/sec. is the maximum rate of transmission through a human channel with 30 bits/sec. coming closer to the actual rate; thus he sees man as a narrow band channel. The need to pre-filter information by coding to minimize delays is discussed along with ways of solving this problem. Man's discriminative capacity appears to be relatively fixed and not a function of the particular dimensions of the signal space or display but on the ratio between the physical difference of signals and total range of permissible variations. The practical implications of this finding are noted. Multi-dimensional coding possibilities are discussed briefly. (MEAS)

6531

Russell, G.W. & Boyston, T.E. DEVELOPMENT OF AN EXPERIMENTAL MODEL SPEECH ANALYZER. FINAL ENGINEERING REPORT. Contract AF30(602) 395, Sept. 1954, 105pp. USAF Rome Air Development Center, Griffiss AFB, N.Y. (Nelpar, Inc., Alexandria, Va.).

The purpose of the present program was the development of a speech analyzer to work in conjunction with the previously developed speech synthesizer in order to form a complete experimental voice channel compression system. The object of this compression system was to enable the direct transmission of a spoken message, with no loss in time, over a channel with a bandwidth of 100 cycles or less. Although the message must be reproduced audibly at the receiving end, it is necessary to transmit only the intelligence contained in the word content of the message. The developed analyzer successfully recognizes some 12 vowel-like sounds, but only 4 to 6 are recognized reliably when operated in conjunction with the synthesizer as a system. Although during the synthesizer development some 57 sounds were found adequate to create intelligible speech by the patching technique, it was found impossible to recognize these as basic sounds in the analyzer development. In addition, qualities of the basic sounds which remained invariant with time for the same voice were difficult to discover; the problem is much more severe, of course, for a range of voices. However, these results do not imply that there is fallacy in the basic assumption that speech is redundant and that by removing this redundancy the bandwidth can be compressed to a fraction of normal. In fact, the forward strides made in this field during this period indicate that future work should prove fruitful. It is recommended that further work in this field follow a continuous analysis approach as represented by the parametric method. This technique shows considerable promise as an immediate answer to the problem of a practical speech compression system.

Gell, C.F. & Hunter, H.M. PHYSIOLOGICAL INVESTIGATION OF INCREASING RESISTANCE TO BLACKOUT BY PROGRESSIVE BACKWARD TILTING TO THE SUPINE POSITION. Proj. NM 001 060, Study NM 001 060. 01, Rep. NM 001 060.01.03, TED MACC AE 6300, June 1954, 26pp. USN Air Development Center, Aviation Medical Acceleration Lab., Johnsville, Penn.

A supine seat, capable of back tilting at 10° increments to 85° backward tilt, was built and installed on one of the swinging platforms of the Aviation Medical Acceleration Laboratory Centrifuge. In this, as in previous studies, it was demonstrated that when fully supine, exposure to 15 transverse G can be tolerated for 5 seconds with no indication of impending blackout. It was further demonstrated that at 77° backward tilt the antiblackout protection did not exceed that protection afforded by an inflated anti-G suit with the subject in the upright seated position. This study indicates that to receive the full protection against blackout afforded by supination the subject must be back tilted beyond 77°. A close relationship was observed between the degree of backward tilt of the seat, the vertical angle of the retinal-aortic dimension, and the degree of blackout protection afforded.

Gibson, J.J., Purdy, Jean & Lawrence, Lois. A METHOD OF CONTROLLING STIMULATION FOR THE STUDY OF SPACE PERCEPTION: THE OPTICAL TUNNEL. J. exp. Psychol., July 1955, 50(1), 1-14. (Cornell University, Ithaca, N.Y.).

A method is described for inducing and controlling a perception of surface and space. Conclusions are: a) There is evidence that surface quality depends on the density of transitions in the optical stimulus. When the transitions are absent, surface quality disappears. b) There is evidence that the gradient of texture density in isolation need not always determine the qualities of slant and recession. It is ambiguous, but only with respect to the members of a family of surfaces. c) There is evidence that the gradients of textural disparity and motion can determine the qualities of slant and recession. Presumably when the gradients are concomitant, ambiguity is removed.

Goldstein, A.G. JUDGMENTS OF VISUAL VELOCITY AS A FUNCTION OF LENGTH OF OBSERVATION TIME. Proj. 6 95 20.001, Subtask S 2, Rep. 239, May 1956, 15pp. USA Medical Research Lab., Fort Knox, Ky.

To investigate the effect of increasing prior exposure to visual movement upon apparent (subjective) velocity judgments of this movement, 29 subjects observed moving stimuli and made velocity judgments by moving a stylus over a contact bar at same speed as stimulus. Three physical velocities (approximately 2.4, 4.8, and 14.3 centimeters per second) were viewed for six different observation periods (2, 8, 15, 22, 30, and 60 seconds). The data (time in seconds to move stylus across the bar) were subjected to a non-parametric analysis of ranked data for evidence of a systematic relation between duration of time of observation of a moving stimulus and its apparent velocity. Implications of the findings for practical situations were discussed.

Gray, R.F. THE EFFECTS OF TONIC ELECTRICAL STIMULATION AS A MEANS OF COMBATING ADVERSE CIRCULATORY DISTURBANCES CAUSED BY ACCELERATION. Proj. NM 001 060, Study NM 001 060.12, Repts. NM 001 060.12.62 & NM 001 060.12.63, Jan. 1955, 14pp. Aviation Medical Acceleration Lab., USN Air Development Center, Johnsville, Penn.

Electrical stimulation which caused strong painful contractions of the muscles of the abdominal wall did not significantly increase the G-level at which the subject lost sight of peripheral lights. Nor was there a significant increase in the G-level at which peripheral light loss occurred when the muscles of the thighs were contracted by the electrical current. Because of the low protection afforded and the high degree of subject discomfort, this method of protection against G-force is considered to be impractical.

6539

This document describes the Volcan Air Traffic Control System, an automatic device for converting randomly arriving aircraft into an orderly flow of entry into the final approach path at the precise instant the landing system is ready. The system is reported able to handle 120 jet aircraft or 125 turbo aircraft per hour on the basis of field tests.

Guedry, F.E., Jr. & Kalter, H. DESCRIPTION OF HUMAN ROTATION DEVICE. Proj. 6 95 20 001, Subtask AMRL 55, Rep. 242, May 1956, 17pp. USA Medical Research Lab., Fort Knox, Ky.

A turntable was constructed for rotating Ss positioned within a radius of 3 feet from the center of rotation. Recorded performance of this device indicates that control of angular velocity is excellent. Control of angular accelerations and decelerations below 30°/sec. is very good and easily obtained with a cam system for driving the speed control potentiometer. Accelerations of 60°/sec. and decelerations of 50°/sec. can be obtained with the cam control system. However, to obtain these higher magnitudes, the cam must be cut to compensate for a lack in linearity of response. The system provides sufficient range of angular velocities and angular accelerations for conducting a wide variety of experiments in vestibular research.

Hall, J.F. & Polte, J.W. THERMAL INSULATION OF PROTECTIVE CLOTHING (PART 3). Tech. Note WCRD 53 37, Dec. 1953, 30pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

Thermal insulation of various types of USAF standard and experimental clothing items and assemblies has been determined with electrically heated copper manikins, and hand and foot models. Light, medium and heavy clothing types; sleeping bags; as well as hand- and footgear were included in the test measurements. The described method was developed at the Aero Medical Laboratory and results are expressed in "clo" units. Accuracy of the method ranges from ± 2.4 to $\pm 10.0\%$. Measurement of protective clothing insulation with this method serves as an effective screening procedure in the development of new and improved clothing end-items.

Hartman, B.O. GRAPHIC TIME-ON-TARGET: A TRACKING SCORE WITH BOTH QUALITATIVE AND QUANTITATIVE ASPECTS. Proj. 6 95 20 001, Subtask AMRL S 1, Rep. 245, June 1956, 14pp. USA Medical Research Lab., Fort Knox, Ky.

A technique for graphically recording time-on-target is described, which permits the experimenter to record the functioning of scoring clocks and counters. The resulting record is relatively simple to score and appears to be sensitive to intra- and inter-trial changes in performance. This record evaluates the relationship between quantitative measures of performance and the temporal and spatial characteristics of the S's responses.

Hecht, K.F. GROUND TESTS OF A PILOT EJECTION SEAT EJECTED THROUGH MONOLITHIC-, REINFORCED-MONOLITHIC-, AND LAMINATED-TYPE CANOPIES. Tech. Rep. 53 361, Oct. 1953, 20pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

5 tests were conducted by the Aircraft Laboratory, Wright Air Development Center, Wright-Patterson Air Force Base, during the latter half of 1951 to determine the feasibility of ejecting pilots through canopies in the event of a canopy release failure. For 3 of the tests the ejection seat and dummy were fired through a monolithic-type canopy used on the F-86A aircraft; the remaining 2 tests were through an F-84 reinforced monolithic-type canopy and a B-47 laminated-type canopy. Ejections were accomplished by duplicating the mechanisms involved in actual flight. Motion picture cameras and metering devices recorded the data. The results of the tests indicate that the trajectory of the seat and pilot after ejection through the canopy is not seriously affected and adequate tail clearance will still be attained.

Horgan, F.D. SLEEP MEASUREMENTS: PSYCHOLOGICAL, PHYSIOLOGICAL AND MEDICAL. Biblio. Series 31, Nov. 1953, 33pp. USA Quartermaster Research and Development Labs., Philadelphia, Penn.

This literature search centers about measurements of sleep and conditions of sleep, that is, measurement of the depth of sleep, the recuperative value of sleep, the determination of when an individual is asleep, relative difference in quality of sleep, the restfulness of sleep and the effect of environmental and other conditions upon the depth and quality of sleep. The scope of the present survey encompasses the psychological, physiological and medical literature. Such related areas as problems of consciousness, hypnosis, narcotics (anesthetic and drug), the hypnagogic state, and the narcoleptic conditions, such as cataplexia and narcolepsy are considered in the present search. No specific limitation has been placed upon the span of coverage, the time element being slanted to cover the intent of the survey. Hence the period covered varies with the relevancy of material found in the particular abstract or periodical source from which the survey abstract was taken. Since most of the abstracts fall within the years 1937 to date, it may be said that the present compilation gives a good cross section of the literature of the past 15 years. Where abstracts on the subject have already been prepared in abstract bulletins, or in the abstract sections of technical or trade journals, such abstracts were used in the survey, and credit given them as a source in subscript symbols placed at the end of the abstract. Abstract sources used include: a) Biological Abstracts, b) Chemical Abstracts, c) Science Abstracts, d) British Abstracts, e) Psychological Abstracts, f) Journal of Mental Science, g) Science Digest, h) Journal of Clinical Psychopathology, i) Science News Letter, j) Quarterly Cumulative Index Medicus, k) Index to Periodical Literature, and l) Current List of Medical Literature. Arrangement of entries is alphabetical by author. Anonymous entries are listed alphabetically by source.

Ittelson, M.H. & Ames, A., Jr. ACCOMMODATION, CONVERGENCE, AND THEIR RELATION TO APPARENT DISTANCE. J. Psychol., 1950, 30, 43-62.

The problem posed in this paper was that of determining whether a change in apparent distance alone will induce a change in accommodation and convergence. Static size change-monocular. Different sizes of a familiar object (playing card) were presented one at a time at a distance of 32 in. Measures of apparent distance, accommodation, and convergence were taken. For 4 out of 5 observers, apparent distance of the double-size card was an average of 1/4 that of the half-size card, accommodation when viewing the double-size card was an average of .25 diopters nearer than when viewing the half-size card, and convergence followed the same pattern. Continuous size change-monocular. The projected image of a playing card which continuously changed size from normal to 1/3 size was viewed from a distance of 16 in. Introspective reports of 4 observers indicated that apparent distance changed continuously with the size of the image, the card appearing to move back and forth as it grew smaller and larger. Measures of accommodation showed an average of .46 diopters nearer for the large size than for the small size. Convergence measurements indicated similar results. Continuous size change-binocular. The same stimulus configuration was used as above. Introspective reports indicated a distinct impression of movement. Some blurring of the images suggested a shift in accommodation. Severe feelings of muscular strain about the eyes were reported after a few minutes.

Hershkovitz, J. EVALUATION OF GAI-PHONE DIAL TELEPHONE STATIONS FOR SPEECH COMMUNICATION IN HIGH AMBIENT NOISE LEVELS. Lab. Proj. 5467-2, Jan. 1955, 7pp. Material Lab., USN, New York Naval Shipyard, Brooklyn, N.Y. (Gai-Tronics Corporation, Reading, Penn.)

Measurements have been made of the electroacoustic properties of the Gai-Phone in combination with other telephone stations. These show that after correction of several defects the Gai-Phone could be substituted for a standard type telephone and provide an adequate level to the line. A psychoacoustic evaluation has been conducted to determine its efficiency in high noise ambients relative to standard type telephone stations. The Gai-Phone was found to be superior to the other phones at high noise levels. Results lead to the recommendation that Bureau of Ships should consider procurement of a telephone station along the lines of the Gai-Phone (i.e., noise cancelling microphone, linear transducer, electronic amplifier for receiving and transmitting, slide-tune control) but ruggedized to survive Naval usage.

Inoué, H.A. EVALUATION OF EYE EXAMINATION, NUSAV FORM 1, Proj. X-395 (AV 213 k), June 1947, 29pp. USN School of Aviation Medicine and Research, Pensacola, Air Station, Fla.

In order to evaluate the visual portion of the flight physical examination, 350 Naval Aviators, recently returned from combat or operational tours of duty, were given a complete eye examination, including all of the tests required for flight status. The subjects presented very superior scores of visual acuity and near vision, low refractive errors, mild degrees of anisometropia and normal variations of heterophoria. Their stereoscopic depth perception was no better than that found in an average population having normal vision. The compensatory fusional innervation varied from extremely poor to very high, and the amplitude of accommodation varied widely as compared with that expected according to standard age tables. Only 2 subjects failed the color vision test plates, but the color deficiency was not great. About 10% of the subjects reported diplopia with the red lens test, especially in the upper field; however, no evidence of paralysis or paresis was found. In general, it can be stated that these subjects, who were selected originally for superior visual capacity, retained their superiority. Their visual acuity, however, was considerably above the passing standard of 20/20, whereas their stereoscopic depth perception was not outstanding.

Jerison, M.A., et al. EFFECT OF ACOUSTIC NOISE ON TIME JUDGMENT. Contract AF 18(600) 50, Proj. 7193, Tech. Rep. 55-358, Oct. 1955. 12pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

14 volunteer male undergraduates with normal hearing were asked to press a telegraph key at 10 minute intervals while working on another job that kept them almost completely occupied. In a 2-hour control session the overall noise level was about 77.5 db. In another 2-hour experimental session the first half hour was in the 77.5 db noise field and the last one and one-half hours were in an overall noise field of about 111.5 db. The lower noise level served as a measure of performance under "normal" conditions and also to mask extraneous laboratory noises, and the higher noise level provided the experimental condition studied. It was found that under quiet conditions subjects responded about every 9 minutes on the average. Under noise conditions subjects responded about every 7 minutes. The difference between time judgments in noise and quiet was significant at the .02 level. It is concluded that noise affects time judgments as measured in this experiment. The results are discussed in terms of effects of motivation on time judgment and in terms of a neural model for the construction of subjective time involving the normal activity of the central auditory nervous system.

6558 Taylor, H.L., Anderson, J.T., Buskirk, E., et al. THE EFFECT OF A LOW CALORIE CARBOHYDRATE DIET WITH HARD WORK ON THE BODY COMPOSITION AND PERFORMANCE CAPACITY OF YOUNG MEN. Contract DAM 109 on 1526, Proj. 7 84 12 011, Rep. 1, 13pp. Quartermaster Food & Con-tainer Institute for the Armed Forces, Chicago, Ill. (University of Minnesota, Minneapolis, Minn.).

A study of the effects of a daily intake of 580 calories derived from carbohydrate for 12 days on the body composition and performance capacity was carried out. 12 Ss were divided into an experimental (E) and a control (C) group of 6 men each. The E group went through a control period of 11 days, a 12-day period of caloric restriction, and a rehabilitation period of 15 days. The C group followed for 38 days the same activity and testing program as the E group but did not eat the survival rations. Physical activity included a 4.5 mile road walk, an hour's walk on a motor driven treadmill, and a run to exhaustion every other day. Among the findings were: E group lost, on the average, 7.2% of their initial body weight; the plasma and thioyanate space did not decrease; it was estimated that an average of 2.47 kg of fat and 3.15 kg of active tissue were lost; during the semistarvation period the men lost an average of 85.5 grams of Nitrogen or 534.3 g of dry protein; speed and strength measurements showed no significant deteriorations. Klemmer, E.T. TIME UNCERTAINTY IN SIMPLE REACTION TIME. J. exp. Psychol., March 1956, 51(3), 179-184. (USAF Operational Applications Lab., Bolling AFB, Washington, D.C.).

6562

In an investigation of the role of time uncertainty in simple reaction time, six Ss were presented with two series of reaction-time tests. In the first series, a warning click was presented at 11-second intervals and changes in foreperiod variability and mean foreperiod were investigated. In the second series, spacing between stimuli was investigated (with no warning click). The results are presented and discussed in terms of reaction time as a function of foreperiod variability, mean foreperiod, and the immediate foreperiod.

Krumm, R.L. & Kirchner, W.K. HUMAN FACTORS CHECKLISTS FOR TEST EQUIPMENT, VISUAL DISPLAYS AND GROUND SUPPORT EQUIPMENT. Contract AF 29(501) 175, Proj. 7800, AFSC TN 56-12, Feb. 1956, 5pp. USAF Special Weapons Center, Kirtland AFB, N.M. (American Institute for Research, Pittsburgh, Penn.).

This report consists of a series of checklists intended to aid in the human engineering analysis of general design features of certain types of equipment. The checklists can be used to identify human factors design deficiencies. Since deficiencies in design contribute in varying degrees to system degradation, the checklists are scaled to indicate design characteristics that are minor, important, and serious. In their present stage of development, the checklists are a diagnostic tool; they point out equipment shortcomings which require improvement and they suggest the relative seriousness of these shortcomings. It is possible that field experimentation will lead to refined scoring techniques so that various pieces of equipment can be compared on a more precise quantitative basis.

Kryter, K.D. NOISE SAFETY CRITERIA. A.M.A. Arch. Industr. Hyg. Occup. Med., 1952, 2, 117-120 (NRL, Bolling AFB, Washington, D.C.).

Noise conditions are described and their effects on people are reviewed. The discussion is restricted to more or less steady-state or regular noise at intensities such as may be found in heavy industrial factories. On the basis of present knowledge 3 rather tentative safety criteria for this type of noise are proposed: a) Criterion for voice communications: For perfect work conditions in offices or other work situations in which person-to-person voice communication at near conversational intensities is required, the noise or 'unwanted sound' spectra should not exceed about 40 db. re 0.0002 dyne/sq. cm. at 2,000 cps or for the critical band at that point and even less at higher frequencies. b) Criterion for deafness: For work situations requiring minimal amounts of voice communication the maximum safe intensity for exposure for indefinite periods is around 85 db. re 0.0002 dyne/sq. cm. for tones or critical bands in the case of noises of continuous spectra. This 85-db. criterion is an extra safe figure; further research will probably indicate the necessity for revising this value upward for the frequencies below 1,000 cps and above 3,500 cps. c) Criterion for non-auditory work output: Except for possible damage to the ear, regular or expected noise as high as 100-110 db. re 0.0002 dyne/sq. cm. per critical band can be tolerated with no detrimental psychological or physiological effects, provided the worker has had sufficient time to adapt.

Sanders, Virginia L., Cohen, J. & Argenteanu, Mary. THE EFFECTS OF ABSOLUTE AND CONDITIONAL PROBABILITY DISTRIBUTIONS ON INSTRUMENT READING: II. A COMPARISON OF A LINEAR AND A LOGARITHMIC SCALE. Contract AF 18(600) 50, Proj. 7186, Tech. Rep. 54 253, Part 2, July 1955, 33pp. USAF Wright Air Development Center, Aero Medical Lab., Wright-Patterson AFB, Ohio. (Antioch College, Yellow Springs, Ohio).

The readability of a logarithmic scale was compared with that of a linear scale. Pointer settings were grouped into sequences of 9 settings each. The settings increased either linearly or logarithmically. The stimuli were presented tachistoscopically for exposures of .8 seconds and each of 16 Ss was tested under every experimental condition. Results indicated that when error is expressed in scale units, the linear scale is superior to the logarithmic, the skewed distribution to the rectangular, and the regular order to the random. The use of a regular order improves performance more on the logarithmic scale than on the linear. In terms of angular deviation of response from settings, the logarithmic scale is not significantly different from the linear scale. On the logarithmic scale, the log mean error is directly related to the logarithm of the numerical value of the pointer settings, but the slope of the line is .54, indicating that errors at the low end of the scale are proportionately higher than errors at the high end. When log median error, instead of log mean error, is plotted against the logarithm of the pointer setting, an almost direct proportionality is found.

Lawrence, W. & Eades, R.J. THE DISPLAY OF SPECTRAL MAXIMA WITH A SPEECH SPECTROGRAPH. S.R.D.E. Rep. 1087, May 1955, 8pp. Signals Research and Development Establishment, London, England.

In the analysis of speech sounds by means of a speech spectrograph, described in S.R.D.E. Report 1375, methods have been devised to show the frequencies of spectral maxima (formants) with greater accuracy than with the orthodox spectrograph. This report describes the use of sharpened circuits, of phase filters and of differential spectrography. Differential spectrography was developed at S.R.D.E. and is of particular use in the analysis of speech towards the production of an analysis-synthesis method of speech transmission. Differential spectrograms are obtained by using a discriminator instead of a band-pass filter; the location of a spectral maximum is shown on Teledeltos paper as a sharp boundary between 2 fields of unequal appearance.

Levine, L.M. & Hershkovitz, J. EVALUATION OF THE INTELLIGIBILITY OF SOUND POWERED TELEPHONE EQUIPMENT INSTALLED IN OXYGEN RESCUE BREATHING APPARATUS. Lab. Proj. 5619 I, NS 683 034, Final Rep., Jan. 1955, 7pp. Material Lab., New York Naval Shipyard, Brooklyn, N.Y.

An evaluation to determine the feasibility of using sound powered telephones with the Navy Oxygen Breathing Apparatus has been conducted. 2 arrangements were tested, one in which the standard speaking diaphragm in the face piece was replaced by a sound powered transmitter, and another in which a modified sound powered transmitter is fitted over the speaking diaphragm. Articulation tests showed that acceptable intelligibility may be expected from both arrangements which is far superior to intelligibility obtained by direct transmission through the speaking diaphragm alone. It is recommended that the newly developed standard models of sound powered phones (Lab. Project 5476-3,4) be adapted for use with the breathing apparatus and performance compared with those used in this evaluation.

Licklider, J.C.R., Stevens, K.W. & Hayes, J.R.M. STUDIES IN SPEECH, HEARING AND COMMUNICATION. FINAL REPORT. Contract W19 122 ac 14, AFRC TR 54-159, Sept. 1954, 68pp. Acoustics Lab., Massachusetts Institute of Technology, Cambridge, Mass.

Memory span has been measured for 13 ensembles, the smallest of which was 2 items in size and the largest 355,000 items in size. Reliable differences in memory span among these ensembles were observed. Memory span decreases as ensemble size increases from 2 items to 16 or 32 items. As ensemble size increases beyond 32 items, memory span changes slowly or not at all. Factors other than ensemble size are important in determining memory span. The amount of information retained in immediate memory is greatest for ensembles of 17,000 to 55,000 items.

Davis, S.W. & Taylor, J.C. STRESS IN INFANTRY COMBAT. Tech. Memo. ONR T-295, Sept. 1954, 103pp. Operations Research Office, Johns Hopkins University, Baltimore, Md.

There is evidence that being in blocking position behind the MLR does not alter the normal physiological function of combat infantrymen. A short period of intense combat results in a characteristic set of physiological changes for the average infantryman (a high degree of adrenal responsiveness, increased protein destruction, and a shift in the balance of body salts). A period of prolonged, less intense combat results in a different set of physiological changes in the average infantryman (a low degree of adrenal responsiveness, normal protein destruction, and a shift in the balance of body salts opposite to that observed in short, intense combat). Although the response of both groups can be considered normal stress responses, that of the short, intense group is characteristic of the initial or adaptation phase of the stress reaction, and that of the prolonged, less intense group is characteristic of the second or resistance phase of the stress reaction. Men exposed to the same combat reach the period of maximal physiological adaptation to stress at different times. Time taken to recover to normal physiological levels after intense combat of 18 hours is approximately 6 days; after less intense combat of 5 days it takes approximately 13 days. Based on physiological function alone, combat of a high level of intensity is more costly than combat of a low level of intensity in that recovery time is longer in proportion to the duration of the stress. Based on physiological function alone, the initial period of combat is more costly than continuing in combat past the initial period in that recovery time is longer in proportion to the duration of the stress.

Lincoln, R.S., & Averbach, E. SPATIAL FACTORS IN CHECK READING OF DIAL GROUPS. J. appl. Psychol., 1956, 40, 105-108. Contract N6ori-166, Rep. 166-1-197. ONR, Johns Hopkins University.

6574

To study some aspects of learning and retaining skilled movements, three groups of subjects (18 each) were trained to turn a handwheel at a constant linear rate (160 feet per minute). Training variables were: 1. amount and direction of error given verbally, 2. amount of rate error given kinesthetically, directional error verbally, and 3. standard rate given kinesthetically. After training S attempted to produce the same rate without aid of external cues (either immediately, after one-hour delay, or after 24-hour delay). Rate accuracy and constant error were studied by analysis of variance to determine relative value of kinesthetic and verbal cues for such performance.

G. R 7

6575

To investigate the effects of spatial location on the accuracy with which check dials are read, three groups of subjects (14 each) were required to detect deviant pointers (null point 9 o'clock position) within a display panel of 16 circular dials. The panels (42 variations) were displayed for exposures of .35, .70, and 1.40 seconds (one duration time for each group). The data (percentage of detection) are analyzed as functions of exposure duration, number of trials (28), quadrant of panel and position of dial within the quadrant (corners, sides, middles). The pattern of detection is interpreted in terms of scanning habits which, in turn, are related to previously learned reading habits.

 Lockard, R. THE EYE AS A CONTROL MECHANISM (INTERIM REPORT). Tech. Note 304-14, June 1956, 17pp. Naval Ordnance Test Station, Electronics Systems Branch, China Lake, Calif.

6576
 This "interim report" was taken from a longer manuscript entitled "The Eye as a Control Mechanism." The use of the human eye as an error-correcting device to partially fulfill the role of cinematolite cameras for obtaining trajectory data about missile and rocket tests is suggested. Types of eye movements are discussed, standard eye-movement recording techniques are reviewed and the tracking accuracy of the eye is experimentally approximated. Applications to a tracking system capable of providing immediately available trajectory data are discussed.

 Mangelsdorf, J.E. VARIABLES AFFECTING THE ACCURACY OF COLLISION JUDGMENTS ON RADAR-TYPE DISPLAYS. Contract AF 33(616)-43, Proj. 5-1(7-7192), Tech. Rep. 55-462, Dec. 1955, 51pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio. (Ohio State University).

6578
 To investigate man's ability to judge collision courses (point of intersection) of aircraft on radar-type displays, four practiced subjects made a total of 4400 judgments by the psychophysical method of adjustment. The subject observed a pair of converging trails projected on a screen and adjusted the position of one so as to produce a "collision" situation. Target speed, distance-to-go, and angle of convergence were varied. Constant, average, and variable error were calculated for each problem and pooled for all subjects and studied as functions of training and for the three variables, of speed, distance, and angle. A mathematical model was developed to relate variable error to the experimental variables. Both general and applied aspects of the model are discussed. T. G. I. R-14.

 Morant, G.N. SURVEYS OF THE HEIGHTS AND WEIGHTS OF ROYAL AIR FORCE PERSONNEL: VII. HEIGHTS AND WEIGHTS OF 137 ROYAL AIR FORCE APPRENTICES RECORDED ON FIFTEEN OCCASIONS. FPRC 7111(7) March 1952, 17pp. Flying Personnel Research Committee, RAF Institute of Aviation Medicine, England.

This report deals with records of the heights and weights of 137 RAF apprentices who were measured on 15 occasions over a 3-yr. period. Their medical histories, assessments of their physical fitness and final examination results were examined. The following are some of the conclusions reached: a) no evidence was found of significant association between the assessments of health, physical fitness and ability, on the one hand, and age, on the other, or between any pair of the 3 criteria; b) no seasonal fluctuations in growth rate was observed; c) it was suggested that the growth rate was accelerated appreciably in the 2nd and 3rd year of observation; d) all 55 probably reached their maximum height between their 17th and 22nd years of age; e) no correlation was found between maximum height and the age at which it was attained; f) for those who had not reached their maximum height, there was no correlation between height at 17 yrs. 4 months and increase in height between 17 yrs. 4 months and 18 yrs. 4 months; g) no evidence was found of any significant association between weight levels or changes in weight during particular intervals, on the one hand, and health, physique or examination results, on the other.  Finkelstein, Beatrice, Pippitt, R.G., & Taylor, A.A. EVALUATION OF IMPROVED COMPACT BOX LUNCH, NUTRITIONAL CHARACTERISTICS, STABILITY, EASE OF FLIGHT KITCHEN PREPARATION, EASE OF HANDLING IN FLIGHT, AND ACCEPTABILITY OF COMPONENTS. Proj. 7156, Tech. Rep. 56-363, July 1956, 40pp. Aero Medical Lab., USAF Wright Air Development Center, AFMCC, Wright-Patterson AFB, Ohio.

An improved Compact Box Lunch, designed to be eaten aboard jet bomber aircraft during flights of extended duration, is evaluated. In appraising this system of feeding, consideration was given to the findings of a previous field trial of the Compact Box Lunch. Results of that study were used to formulate an improved lunch. Meals in this system of feeding are nutritionally adequate. They can be satisfactorily produced by Air Force flight kitchen. Assignment of additional food service personnel and an increase in flight kitchen work and storage space may be necessary if the lunch is used at bases from which large numbers of jet bomber aircraft depart. Because of the small size of the foods and convenient packaging, jet lunch can be consumed easily under restricted flight conditions. The foods which are used retain their wholesomeness when stored without refrigeration for periods up to 20 hours. Consumer acceptance of these foods is high. However, desire was expressed for an increase in the amount of beverage in each lunch. Accordingly, menus have been modified to reflect this need. Since the Compact Box Lunch meets the requirements of nutrition, utility, stability, and acceptability, this feeding system, as revised by this study, is suitable for use aboard jet bomber aircraft.

 Morin, R.E., Grant, D.A., & Nyström, C.O. TEMPORAL PREDICTIONS OF MOTION INFERRED FROM INTERMITTENTLY VIEWED LIGHT STIMULI. Contract AF18(600) 54, Tech. Rep. 54-69, Jan. 1955, 14pp. USAF Wright Air Development Center, Aero Medical Laboratory, Wright-Patterson AFB, Dayton, Ohio. (University of Wisconsin, Madison, Wisc.).

The accuracy of predicting when a moving object will reach a target was studied in the following procedural context: No real movement occurred, but instead the subject viewed the successive illumination of two or four cue lights which were placed at even intervals in a horizontal row. Illumination of the cue lights represented momentary viewings of a moving object as it might be seen on a radar scope. After the illumination of the last cue light, the subject estimated the time it would take the imaginary object to reach a target light by pressing a button at the moment of predicted arrival. The results indicated that among the above main variables of the experiment, computed object velocity produced the greatest effect upon accuracy of estimation. Marked underestimations occurred at the slower velocity. Highly significant effects, temporal estimations for the shorter distance being more accurate than for the longer distance, were also observed. Temporal estimations for the longer distance were less important, although they introduced statistically significant results. Temporal estimations were more accurate following longer interval sweep times and were more accurate following four cues than they were following two cue lights.

Moser, H.M., Dreher, J.J., & Adler, S. EFFECT OF RATE AND PHRASING ON INTELLIGIBILITY OF AIR MESSAGES. Contract AF 19(604) 1577, Proj. 7681, AF Proj. 664, Tech. Rep. 29, AFRC TH 55 68, May 1955, 12pp. USAF Cambridge Research Center, Bolling AFB, Washington, D.C. (Ohio Research Foundation, Columbus, Ohio).

6582

To examine effects of word grouping and rate of speaking on reception of messages, a test was devised in which listeners (40, 48, 57) heard messages (six lists of 15 signals) from the typical environment of control talk. Six categories of syntactical forms were used: imperatives, interrogatives, informatives, verbless compliments, propositional phrases, and infinitive phrases. Five trained speakers contributed three messages to each list using three rates of delivery: normal, fastest rate commensurate with precise articulation, and spaced by use of signal lights. Signal to noise ratio was -3 decibels; mean signal level (speech) was set at 82 decibels. Percent of messages correctly received for each message type are analyzed in relation to rate of presentation. T.I. R 18

Moser, H.M., Dreher, J.J., & Harbold, G.J. RECOGNITION OF THREE MAGNITUDES OF INTERPHONETIC TRANSITIONAL INFLUENCE. Contract AF 19(604) 1577, Tech. Note 33, RP Proj. 664, AFRC TH 55-74, Dec. 1955, 23pp. AFRC, Bolling AFB, Washington, D.C.

6583

To investigate the interphonic transitional influence (result of equal combinations of spoken speech) on recognition, monosyllabic nonsense syllables were formed by combining consonants and vowels with respect to hub location to form discrete magnitudes of transition (minimum, medium, maximum). Six male speakers recorded the syllables to which 24 trained listeners responded (syllable and speaker orders randomized) in progressively destructive signal to noise ratios (+24 to 0 decibels). Criterion measure was magnitude of recognition irrespective of transition direction. Data for the +3db S/N ratio were evaluated by triple analysis of variance. T.I. R 26

Jeely, K.K. A COMPARISON OF THE ICAO I AND ICAO II PHONETIC ALPHABETS AT VARIOUS ALTITUDES. Proj. 118 43-108, Rep. 118-1, Dec. 1954, 27pp. Defence Research Medical Labs., Department of National Defence, Toronto, Ontario, Canada.

A study of the ICAO I and ICAO II Phonetic Alphabets at various altitudes (sea-level, 15,000 feet, and 30,000 feet) indicated: a) no statistically significant difference in word-intelligibility between the 2 alphabets; b) no statistically significant difference in alphabet item word-intelligibility scores among positions in a 3-word phrase; and c) a highly significant difference, statistically, in the word-intelligibility of the alphabet items among the 3 altitude conditions.

Neely, K.K. ACOUSTIC PROPERTIES OF HEADGEAR WITH NOISE ATTENUATION DEVICES. Proj. 100 43 72, Rep. 100 4, Nov. 1954, 8pp. Department of National Defence, Defence Research Medical Labs., Toronto, Ontario, Canada.

Results of sound attenuation tests indicated that the NDRC V-51R Ear Warden afforded the most protection from noise in the frequency range 100 to 3,000 cps and the straightaway Sound Protector (Helmet and Headband types) was the most efficient sound-attenuating device in the frequency range 3,000 to 10,000 cps. Wet cotton was found to have more efficient sound-attenuation properties than dry cotton or the Billsholme Hoerselskyd, but was less efficient in this respect than was either the NDRC V-51R Ear Warden or the Straightaway Sound Protectors. Newman, R.W. THE ASSESSMENT OF MILITARY PERSONNEL BY 1912 HEIGHT-WEIGHT STANDARDS. Rep. 194, Nov. 1952, 18pp. Climatic Research Lab., Environmental Protection Branch, USA Office of Quartermaster General, Washington, D.C.

This study was made to establish and compare relative weights in 3 Arm. Series, White male separablees measured in 1946, Negroid male separablees measured in 1946, and White male inductees measured in 1946 and 1949, with the height-weight table established by the medico-actuarial mortality investigation of 1909-1912, utilized as the standard in this assessment. The 3 Army series were uniformly higher than the 1912 medico-actuarial standards in weight. The White and Negroid separablees demonstrated an unexplained decrease in the average relative weight with age. The White inductees did not show this decrease over the limited available age range. The largest Army group, White male separablees, was compared to 2 other standards, a European standard which proved unsatisfactory because age was not taken into account, and a study of civilians in 1940 by the Equitable Life Assurance Society. The Equitable Life data showed overall average weights that more nearly approached the Army data but a curious discrepancy in tall-statured men occurred.

6587 Newman, R.W. & Winston, G. COMPARISON OF TEN ANTHROPOMETRIC AND TAILORING MEASURES ON THE SAME MEN. Rep. 210, June 1953, 11pp. Climatic Research Lab., USA Office of Quartermaster General, Lawrence, Mass.

This study was undertaken to determine the relationship between 2 types of measurements, i.e., anthropometric and tailoring. The information could then be applied to the large amount of anthropometric data available on military personnel and would facilitate a translation of anthropometric data into meaningful pattern measurements. Data on 10 bodily measurements: neck, shoulder, chest, waist, and hip (seat) circumferences, sleeve length, scye depth, inside arm length, outseam, and inseam were presented and analyzed for the relationship between the 2 types of measurements on 42 men. The relative reliability of the techniques was assessed and was found to be roughly similar and the relationship appeared sufficiently consistent to warrant translation from one technique to the other without undue loss of accuracy. Methods for conversion from one type of measurement to the other were presented in several forms if appropriate to individual situation.

 USN Personnel Research Field Activity. PROFICIENCY MEASURES IN A/S SONAR MAINTENANCE. II. JOB SAMPLE TESTING FOR TROUBLE-SHOOTING. NavPers 18409, Tech. Bull. 55 1, Feb. 1955, 15pp. Bureau of Naval Personnel, USN Personnel Research Field Activity, San Diego, Calif.

This study reports the preliminary phases in the development and administration of a sonar trouble-shooting performance test. This test was to be the first in a series of performance, tab-type, and multiple-choice printed tests in the area of sonar maintenance. After preliminary try-out of a one-problem QMBa trouble-shooting job-sample test, a 6-problem SQS-11A job-sample test was developed and administered to 15 graduating students of the Advanced Sonar Maintenance Course at Fleet Sonar School, San Diego. 15 of these examinees completed an 80-item printed electronics test also. The reliability of the performance test was not significantly different from zero. The reliability of the printed test was fairly adequate (.78); its correlation with the performance test was very low (.18).

 Bureau of Aeronautics. ENGINEERING ANALYSIS AND ESTIMATE OF THE EFFECTS OF CONVERTING TO VERTICAL-READING SCALES. Contract N045 53 476 c; April 1954, 10pp. Bureau of Aeronautics, (Kollsman Instrument Corporation, Elmhurst, N.Y.)

This report deals with engineering analysis and estimate of the effects of converting to vertical reading scales. Its main concern is the problems involved in the design of vertical reading instruments of the electro-mechanical type and their relative indicator complexity, and panel space requirements. The considerations evaluated are the relative size and weight of the instruments along with the relative cost and reliability. Consideration is given to the man-machine efficiency and the estimation of the man-machine benefits to be derived from the partial or complete adoption of the vertical instrument presentation idea. A literary and historical review of the use of vertical-dial instruments was made and a list of advantages and disadvantages compiled. (HEIAS)

 Winsmann, F.R. PACK CARRYING IN THE DESERT. Proj. 7 64 12 004, Rep. EP 28, May 1956, 27pp. USA Quartermaster Research and Development Center, Natick, Mass.

The energy cost of walking, climbing, and carrying loads over 3 different types of desert terrain has been studied. The surfaces studied included level hard surface, level sandy surface, and sand dune slopes. Pulse rates and rectal temperatures were measured, along with oxygen consumption, as indicators of stress. The energy expenditure of walking, climbing, and carrying loads expressed as Calories per square meter body surface area per hour (Cal/m²/hr) shows a striking increase from hard surface to sandy areas (mean-increase 104%). The increased pulse rates and rectal temperatures over the sand and slope (dune) areas are also indicative of added stress. The 40-pound pack carried at a rate of 2.5 mph continuously for one-half hour would appear to represent the extreme upper load limit to carry in any sandy area on the desert. It is expected that the quantitative measurements of heat production contained herein will be useful in the calculation of total heat load on a man under desert conditions.

 Wulfeck, J.W., Crook, D.J. & McBride, Patricia. STUDIES ON DARK ADAPTATION. EXPERIMENTS I, II, AND III: THE PRE-EXPOSURE TOLERANCE OF THE HUMAN FOVEA ADAPTED TO DIFFERENT BRIGHTNESS LEVELS, INCLUDING DARKNESS. Contract AF30(602) 199, RADC TR 54 88; Final Report, Oct. 1954, 34pp. Rome Air Development Center, Griffiss AFB, Rome, N.Y. (Tufts College, Medford, Mass.)

The effect on foveal dark adaptation of pre-exposure of the eye for brief durations to light of relatively low brightness was investigated. Monocular measurements were made of both absolute brightness sensitivity (RL) and difference or contrast sensitivity (DL). In DL determinations background brightness and Adaptation Level were of the same value. The extent of dark adaptation as measured by the RL was found to increase as pre-exposure duration and brightness increased above critical values. The extent of dark adaptation as measured by the DL increased with increasing duration and brightness of pre-exposure above critical values. Dark adaptation was too slight to be measured following certain pre-exposures of the dark-adapted eye to quantiles of light in which the brightness x duration product was 100 ft.-lambert-sec. or less. In the case of both RL and DL experiments there were also certain pre-exposure combinations yielding a brightness x duration product of 100 ft.-lambert-sec. or less which, when superimposed on the 3 Adaptation Levels other than darkness, did not produce dark adaptation as measured by the techniques used in these investigations.

O'Hare, J.J. INTERSENSORY EFFECTS OF VISUAL STIMULI ON THE MINIMUM AUDIBLE THRESHOLD. *J. gen. Psychol.*, 1956, 54, 167-170. (U.S.N. Medical Research Laboratory, Naval Submarine Base, New London, Conn.).

6602
To investigate the effect of visual stimuli on the minimum audible threshold, measurements were made of the intensity limits of four pure tones (200, 700, 2,000, and 5,000 cycles per second) while subject fixated a patch of color or in darkness. Colors and effective brightnesses (in foot-lamberts) were: yellow, 07.4; green, 55.6; blue, 16.5; and red, 10.9. Comparisons were made between auditory threshold data in the dark or "no-color" situation and in a particular color situation and significant shifts were observed for intersensory effects.

Platzner, H.L. THE PHASE-PLANE AS A TOOL FOR THE STUDY OF HUMAN BEHAVIOR IN TRACKING PROBLEMS. Contract AF 33(038) 70420, Proj. 7182, Tech. Rep. 55 444, Nov. 1955, 10pp. Aero-Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Franklin Institute).

The phase-plane technique has been used to study human behavior in specific tracking problems. This technique is well suited to the study of the response characteristics of the human operator when step inputs are used. For these inputs, the appearance of sharp corners in the phase trajectories is evidence of non-linear behavior by the human operator. Evidence of strong non-linear behavior has been observed experimentally when the dynamic system is stable or unstable. Phase-plane techniques are not so useful when more general inputs, and in particular when random inputs are used. The reason is that the appearance of a sharp corner in the phase trajectory may be caused by the random input as well as by non-linear response of the human operator. However, useful information can still be extracted from the phase trajectory, such as time on target, average error, error variance, etc.

Pollack, I. THE ASSIMILATION OF SEQUENTIALLY-ENCODED INFORMATION, 5. BINARY-ENCODED MATERIALS. Rep. TR 54 5, Jan. 1954, 11pp. USAF Human Factors Operations Research Labs., Bolling AFB, Washington, D.C.

This report considers the immediate recall of binary-coded verbal materials--messages in which each unit could assume only one of 2 possible alternatives. Binary materials are of special interest because of the ease of recoding the materials into alternative units which, presumably, aid in their reproduction. The contribution of 4 variables, which were believed to influence the assimilation of binary messages, has been examined. Of these, 3 are significant: the length of the message--the number of binary units per message; the rate of presentation of the message--the number of binary units presented per unit time; and, the statistical restriction of the message source--the maximum length run permitted. In general, over the experimental conditions examined, the information transmitted increased as: the length of message increased, as the rate of presentation decreased, and, as the statistical restriction upon the message-source decreased. More important, however, were the interactions among the several variables. These interactions may be accounted for by a few assumptions regarding the recoding operations reported by the subjects. While these assumptions are entirely reasonable, it is concluded that a further continuation of this type of indirect analysis of encoding operations will not be fruitful. Rather, a direct examination, of encoding operations e.g., as performed by Miller and Smith, appears to offer a more promising hope for elucidation of these operations.

Pollack, I. SOUND LEVEL IDENTIFICATION AND INTERNAL STIMULUS VARIATIONS, 1. *J. acoust. soc. Amer.*, Nov. 1955, 27(6), 1222-1223. (Operational Applications Lab., Bolling AFB, Washington, D.C.).

Sound level identification was examined for 2 restricted ranges of sound-levels concurrently. The principal variable was the rate of shifting between the 2 restricted ranges. In general, identification performance decreases as the rate of shifting between the 2 ranges increases. However, because of the loss of stimulus information, the arbitrary restriction of the stimulus range results in a lower-over-all information transmission than without the procedural restriction. An implication for the scaling of elementary aspects of auditory displays is discussed.

Pollack, I. IDENTIFICATION OF SOUND LEVEL AND MATCHING FROM SAMPLE. *J. acoust. soc. Amer.*, May 1956, 28, 412-415. (USAF Cambridge Research Center, Bolling AFB, Washington, D.C.). (Tech. Rep. 56-3).

6607
A direct comparison between the identification and the discrimination of the loudness level of a tonal signal can be made by reference to the contiguity between the signal and the "catalog" of possible signals. Seventy different "catalogs" of sound levels were established differing in the size of the differences between the items (0.2% to 64 db) and the number of items (2 to 17). The subject: 1) identified the signal, 2) identified the signal after also hearing others in that catalog, 3) identified the signal after hearing it and others in that catalog as often as he wished. The results obtained on five listeners are expressed in terms of the matching error made in identifying, recognizing and discriminating the signal.

 WSN Air Test Center. OPERATIONAL TEST OF RANGING THRUSTLE GRIP, 2040-40. FINAL REPORT. Proj
 WSN PTC 22 42384, Letter Rep. 1, June 1953, 4pp. WSN Air Test Center, Patuxent River, Md.

Tests were conducted on 2 Ranging Thrustle Grips, 2040-40, which were mounted in an
 F3F-5 and an F3F-5 airplane. Operations of 4 pilots during 32 flights led to the conclusion
 that the Thrustle grips are unsuitable for service use because of pilot discomfort which is
 a result of the poor location of the speed brake switch on the grip. It is recommended that
 an investigation be made to determine the possibility of employing one of the presently un-
 used buttons on the control stick now installed in the F3F-5 airplanes to accomplish the
 range out function.

 Rappaport, M. THE ROLE OF REDUNDANCY IN THE DISCRIMINATION OF VISUAL FORMS. Presented in
 partial fulfillment of the requirements for the Ph.D. degree in the Graduate School of the
 Ohio State University, 1954, 79pp. Ohio State University, Columbus, Ohio.

Experiments were performed to test the effects of type of redundancy upon the discrimina-
 tion of visual patterns. It was also attempted to determine the degree of redundancy that
 allows discrimination to take place optimally. The series of 4 experiments constitute a new
 and quantitative approach to the problem of form perception using concepts stemming from in-
 formation theory. In general, it was shown that redundancy is more effective in a visual
 discrimination situation where visual noise is present than where visual noise is not present.
 It was also concluded that information theory provides a fruitful approach to the study of
 form perception. (NEIAS)

 Robinson, S. THE PHYSIOLOGICAL EFFECTS OF ATROPINE AND POTENTIAL ATROPINE SUBSTITUTES. Con-
 tract DA M 126 DM 2597, Rep. 15, Aug. 1953, 150pp. US Army Chemical Corps Medical Laborato-
 ries, Army Chemical Center, Md. (Indiana University, Bloomington, Ind.)

The object of this study was to determine the effects of atropine and 4 atropine substi-
 tutes on the response of men to stresses of work and temperature. The effects on men of in-
 tramuscular doses of 2 mg. atropine sulfate, 0.5-2 mg. netropine, 8 mg. parpanit, 4 mg.
 lergigan and 5 mg. artane were determined in 2 series of work experiments. In the first
 series a study was made of temperature regulation of men doing prolonged walks at 3.5 mph on
 a treadmill. In the second series physiological responses of men to 3 different intensities
 of work were studied. Neither lergigan nor parpanit caused any measurable ill effects. Ar-
 tane caused interference with mental concentration and psychomotor performance. The effects
 of atropine and netropine on the physiological responses of men to work in the heat are seri-
 ous enough to limit performance. (NEIAS)

 Rupp, J.C. & Westen, R.J. RESEARCH INTO BASIC METHODS AND TECHNIQUES OF AIR FORCE JOB AN-
 ALYSIS--II. Proj. 507 015 0302, Res. Rep. AFPTC-TN 55 51, Nov. 1955, 69pp. USAF Personnel &
 Training Research Center, Training Aids Research Lab., Chanute AFB, Ill.

This study is concerned with determining the relative merits of 5 techniques of job analy-
 sis. They are: a) questionnaire survey; b) group interview; c) individual interview; d) ob-
 servation interview; e) technical conference. 12 jobs were selected as meeting the require-
 ments for the experimental design in that they: a) represent as many career fields as possible
 b) range from simple to complex; c) represent varying degrees of manual, intellectual, mech-
 anical, and manipulative requirements; d) represent Air Force-wide performance requirements.
 This report covers 4 of those jobs. Among the conclusions reached are: for Air Force require-
 ments, the technical conference appears to be best and is the most expensive; the question-
 naire survey method is the least expensive and except for the group interview is the least
 productive; it appears that the techniques which make the most demands upon the talents of
 the job analysts (individual interview, observation interview and technical conference) pro-
 duce more information than the other 2 methods; of the 4 methods requiring the use of job
 analysts, the group interview is significantly less effective than the other 3, which do not
 differ significantly from each other in reporting work activities. (NEIAS)

Saul, E.V., Cornblisen, J.M., Jr., Devoe, D.B., Nicoll-Ebner, Mary, et al. A REVIEW OF THE LITERATURE PERTINENT TO THE DESIGN AND USE OF EFFECTIVE GRAPHIC TRAINING AIDS. Contract Monr 494(08), Proj. 23 D 3, Tech. Rep. SEC 494 08 1, Feb. 1956, 216pp. Special Devices Center, Fort Washington, N.Y. (Tufts University, Medford, Mass).

The aim of the report is to present annotated reviews of the literature in specified areas pertinent to the problem of developing standards and criteria in the design, preparation and utilization of effective graphic training aids. The reviews are also intended to serve as a preliminary basis for the formulation of principles of design and utilization of graphic training aids. It was concluded that much of the literature and information available is contradictory and inconsistent and that detailed study and evaluation of these data are necessary prior to their application as criteria in the design and use of visual training aids. In addition an interdisciplinary approach must be used to cope with the present graphic training aid problem. Material for the report was derived from a literature search in the areas of: psychophysiology of vision, visual perception, experimental aesthetics, advertising visual education, psychology of learning, visual art, engineering drawing and quantitative presentation. The time period covered is approximately from 1920 to 1954. (NEIAS)

Schipper, L.M. PREDICTION OF CRITICAL EVENTS IN CONTEXTS OF DIFFERENT NUMBERS OF ALTERNATIVE EVENTS. Contract AF-33(616) 43, Proj. 7192, Tech. Note 55-744, Dec. 1955, 7pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Ohio State University, Columbus, Ohio).

In the present experiment, subjects predicted the occurrence of the critical event within contexts of 3 different numbers of alternative events. It was hypothesized that as the number of alternative events increased, the subjects would perceive the occurrences of the critical event as more frequent. The critical event was a short flash of a particular light; alternative events were flashes of similar lights. The design was an orthogonal arrangement of the relative occurrences of the critical event, 1/2, 1/4, 1/6, and 3 levels of alternative events, 1, 3, 5. Rates of omission of positive responses were significantly influenced by the proportions of occurrences of the critical event. However, the number of alternative events appeared to have no effect on subjects' performance. This lack of effect was consistent at all 3 probability levels. The results at the 1/2 and 1/4 levels with one alternative event corroborate earlier work; results at 1/6 offer an extension. It is concluded that under instructions to classify events simply into critical and non-critical categories, subjects' behavior is not significantly influenced by the number of non-critical possibilities.

Ramond, C.K. & Myhill, C.R. TARGET PLACEMENT ON A DETECTION PROFICIENCY COURSE. June 1954, 20pp. Human Resources Research Office, George Washington University, Washington, D.C. (USA Human Research Unit No. 3, Fort Benning, Ga.).

6626

To design a precise and economical target detection course, the ranges of the minimum number of targets necessary to cover all discriminable ranges within any given interval were investigated. Each day for four days, 15 enlisted soldiers, aligned facing a level grassy field, made 60 estimates as to the relative closeness of two successively presented targets (human figures), one of which was either 2, 4, 6, 8, 10, 12, 14, 16, 18, or 20 yards more distant than the other. The subject's task was to record which target seemed nearer, the first or second. The near target in either kneeling or standing position was 100 or 200 yards from the subject, who was either prone or standing. The data were analyzed to determine target separations beyond which no errors would occur. T. G. R 8

Simon, C.W., Slocum, G.K., Hopkins, C.O. & Roscoe, S.N. ALTIMETRY STUDIES: I. AN EXPERIMENTAL COMPARISON OF THREE PICTORIAL AND THREE SYMBOLIC DISPLAYS OF ALTITUDE, VERTICAL SPEED, AND ALTITUDE COMMANDS. Tech. Memo. 425, Jan. 1956, 14pp. Weapon Systems Development Labs., Hughes Aircraft Company, Culver City, Calif.

6627

This is an experimental evaluation of six displays (three pictorial and three symbolic) whose design was directed toward displaying aircraft altitude, vertical speed, and altitude commands. The displays were presented in a decision-making task requiring integration of the three types of information for successful performance. Two groups of 12 subjects each were employed and consisted of professional pilots vs. individuals with some previous pilot experience. A paper and pencil test was utilized to present two problems for each of the six displays. The results are presented in terms of the time and error scores for each of the groups with each of the displays. Pictorial displays are evaluated against symbolic displays and the specific positive features of each of the displays are discussed. T. G. I. R 17

Summy, W.H. & Pollack, I. SHORT-TIME PROCESSING OF INFORMATION. Rep. TR 54 6, Jan. 1954, 12pp. USAF Human Factors Operations Research Laboratories, AFRC, Bolling AFB, Washington, D.C.

This report is concerned with the information handling capabilities of human operators. It considers the reproduction of artificial language materials which approach, to various degrees of statistical approximation, everyday English. It deals with the effect of manipulating the sequential restrictions of the materials (altering their structural approximation to English) and the effect of the manipulation of the size of the vocabulary available for reproduction (controlling the information of the units of material themselves). It was observed that when the sequential restrictions were altered, the time for processing the materials is approximately proportional to the information of the materials (the materials are processed, approximately, at a constant informational rate). When the information of the units was varied, the time for processing the materials was approximately independent of the information of the materials (the materials are processed, approximately, at an informational rate proportional to the information of the materials). In the first procedure the Ss reproduced the material orally, in writing and by typing. Each method was used by 22 to 25 Ss. In the second procedure 17 Ss used 6 lists of 50 words each. Before being given the lists, they were given the vocabulary of possible words. Each list had a different vocabulary size. (HEIAS)

Tanner, W.P., Jr. PSYCHOPHYSICAL APPLICATION OF THE THEORY OF SIGNAL DETECTABILITY. Contract DA 039 sc 15358, Task EDG-6, DA Proj. 3 99 04 042, SC Proj. 29 1948 0, EDG Rep. 18, Feb. 1954, 12pp. Armed Forces-NAC Vision Committee, Electronic Defense Group, University of Michigan, Ann Arbor, Mich.

This paper is concerned with the human observer's behavior in detecting light signals in a uniform light background. As detection of these signals depends on information transmitted to cortical centers by way of the visual pathways, an analysis was made of the form of this information and the types of decisions which can be based on information of this form. Based on the analysis, the expected form of data collected in "yes-no" and "forced-choice" psychophysical experiments is defined. Experiments demonstrating the internal consistency of this theory are presented in the paper. The conclusions reached were: a) the conventional concept of a threshold, or a threshold region, needs re-evaluating in the light of this theory; b) the guessing hypothesis is rejected on the basis of statistical tests; c) change in neural activity is a power function of change in light intensity; d) the mathematical model of signal detection is applicable to the problems of visual detection; e) the criterion of seeing depends on psychological as well as physiological factors; f) the experimental data support the logical connection between "forced-choice" and "yes-no" techniques developed by the theory. Thornton, G.B. DETECTION TIME OF RADAR PIPS UNDER IDEAL OPERATING CONDITIONS. Proj. 107-134-41, Rep. 10-2, Dec. 1954, 10pp. Defence Research Medical Laboratories, Toronto, Ontario, Canada.

5 experiments were performed to determine a) the time required by an alerted operator to detect clear bright pips on a noise-free CRT, b) how detection time is related to number of pips already displayed, c) work decrement over a 30-minute period at an average rate of acquisition of 6 pips per minute and at a rate of 17 per minute, and d) the effect of one to 60 seconds delay time after a ready signal. Detection time under the best conditions was found to be approximately 0.30 second. Detection time was a negatively accelerated increasing function of the number of pips displayed, increasing to more than 0.50 second with 40 pips acquired. No evidence of decrement over a 30-minute period was apparent, and no relationship was observed between detection time and a delay of one to 60 seconds after alerting. Detection times were found to be shorter when new pips were presented at an average rate of 17 per minute than when a rate of 6 per minute was employed. Thus, high traffic loads, resulting in a high saturation of marked pips on a CRT, will almost double the time taken to detect a new pip. Most of this penalty is due to the first 6 pips acquired. On the other hand, high rates of acquisition of new pips improves detection time performance.

Konecni, E.B. HYPOXIA AND UNDETERMINED JET ACCIDENTS, 1 JULY 1954 THROUGH 31 DECEMBER 1955. Publ. 43-56, Oct. 1956, 20pp. Directorate of Flight Safety Research, Office of the Inspector General, USAF, Norton AFB, Calif.

6638

In order to determine the potential role of hypoxia in undetermined jet aircraft accidents, an analysis was made of 194 such accidents. The relative incidence of hypoxia as a probable cause is specified and discussed in terms of the factors responsible for the occurrence of hypoxia, e.g., improper oxygen mask fit, loose or dirty valves in masks, defective regulators, etc. The Flying TAF Non-Fatal Hypoxia Incident Report is described as an effective means of discovering the causal factors in the occurrence of hypoxia. Recommendations are offered concerning the prevention of hypoxia episodes.

Torrance, E.P. PSYCHOLOGICAL ASPECTS OF SURVIVAL: A STUDY OF SURVIVAL BEHAVIOR. Memo. TN 54-4, Jan. 1954, 93pp. USAF Human Factors Operations Research Laboratories, ARDC, Bolling AFB, Washington, D.C.

This composite report of several studies on the psychological aspects of survival behavior deals with the following areas: a) fear in survival; b) specific enemies of survival, i.e., pain, cold, thirst, hunger, fatigue, boredom, and loneliness; c) group behavior under survival conditions; d) personality requirements for survival; e) relationships of downed air crew members with individuals and groups in enemy territory; f) psychological "set" as a factor in survival; g) conflict as a factor in survival; h) concessions to comfort; i) how to enjoy yourself in survival. The report takes the form of a series of non-technical discussions. The information sources were: a) Air Force evadees, escapees, and survivors in World War II and in the Korean combat; b) Arctic survival and rescue reports; c) intelligence reports of the Far Eastern Air Force; d) studies of behavior under the simulated survival conditions of the SAC Advanced Survival School; e) a survey of the related psychological literature. (HEIAS)

Torrance, E.P. PSYCHOLOGICAL ASPECTS OF SURVIVAL. Rep. 35, March 1953, 28pp. Human Factors Operations Research Labs., ARDC, Bolling AFB, Washington, D.C.

Information relevant to the psychological aspects of survival have been brought together from widely-scattered sources. Although almost nothing has been written directly concerning the psychological aspects for survival, there is a considerable body of data concerning psychological reactions to stresses which make up a part of "survival" which may be expected to apply to survival. Even in this, there are many gaps in present knowledge and the investigator interested in developing "a psychology of survival" is working in almost virgin territory. Perhaps the biggest gap in our knowledge occurs in relation to the application of the psychological principles which have been outlined to the practical problems of specific survival problems and survival training problems and the communication of these principles to trainees. It would seem that much of the emphasis of future research should be directed toward filling this important gap.

Warren, J.M. & Pinneau, S.R. INFLUENCE OF FORM ON JUDGMENT OF APPARENT AREA. Percept. Motor Skills, March 1955, 5, 7-10. (University of Oregon, Eugene, Ore. & University of California, Berkeley, Calif.).

The geometrical area of the circle, square, cross, and triangle judged subjectively equal to a 600 mm. standard circle was determined for 32 experimentally naive Ss by the method of constant stimuli. It was found that: a) With regard to subjective equality the 4 forms constituted 2 significantly different populations. The subjectively equal square was slightly larger than the standard circle in geometrical area; while the subjectively equal triangle and cross were approximately 20% smaller. The PSEs of the square and circle did not differ significantly, nor did the PSEs for triangle and cross. b) The data indicated that the Ss, although instructed to equate the figures in area, tended to equate the forms in the maximum vertical dimension.

Webster, J.C. A RECORDED WARBLE TONE AUDIOMETER TEST SUITABLE FOR GROUP ADMINISTRATION OVER LOUDSPEAKERS. J. Speech and Hearing Disorders, June 1952, 17(2), 213-223. Title also used: DEVELOPMENT AND USE OF THE NEL RECORDED WARBLE TONE HEARING TEST: PART II. Rep. 546, Part II, Dec. 1954. USN Electronics Lab., San Diego, Calif.

A pulsed-tone group hearing test has been developed which a) uses warble tones (tones that vary in frequency at a given rate, 5 cps), and vary over a given extent as from 885 to 1125 cps; b) uses within-group attenuation (each pulse within a group of pulses is softer than the pulse preceding it); c) is recorded on a phonograph disc (or magnetic tape) and therefore requires a less skilled operator to administer it. This test was tried out on 200 college students under 2 conditions; a) It was played back over a multiple array of loudspeakers in a reverberant room to groups of as many as 80 people, listening binaurally; b) It was played back over a network of 36 pairs of headsets to as many as 36 people listening binaurally. These same students also were given the more usual type of group tests over both loudspeakers and headsets. The test-retest reliability was a function of frequency and whether or not the person changed positions or headsets between test and retest, but in general the new test was as reliable as the better of the 2 control tests whether heard over headsets or loudspeakers. The comparison of the results of this test with the results of an individual clinical audiometer test, although based on a small sample, indicate that as a screening device it is satisfactory.

Webster, A.P. HIGH ALTITUDE-HIGH VELOCITY FLYING WITH SPECIAL REFERENCE TO THE HUMAN FACTORS. IV. OPENING SHOCK OF PARACHUTE DESCENTS. Proj. NM 006 014.09.01, Jan. 1953, 28pp. USM Medical Field Research Lab., Camp Lejeune, N.C.

The purpose of the paper was to discuss in detail the opening shock of parachutes and determine human tolerance to altitude and velocity for a particular type of parachute. The opening shock of standard American parachutes is shown to increase directly with the 4th power of the velocity (true air speed) of the jumper when the parachute opens; to increase directly with the weight of the jumper; and to increase directly with the mass density of the air, i.e. decrease with increase in altitude. A velocity-altitude tolerance table and chart were prepared showing a Safe Region producing 20 G. or less, a Dangerous Region producing 30 G. or more, and a Borderline Region producing between 20 and 30 G. (NEIAS).

Whiteside, T.C.D. VISION IN AN EMPTY VISUAL FIELD: A SUBJECTIVE TECHNIQUE FOR THE MEASUREMENT OF ACCOMMODATION. PPRC 850, Sept. 1953, 5pp. RAF Institute of Aviation Medicine, Farnborough, Hants, England.

6652 Weiss, H.S., Edelberg, R., Charland, P.V., & Rosenbaum, J.I. THE PHYSIOLOGY OF SIMPLE TUMBLING. PART II. HUMAN STUDIES. R00 695 61, Tech. Rep. 53 139, Part 2, Jan. 1954, 20pp. Aero Medical Lab., USAF Wright Air Development Center, Wright-Patterson AFB, Ohio.

In order to assess the tolerance limits to head-over-heels rotations or flat spins, as likely to be encountered in escape from aircraft, human subjects were spun on the horizontal spin-table. The experiments were guided by previous animal investigations but runs on human subjects were limited to 125 rpm because of the onset of pressure pain in the head or feet. During the spin, the physiological behavior of the human closely resembled that of dogs and, on the basis of this, curves for the responses of humans at speeds up to 110 rpm were extrapolated to the level of circulatory failure. By this procedure, it was estimated that the border line of unconsciousness would be reached after 3 to 10 seconds of rotation at 140 rpm and complete unconsciousness after 3 to 10 seconds at 160 rpm with the center of rotation at the heart. The data, together with performance tests and the observation of conjunctival petechiae, were used to determine the time-intensity areas of safe and dangerous rotations.

6654

To further investigation of such matters as the best form for a stimulus which might be fixated while searching in an empty visual field, a test is described by means of which accommodation can be measured without requiring the subject to fixate any object. The test was calibrated against measurements obtained with the coincidence optometer. The difference between the degrees of accommodation really exerted and the degree of accommodation expected when a test object is being observed is given.

Teichner, W.H., Kobrick, J.L., & Wehrkamp, R.P. THE EFFECTS OF TERRAIN AND OBSERVATION DISTANCE ON RELATIVE DEPTH DISCRIMINATION. Amer. J. Psychol., June 1955, 68, 193-208. (Quartermaster Research & Development Center, Natick, Mass.).

6661

To investigate the effects of terrain and observation distance on the precision of relative depth discrimination, (see 6662) and experimental situation modeled after the Howard Dolman apparatus was used. Four subjects made daytime equality judgments of the relative spatial positioning of two large targets at nine observation distances (from 200 to 3000 feet) over different types of flat terrain (meadow, airstrip, desert sand, desert pavement, and silt). Both monocular and binocular observations were made. Threshold data (standard deviations of settings) were analyzed in terms of distance and terrain functions. A prediction formula for the distance function in outdoor viewing is proposed.

Teichner, W.H., Kobrick, J.L., & Dusek, E.R. COMMONPLACE VIEWING AND DEPTH DISCRIMINATION. J. Opt. Soc. Amer., Nov. 1955, 45, 913-920. (Quartermaster Research & Development Center, Natick, Mass.).

6662

To determine the effects of terrain and observation distance on the precision of relative depth discrimination (see 6661), an experimental situation modeled after the Howard-Dolman apparatus was used. Four subjects made daytime equality judgments of the relative spatial positioning of two large targets at observation distances of 200, 750, and 1500 feet in an Arctic area over flat terrain. The data were compared with measurements taken over desert terrain and with similar data from other investigators. The standard deviations (precision) of depth discriminations were analyzed as functions of observation distance and type of terrain. The basis for commonplace depth discrimination is discussed.

6666

This paper presents a theoretical analysis of the factors influencing stress in warm and hot environments developed by means of physical equations of heat and moisture transfer. Two different situations are considered: (1) where all sweat is evaporated and cooling limited by sweat secretion, and (2) with the skin wet where cooling is limited by the amount of sweat which can be evaporated. Unequal evaporation over body area is also considered. Graphical presentation demonstrates the separate and combined effects of various environmental factors and indicates how clothing alters these effects. The theoretical results are compared with experimental findings of previous research.

Webb, W.D. ELEMENTS IN INDIVIDUAL-TO-INDIVIDUAL COMMUNICATION. Proj. NM 001 108 107, Rep. 4, May 1956, 6pp. U.S. Naval School of Aviation Medicine, Pensacola, Fla.

6667

To investigate some aspects of oral communication of information, test materials of relatively unfamiliar material (three Greek myths) were prepared. A communicator was selected at random from groups of twenty air cadets. After a period of study, the communicator transmitted the stories to a communicatee, who then answered a 45-item true-false test (reliability of .72). Eight communicators repeated the procedure for successive subjects varying in number from three to seven. Time per session was recorded. Test scores and time scores were evaluated by analyses of variance for differences due to communicator, time required to transmit information, and communicator-communicatee interaction.

Casperson, R.C., Lenzycki, H.P. & Orlansky, J. TAXIWAY LIGHTING, ROUTING AND DESTINATION MARKING SYSTEM FOR AIRFIELDS. Contract NOAS 51-1017 C, Tech. Rep. 32 1, March 1952, 79pp. Dunlap and Associates, Inc., Stamford, Conn.

6674

This report describes a study undertaken to develop a taxiway lighting, routing and destination marking system for airfields. The following procedures were used: survey of literature, survey of airport designs and existing equipment; pilot interviews and questionnaires; analysis of operating procedures to assess the present and future requirements for taxiing; and objective field and laboratory investigations, including tests of coding and legibility. The conclusions are presented in the form of recommendations for an optimum system: general operational requirements, marker content (terms and symbols), design of marker figures, lighting, circuiting, and placement and construction of signs.

Orlansky, J. IMPLICATIONS OF HUMAN ENGINEERING RESEARCH FOR TRAINING. No date, 11pp. Dunlap and Associates, Inc., Stamford, Conn.

6675

This report of a speech stresses the need for human engineering design of complex equipment in order to simplify training problems. The purposes and range of human engineering are described and illustrated in some detail, and the paper concludes with a discussion of the relation of human engineering to training.

6676

Peters, G.A., Jr. PRELIMINARY ANTHROPOMETRIC ESTIMATES OF HUMAN SURFACE AREA. Tech. Memo 7, June 1956, 20pp. Samuel Peltzman Assumption Laboratories, Picatinny Arsenal, Dover, N.J.

6676

To derive estimates of the amount of projected human surface area, a sample of anthropometric photographs in the Atlas of Man (Dr. W. H. Sheldon) were chosen. An integrating planimeter was used for obtaining area measurements of both front and side views. Descriptive statistics, correlations with other human physical attributes and predictive charts were obtained for both front and side projected surface areas. The relation of projected area to the total radiating surface was determined. Comparisons were made with data currently in use, particularly in the design of Ordnance items. Selective factors which tend to influence the anthropometric characteristics of a group are discussed. Recommendations for future study are made.

Müller, F.A. COMMUNICATION IN THE PRESENCE OF ADDITIVE GAUSSIAN NOISE. Contract DA36-039 sc 100, Proj. 8 102B 0, DA Proj. 3 99 10 022, Tech. Rep. 244, May 1953, 17pp. USA Signal Corps, Office of Naval Research, AFPC, Washington, D.C. (Research Lab. of Electronics, Massachusetts Institute of Technology, Cambridge, Mass.).

This report presents an analysis of the properties of finite segments of noise taken from correlated gaussian noise. This analysis is applied to the problem of optimal detection of signals when a communication channel adds gaussian noise and introduces a linear distortion. Some specific examples are discussed briefly.

Moser, H.M., Dreher, J.J., & Adler, S. NUMBER TELLING OF REPEATED DIGITS, EXACT HUNDREDS AND THOUSANDS. Contract AF 19(604)-1577, Proj. 664, Tech. Rep. 32, AFPCRC TN 55-73, June 1956, 8pp. Operational Applications Laboratory, AFPCRC, Bolling AFB, Washington, D.C. (Ohio State University Research Foundation).

6682

Moser, H.M., Dreher, J.J., O'Neill, J., & Adler, S. EFFECTS OF REPEATING THE INITIAL SOUNDS OF WORDS ON THE INTELLIGIBILITY OF AIR MESSAGES. Contract AF 19(604)-1577, Proj. 664, Tech. Rep. 30, AFPCRC TN 55-69, June 1956, 33pp. Operational Applications Laboratory, AFPCRC, Bolling AFB, Washington, D.C. (Ohio State University Research Foundation).

6682

To examine the effects of repeating initial sounds of words (a so-called "bounce" pattern) on the intelligibility of air messages, ten trained listeners indicated in writing their response to words spoken with "single-bounce" and with "double-bounce" technique (speech-to-noise ratio, -17 decibels). Percent correct responses was compared with data from a previous study using normal and "single-bounce" techniques. Messages patterned on current traffic control style were tested for intelligibility on 75 listeners using both normal and "single-bounce" telling techniques (speech-to-noise ratio, -5 decibels). The data were analyzed for effect of telling techniques and practice. Recommendations for further assignment of technique are made.

Moser, H.M., & Dreher, J.J. PRELIMINARY TEST OF AIR DEFENSE COMMAND PROCEDURE WORDS. Contract AF 19(604)-1577, Proj. 664, Tech. Rep. 34, AFPCRC TN 56-54, July 1956, 14pp. Operational Applications Laboratory, AFPCRC, Bolling AFB, Washington, D.C. (Ohio State University Research Foundation).

6683

The purpose of this study was to determine the relative intelligibilities of certain procedural words used in Air Defense operations when spoken by American, French, and Spanish speakers to American listeners. Six key words of the telling procedure (Track, At, Range, Course, Objects, Speed) were combined into word lists with 36 other words and recorded by foreign and American speakers. They were played back to three groups of listeners (32, 45, and 50) in quiet, with white noise (+5 signal-to-noise ratio) and with voice babble (+5 signal-to-noise ratio). Articulation scores were analyzed for effect of speaker nationality under all conditions. Recommendations for further research are made.

Muller, P.F., Jr., Sidorosky, R.C., Slivinske, A.J., Alluisi, E.A., & Pitts, P.M. THE SYMBOLIC CODING OF INFORMATION ON CATHODE RAY TUBES AND SIMILAR DISPLAYS. Contract AF 33(616)-43, Proj. 7192, Tech. Rep. 55-375, Oct. 1955, 123pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio. (Ohio State University Research Foundation).

6684

This report summarizes the results of a series of eleven studies of the feasibility of several different types of symbols for the coding of information on cathode ray tubes (CRT) and similar displays for use in future air traffic control and related systems. Section I contains specifications and recommendations for engineering applications to CRT displays. Section II contains detailed results of the laboratory investigations. Four basic code symbols (inclination, ellipse ratio, blip diameter, and color) are dealt with, and then multi-dimensional alphabets combining two or more symbols. Psychophysical data on absolute discrimination and on information-handling ability with the various symbols are given.

6681

To measure relative intensities of sustained vowel sounds at various locations from the larynx to the top of the head, three subjects (representing three distinct body types) practiced until they could maintain each of twelve vowel sounds at 76 decibels for five seconds. A bone oscillator was placed in each of 16 positions on head and neck; the signals, fed into an Ampex recorder, were recorded at constant gain setting. The resultant 576 readings were analyzed for relative intensities by power level tracings and evaluated by analysis of variance. Anatomical locations were ranked on basis of intensity of transduced vowel sounds. Subjective judgments were made of the position yielding the most faithful reproduction. Implications for recording speech signals are discussed.

6685

Muller, P.F., Jr. EFFICIENCY OF VERBAL VERSUS MOTOR RESPONSES IN HANDLING INFORMATION ENCODED BY MEANS OF COLORS AND LIGHT PATTERNS. Contract AF 33(616) 43, Proj. 5 (7 7192), WADC TR 55 472, Dec. 1955, 15pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Ohio State University, Columbus, Ohio).

6685

To compare the relative compatibility of verbal and motor responses to different types of visual stimuli and to determine the effect of verbalization as a factor in transfer from one type of response to the other, four experimental and four control groups made verbal (number-naming) and motor (key-pressing) responses to spatial and to color symbols. Control groups made the same response during training and transfer trials; experimental groups trained on one type of response and used the other in transfer trials. Data (reaction times and information-handling rates) were analyzed for most compatible stimulus-response conditions and for transfer effects. The results are discussed in relation to general concept of stimulus-response compatibility.

Maag, C.H., & Hall, A.L. CHARACTERISTICS OF MENTAL IMPAIRMENT UNDER HYPOXIA. Proj. NM 001 101 104, Rep. 2, March 1956, 24pp. U.S. Naval School of Aviation Medicine, Pensacola, Fla.

6686

To investigate the characteristics of the decrement in performance on a conceptual reasoning test under conditions of oxygen deprivation, ten subjects were given pre-experimental training to a learning plateau on a conceptual reasoning test. A criterion for impaired responses (three standard deviations above mean time to complete a problem after training) was used to evaluate performance under exposure to various simulated altitudes (sea level, 13,000, 16,000, 17,000, and 18,000 feet) for 129 minutes or until unconsciousness. Performance data for each subject were divided into five phases of equal numbers of responses made during period of consciousness. Altitude and phase effects are analyzed in terms of performance means and performance meeting the criterion. Typical behavior under oxygen stress is discussed. T.G. I. R 18

6688

Mann, C.W., & Ray, J.T. THE PERCEPTION OF THE VERTICAL. XIV: THE EFFECT OF RATE OF MOVEMENT ON THE JUDGMENT OF THE VERTICAL. Tulane University Contract Nonr-475-05, Proj. NM 001 110 500, Rep. 40, (ONR Proj. NR 142-455), May 1956, 11pp. U.S. Naval School of Aviation Medicine, Pensacola, Fla.

6688

To investigate the possibility of right and left quadrant differences in the judgment of the postural vertical without aid of visual reference, four subjects were tested. Time out of vertical (movement time to inclination, delay at inclination, and return to vertical) was held constant at approximately 82 seconds with varying movement rates (0.77, 1.10, and 1.33 degrees per second), and degrees of tilt (10, 20, and 30 degrees). Error data were evaluated by analysis of variance techniques for differences due to quadrants, rates, tilts, and subjects. The findings are related to other studies in the literature.

6691 Nottingham, W.B. SURVEY OF METHODS USED TO DETERMINE THE OPTICAL PROPERTIES OF PHOSPHORS. Contract N36 039 sc 32037, Proj. 1028, DA Proj. 3 99 10 022, Tech. Rep. 110, May 1949, 13pp. Army Signal Corps, ONR, Air Materiel Command, Research Laboratory of Electronics, Massachusetts Institute of Technology, Cambridge, Mass.

A brief review of the theory of phosphors is given in terms of the electron-band picture of impurity semiconductors in order to show the reasons for researches designed to obtain the optical properties of phosphors. The automatic spectroradiometer is described, since it is an instrument which yields so much information of value in phosphor research, development and quality control. Some problems of spectroradiometer standardization are discussed in detail; since the data obtained cannot be correctly explained by the I.C.I. system of color specification and interpretation unless satisfactory standards are maintained and used. A brief discussion is given of the application of the I.C.I. system to aid in the choice of phosphors required to produce a suitable white for television cathode-ray tubes. Other researches discussed include the determination of phosphor excitation curves, the emission of light as a function of temperature and of time, and the correlation of spectral excitation and absorption data.

Newman, R.W. SKIN-FOLD CHANGES WITH INCREASING OBESITY IN YOUNG AMERICAN MALES. *Hum. Biol.*, May 1955, 27 (2), 53-64. (Quartermaster Research & Development Center, Natick, Mass.).

6692

Two problems involving skin-fold measurements to calculate body fat were examined in this paper. Data used were taken on 2,000 young American men (1,702 white, 292 Negro) soon after induction into the United States Army. (1) Negro and white skin-fold relationships were analyzed by comparing correlation coefficients between skin-fold sites and average skin-fold values for increments of obesity. (2) A graphic comparison was made of the various skin-fold sites in a combined series of the 2,000 men to study changes in proportional representation of the average site values between lean and fat subjects. The uses and limitations of the data are discussed.

Katchmar, L.R., & Azrin, N.H. EFFECTIVENESS OF WARNING LIGHTS AS A FUNCTION OF FLASH RATE. *Tech. Rep.* 23, Aug. 1956, 5pp. Human Engineering Laboratory, Aberdeen Proving Ground, Md.

6695

To investigate the extent to which changes in flash frequency would change the effectiveness of a warning light in eliciting a reaction, ten subjects were required to judge which of two flashing lights they would turn off first. Two light sources were used each flashing at a different rate, duration of flash was constant, flash rates varied, from one to sixty cycles per second, intensity of light was approximately one foot candle (at source). The data (preferences) are analyzed as a function of flash rate. Discussion relates the results to subjective feelings caused by intermittent stimulation of various frequencies. Study of other factors is recommended.

6696

Kobrick, J.L. A STUDY OF PERFORMANCE DIFFERENCES AMONG FIVE TYPES OF BUTTONS. *Proj.* 7-95-20-0038, Oct. 1955, 7pp. *Quartermaster Research and Development Center*, Natick, Mass.

6696

To investigate design factors, exclusive of size, which contribute to ease of operation, five types of buttons 3/4 inch in diameter were tested for differences in ease of buttoning and unbuttoning. Subjects (75) performed on each type of button using the bare hand or wearing the wet-cold glove ensemble. Performance data (time to button and unbutton) were analyzed for differences among the five types. The results were compared to those of a previous study where size was the variable to establish the critical design variable. Recommendations are included.

Mackworth, J.F. & Mackworth, N.H. THE OVERLAPPING OF SIGNALS FOR DECISIONS. *Amer. J. Psychol.*, March 1956, 62(1), 26-47. (Applied Psychology Research Unit, MRC, Cambridge, England). (APU Rep. 225/56).

6697

To investigate the effect of varying the number of sources of visual information upon performance, 28 subjects performed a task in which symbols on a fixed card were matched to those on moving cards. Channels supplying cards for matching were varied from two to twelve; speed was varied from five to ten seconds per comparison in one experiment but was constant at six seconds in another; only one moving card could be seen at any stage; criterion of performance was percentage of failures (wrong plus omitted answers). An index of signal-overlap (total sum in seconds of the various periods during which any signal is overlapped by any other signal) was used in analyzing speed-stress produced by multichannel displays and its effect upon accuracy of performance.

6703 Goldsmith, C.T. NOTE ON THE PORTABILITY OF AMMUNITION BOXES (U). Tech. Memo. 6, June 1956, 12pp. Samuel Peltman Ammunition Laboratories, Picatinny Arsenal, Dover, N.J.

6703

To provide design recommendations for a class of boxes with single rope handles on the end, a preliminary investigation of problems of portability was conducted. Anthropometric measurements were made from photographs on a sample taken from The Atlas of Man (W.H. Sheldon) of the distance from middle knuckle to ground. Six boxes (20 to 26 inches in length) with rope handles on the end (position varied) with load varying (from two to 88 pounds) were carried by three subjects over a slightly inclined terrain. The subjects represented the 29th, 71st, and 96th percentiles in hand-to-ground characteristics. On the basis of subjective preferences and observations, tentative recommendations for box design are given. The need for a systematic study is pointed out.

6708 Lee, R.H., Pilon, K., Catchpole, H.R., & Finch, E.M. PERIODIC FLUCTUATIONS AND THRESHOLD LEVELS IN DARK ADAPTATION AND THE EFFECTS PRODUCED BY PAREDRINE, OXYGEN, CARBON DIOXIDE, AND ASCORBIC ACID. Res. Proj. X 211, Res. Rep. 2, Sept. 1944, 7pp. USN Medical Research Institute, National Medical Center, Bethesda, Md.

Threshold fluctuations have been observed during the course of dark adaptation in human Ss. These fluctuations have a period of several min. and amplitudes from crest to trough as much as 0.5 log units. Absence of fluctuations in the curves of some individuals and occasional variations in the amplitude and period, characteristic of the curves of individuals who exhibit them suggested that environmental factors might be discovered which would produce or suppress these variations. Breathing a 3% mixture of CO₂ and air for 1/2 hr. elevated the threshold by as much as 0.16 log units but had no effect on the fluctuations. A 2% mixture of CO₂ and air had no effect on threshold level or on fluctuations. 100% oxygen, likewise, had no effect. During mydriasis, produced in 4 Ss by administration of paredrine, dark adaptation thresholds were significantly lower for the first 20 min. of testing. Ss normally exhibiting fluctuations continued to do so under the influence of paredrine. Changes in pupillary diameter, therefore, are not the cause of the fluctuations. The juice of 15 oranges consumed daily for 3 days did not significantly lower the threshold of the group. One gram of ascorbic taken daily by 2 Ss for 4 days failed to affect their thresholds. R 4

6709 Noble, Rosalie. HUMAN ENGINEERING INVESTIGATIONS OF AIRCRAFT COCKPIT VISUAL DISPLAYS: PART 19. DESIGN AND DEVELOPMENT OF AN ELECTRONIC TACHISTOSCOPE. TED NAM AE-7047, Rep. 290, Part 19, Oct. 1956, 18pp. Naval Air Experimental Station, NAWC, Philadelphia, Penn.

6709 A tachistoscope, composed primarily of commercially available components and designed for use in short interval visual presentation studies, is described. Calibration curves, derived from tests to determine the relationship between the frequency setting on the audio oscillator and actual flash duration, are given with the useful position from about six milliseconds to 1.5 seconds flash duration. Photographs, wiring circuits and directions for use are included. I. C.

6710 Peters, G.A., Jr. HUMAN ENGINEERING--A NEW APPROACH TO OPERATIONAL DESIGN. Mechanical Engng., Oct. 1956, 78, 926. (Samuel Feltman Ammunition Laboratories, Picatinny Arsenal, Dover, N.J.).

6710 This paper gives a short resume of the background for the emergence of the field of activity known as "human engineering." The varied sources of knowledge for this field are mentioned. The need of some formal organization for individuals working in this field is pointed out--the primary need being opportunity for communication. R 6

6711 Peters, R.W. STUDIES IN EXTRA-MESSAGES: THE EFFECT OF VARIOUS MODIFICATIONS OF THE VOICE SIGNAL UPON THE ABILITY OF LISTENERS TO IDENTIFY SPEAKERS' VOICES. Contract N60MR 22525, Res. Proj. M1 001 104 500, Joint Res. Proj. Rep. 61, May 1956, 14pp. U.S. Naval School of Aviation Medicine, Pensacola, Fla.

6711 To evaluate factors relative to listener identification of speakers' voices, six groups (24 listeners in each) heard 150 speech samples which had been recorded by five speakers, and attempted to identify the speaker. Six modifications of the voice samples were tested: variations in sound pressure level--both increased and decreased 14 decibels by two-decibel steps, short interruptions at rates from one to twelve per second, addition of octave frequency bands of the signal to the original signal, high-pass filtering, low-pass filtering, variations in signal-noise ratios from plus to minus ten decibels. Identification scores (percent correct) were analyzed to assess the effect of these factors. T. R 3

6712 Rakes, C.E., Kaune, J.E. & Burch, W.J. ACOUSTIC POWER LEVEL DETERMINATION FOR MACHINERY IN HARD AND SEMI-HARD ROOMS. R & D Rep. 050016, NS-713 212, Feb. 1956, 5pp. USN Engineering Experiment Station, Bureau of Ships, Annapolis, Md.

6712 To determine the feasibility of writing machinery noise specifications in terms of acoustic power (or acoustical power level, PML) instead of sound pressure levels, tests were made determining the validity of power level measurements in acoustically untreated rooms. Measurements of the acoustical power of three different sound sources (1/6 horsepower refrigerator compressor, 3 horsepower air compressor, white noise generator) were made in an anechoic chamber and in a variety of hard and semihard rooms. The room constant or acoustical index of each room was established. The data consist of PML Estimated, PML Calculated, and the diffuse field sound power level (SPLd) for the various sound sources and rooms. Equations and procedures used are given in appendices. T. G. I

6713 Provins, K.A. A STUDY OF SOME FACTORS AFFECTING SPEED OF CRANKING. R.N.P. 53/755, O.E.S. 237, June 1953, 19pp. Research on Climate and Working Efficiency Unit, MRC, Oxford University.

6713 To study some of the factors affecting speed of cranking, times for six subjects to turn a crank against a known load at maximum speed for a set number of revolutions under a variety of operating conditions were recorded. These conditions included differences of height and forward positioning of the crank, direction of rotation, and hand used. Tables giving means, tests of significance, analysis of variance, and correlations between the various measures are presented and discussed. T. G. I. R 18

6714 Holzman, P.S. & Klein, G.S. INTERSENSORY AND VISUAL FIELD FORCES IN SIZE ESTIMATION. Percept. Mot. Skills Res. Exch., 1956, 6, 37-41. (Menninger Foundation & New York University).

6714 To study some factors in size estimation, sixty subjects judged the sizes of disks which were varied as to weight and figural compactness. Three disks (48.5 millimeter, 65 gram, gray; 48.5 millimeter, 10 gram, gray; and 50 millimeter, 10 gram, black) were hand-held while subject adjusted a circle of light to match it. Four disks (42 millimeters, pink mounted on black, with a picture placed in center) were placed on a wall while subject matched the size. Percentages of over- and under-estimations were analyzed for size-weight interactions and for effects of phenomenal compactness (strong contour and centered figure). The findings are discussed in relation to size distortions attributed to value and need. T. R 10

Borg, J.C. RESEARCH INTO BASIC METHODS AND TECHNIQUES OF AIR FORCE JOB ANALYSIS-IV. Train-
ing. AFTRC TR-66-61, April 1956, 69pp. Train-
ing Air Research Lab., AFTRC, AEC, Chasote
AFB, Ill.

6716
This paper presents the results of a project in which five commonly used job analysis techniques were evaluated in the military situation. Teams of four analyzed four jobs each at 25 Air Force bases using the following techniques: questionnaire survey, group interview, individual interview, observation interview, and technical conference. The relative efficacy of the methods was evaluated through the determination of the coverage of job elements, tasks, equipment, and inter-
able verbal cues, which were provided.

Roby, T.B., & Lanzetta, J.T. AN INVESTIGATION OF TASK PERFORMANCE AS A FUNCTION OF CERTAIN ASPECTS OF WORK-GROUP STRUCTURE. Rep. AFTRC-TR-56-74, June 1956, 12pp. Crew Research Laboratory, AFTRC, Randolph AFB, Tex.

6720
To make a preliminary investigation of the relation-
ship of the task communication structure to team per-
formance, groups of three subjects were required to per-
form a laboratory task which simulated an aircrew task
at a general level. Four communication structures were
used varying from that in which control agents had direct
access to none of the information needed to operate their
six controls to that in which they had direct access to
information for all but one of their controls. Scores
consisted of number of errors made in a period of 27
trials (15 seconds/trial) and were evaluated by analysis
of variance for effects of communication structures,
training, and specific controls. Further experimentation
is recommended.

CODED CHARACTERS FOR TACTICAL IDENTIFICATION OF CERTAIN
PERFORMANCES. Contract DAM-20-617-501-600-77-1294,
Aug. 1956, 7pp. Quincy and Associates, Inc., Stamford,
Conn.

6721
To establish a system for identification of pyro-
technic items for use under combat field conditions;
experimental comparisons were made between two sets of
experimental letters (single and paired, height 7/8 inch,
width 5/8 inch, embossing 1/16 inch), one set of symbols
(diagonal, period, and dash), and the letters currently
in use (paired letters, height 1/2 inch, width 3/8 inch,
embossing 1/22 inch). Subjects (22) wore opaque goggles
and attempted to "read" symbols by touch, either with the
bare hand or wearing various combinations of the tactile
mitts. Mean discrimination times and percentages of
errors of identification were analyzed. Recommendations
for identification systems are made on basis of the
findings with a discussion of human engineering factors.

Rispoli, A.J. ACCLIMATIZATION AND INDOCTRINATION STUDIES RELATING TO COLD WEATHER LIVING AND THE USE OF QUARTERMASTER CLOTHING AND EQUIPMENT. Contract DA-44-100-gp-1129, Proj.
7-65-20-0034, Tech. Rep. EF-32, Aug. 1956,
76pp. Quartermaster Research & Development
Center, Natick, Mass.

6722
To establish a sound basis for developing training
doctrine about cold weather living and the care and use
of Quartermaster cold weather clothing and equipment, a
cold weather information survey was developed. The sur-
vey was used to assess knowledge of correct principles
and practices of cold weather living from (1) enlisted
soldiers with and without overseas experiences, (2)
soldiers at various stages of military training, (3)
trainers receiving cold weather indoctrination at dif-
ferent stages of training, and (4) soldiers at varying
intervals after leaving basic training. Implications for
the development of training doctrine are discussed.

Sandberg, K.O.W., & Lipschultz, H.L. RELATIVE PERFORMANCE FOR CRANKING A HAND WHEEL AT DIP-
PERENT POSITIONS ON A VERTICAL SURFACE. Con-
tract W5ori-166, Task Order 1, April 1948,
22pp. Industrial Engineering Lab., New York
University.

6723
This investigation measured the speed with which
subjects can crank a hand wheel at different positions
on a vertical surface. Eleven male subjects were used.
During all tests the subjects were seated in a straight-
backed chair whose back was 24 inches from the vertical
surface. Test positions were spaced at four inch
intervals vertically and horizontally and covered an
area of 44 inches vertically and 40 inches horizontally.
The areas of best performance were determined for each
hand and the relative performance at all test positions
is charted.

Schipper, L.N., & Versace, J. HUMAN ENGINEER-
ING ASPECTS OF RADAR AIR TRAFFIC CONTROL: I. PER-
FORMANCE IN SEQUENCING AIRCRAFT FOR LAND-
INGS AS A FUNCTION OF CONTROL TIME AVAILABIL-
ITY. Contract AF 33(616)-43, Proj. 5-(7-7192)
Tech. Rep. 56-67, Feb. 1956, 12pp. Aero
Medical Laboratory, WADC, Wright-Patterson
AFB, Ohio.

6724
To investigate some problems of radar air-traffic con-
trol, four inexperienced controllers were required to
vector blips representing aircraft on a dynamic display
to a hypothetical GCA gate. Air speeds and turn rates
of aircraft were fixed (120 knots and three degrees per
second), thus control was effected with turn only.
Four aircraft were represented at equal distances from
GCA gate; azimuth positions and distances were varied
systematically in five problem-difficulty levels. Ef-
ficiency (solution time over minimum possible time) and
safety (frequency counts of aircraft closer than 15 se-
conds in-transit and 30 seconds at GCA gate) were analyzed
as functions of difficulty or available control times
and practice.

Schoeffler, M.S. THE AMOUNT OF INFORMATION PRESENTED AS A PARAMETER OF TRACKING PERFORMANCE. AMRL Proj. 6-95-20-001, Rep. 197, June 1955, 12pp. USA Medical Research Lab., Fort Monmouth, Ky.

6726

An attempt was made to relate the amount of information received by a subject regarding the position of a target to time-on-target scores in a compensatory tracking situation. The 60 subjects manipulated a control handle according to "instruction" from a panel of lights. One group received no information regarding the size or direction of their error, while each of three other groups received increasing amounts of information from the display. Time-on-target and number-of-hit scores were averaged over each two-minute session for each group and the data were then treated by analysis of variance techniques.

PHASE II, VISIBILITY DATA AS IT APPLIES TO PYROTECHNICS. Contract DAI-28-017-501-045-(P)-1254, April 1955, 54pp. Dunlap and Associates, Inc., Stanford, Conn.

6730

To integrate and evaluate the available information regarding human visual performance that is important in the design and development of military pyrotechnics, this manual was prepared. Two primary areas are considered: illumination of a selected area (effects of color, duration, and brightness of light, and the contrast and size of target objects), and visual signaling (visibility and recognition as a function of flare or smoke characteristics and ambient conditions). Recommendations for design are accompanied by plans for experimental field evaluation. The appendices include: definitions of visual terms, conversion factors for brightness and illumination units, reflectance values of various surfaces, and some simplified approximation techniques. Swanson, P.A. & Ashes, L.E. EVALUATION OF TRAINING DEVICES FOR B-47 FUEL, HYDRAULIC, AND RUDDER POWER CONTROL SYSTEMS. Proj. 7714, Rept. AFPTAC TN 56-2, Jan. 1956, 43pp. USAF Personnel & Training Research Center, Training Air Research Lab., Chanute AFB, Ill.

The purpose of this study was to provide information as to whether there are differences in the relative effectiveness of representative types of training devices when these devices are used as visual aids in lectures in the transitional maintenance training of skilled mechanics. 1906 skilled technicians were given instructions on one or another of 3 aircraft systems: fuel, hydraulic, and rudder control. Under one procedure the 5s were taught by lectures and under another procedure were taught solely by letting them inspect the devices. Following the instruction periods, the criterion test appropriate to the system was administered. 5 - 8 weeks later they were retested with the same examination. It was found that within any one system none of the differences among groups taught by means of a common lecture, but different devices, was statistically significant. In the "alone" procedure, significant differences were found among devices in the case of immediate recall scores for the hydraulic and rudder power control systems only. In terms of delayed recall scores no significant differences were found among the hydraulic or fuel devices. (MEIAS)

6731

To study human engineering problems in design of the Armored Infantry Vehicle, M59, from the point of view of the using soldier, an interview schedule was prepared covering problem areas for each crew position and a rating of the most serious problems. A group interview technique was used to gather information from 322 men in the First Armored Division. Questions asked and percentage results are listed followed by analysis of the problem, discussion and recommendations. Problems covered were temperature, intercommunication, equipment storage noise and vibration, placement of controls and displays, seating, bracing, entrances, visual requirements, and other miscellaneous problems.

Davenport, R.W. AN INVESTIGATION OF FATIGUE
IN ASW HELICOPTER CREWS. Rep. 610, June 1955,
15pp. USN Electronics Lab., San Diego, Calif.

6733
To investigate the factor of fatigue in ASW (Air-
Search and Warning) helicopter operation, inflight per-
formance measures, postflight performance measures, and
subjective measures of fatigue were devised for use with
4 pilots, 4 sonar men, and 4 nonflying pilots who served
as controls. The experimental program consisted of 3
two-hour flights and 3 one-hour testing periods daily,
for 5 consecutive days. The flight performance was anal-
yzed in terms of the change in hovering performance on
the part of the pilots and change in accuracy of sonar
echo detection. Decrement in postflight steadiness,
speed, and coordination were checked, as well as flicker-
fusion threshold, auditory threshold, and subject atti-
tudes after flight.

Corbin, H.H., Reese, E.P., Reese, T.W., &
Volkmann, J. EXPERIMENTS ON VISUAL DISCRIM-
INATION, 1952-1955. Contract AF 18(600)-344,
Rep. AFRC-TR-56-52, April 1956, 55pp. Oper-
ational Applications Laboratory, AFRC, Psy-
chophysical Research Unit, Mount Holyoke Col-
lege.

6734
This report is a summary of a research program (ap-
proximately twenty experiments) investigating four areas
of visual discrimination. 1) Judgment and scaling:
estimation of visual position and visibility of stimuli
in a large homogeneous field. Number of categories se-
lected by subjects to judge various distributions. Size
of constant error for bisection of visual position.
Comparison of two methods for scaling verbal items. 2)
Subjective Statistics: judgments of means, median,
range, and contingency. 3) Visual Grouping: identifica-
tion of groups of planes converging on a friendly target,
and 4) Judgment of position after Enforced Delay.

Faño, R.M. THE TRANSMISSION OF INFORMATION - II.
SC Contract W36 039 SC 32037, Proj. 102B, DA Proj.
399 10 022, Tech. Rep. 149, Feb. 1950, 29pp. Research
Lab. of Electronics, Massachusetts Institute of Tech-
nology.

6736
This report deals with the transmission of in-
formation through a discrete channel disturbed by noise.
The problem of reducing the equivocation by coding is
considered in particular. The behavior of the per-
unit equivocation as a function of the channel equi-
vation is computed in an approximate manner for a
number of coding schemes of increasing complexity.
The results indicate that the limiting condition of
vanishing per-unit equivocation is approached rather
slowly with increasing code complexity.

Hackman, R.C. & Korshner, A.H. THE DETERMINATION OF CRITERIA OF READABILITY. Contract IR-
153 024, Tech. Rep., Aug. 1951, 59pp. SMR, University of Maryland, College Park, Md.

The purpose of this study was to develop a practical method for establishing readability
criteria. 200 reading passages were ranked on a 7-point scale. 2 groups of 121 passages were
set up. Sets of passages were administered to 420 Ss. Each S judged relative reading diffi-
culty for him for each pair of passages and unknown to him was timed in the process of read-
ing. Upon the basis of judged relative difficulty and relative reading time, 22 criterion
reading passages were selected, 11 "hard" and 11 "easy". An analysis of these passages yield-
ed 11 predictor variables and a discriminant function was calculated using 9 of the variables.
This produced a prediction equation which differentiated between the means of the predicted
values for the criterion passages at a highly significant level. Implications of this method
for the determination of readability parameters and for the solution of specific readability
problems are presented. These results suggest the readability of the method for the develop-
ment of practical readability criteria.

Goldstein, A.G. JUDGMENTS OF VISUAL VELOCITY AS A
FUNCTION OF THE LENGTH OF OBSERVATION TIME OF MOVING
OR NON-MOVING STIMULI. Proj. 6-95-20-001, Rep. 258,
Jan. 1957, 11pp. AHRL, Fort Knox, Ky.

6739
To investigate the effect of increasing the duration
of prior observation of movement and non-movement stimuli
upon apparent (subjective) velocity judgments of visual
movement, three types of pre-test stimuli were used:
moving black and white stripes, stationary stripes, and
a blank area. Twenty-six subjects viewed each of these
stimuli for various periods of time (2, 8, 15, 22, and 30
seconds) before making judgments of the velocity of the
test stimulus (black and white stripes velocity, 14.28
centimeters per second). The data (time to move a stylus
across the field at the velocity of the test stimulus)
were studied by analysis of variance techniques for ef-
fects of type and duration of observation of pretest
stimuli.

Hodge, D.C. THE EFFECTS OF MODIFIED M1-RIFLE SIGHTS ON MARKSMANSHIP AT LOW LEVELS OF ILLUMINATION. Proj. TBI-1000-22, Tech. Memo. 25, Aug. 1956, 15pp. Human Engineering Laboratory, Aberdeen Proving Ground, Md.

6741

To determine the optimal rifle sight for use under low and high illumination, several previously tested experimental sights together with some sights in use on rifles were compared with the standard M1 rifle sight. Testing was done in the laboratory situation where the task was reduced to alignment of target and sights. Two levels of illumination were used: fifty and one foot candles; eighty subjects (five for each of 16 combinations of sights and illumination). The accuracy data for the last five out of ten trials were analyzed for significant differences due to sight. Rank orders of sights for each illumination level were compared. Field tests are recommended.

6748 Goldsmith, C.T. & Vandenberg, J.D. A HUMAN ENGINEERING EVALUATION OF OPENING DEVICES FOR AMMUNITION CONTAINERS UNDER ARCTIC CONDITIONS. Tech. Memo. 2, Jan. 1956, 14pp. Samuel Feltman Ammunition Laboratories, Picatinny Arsenal, Dover, N.J.

To evaluate the methods of opening fiber and metal containers for use under Arctic conditions, 25 subjects were required to open the containers under simulated cold-weather conditions (wearing Arctic handgear) and containers aged at temperature of -65, -45, -25 degrees Fahrenheit, and room temperature (control). Fiber containers were sealed by wrapping tape with extended tab varying length (1.25, 1.50, 1.75, and 2.00 inches) to be grasped and pulled. Metal containers had key on top to be removed and used on a metal tear strip. Tests were run on three successive days; measure of performance was the time required to open container. The results are analyzed for effect of tab length, temperature, type of hand gear, and practice. Recommendations are included.

Gagne, R.M. RESEARCH PLANNING CONFERENCE ON PERCEPTUAL AND MOTOR SKILLS. Conf. Rep. 49 2, Nov. 1949, 98pp. Perceptual & Motor Skills Research Lab., USAF Human Resources Research Center, Lackland AFB, San Antonio, Tex.

This report is divided into 7 parts. Part I lists the conference participants. Part II presents the condensed minutes of the meetings, supplementing the Agenda, which is given as Appendix A. Part III consists of the synopses and discussions of reports on Armed Forces problems of classification, selection, training and equipment design which require research on perceptual and motor skills. The complete texts of 2 of these reports were submitted and are presented in Appendix B. Part IV presents the synopses and discussions of reports given by conferees associated with the Perceptual and Motor Skills Research Laboratory concerning suggested organization, methodology and programs of perceptual and motor skills research. Certain of these reports were based in part upon a preliminary analysis of factors in psychomotor performance, which is included as Appendix C. The complete texts of a number of these reports are presented in Appendix D. Part V incorporates the synopses and discussions of the views of a number of the conferees regarding important theoretical and methodological problems in perceptual and motor research. Part VI, the report of the Subcommittee on Perception, and Part VII, the report of the respective Subcommittees with regard to the organization of research within these 2 areas, priorities to be assigned to various programs, and the nature of contracts with outside agencies for research and literature surveys relevant to the mission of the laboratory.

Lindsay, D.B. (Proj. Direc.). A STUDY OF THE SCR-584 BASIC TRAINER AS A TRAINING DEVICE FOR LEARNING RANGE TRACKING. Contract DEMR 919, Proj. SC-70, NS 146, OSD Rep. 3344, Res. Rep. 7, Feb. 1954, 14pp. Applied Psychology Panel, National Defense Research Committee. (Verkes Laboratories of Primate Biology, Orange Park, Fla.).

An experimental investigation was made on the use of the SCR-584 Basic Trainer to determine the value of the trainer as an aid in improving tracking ability. Specifically it was desired to find the degree of skill obtainable by the uninitiated subject at various stages of practice. 25 enlisted men without prior tracking experience were trained on the device to carry out the study. An attempt was also made to determine how closely tracking ability acquired on the actual SCR-584 equipment corresponds to that developed by means of the trainer. For this purpose 66 enlisted men were studied. Conclusions are given to the effect that the task as such is dependable as a measure of operator tracking skill.

Flanagan, R.E. & Latham, A.J. USE OF A CONTACT FLIGHT SIMULATOR IN THE TRAINING OF BASIC STUDENT PILOTS. Proj. 508 017 0002, Res. Note 52 1, April 1952, 5pp. USAF Human Resources Research Center, Air Training Command, Lackland AFB, San Antonio, Tex.

In summary, 10 airmen who had no previous pilot time were taken to the University of Illinois to act as students in the training of the 10 flight instructors from Pilot Training Research Laboratory. This note presents information on student which, while incidental to the primary purpose of the activity (that of instructor training) and unsuitable for statistical analysis, contains interesting implications for training research. A large proportion of the pre-solo maneuvers and skills appeared to have been learned in the P-1 trainer by the rather highly selected sample of men utilized. The extent to which these can be learned by regular cadet samples, what other skills can be so gained, and the best combination of trainer and aircraft time, are topics which require a major and rigorously controlled investigation.

6757

Breher, R.E., Peterson, P.G. & Deuel, P.D., Jr. AN ANALYSIS OF THE RADAR FLIGHT GRADING SYSTEM AT MATHER FIELD. Res. Notes DQM: 50 4, Sept. 1950, 20pp. USAF Human Resources Research Center, Mather AFB, Calif.

The purpose of this project has been to evaluate the present serial check missions in the radar phase of AOB training at Mather Air Force Base. This project represents one aspect of a broader program in progress to determine the adequacy of proficiency measures now in use at Mather Field. 2 closely related problems present themselves in an evaluation of this type. The first has to do with the discriminability of the flight check as a measuring device--the adequacy of the items used on the check. The second problem places emphasis on the actual use or functional value of the flight checks, as administered by the flight instructors. It is obvious that these 2 problems are inextricably interrelated in this evaluation. For purposes of clarity, however, they will be considered separately.

Molunphy, G.G. REPORT OF DIVING TRAINING IN USS CHANTICLEER OFF KEY WEST, FLORIDA DURING THE PERIOD 19 OCTOBER TO 8 DECEMBER 1948. Proj. NS 186 042, Rep. 1, 5pp. Bureau of Ships, Navy Dept., Washington, D.C.

This report deals with the results of diving training the object of which was to: a) train members of the diving party in operations at deep depths; b) evaluate surface decompression procedures; c) test modified diving gear; d) prove newly computed decompression schedules; e) promote confidence in helium-oxygen diving. After equipment was tested and divers drilled in ventilating, circulating and going on open circuit in shallow water alongside the dock, a total of 67 dives were performed between 272 and 485 ft. Conclusions drawn are as follows: a) the training is valuable; b) surface decompression procedures as used proved satisfactory for all dives made; c) tentative decompression schedules to at least 550 ft. may be computed without considering tissues slower than the 70 min. tissue for dives up to 20 min.; d) a larger venturi discharge nozzle and larger high pressure nozzle used with gas at 50 lb. over bottom pressure gave satisfactory results; e) helium-oxygen diving is safe to partial pressures of 410 ft.; f) current is a major obstacle to planned diving operations; g) 40 lb. diving shoes are useful on a hard bottom; h) the personnel involved have confidence in helium-oxygen diving. (HEIAS)

6759

De Valois, R.L. & Law, O.T. STUDIES OF ALLEGED D-C ELECTROSENSITIZATION OF NIGHT VISION. Contract DA36-039-SC-52654, Proj. DA 3-99-10-024, Rep. 2144-56-T, Jan. 1956 31pp. Vision Research Laboratories, Engineering Research Institute, University of Michigan.

6759

To assess the feasibility of increasing the sensitivity of visual detection at night by direct electrical stimulation of the eye (d-c), experiments were conducted in which peripheral visual sensitivity at low luminance was measured before, during, and after the application of direct current to the eye. Comparison measurements were made in the absence of current. Both anodal and cathodal currents, variations from 0.05 to one milliamperes, and two electrode positions temporal and infratemporal were utilized. The data were analyzed by comparing thresholds obtained in the series with and without current, and threshold obtained before, during, and after stimulation. These results are discussed in relation to previously reported studies of similar nature.

Staff & Consultants, Bio-Systems Group. HUMAN PERFORMANCE IN INFORMATION TRANSMISSION. Contract DA-36-039-SC-56695, Projs. 8-103A, D/A 3-99-10-101, Rep. R-62, March 1955, 70pp. Control Systems Laboratory, University of Illinois.

6760

To explore the limitations of human information-processing abilities, a series of experimental studies on well-learned activities were conducted. Piano playing was investigated as an example of information transmission through sequential acts. Three expert pianists played at eight sequences of random notes; speed and range were varied and for each changes in precision measured. Typewriting, reading English text, and mental arithmetic were investigated in similar manner. The results were analyzed in terms of rate of transmission and limiting factors of speed, range, channel capacity or confusion due to overabundance of information. General discussion centers about the contribution to methodology, importance of estimates obtained, and implications on mechanisms of information processing. T. G. I. R

6761 Brown, W.B. THE SHIP RECOGNITION TRAINER. BuMed Proj. X 271 (Av 159 c), NRL Rep. 75, Sept. 1945, 13pp. USN Medical Research Laboratory, New London, Conn.

This report on the ship recognition trainer includes a history of its development, a description of the construction of the stage, with photographs and blueprints, a discussion of the methods of instruction recommended, and a summary of the advantages of the stage over other methods of ship-recognition instruction. The advantages in the use of the trainer over other methods are: a) extremely realistic setting; b) elimination of all irrelevant detail; c) theoretically infinite number of views of any one subject; d) ease and simplicity of operation. The total appearance of a ship--from broadside through all possible target angles--can be presented. At least a half dozen slides would be necessary to achieve this; e) ease with which comparisons can be made. Any number of ships can be exposed to the class at the same time for purposes of comparison. This is impossible with slides; f) face validity; presents ships at distances and angles of observation closest to reality, and under realistic conditions of observation; g) control of illumination intensities from twilight to bright daylight making possible a broad range in the presentation of material--either in sharp detail, or as a dim mass silhouetted against the horizon.

5762

Verplanck, W.S. NIGHT LOOKOUT TRAINING STAGE. BuMed Proj. X-350(Av 197 p), NAL Rep. 99, March 1946, 14pp. USN Medical Research Lab., New London, Conn.

This report covers the development and use of the Night Lookout Training Stage at the Lookout School, Medical Research Department, U.S. Submarine Base, New London, Connecticut. Included is a brief history of its development, a description of the construction of the stage, a discussion of the instruction methods recommended for use with the stage, with suggested drill techniques, and a summary of the advantages of this stage.

6763

Verplanck, W.S. EXPERIMENTAL EVALUATION OF THE SHIP RECOGNITION TRAINER. BuMed Proj. X-271(Av 159 c), NAL Rep. 101, March 1946, 10pp. USN Medical Research Lab., New London, Conn.

A classroom experiment, designed to determine the relative effectiveness of slides and models in ship recognition training has been performed. The results indicate that these 2 media are almost equivalently effective, although there is a definite and reliable margin in favor of models.

6765

Saul, E.V. & Jaffe, J. RELIABILITIES AND CORRELATIONAL INDEPENDENCE OF MEASURES OF MARKSMANSHIP PERFORMANCE. Contract DA 19 020 ORD 3461, Proj. TB 1 1000, Proj. Rep. 5, July 1955, 30pp. Human Engineering Services in the Design of Small Arms, Tufts University, Medford, Mass.

The present study was designed to provide empirical information on the reliabilities and correlational independence of 11 measures of marksmanship performance. The results of the study are based on the performance of 2 groups, one having 29 subjects and the other 22. The first group fired a 2-string test (total 16 rounds) and the second a 4-string test (total 32 rounds), both under standard conditions. Evaluation of the obtained data in terms of the criteria of score reliability, independence, diagnostic value, and ease of computation permits the recommendation that 2 specific scores, one reflecting precision and one accuracy, be used for rigorous marksmanship research. In addition, the results permit tentative recommendations in regard to minimum test length and minimum sample size for such experimental research.

Willard, N. Jr., Bancroft, C.A. & Fiddan, J.G. THE TRAINING EFFECTIVENESS OF A STEREOSCOPIC RANGE-FINDER TRAINER. Tech. Rep. 12, Oct. 1954, 18pp. Human Resources Research Office, George Washington University, Washington, D.C.

This experiment was designed to answer specific questions about a range-finder training instrument, Device OROPT-T1: Will it satisfactorily identify potentially good operators, as distinguished from those who need special training? Will it be suitable for remedial training for poor operators? Will it provide for satisfactory range-finder training? The data from the experiment show that a) Device OROPT-T1, after about 130 rangings, will aid in differentiating those operators who will make normal progress from those who need special training; b) the device has no special value for training poor students; c) although the trainer group did not demonstrate improved performance on the trainer, there is evidence that as a result of their instruction on the trainer their performance on the range finder improved; d) the range-finder group is significantly more proficient at the end of training than the trainer group; e) the trainer is useful as a familiarization device; and f) it speeds up the ranging operation during training.

6767

Rittenhouse, C.H., Goldstein, K. & Woodward, D.H. A PRELIMINARY STUDY CONCERNING THE EFFECT OF SPECIAL TRAINING IN RANGING ON PERFORMANCE OF THE TOTAL PEDESTAL SIGHT TASK. Res. Note FG: 52 3, Proj. 512 024 0001, July 1952, 9pp. Human Resources Research Center, USAF Air Training Command, Lackland AFB, Tex.

A preliminary study concerning the effect of special training in ranging on performance of the total pedestal sight task has yielded the following tentative conclusions: a) Practice on the ranging task in isolation results in improved performance of the total pedestal sight task. This improvement is most clearly demonstrated in the later stages of practice on the total task. b) Airmen given 15 daily periods of training on the Pedestal Sight Manipulation Test, 5 periods of which were devoted to special instruction on ranging exclusively, performed at the total task at about the same level of proficiency on the 15th day as did airmen given 15 days training on the total task without special ranging instructions. In this respect, the introduction of 5 periods of special ranging practices proved no more (but not appreciably less) effective than devotion of all training periods to practice on the complete task.

Dickson, E.D.D., Hinchcliffe, R., Wheeler, L. J., et. al. EAR DEFENDERS. FPRC 884, June 1954, 106pp. FPRC, Central Medical Establishment, Air Ministry, England.

6769

To investigate the sound attenuating properties of ear defenders, a binaural free-field audio-metric method was used. Attenuation versus frequency curves were determined on twenty subjects and for sixteen ear defenders (six of the insert type, seven noise occluding pads, and three helmets). Additional tests were made on a few defenders using a miniature microphone and objective measurements of attenuation. Auditory fatigue-protection was measured by listening for speech hearing loss after listening to aircraft noise for durations of 1/2, one, or two hours. Assessment of the defenders was made with reference to attenuating factors and subjective comfort of wearing the device. Recommendations are included.

Gogel, W.C. RELATIVE VISUAL DIRECTION AS A FACTOR IN RELATIVE DISTANCE PERCEPTIONS. Psychol. Monogr., 70, (11), (Whole No. 418), 1956, 1-15.

6770
Two hypotheses concerning visual direction were tested by using them to predict the apparent path of movement of a small object attached to an Ames rotating trapezoidal window. In the experiment the trapezoidal window was viewed either monocularly or binocularly with four conditions of attaching the object to the window. The differences between the results from the various conditions were used to confirm or deny the predictions made from the two hypotheses. An equation for predicting the apparent relative depth of a binocular object as a function of its physical relative position and the physical and apparent relative positions of other objects in the field is given.

Burrows, A.A., & Ford, H.K. SOUNDS AS WARNINGS IN AIRCRAFT. FFRC 966, May 1956, 21pp. Flying Personnel Research Committee, RAF Institute of Aviation Medicine, Farnborough, Hants, England.

6778
The problem of auditory aircraft warning is discussed in terms of the potential and existent requirements of such systems and the results of previous applications of auditory signals as aircraft warning devices. Three experiments were conducted to investigate the following aspects of the problem: (1) to compare the choice reaction time for six different sounds and six words; (2) to evaluate the potential effect of a noise background upon signals presented at varying intensity levels; and (3) a replication of the second experiment with a modification imposed to reduce the effects of learning. Results are discussed in terms of the relative reaction time and number of errors incurred with sounds vs. words and the differential effect of noise upon the perception of such signals. T. G. I. 6779
Howarth, C.I. THE TIME COURSE OF PRESSURE BLINDNESS. FFRC 968, Aug. 1956, 2pp. Flying Personnel Research Committee, RAF Institute of Aviation Medicine, Farnborough, Hants, England.

6779
On the basis of self-observation and data obtained with five subjects the author discusses three possible causes of peripheral vision restriction. These are said to consist of: "the higher sensitivity of the fovea; a possible storage of oxygen in the macula pigment; and the greater effectiveness of a minimal blood flow around the optic disc and along the course of the main retinal arteries." The time course of pressure blindness is discussed briefly and related to the phenomenon of blackout.

Westheimer, G. RESPONSE OF THE ACCOMMODATION MECHANISM TO VISUAL STIMULI. Contract Nonr-495(09); Proj. NR 140-105, Tech. Rep. 1, RF 654, Nov. 1955; 23pp. Research Foundation, Ohio State University.

6783

To study the effectiveness of an empty visual field for inducing accommodative responses in the human eye, measurements were made on five trained subjects. A beam was flashed into the same eye for 0.05 second every ten seconds whose configuration (recorded by subject pressing appropriate response button) indicated correct accommodation, over-accommodation, or under-accommodation for the measuring level. Changes in accommodation were followed by a bracketing procedure. The stimulus conditions were (1) dark empty visual field, (2) bright empty visual field, and (3) red fixation spot at optical infinity. Variations in the refractive state were analyzed for effects of the various conditions. The results are discussed in relation to "night myopia" and "space myopia" reported in the literature. T. I. R-8

Brown, R.H. THE EFFECTIVENESS OF A COLLIMATED RETICLE AS AN AID TO VISUAL DETECTION OF AIRCRAFT AT HIGH ALTITUDE. NRL Prob. Y02 03, Proj. NR 401 000, NRL Rep. 4863, Nov. 1956, 12pp. NRL, Washington, D.C.

6784

To determine the effectiveness of a collimated reticle in improving the detection of small targets, experimental conditions were chosen to simulate search for aircraft against a bright uniform background. Cases for near vision were such as a plane's cockpit and windshield framework might provide. Fourteen subjects, using binocular vision, identified the position of a target dot (systematically varied in size) seen at optical infinity. The minimal size of target for detection was measured with three reticle patterns (collimated, checkerboard, and gunsight) and with no pattern. Data were analyzed by comparisons of geometric means and analysis of variance techniques for differences due to reticles, target positions, and subjects. Discussion is relative to operational applications of results. T. G. I. R-17

Stevens, S.S., & Poulton, E.C. THE ESTIMATION OF LOUDNESS BY UNPRACTICED OBSERVERS. *J. exp. Psychol.*, 1956, 51, (1), 71-78. (Psychology-Acoustics Laboratory, Harvard University).

6793

To test the ability of unpracticed subjects to make consistent quantitative judgments of the relative loudness of tones on their first trial and to explore some of the biasing factors of such experiments, three studies are reported using 65 subjects and the methods of adjustment and magnitude estimation. Additional factors evaluated were 1. none potentiometer with turn of knob proportional to loudness produced and decibel attenuation, 2. initial measurement of absolute threshold or no measurement, 3. bracketing on single adjustment procedure, and 4. order of adjusting fractional loudnesses. Group means in decibels were calculated and analyzed. Suggestions as to methodological procedures are given.

6795
Daddy, R.R. THE QUANTITATIVE EVALUATION OF AN AIRCRAFT CONTROL SYSTEM. Rep. 29, Feb. 1956, 4pp. North Atlantic Treaty Organization, AGARD, Paris, France.

6795
This paper was prepared as an introduction to a panel discussion on the quantitative measurement of the ability of an aircraft-pilot system to perform given tasks. Two examples are given to illustrate the inadequacy of simple measurements of the accuracy of task performance primarily due to increased pilot effort. It is suggested that measurements of this effort need to be made. Measurement of the pilot's transfer function, which is known to vary with the severity of the task, is discussed.

6797
Dept. of Labor. JOB PERFORMANCE AND AGE: A STUDY IN MEASUREMENT. Bull. 1203, Sept. 1956, 72pp. Bu. of Labor Statistics, Dept. of Labor, Washington, D.C.

6797
To develop objective measures which would be useful for comparing the performance of production workers in different age groups, a pilot investigation of eight manufacturing establishments in two industries (footwear and men's clothing) was made. Output data were obtained for 2,217 workers, attendance data for 4,009, industrial injury data for 2,637, and records of separation for 2,734. A schedule for collecting the data was developed and tested in the plants visited; the method is fully described. Statistical treatments of the data are described together with clarification of underlying assumptions. The findings on the relation between job performance and age are presented as preliminary to further work in the area.

Oyer, H.J. RELATIVE INTELLIGIBILITY OF SPEECH RECORDED SIMULTANEOUSLY AT THE EAR AND MOUTH. J. acoust. Soc. Amer., Nov. 1955, 27, (6), 1207-1212. (Dept. of Speech, Ohio State University).

6798
To determine the relative intelligibility of simultaneously recorded speech picked up at the lips and the ear, six male speakers recorded lists of monosyllabic words. The lists were randomly presented (with respect to origin and speaker) to 24 trained listeners at -12, -15, and -18 signal-to-noise ratios (white noise was mixed with the tape to produce the S/N ratios). The criterion measure was the total number of correct responses to six speakers for one listener at one S/N ratio. The data were evaluated by analysis of variance techniques for differences due to origin of signal pickup, S/N ratio, and listeners. Implications for practical usage are discussed.

Moser, H.M., & Dreher, J.J. EFFECTS OF TRAINING ON LISTENERS IN INTELLIGIBILITY STUDIES. J. acoust. Soc. Amer., Nov. 1955, 27, (6), 1213-1219. (Ohio State University).

6799
To test the effects of training on listeners (in the typical intelligibility study), 12 subjects skilled in listening under conditions of noise were presented initially with lists of words (total of 600) formed by agglutination of English monosyllables and asked to record the words. Noise for the test sessions was furnished by a Harvard-type white noise generator. Following the initial test, alternate training and testing sessions were conducted. Differential responses to the words were plotted. The results are analyzed in terms of the effects of training and correct response as a function of the number of speech sounds contained in the particular word.

Phillips, W.H., Brown, P.B., & Matthews, J.T. Jr. REVIEW AND INVESTIGATION OF UNSATISFACTORY CONTROL CHARACTERISTICS INVOLVING INSTABILITY OF PILOT-AIRPLANE COMBINATION AND METHODS FOR PREDICTING THESE DIFFICULTIES FROM GROUND TESTS. RM L53F17a, Aug. 1953, 57pp. Langley Aeronautical Lab., NACA, Langley Field, Va.

6805
A number of examples are given of control difficulties which appear to result from a tendency for dynamic instability of the combination of the pilot, the control system, and the airplane. These difficulties have occurred in both conventional and power control systems. Tests of a bomber and a fighter equipped with hydraulic power controls were made to study this problem. The effect of friction in the control valves of the power control systems is discussed. An analytical study of the problem and a method of detecting such control difficulties by means of ground simulator tests are presented.

Adler, R.B. & Fricker, S.J. SUMMARY REPORT ON THE FLOW OF SCHEDULED AIR TRAFFIC. Contract Cca 28152, Dec. 1951, 29pp. Electronics Research Lab., Massachusetts Institute of Technology, Cambridge, Mass.

Some of the effects upon air traffic of scheduling the aircraft and of controlling them en route are presented quantitatively in this report in the form of theoretical studies of 4 problems: a) Relations between the random en route deviations of aircraft from their schedules, and the resulting stack and total delays; b) Effectiveness of a single en route control point when 1) it reschedules the aircraft in an attempt to reduce terminal congestion, 2) it attempts to bring each plane back onto its original schedule; c) Congestion caused by relaxing the schedule; d) Effect of a sudden shutdown of the terminal. The limiting cases of random arrival and continuous control are discussed briefly, and some aspects of multipoint discrete en route control are treated. Numerical analysis, using IBM punched-card machines, is employed extensively in problems a)-c). Problem d) has been simplified enough so that purely analytic methods could be applied. It is presented merely for comparison purposes.

Army Medical Research Laboratory. 2ND ANNUAL ARMY ENGINEERING PSYCHOLOGY CONFERENCE - 7-9 November 1956. Status Rep., 1956; 61pp. Research and Development Division, AMRL, Fort Knox, Ky.

6810

This report on the Army Medical Research Laboratory gives details of its history (1942-1956), objectives, organization, research, and development projects (biological, biophysical, psychological, and physiological problems of military significance). A bibliography of laboratory reports and journal publications is included covering operations at high and low temperatures, ration anthropometric measurements, ventilation, fire and flame protection, vision in tanks, errors in gunnery, and miscellaneous articles on methodology, instrumentation, and others.

6811
Bowers, R. UTILIZATION STUDY OF MANEUVERING TACTICS TRAINER, DEVICE 1 BZ 2. HUMAN ENGINEERING REPORT SPECDEVEN 20 A 10. NAVEXOS P 1060, Sept. 1952, 37pp. Special Devices Center, Port Washington, N.Y.

This study deals with the utilization of maneuvering tactics trainer, device 1 BZ 2. The purpose of the study was to examine the utilization of the trainer to recommend if possible, additional uses or new instructional procedures to improve its utilization, and to develop procedures for reviewing the utilization of other tactical trainers. By joint analysis of the function of the device and training requirements of the Navy, the best uses for the device were determined. By application of established principles of learning to the recommended uses, the best instructional procedures were determined. The results indicated that: a) the device is suited for training experienced or inexperienced officers; b) enlisted talkers and helmsmen can also be trained on it; c) the device should be used for practicing complete operational tasks and all operational procedures; d) officers in charge of training should conduct briefing sessions before using the device and self-assessing sessions following use of the device; e) the installation of time lapse motion picture equipment will provide a way of obtaining records of performance of device operations. Such records will permit broader and better utilization of the device by present users and will open up new important uses for the device. (HEIAS)

Simons, C.W. & Roscoe, S.M. ALTIMETRY STUDIES: II. A COMPARISON OF INTEGRATED VERSUS SEPARATED LINEAR VERSUS CIRCULAR, AND SPATIAL VERSUS NUMERICAL DISPLAYS. Tech. Memo. 435, May 1956, 8pp. Weapon Systems Development Laboratories, Hughes Aircraft Company, Culver City, Calif.

6812

To determine the effects of three display variables upon pilot performance in making routine decisions required to follow vertical flight commands, time and error scores were obtained from 24 pilots (12 professional, 12 casual). Four altimetry displays were designed: (1) integrated vertical scale (spatial analogue), (2) integrated circular-scale (distorted spatial analogue), (3) counter (numerical analogue), and (4) separated circular-scale (distorted spatial analogue); printed problems for practice and for testing were used. Preference ratings were obtained after testing was completed. The data were analyzed in terms of differences due to shape, integrated versus separate presentation, and symbolic versus spatial analogue presentation of information. T. G. I. R 4

Kunnick, Lillian S. AGING AND PUPILLARY RESPONSES TO LIGHT AND SOUND STIMULI. J. Geront., Jan. 1956, 11, (1), 38-45.

6814

To study the relationship between aging and pupillary responses, data were obtained for 94 normal subjects between the ages of 7-1/2 and 90 years of age. Cinephotography utilizing infrared illumination was used to record pupil responses when exposed to a light stimulus (12.2 foot candles) of one second duration, every four seconds. After 60 such presentations, a sound stimulus (97 db.) was presented to restore pupillary functioning. Pupil size, speed, and extent of pupillary constriction were evaluated in terms of: 1) increasing age and rate of change in pupillary response to light and sound stimuli, 2) velocity of response during total process of restriction, and 3) relative control of the iris over amounts of light admitted to retina. (See also 6815, 6816, 6817). T. G. R 3

6815

Kunnick, Lillian S. AGING AND THE EFFICIENCY OF THE PUPILLARY MECHANISM. J. Geront., April 1956, 11, (2), 160-164.

6815

To study the efficiency of the pupillary mechanism in response to light stimuli in relation to aging, cinephotography utilizing nonstimulating infrared illumination was used to record the size of the pupil as it alternately constricted and dilated. Sixty light stimuli (12.2 foot candles) of one second duration were presented every four seconds followed by an auditory stimulus (97 decibels) to elicit psychosensory restitution; fifteen additional light stimuli followed. Subjects (94) were divided into four age groups (7 1/2 to 90 years). Measurements (maximal and minimal pupil diameters and time between, extent and speed of pupillary constriction) were analyzed for states of rest, fatigue, restitution, and decay of restitution as a function of age. (See also 6814, 6816, 6817). T. G. R 4

6916
Kumlick, Lillian S. AGING AND DECAY OF PUPIL-
LARY PSYCHOSENSORY RESTITUTION. J. Geront.,
Jan. 1956, 11, (1), 45-52.

6816
To study the decay of pupillary psychosensory resti-
tution (reconstitution of pupillary response following
fatigue) in relation to aging, measurements were ob-
tained (94 normal subjects, age range 7 1/2 to 90 years)
by means of pupillometry. A second stimulus (98 decibels)
was given following 50 light stimuli, to obtain psycho-
sensory restitution. Fifteen additional light stimuli
were then given to record decay. Measurements of pupil
size, extent of constriction and response velocity were
analyzed as functions of age. (See also 6815, 6817).

6817
Kumlick, Lillian S. AGING AND THE LATENCY AND
DURATION OF PUPIL CONSTRICTION IN RESPONSE TO
LIGHT AND SOUND STIMULI. J. Geront., Oct. 1956,
11, (4), 391-396.

6817
To study pupillary responses in relation to aging,
cinematography utilizing nonstimulating infrared il-
lumination was used to record the size of the pupil as it
alternately constricted and dilated. Sixty light stimuli
(12.2 foot candles) of one second duration were presented
every four seconds, followed by an auditory stimulus
(97 decibels) to elicit psychosensory restitution;
fifteen additional light stimuli were then given. Normal
subjects (54) ranging in age from 7 1/2 to 90 years of
age were used. Data on the maxima and minima pupil
diameters and the time between them, extent and speed of
constriction were evaluated in terms of age and (1)
latency of dilation and constriction, (2) duration of
constriction, and (3) occurrence of maximum velocity of
constriction. (See also 6816, 6815, 6816). T. G. R 3

Pinkel, I.I., & Rosenberg, E.G. SEAT DESIGN
FOR CRASH WORTHINESS. Tech. Note 3777, Oct.
1956, 42pp. Lewis Flight Propulsion Labora-
tory, NACA, Cleveland, Ohio.

6818
"On the basis of deceleration data obtained in full-
scale crashes, a description of crash deceleration pulses
is presented which is suitable for seat design. Charts
are presented for obtaining the maximum deceleration
loads experienced by the seat and passenger in response
to their deceleration pulses. Finally, a method is
presented for determining the seat strength, spring
stiffness, and deformation beyond the elastic limit re-
quired to serve in a crash deceleration pulse of given
description. Measurement of passenger decelerations in
full-scale laboratory and crash studies shows the general
principles presented in the report apply."

6819
Pesman, G.J., & Eiband, A.M. CRASH INJURY.
Tech. Note 3775, Nov. 1956, 36pp. Lewis
Flight Propulsion Lab., NACA, Cleveland, Ohio.

6819
To determine how impact injuries occur and how the
chance of such injuries may be reduced, airplanes
manned with dummies were guided into obstacles that pro-
duced the desired crash events. Motion pictures, the
acceleration and crash loads data, and a post-crash
examination of the wreckage constituted the experimental
data. The following hazards were considered: (1) being
crushed, (2) being struck by missiles, (3) striking ob-
jects, and (4) being injured by crash deceleration.
Transport, cargo, fighter, and light airplane crashes
were evaluated.

Webb, V.A., & Jones, F.R. REPEATER PILOT ACCIDENTS IN THE UNITED STATES AIR FORCE. Contract
AF 33(038) 10506, HRL Rep. 30, Aug. 1952, 46pp. USAF Human Resources Research Lab., Wash-
ington, D.C. (Psychology Dept., Washington University, St. Louis, Mo.).

A comparison of pilots having accidents during 1941-1944 with those not having accidents
during the same period in terms of their accidents from 1945-1949 revealed that the first
period non-accident pilots did not differ from the first period accident pilots during the
second period. Accidents prior to jet flying did not predict jet accidents. Accidents in
training were not related to later accidents. Accidents on odd days during odd years
and even years when compared with accidents on even days during odd years and odd days
on even years for an 8-year period revealed a limited but consistent tendency for some pilots
to have accidents beyond chance expectancy. Grade increased control over exposure differ-
ences by separating groups into plane types or length of service decreased this beyond chance
factor in all cases except one. A limited but significant deviation from a chance distribu-
tion was found in the distribution of accidents. Increased homogeneity of exposure condition
by the crudest methods, reduced the amount of deviation from chance. Accident rates were
found to be related to instrument ratings, pilot ratings, age, and grade.

USAF Human Resources Research Center. PRESENTATION MADE TO THE SIXTH MEETING OF THE AIR
TRAINING COMMAND HUMAN RESOURCES RESEARCH ADVISORY BOARD, Feb. 1953, 195pp. USAF Human Re-
sources Research Center, Air Training Command, Lackland AFB, San Antonio, Tex.

The conference included reports on the following topics: Methods of Operational Utiliza-
tion of Research Results; Training Analysis and Development Evaluation of the Operations Ap-
plicability of Human Resources Research Center Publications; Technical Training--Air Force;
Flying Training--Air Force; Crew Training--Air Force; Present and Anticipated Operational Utili-
zation of Research of the Personnel Research Laboratory, of the Technical Training Research
Laboratory, of the Perceptual and Motor Skills Research Laboratory and the Armament Systems
Training Research Laboratory; Present and Anticipated Operational Utilization of Research of
the Aircraft Observer Training Research Laboratory, of Research of the Pilot Training Research
Laboratory, of the Combat Crew Training Research Laboratory; Present and Anticipated opera-
tional problems within the Air Training Command; present and anticipated personnel problems
within the Air Training Command; some air force-wide research requirements in the personnel
and training areas; procedures for coordinating and validating research requirements and pro-
jects in the Air Training Command; Organization and Facilities of the Human Resources Research
Center; the functional organization of the Human Resources Research Center to maximize its
contribution to the air force. (HEIAS)

Selinger, M., Rippelhouse, C.M. & Woods, J.P. STUDIES OF PERFORMANCE ON THE E-26 FLEXIBLE GUNNERY TRAINER. Res. Bull. 52 17, May 1957. 31pp. USAF Human Resources Research Center, Air Training Command, Lackland AFB, San Antonio, Texas.

2 studies of performance on the E-26 flexible gunnery trainer were conducted. Data were collected from 4 S-grades with samples of 4, 8, 9 and 11. Practice without tuition was given for 5 days to 2 of the groups (Study II) and for 11 and 12 days, respectively, to the 2 groups of Study III. Practice then continued with tuition in the case of the 2 later groups for 5 and 7 days, respectively. The results were during Study III satisfactorily high degrees of inter-day and odd-day vs. even-day reliability were obtained; scores for time-on-target, its azimuth and elevation were fairly high, while those for time-on-target in range, simultaneous azimuth-elevation range, and simultaneous azimuth-elevation range-triggering were low; practice on the trainer in the absence of tuition generally resulted in improved performance; all Ss had a tendency to overrange the target, and poor performers tended to participate the sight and range knob in an awkward manner; there were no consistent differences in reliability or learning among the 10 situations provided by the trainer; scores for azimuth and elevation were positively correlated with range scores did not display any consistent relationship with azimuth or elevation.

Baker, F.C. & Tacher, J.A., Jr. A MOTION PICTURE TEST OF NOSE AIMING POINT DETERMINATION. Proj. 525 006 0002, Res. Note AD 51 1, Feb. 1952. 7pp. USAF Human Resources Research Center, Air Training Command, Lackland AFB, San Antonio, Tex.

This test was developed to serve as a reliable and valid measure of performance in scope interpretation and aiming point determination. Also information on several aspects of the test was sought: when aiming point is first located, accuracy of this location, duration of correct aiming point identification, and point in target break-up at which target is lost. Two experimental tests were administered to 39 officer navigators. Intercorrelations among subjects and test scores were obtained as well as odd-even reliability coefficients. A detailed item analysis for each test was also performed. (HELAS)

Trautman, D.C. USE OF JOB ANALYSIS DATA TO IMPROVE TRAINING COURSE CURRICULA. HRP 200/1, June 1951, 6pp. Air Training Command, USAF Human Resources Research Center, Department of Defense, Washington, D.C.

With the possible exception of the Military Departments it appears to be a common practice for job analysis to be used specifically to develop or to improve job training course curricula. Within the Air Force, however, there has been little or no specific job analysis designed to provide direct support for training. This paper proposes the establishment of a program of job analysis which continually would provide as many as possible of the Air Force technical schools with complete field information as to the nature, scope, and requirements of the jobs for which the schools are training. Such a continuous flow of information, collected in the many places where the jobs are actually performed, would permit the schools to keep their curricula vital and up-to-date, to keep posted as to changes in the scope and nature of jobs, to keep abreast not only of technological changes but also of changes in duties and tasks performed, to note changed skills and knowledge required, to find the relative importance of and time consumed by various aspects of the jobs, and in other ways to keep the courses most realistic in terms of actual field job performance and requirements.

Johnson, H.O. THE DEVELOPMENT OF MORE EFFECTIVE METHODS OF TRAINING ELECTRONIC TECHNICIANS. Res. Rep., June 1951, 42pp. Research & Development Board, Department of Defense, Washington, D.C.

This report is concerned with the experimental development of more effective methods of training electronic technicians in the Navy. 5 classes (U.S. Navy School—Electronics) of 14 students each were selected for the experimental instruction; each S was assigned a contemporary in the regular course of instruction for comparison purposes. Instruction was evaluated during the course presentation and after the Ss had entered the equipment phase. The salient features of the experimental method and the principles of teaching and learning on which this were based are enumerated. The achievements of the experimental and regular classes were evaluated by means of examinations and practical work situations. The performance of the experimental classes was attributed to: improved scheduling of course work, mathematics instruction, and modified classroom size and arrangement. (HELAS)

Stapp, J. EDMAN AND CHIMPANZEE TOLERANCE TO LINEAR DECELERATIVE FORCE. Tech. Rep., 1952, 52pp. Wright Air Development Center, ARDC, Wright-Patterson AFB, Ohio.

6828

As part of an investigation leading to the development of automatic air traffic scheduling and display equipment, the theoretical response of a human pilot-aircraft combination in a control loop is analyzed in level flight. Included are cases in which pilot transfer function consists of proportional, derivative, and integral, plus combinations of these types of controls. Experimental results were obtained from human jet pilots operating the throttle within the level flight control loop as simulated on a Reeves Electronic Analog Computer. Results are discussed in relation to the display problem involved.

I. G.

6829

To obtain accurate information concerning the tolerable and survivable limits of men exposed to dynamic forces of short duration encountered in crash type decelerations, a special linear decelerator (a rocket propelled sled with mechanical friction brakes) was designed and constructed. A preliminary series of runs (72) were accomplished with chimpanzee subjects while oriented in six body positions to explore performance range of the decelerator and establish safe parameters for human experimentation. Human subjects (53 runs) were exposed to progressively higher decelerations in two body positions—facing forward and facing aft. In addition to records of the space-time forces, appropriate clinical and physiological observations were made and analyzed.

Brogan, F.A. A DISCRETE-FREQUENCY AUTOMATIC AUDIOMETER
SIMULATING MANUAL TESTS. USAF Rep. 55-125, Sept. 1955.
12pp. USAF School of Aviation Medicine, Randolph AFB,
Tex.

6828

An automatic audiometer is described which utilizes discrete frequencies, offers one-second tones at random, and simulates manual audiometry. The time required for testing both ears and the frequencies at which this can be done are reported, as well as the intensity range available with the equipment. All types of recording equipment may be used in conjunction with the basic equipment and a feature of the device is that it prevents the subject from controlling the test results directly.

Pearson, R.G., & Bauer, R.P. THE EFFECTS OF MORPHINE-
NALOXONE MIXTURES ON FLYING PERFORMANCE. USAF
Rep. 55-137, June 1956, 8pp. USAF School of Aviation
Medicine, Randolph AFB, Tex.

6829

To assess the side effects of certain opiate-anesthetist treatments, 50 subjects received preliminary training on a complex compensatory pursuit task involving simulated aircraft instruments and controls. Six different drug treatments were then administered to the various groups: (1) saline solution, (2) 3 milligrams morphine, (3) 3 milligrams naloxone, (4, 5, 6) morphine-naloxone mixtures of 2:1, 1:1, and 1:2 milligrams. Work was continued for four hours. Two motivational levels were included: (1) knowledge of results and (2) no information on performance. Performance scores were evaluated by analysis of variance for drug and motivational effects.

EYE MOVEMENTS DURING INCREASING SPEED OF ROTATION. Rep. 56-33, April 1956, 19pp. USAF
School of Aviation Medicine, Randolph AFB,
Tex.

6833

To study the basic pattern of guided circular eye-movements with regard to form and speed, a Master Ophthalmograph was used to record the saccadic eye-movements of ten subjects performing a visual pursuit task. Measurements were made with (1) a constant speed of 15 rotations per minute, (2) during increasing speeds from twenty to 45 rotations per minute, and (3) from forty to 85 rotations per minute. Both clockwise and counter-clockwise rotations were used. The data were evaluated with regard to number and extent of eye movements per cycle, per second, and per movement. Some tentative explanations for the findings are discussed.

6837 U.C. & Bancroft, R.V. TRANSTHORACIC PRESSURE IN MAN DURING RAPID DECOMPRESSION. Sep.
Luf. 56-61, Aug. 1955, 13pp. USAF School of Aviation Medicine, Randolph AFB, Tex.

Pressures were recorded in the human chest during rapid decompression under controlled conditions in a low-pressure chamber and compared with those observed in a dry, rigid container under similar conditions. Whereas the peak pressures measured in the mechanical analog varied in direct proportion to the absolute differential, regardless of the initial cabin pressure, the pressures in the human chest increased with the fractional differential (differential/initial pressure) in decompression. The analysis of transthoracic pressure transients permits an estimate of the radial decompression orifice permeability in a cabin of known volume without causing a significant rise in transthoracic pressure when decompression is sustained with open airways. The mean flow resistance offered by the human airways appears to be considerably greater in rapid decompression than during spontaneous, quiet breathing.

Gibson, J.J., & Gibson, Eleanor J. CONTINUOUS PERSPECTIVE
TRANSFORMATIONS AND THE PERCEPTION OF RIGID MOTION.
Contract N0001 401(14), Sept. 1955, 16pp. Cornell
University.

6838

To explore various aspects of the perception of continuous perspective transformations with polar projection, judgments of the degree of slant of the stimuli were made under two conditions: (1) continuous perspective transformation patterns, differing with respect to regularity of form and texture, were presented in two-second cycles (five degrees of semi-rotation 15 to 70 degrees) on a flat translucent screen to twenty subjects, (2) the same patterns were presented motionless at the end of a transformation sequence (sixty degrees of semi-rotation) to thirty subjects. Changes in observed slant and degrees of slant are evaluated in relation to length of transformation sequence versus stationary pattern and type of pattern—regularity of form and texture. T.G.I. 6839

Gibson, J.J. OPTICAL MOTIONS AND TRANSFORMATIONS AS
STIMULI FOR VISUAL PERCEPTION. Contract N0001 401(14)
Sept. 1956, 14pp. Cornell University.

6839

This essay concerns the way nations of objects are seen. An optical geometry is expounded which serves as a possible basis in optical stimulation for the ability to distinguish between and among rigid, elastic, and multiple moving things. Topics considered are physical motions and optical motions, continuous perspective transformations, continuous nonperspective transformations, disjunctive or separate optical motions, different degrees of transformation of superimposed patterns, and the internal depth of objects. An apparatus for producing optical transformations is described.

6840 Townsend, J.C. EVALUATION OF THE LINK, MC-1, BASIC INSTRUMENT FLIGHT TRAINER. Develop. Rep. AFPTC TN 56-84, June 1956, 80pp. Personnel Research Lab., USAF Personnel and Training Research Center, Lackland AFB, Tex.

The Link, MC-1, basic instrument flight trainer was evaluated at Tyndall Air Force Base, Florida, during a 17-week period by personnel of the Air Force Personnel and Training Research Center. More than 70 individuals, representing all levels of skill in piloting conventional and jet aircraft, flew the trainer during the evaluation. 22 of these subjects were given structured training, which consisted of an hour ride on each of 4 successive days, during which time their performance was measured on a flight check which had been developed by the evaluation team. The results of the evaluation indicated that the MC-1 was rated average in housing requirements, excellent in instructional facilities, above-average in unloading, installing and calibrating, excellent in maintenance, below-average in human engineering, average in engineering, excellent in validity and stability of performance curves, excellent in cockpit motion and rough air capability, and excellent in training requirements. Evaluative opinion by all persons who flew the trainer was generally highly favorable.

6841 Briggs, G.E., Pitts, P.W., & Bahrck, H.P. LEARNING AND PERFORMANCE IN A COMPLEX TRACKING TASK AS A FUNCTION OF VISUAL NOISE. Res. Rep. AFPTC TN-56-67, June 1956, 15pp. Personnel Research Lab., AFPTC, ARDC, Lackland AFB, Tex.

6841 To examine the effect of degradation, in the form of visual noise, on learning, performance, and transfer of training in a tracking task, four groups of Air Force ROTC students were trained for five days in a simulator having some of the characteristics of the F-86D aircraft with its P-4 fire control system. On the first day, all groups were trained under no-noise conditions and, on the last day, tracking accuracy was measured under a varied noise condition. On the intervening days, Group 1 was trained with no noise, Group 2 with a moderate amount, Group 3 with a large amount, and Group 4 with varied amounts. Per cent time on target is plotted for each group by five-trial blocks.

6843 Larnette, J.T. & Ruby, T.B. GROUP PERFORMANCE AS A FUNCTION OF WORK-DISTRIBUTION PATTERNS AND TASK LOAD. *Scientific*, 1956, 19, 95-104. (USAF Personnel Lab., Lackland AFB, Tex.). (AFPTC TN 56 97).

6843

To compare team performance under two conditions of task load and two methods of work distribution, three-man teams were assigned a simplified Air Defense task. They were to display interceptors to defend three target areas against enemy bombers. High task load was fifteen and low load was ten planes. The two methods: each individual performed one of the three essential activities -- observation, fuel calculation and identification, and decision making; and each individual performed all activities to defend a single target area. Performance scores (algebraic summation of scores for downing enemy planes and penalty scores) were studied by analysis of variance for effect of load and work method.

Archer, J.E., Kent, G.W., & More, F.A. EFFECT OF LONG-TERM PRACTICE AND TIME-ON-TARGET INFORMATION FEEDBACK ON A COMPLEX TRACKING TASK. AFPTC-TN-56-102, Res. Rep., Aug. 1956, 12pp. AFPTC, Lackland AFB, San Antonio, Tex.

6844

To study changes in complex tracking performance over a relatively long training period and to examine the effect of delayed information feedback signal upon time continuously on target, thirteen subjects tracked a target in three dimensions (West Pedestal Sight Manipulation Test) in a 66-day experiment. One group (6 Ss) heard a tone after they had been on target for one second; the other group (7) heard no tone; tone reinforcement discontinued after forty days. All subjects were kept informed of daily progress by chart. A two-week rest was interposed between sessions 45 and 46. Total time on target and time continuously on target are analyzed as functions of practice and delayed reinforcement.

Pollack, I. EVALUATION OF THE PRINCIPLE OF A NOISE-OPERATED AGC SYSTEM. AFPTC-TN-56-4, Aug. 1956, 7pp. Operational Applications Laboratory, AFPTC, Bolling AFB, Washington, D.C.

6845

To evaluate the feasibility of a noise-operated AGC (Automatic Gain Control) interphone system, speech and noise were presented to the listener with absolute levels changing sharply and often. In three test series four 50-item word lists were used with the conditions varied as to signal/noise ratio (12, 12, and 5 decibels), rate of alternation between two overall noise levels (constant or one to ten cycles per second), highest noise level (105 or 125 decibels), and difference between gain levels (constant or zero to 50 decibels). The data were average percentage of items correctly received by one listener (mean articulation scores) and were analyzed in terms of effect of varying the rate of alternation of noise levels and varying the difference between the noise levels.

Moser, H.M., Dreher, J.J., Oyer, H., & O'Neill, J. EFFECTS OF SEQUENCE UPON THE RECEPTION OF RELATED AND NON-RELATED MESSAGE ELEMENTS. Contract AF 19(664)-1577, Proj. 664, Tech. Rep. 35, Aug. 1956, 35pp. Operational Applications Laboratory, AFPTC, Bolling AFB, Washington, D.C., (Ohio State University).

6846

To evaluate word order on the reception of short identification sequences of related and unrelated words, 295 listeners and five speakers participated in a series of experiments. (1) Loudness judgments were made between monosyllables and their equally intense time-ordered reversals (word recorded on tape and played backwards). (2) Identifications were made of whole word (spondees) with aural presentation of either the first or last half, and likewise for couplets (two commonly associated free forms). (3) Identifications were made of syntactically related two-unit call-signs and nonsyntactically related three-unit call-signs presented in various orders. The data are analyzed for order effects and related to the problem of optimum word ordering of typical air messages

6847

White, W.J., & Jorve, W.R. THE EFFECTS OF GRAVITATIONAL STRESS UPON VISUAL ACUITY. Proj. 7193, Task 71611, Tech. Rep. 56-247, Nov. 1956, 29pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio.

6847

To determine the relation between gravitational stress and visual acuity when the factor of cerebral circulatory competence is minimized, nine subjects were tested. All subjects had a visual acuity of 20/20 or better, were free from ocular disease and were experienced with the equipment--human centrifuge. Visual acuities (binocular, right and left eyes both near and far) were measured with the checkerboard targets of Bausch and Lomb Ortho-Rater in the seated position (wearing anti-g suit), in the prone, supine, and semi-supine positions while exposed to a force environment ranging from one to eight "g's". Acuity values (expressed in means) were analyzed as a function of "g" units for each position and comparison made for all four positions. Hypotheses are advanced to account for the results. T. I. G. R 26

6848

Dupertuis, C.W., & Emanuel, I. A STATISTICAL COMPARISON OF THE BODY TYPING METHODS OF HOOTON AND SHELDON. Contract AF 18(600)-30, Proj. 7214, Tech. Rep. 56-346, Aug. 1956, 26pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio. (Western Reserve University & Aero Medical Laboratory).

6848

To compare the Sheldon and Hooton methods of body-typing, a sample of 500 Air Force flying personnel was selected from approximately 4000 body-build photographs of an anthropometric survey (photographs had been rated by the Sheldon method). Selection basis was a flat distribution for all somatotypes occurring in the original analysis. The sample was then rated by Hooton and his associates. Results from the two sets of ratings were compared: the three primary components, dysplasia (uneven strengths of components in different body regions), and gynandromorphy (degree of bodily characteristics of opposite sex). Regression equations are given for the relationships between the primary components. T. I. G. R 14

6849

Alluisi, E.A. & Muller, P.F., Jr. RATE OF INFORMATION TRANSFER WITH SEVEN SYMBOLIC VISUAL CODES: MOTOR AND VERBAL RESPONSES. Contract AF 33(616) 43, Proj. 7192, WADC TR 56 226, May 1956, 25pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio. (Ohio State University Research Foundation, Columbus, Ohio).

6849

To assess the relative merits of seven symbolic visual codes with respect to speed and accuracy of response, two experiments were conducted using motor (key pressing) and verbal readout responses. Coding alphabets were: conventional Arabic Numerals, symbolic numerals, three types of inclination symbols, ellipse-axis ratio symbol, and color. Subjects were required to respond under both self-pacing and forced-pacing conditions. The data were analyzed in terms of information transmission (bits) for the seven codes as a function of rate of information presentation and type of response. The importance of stimulus-response compatibility is discussed together with implications for engineering application to future radar air traffic control systems. T. G. I. R 14

6850

Cole, J.W. NOISE EVALUATION OF AIR FORCE GROUND SUPPORT UNITS. Proj. 7211, Task 71705, Tech. Note 56-335, Aug. 1956, 24pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio.

6850

To study noise problems presented by the use of auxiliary ground power units of the Air Force, the sound radiating characteristics of several types of reciprocating and gas turbine units were measured. The data are evaluated in terms of exposure risks (hearing damage) and speech communication. The noise characteristics of the various units are discussed with some conclusions and recommendations for quieting the units are formulated. T. I. G. R 2

ertzberg, H.T.E., Emanuel, I., & Alexander, THE ANTHROPOMETRY OF WORKING POSITIONS. A PRELIMINARY STUDY. Contract AF 18(600)-, Proj. 7214, Tech. Rep. 54-520, Aug. 1956, pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio.

6851

To ascertain new body size data for various representative working positions, forty adult males, selected to insure a sample statistically representative of the Air Force, were studied. Measurements were made by use of photographs (maximum body depth), anthropometer, prone measuring board, and a measuring block (overhead reach, kneeling position height and length, crawling position height and length, and prone position height and length). Means, standard errors, standard deviations, and percentiles are accompanied by a pictorial representation of each position. Problems met in developing procedures for an anthropometry of working positions are discussed, along with possible approaches for data gathering. T. I. R 22

6852

Emanuel, I., Chaffee, J.W., & Wing, J. A STUDY OF HUMAN WEIGHT LIFTING CAPABILITIES FOR LOADING AMMUNITION INTO THE F-86H AIRCRAFT. Contract AF 18(600)-30, Proj. 7214, Tech. Rep. 56-367, Aug. 1956, 12pp. Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio. (Aero Medical Laboratory & Antioch College).

6852

To present data on weight lifting ability of young adult males in a representative work situation, nineteen subjects were studied. Lifting procedures were standardized and controlled in order to simulate a precise task (loading ammunition into the F-86H aircraft). An ammunition case with varying amounts of weight (based on a preliminary study of each individual's lifting ability) was lifted to platforms one, two, three, four, five, six, and seven feet above the floor. Weights were added (or subtracted) in units of ten pounds for the various heights. The results are based on the average of two tests at each level and include range, mean, standard deviation and percentiles. Suggested maximum weights required for actual lifting tasks are presented. Kobrick, J.L. QUARTERMASTER HUMAN ENGINEERING HANDBOOK SERIES: I. SPATIAL DIMENSIONS OF THE 95TH PERCENTILE ARCTIC SOLDIER. Proj. 7-83-01-004, Tech. Rep. EP-39, Sept. 1956, 86pp. Environmental Protection Research Division, Quartermaster Research & Development Center, Natick, Mass.

6853

This report presents human engineering information on the body size of the soldier clothed in the full Arctic uniform. It should be used as a handbook by engineers and designers for establishing space allowances in the design and sizing of man-operated equipment. The criterion used is the 95th percentile of Army nude body size so that the data are concerned with upper size limit. Various body poses (standing, with arms in a variety of positions, sitting, with arms and legs in different positions, squatting, kneeling, on hands and knees, etc.) are presented pictorially with index scales so that dimensions can be measured on the pictures and referred to the index scale to establish actual size. I. R 10

Iampietro, P.F., et al. CALORIC INTAKE AND ENERGY EXPENDITURE OF ELEVEN MEN IN A DESERT ENVIRONMENT. Proj. 7-83-01-004C, Tech. Rep. EP-40, Oct. 1956, 22pp. Environmental Protection Research Division, Quartermaster Research & Development Center, Natick, Mass.

854

To assess food requirements for active men in a hot dry climate, caloric intake and expenditure were studied in eleven men during a sojourn at Yuma, Arizona, (mean ambient temperature, 33 degrees Centigrade; relative humidity, 35 per cent). All foods were carefully weighed to determine the intake of each man. Time-motion studies were performed and energy expenditures for all activities were determined. Together with measures of body stores of fat and weight changes, a precise measure of caloric intake and expenditure was made. The results are discussed in terms of relation of environmental temperatures to caloric intake. Implications for army supply problems are noted. T. G. R 17

Baker, P.T. BODY COMPOSITION IN THE DESERT--RELATIONSHIP OF DESERT HEAT STRESS TO GROSS MORPHOLOGY. Proj. 7-79-01-0020, Tech. Rep. EP-7, March 1955, 23pp. Environmental Protection Division, Quartermaster Research & Development Center, Natick, Mass.

6856

To investigate the effect of a desert climate on gross morphology and the relationship between ability of the individual to resist heat stress and gross morphology two studies are reported. (1) Measurements of body composition (skin-fold test and x-rays) were made on 83 men before reporting for duty and at intervals during duty at Yuma Test Station in Arizona. Measurements were compared for significant changes. (2) Individual resistance to heat stress was measured by walking the men (fifty) for one hour at constant pace, then recording sweat loss, rectal temperature, and pulse rates. Measures of lean body mass, percent of fat, and stature were studied in relation to the stress measures. Possible uses of the findings are suggested.

Miller, B.P. A BRIEF HISTORY OF AERIAL EMERGENCY ESCAPE. ca. 1954, 24pp. USAF Wright Air Development Center, Aircraft Lab., Wright-Patterson AFB, Ohio.

The major reasons for failure to effect aerial escape from a disabled aircraft are indicated: deceleration, dynamic pressure, relative velocity of the bailout subject with respect to the tail of the aircraft, and lack of sufficient time. The characteristics of the ejection seat catapult are delineated and the record of successful AF emergency ejections is examined in terms of seat limitations. The other problems attendant to ejection also are considered relative to their solution. (HEIAS)

Blau, B. A PRELIMINARY EVALUATION OF THE USE OF THE PRONE POSITION IN OPERATING A TRACK LAYING VEHICLE. Rep. 2, May 1953, 29pp. Human Engineering Lab., Aberdeen Proving Ground, Aberdeen, Md.

6859

To evaluate the use of the prone position in operating a track-laying vehicle, 22 experienced subjects drove four laps in the seated position and four laps in the prone position over a smooth course. Keeping their original starting positions (prone or seated laps first), 18 of the subjects drove five laps seated and five prone over a fairly rough course. The time required to complete each course was recorded and analyzed. Fatigue was evaluated by having four subjects drive six hours over the rough course. These four subjects received pre- and post-physical examinations.

Mickett, J.C. & Bliss, J.Q. SURVIVAL FEEDING TRIAL OF RCAF SEAT PACK RATION. I.A.H. Rep. 52/4, Oct. 1952, 23pp. RCAF, Institute of Aviation Medicine, Toronto, Canada.

The purpose of this study was to ascertain the effectiveness and acceptability of the RCAF A-10 B Seat Pack Food Packets and to determine the time necessary for the reestablishment of physiological operational efficiency after a 10-day survival period. 31 subjects were placed in the bush under simulated survival conditions and subjected to certain dietary regimens. It was concluded that: a) The A plus B or B plus A Food Packets are adequate for survival over a ten day period during the Canadian summer; b) Carbohydrate as a survival food appears to be preferable to carbohydrate, fat and protein; c) Improvement of the packets is desirable from the standpoint of acceptability; d) A controlled diet for one day allowed a return to full duty. It is recommended that: a) The use of type A Food Packet be discontinued; b) The contents of type B Food Packet be modified to increase acceptability.

6861

Mickett, J.C. & Bliss, J.Q. SURVIVAL FEEDING TRIAL OF RCAF SEAT PACK RATION. I.A.H. Rep. 52/4, Oct. 1952, 23pp. RCAF, Institute of Aviation Medicine, Toronto, Canada.

Anthony, G.C., Dougan, R.R., & Satyendra, K.N. STUDY OF PILOT-ASSIST DEVICES FOR ARMY FIXED-WING LIAISON AIRCRAFT. Contract DA 36-039-ac-63202, Quart. Engng. Rep. 3, Feb.-April 1955, 98pp. Air Arm Div., Westinghouse Electric Corp., Baltimore, Md.

6862

To study pilot-assist devices for Army fixed-wing liaison aircraft, pilot and manufacturer opinion was sampled, a control stick and instrument panel mockup was constructed, and 14 control configurations were evaluated by ranking the performance of the pilot-assist devices during simulated flight. Load droop characteristics, wind gust response, and flyability were determined for each control configuration. The data are analyzed and certain conclusions about the various devices are presented.

Day, W.F. RANDOMNESS OF THRESHOLD RESPONSES AT LONG INTERSTIMULUS INTERVALS. *Percept. Mot. Skills*, 1956, 6, 205-208. (Contract NS-ori-166, Proj. NR 145-089, Task Order 1, Rep. 166-I-206, July 1956. Johns Hopkins University).

6867

This experiment was designed to obtain an adequate sample of serial threshold behavior with a long inter-stimulus interval under conditions favorable to accurate psychophysical performance. Series of 100 threshold increments in the intensity of a 1000 cycle tone were presented at a fixed 15 second interval. Two conditions of stimulus response separation were used. The data were analyzed by the runs test and serial correlation to determine the randomness of serial threshold behavior. T. G. R 9

Chapanis, A., & Malsey, Rita M. ABSOLUTE JUDGMENTS OF SPECTRUM COLORS. *J. Psychol.*, 1956, 42, 99-103. Contract NS-ori-166, Task Order 1, Proj. NR 145 089, Rep. 166-I-206, ONR, Johns Hopkins University.

6871

To express previously published data on percentage of correct absolute judgments of spectrum colors in terms of information measurements, a recomputation on the data was carried out using multivariate contingency analysis. The experimental data were obtained from highly trained subjects with sets of 10, 12, 15, and 17 spectrum colors between 430 and 642 millimicrons. The results are related to practical problems of color coding and to similar studies of other senses that are available in the literature. T. R 11

6872

Duerfeldt, C.W. INSTALLATION AND TEST OF AUTOMATIC LIGHT INTENSITY CONTROL SYSTEM FOR APPROACH AND RUNWAY LIGHTS. Proj. Ted PTR AE 2201, Final Rep. 2, April 1954, 5pp. Electronic Test Division, Naval Air Test Center, Patuxent River, Md.

6872

To evaluate an automatic brightness control system and visibility indicator developed by the National Bureau of Standards, the equipment was installed at the Naval Air Station, Patuxent River. The system, responsive to horizontal visibility, was used on three approach systems for 100 test flights made during varied visibility conditions. Tests were not completed because of unavailability of a control unit to operate in conjunction with new voltage regulators installed in the light system. Recommendations are made to improve the equipment with regard to maintenance and an indicator sensitive to vertical transmissivity data. No test data are included in this report. I. R 4

Stolurow, L.H., Bergum, B., Hodgson, T. & Silva, J. THE EFFICIENT COURSE OF ACTION IN "TROUBLE SHOOTING" AS A JOINT FUNCTION OF PROBABILITY AND COST. *Educ. psychol. Monographs*, 1955, 15, 462-577. Res. Rep. AFPTAC TN 56 71, ARDC Proj. 7714, Task 67003, June 1955. USAF Personnel & Training Research Center, ARDC, Lackland AFB, San Antonio, Tex. (University of Illinois, Urbana, Ill.).

6873

To establish a suitable criterion for evaluating trouble shooting performance, maintenance records were obtained from 46 operational four-engine aircraft (28-cylinder reciprocating engine, R-3350). Instrument indications were analyzed to determine high, normal, and low readings, and each reading was related to both actual repairs performed and average work time for checking components that might have caused malfunction. Probability values of these relationships and patterns of symptoms were computed. Two methods for trouble shooting are given based upon the joint function of probability and cost (time). Experienced instructors were asked to estimate probability and cost factors by means of a questionnaire. Results from the two methods for gaining this information are compared.

6874

Detabel, M.H. & Stolurow, L.H. STIMULUS SEQUENCE AND CONCEPT LEARNING. *J. exp. Psychol.*, 1956, 51, 31-40. Res. Rep. AFPTAC TN 56 79, ARDC Proj. 7714, Task 67003, June 1955. USAF Personnel & Training Research Center, ARDC, Lackland AFB, San Antonio, Tex. (University of Illinois, Urbana, Ill.).

6874

To investigate relationships between concept learning and degree of synchrony (two stimulus components are in synchrony if both maintain their value, or both change value, from one trial to the next) of relevant and irrelevant components, a set of stimulus items (composed of three variable components only one of which was relevant to response called for) was used for training two groups (335, 275). By varying the sequence of items, training procedures were varied in synchrony for each group. Number of correct responses was analyzed for differences due to degree of synchrony and interaction with scholastic aptitude (A C E scores). Discussion relates results to arrangements of stimulus sequences for efficient training procedures. T. G. R 1

6875
Hauman, H.J. & Goldberg, S.C. NONTECHNICAL FACTORS IN THE JOB PERFORMANCE OF AIRCRAFT MECHANICS: STUDY II. Res. Rep. AFPTAC TN 56 59, Proj. 7950, Task 79507, May 1956, 23pp. USAF Personnel & Training Research Center, A/R Research Development Command, Lackland AFB, San Antonio, Tex.

This study is an attempt to verify and extend the findings of an earlier research project concerned with the dimensions of aircraft maintenance mechanics' on-the-job proficiency. This was done by analyzing the mechanics' characteristics, as rated by the mechanics themselves and by their supervisors. Factor analysis of the self-ratings revealed 5 dimensions of attitudes toward the job: Co-worker Relations, Work Satisfaction, Fairness of the Reward System, Crew Chief Ego-Status Behavior, and Acceptance of the Crew Chief. Factor analysis of the supervisors' ratings revealed the general factor, personal interaction, and the 4 other factors: Job Satisfaction, Relations with Co-Workers, Cooperativeness, and Technical Ability. Composite trait scores were also computed. It was concluded that a supervisor's rating of mechanics is bi-factor in nature, with halo and specific trait variance present in each item. (MEIAS) R 7

Gulliksen, H. MEASUREMENT OF SUBJECTIVE VALUES. Contract Monr 270-20, Proj. Nr 150 088.
July 1955, 28pp. Office of Naval Research, Washington, D.C. (Psychology Dept., Princeton
University, Princeton, N.J.).

4 different value laws are developed and tested by using them to predict the scale value of composite stimuli from the scale values of their components. These 4 laws are an additive law, a square-root law, a logarithmic and a negative exponential law. They are tried out on a set of food preferences by means of Pearson's method of false position. The negative exponential law of diminishing returns gave the best fit to the data but was not markedly better than any of the other laws.

Brown, R.H. THE UPPER SPEED THRESHOLD FOR THE DISCRIMINATION OF VISUAL MOVEMENT AS A FUNCTION OF STIMULUS LUMINANCE. NML Problem Y02-03, Proj. NR 401 000, Subproj. NR 401 001, Nov. 1956, 14pp. Applications Research Div., Naval Research Lab., Washington, D.C.

6881
To determine how stimulus luminance affects the upper speed threshold for the discrimination of visual movement, the observer viewed the center of a circular black area surrounded by a dialy illuminated area. A moving spot of white light traversed the path of a horizontal line centered in the circle. Two subjects made 50 responses, one 26 responses, to each of several combinations of luminance and speed of the moving spot, which were systematically varied in counterbalanced order. The results are interpreted in terms of previous research.

Randle, R.J., Jr. VIBRATIONS IN HELICOPTERS: TRAINING CONSIDERATIONS. Proj. 7197, Task 71640, WADC TN 59 61, March 1959, 7pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

6882
To study in detail the role that vibrations play in piloting helicopters, individual interviews were held with helicopter instructor-pilots. Information was gathered about the classes of vibrations that exist during flight and which ones are utilized as cues in both normal control and the detection and diagnosis of system mal-functions. An analysis of the information led to a discussion of training considerations. Recommendations are made for simulation of each of the several classes of vibration in a proposed helicopter instrument trainer.

Duerfeldt, C.H. JET INSTRUMENTATION PROGRAM, EVALUATION OF MODIFIED THREE-POINTER ALTITUDE CONFIGURATIONS. FINAL REPORT. Proj. Ted. PTR A: 7046.2, Rep. 1, July 1954, 11pp. Service Test Div., USN Air Test Center, Patuxent River, Md.

An evaluation was conducted of 5 altimeter presentations for a proposed replacement of the standard presentation in high performance airplanes. All of the proposed presentations were designed for ease of incorporation into standard instruments for immediate backfitting in present equipment. The counter-pointer type presentation, available only for new production, was included in the evaluation as a matter of general interest. The counter-pointer was determined to be the most desirable presentation. The configuration on the left was found to be the most suitable for immediate modifications. The barber pole area is a low altitude warning that appears below 16,000 feet. The instrument in the center was the next most suitable. The standard presentation is shown on the right for comparison. Altitude shown is 800 feet. Both project presentations would require minor changes.

Setzer, L.E. THE TYPE IV ROTATABLE-PANEL PICTORIAL COMPUTER: I. DEVELOPMENT AND INITIAL TESTS. Proj. 43-1, Tech. Rep. 195, May 1954, 25pp. US Civil Aeronautics Administration, Technical Development and Evaluation Center, Indianapolis, Ind.

This report presents a description of the Type IV rotatable-panel pictorial computer for use with the omnibearing-distance navigational system, together with the results of early laboratory and flight tests. A later report will present results of more extensive evaluation studies which are now in progress. Laboratory tests indicate that maximum errors of $\pm 1/2^\circ$ in azimuth indication and ± 0.4 mile in distance indication may be attributed to the computer when it is adjusted for optimum performance, and flight tests indicate that the pictorial computer provides one of the easiest methods of air navigation. The ease with which the navigational problems are solved and the continuous plotting of the position of the airplane make the computer especially valuable for terminal-area operations. The indicated position of the airplane can be kept within 1/4 mile of a desired course drawn on a 1:250,000 scale chart. The utility of the computer can be improved more by improvement of auxiliary features such as chart handling and scale selection than by increasing the accuracy of the position indications.

6887

Setzer, L.E. & Leake, P.H. THE TYPE V PICTORIAL COMPUTER WITH AUTOMATIC CHART SELECTION: I. DEVELOPMENT AND INITIAL TESTS. Proj. 13-1, Tech. Rep. 159, June 1954, 30pp. US Civil Aeronautics Administration, Technical Development and Evaluation Center, Indianapolis, Ind.

This report describes the Type V pictorial computer and presents the results of early laboratory and flight tests. The results of more extensive tests and evaluation will be presented in Part II. The Type V computer is an airborne display of omnibearing and distance navigation information and provides continuous airplane position and heading indications, a mechanical chart selector, and an automatic receiver-tuning mechanism. The charts are printed in route sequence on a roll of 35-mm film and are projected on a 10 inch diameter, see-through-type screen. Laboratory tests indicated that the computer meets specification requirements for an accuracy of ± 0.4 nautical mile in distance, ± 0.5 in bearing, and $\pm 7^\circ$ in heading. Flight-test results emphasize the value of the following features: a) simplicity of control accomplished by the automatic-tuning and scale-selection features; b) an uncluttered chart due to the projected position indicator; and c) the huge amount of chart storage available by use of film. 2 features that can be improved are the contrast of the image projected on the screen and the means of replacing obsolete charts on the film roll.

6889

Lindsay, D.B., et al. USE OF THE PPI FLASH-READING TRAINER IN TRAINING NAVY SEARCH-RADAR OPERATORS. Contract OEMR 919, Proj. SC 70, NS 146, Rep. 17, OSRD Rep. 4831, March 1945, 12pp. Office of Scientific & Research Development, NDRC, Applied Psychology Panel. (Yerkes Laboratories of Primate Biology, Orange Park, Fla.)

A trainer for the Plan-Position Indicator (PPI) has been developed. It consists of a mechanical-optical simulation of the PPI screen. Targets may be presented in any desired order, position, and with varying persistence time. Because short exposure times, 1-5 sec., are used the instrument has been designated the Flash-Reading trainer. Experience and data derived from its use permit the following conclusions to be drawn: a) the trainer can be scored accurately and objectively; b) the best use is obtained when the scope markings are made to simulate the bearing and range scales of an actual radar; c) significant increases in scope reading ability occur with training; d) both individuals and classes may be distinguished reliably by their trainer scores; e) training in battlephone procedure and reporting can be coordinated closely with the scope reading training in a way that duplicates many of the elements of the combat situation; and f) the greatest improvement in performance is secured when the men are given 15 min. practice each day for about 15 days. (HEIAS)

6896

US Civil Aeronautics Administration. GENERAL AVIATION ACCIDENTS (NON-AIR CARRIERS): A STATISTICAL ANALYSIS. CALENDAR YEAR 1954. 13pp. US Civil Aeronautics Administration, Department of Commerce, Washington, D.C.

This statistical analysis covers accidents involving fixed-wing aircraft of 12,500 pounds or under engaged in general aviation (other than air carrier operations). Those incident to crop control activities have been omitted since they are being treated separately in a report entitled "Aerial Crop Control Accidents," which is being published by the Civil Aeronautics Board. The CAB will also publish a statistical analysis of civil aircraft accidents involving fixed wing aircraft over 12,500 pounds and helicopters or other non-fixed wing aircraft. In this publication we have combined the material previously presented in 2 separate publications: "A Statistical Analysis of Non-Air-Carrier Accidents" and "Statistical Details of Non-Air-Carrier Accidents by Individual States." The information previously contained in the publication by individual states is presented in tabular form by state within each Civil Aeronautics Administration region. We believe that such a presentation will not only furnish the state agencies and the CAA regions with the information they have previously received, but will also make available the greater detail found in the overall statistical data. This is intended as a quantitative study of accidents only.

6897

Senders, J.W. TRACKING WITH INTERMITTENTLY ILLUMINATED DISPLAYS. Proj. 7182, Task 71510, WADC TR 55 378, Oct. 1955, 8pp. USAF Aero Medical Lab., Wright-Patterson AFB, Ohio.

Subjects performed a tracking task involving the simultaneous control of 2 indicators by the use of 2 controls. Their view of the indicators was periodically and simultaneously obscured. The data indicate that performance varies as a direct function both of frequency and relative length of the "on" portion of the cycle.

Herrick, R.M., Adler, H.E., Coulson, J.E. & Howett, G.L. THE DETECTION OF SEPARATIONS BETWEEN ADJACENT SIGNALS ON A SIMULATED PPI RADAR SCOPE. Contract AF 33(038) 22616, Proj. 7186, Task 71544, Tech. Rep. 55 424, July 1955, 22pp. USAF Wright Air Development Center, Air Research and Development Command, Wright-Patterson AFB, Ohio. (Columbia University, New York, N.Y.)

A simulated Plan Position Indicator (PPI) scope was used to evaluate the effects of a number of visual variables upon the minimum signal luminance increment (ΔI) required for the detection of a separation between 2 identical signals. The signal luminance increment is the difference between the signal luminance and the scope face luminance. All of the variables, viz., background luminance, distance between signals, scan rate, and simulated phosphorescence decay were of importance in determining threshold log ΔI values. Differences in threshold log ΔI among the observers were also statistically significant. Moreover, most of the interactions among the variables were statistically significant. As the background luminance increases, an increase in log ΔI is required for detection of a given separation. The background luminance is the most important determinant of the threshold log ΔI . In general, for a given background luminance, the threshold log ΔI must increase as the separation between signals decreases. The influence of simulated phosphorescence decay and scan rate upon log ΔI thresholds is relatively small with the type of target display used in the present experiment.

Egan, J.P., Clarke, F.R., & Carterette, E.C. ON THE TRANSMISSION AND CONFIRMATION OF MESSAGES IN NOISE. J. acoust. Soc. Amer., 1955, 28 (4); 536-550. Contract AF 18(600)-571, AFRC-TN-56-51. Operational Applications Laboratory, AFRC, Bolling AFB, Washington, D.C. (Indiana University).

6900

To examine the interaction between sender and receiver utilizing a noisy communication channel, messages consisting of one of a list of 50 syllables and previous messages transmitted by each of three subjects (the authors) were transmitted with a signal-to-noise ratio of 0 to -16 db (which could be varied independently for sender and receiver). The receiver retransmitted the message to the sender who confirmed or transmitted it again. Each message was transmitted until confirmed, or until an arbitrary number of trials had been reached. A theoretical model is developed for determining the probability that any given message will be confirmed. The results are presented in terms of cumulative percent confirmed messages as a function of number of repetitions and signal-to-noise ratio. T. G. R. 12

Dvorak, A., & Wright, C.E. SYMMETRIC CORRELATION MATRIX PROGRAM FOR THE IBM TYPE 650. Prepared under Contract Nonr-477(08), Dec. 1956, 5pp. University of Washington.

6902

This report constitutes the second of a series of program descriptions for the International Business Machines (IBM) Type Magnetic Drum processing machines. A program by which large correlational matrices can be computed readily from raw score data is provided.

6903

Dvorak, A., & Wright, C.E. PREDICTOR SELECTION FOR THE IBM TYPE 650. Prepared under Contract Nonr-477(08), Nov. 1956, 6pp. University of Washington.

6903

In this report, the first of a series of program descriptions for the International Business Machines (IBM) Type 650 Magnetic Drum Data Processing Machine is presented. Due to their complexity and size, a number of computational routines previously submitted are used for the programs included.

6904

Dvorak, A., & Wright, C.E. OPTIMAL TEST LENGTH FOR MAXIMUM DIFFERENTIAL AND ABSOLUTE PREDICTION ON THE IBM TYPE 650. Prepared under Contract Nonr-477(08), Dec. 1956, 7pp. University of Washington.

6904

To supplement two previous papers in which iterative techniques for determining the optimal distribution of testing items for differential and multiple absolute prediction had been presented, this paper presents a program for the International Business Machines (IBM) Type 650 Data Processing Machine designed to determine the distribution of test times so as to maximize differential prediction. With a minor change, optimal test times for maximum multiple absolute prediction may be obtained. R 5

Webb, P., & Veghte, J.H. SEVERAL VARIABLES AFFECTING PERFORMANCE OF VENTILATED CLOTHING. Proj. 7155, WADC TR-56-43, Jan. 1956, 18pp. Aero Medical Lab., WADC, ARDC, Wright-Patterson AFB, Ohio.

6906

To investigate variables affecting the performance of ventilated clothing, the heat protection afforded by light, medium, and heavy clothing assemblies was evaluated at ground level, 10,750 feet, and 27,500 feet in a chamber having temperatures of 120 degrees Fahrenheit, 140 degrees Fahrenheit, or 160 degrees Fahrenheit with the temperature of the ventilating air at 90 degrees Fahrenheit per 10.0 cubic feet per minute, 60 degrees Fahrenheit per 7.3 cubic feet per minute, or 30 degrees Fahrenheit per 5.5 cubic feet per minute, according to the orthogonal square method. Exposure was for three hours. T. G. I. R 6

6907

Sell, R.G. A SURVEY OF THE APPLICATION OF ERGONOMICS TO THE IRON AND STEEL INDUSTRY. PART I. DESIGN OF EQUIPMENT. PE/N/79/56, Jan./Feb. 1956, 25pp. Plant Engineering Division, The British Iron & Steel Research Association, London, England.

6907

This report is the first of two reports which show how ergonomics has been and can be applied to problems in the iron and steel industry. The problems considered here are those of equipment design. Ten large steelworks were visited, control points were inspected in relation to their intended functions and discussions held with personnel. Summaries of available ergonomic information, of the observations and recommendations are presented for each of the following: design of controllers, layout of controls, and design of display systems. T. I. R 15

Kochevar, J.H. LETTER REPORT OF PROJECT Nr AA-1050/1454, INDIVIDUAL PROTECTIVE EQUIPMENT USED WITHIN THE AAFCS M33 VAN and Enclosure. DA Proj. Nr 5-13-07-002, ATDEV-4 413.6/38, May 1956, 12pp. Headquarters, Continental Army Command, Fort Monroe, Va.

6908

To determine the ability of personnel to operate the Anti-aircraft Fire Control System (AAFCS) 733 van while wearing individual protective equipment, the crew, equipped with various types of masks and gloves, tracked radar targets while their performance was observed. The effects of gas masks on visibility and the effects of gloves on manual dexterity are evaluated and specific recommendations are made with respect to the equipment.

6909

Sell, R.G. A SURVEY OF THE APPLICATION OF ERGONOMICS TO THE IRON AND STEEL INDUSTRY. PART I. DESIGN OF EQUIPMENT. PE/N/79/56 APPENDIX, March 1957, 43pp. Plant Engineering Div., The British Iron & Steel Research Association, London, England.

6909

This appendix (see 6907) presents a detailed and comprehensive account of information on design of equipment in eight large steel works. The purpose of the visits was to determine the present stage of development of ergonomics in the steel industry. Data were gathered by direct observation and interviews with engineers and managers concerned with efficient employment of personnel. Work space layouts are included. I.

6910
USAF School of Aviation Medicine. SUBJECT INDEX OF SCHOOL OF AVIATION MEDICINE RESEARCH REPORTS. JANUARY 1942-DECEMBER 1955. 60pp. USAF School of Aviation Medicine, Randolph AFB, Tex.

6910
This index contains research report titles published by the School of Aviation Medicine from 1942 through 1955. The subject headings are arranged by major field of interest with subheadings and cross references where appropriate. The fields of interest are accidents, air evacuation, aviation medicine, dentistry, internal medicine, microbiology, neuropsychiatry, ophthalmology, otolaryngology, pathology, personnel, pharmacology and biochemistry, physiology, psychology (clinical and experimental), radiobiology, space medicine, statistics (medical), preventive medicine, surgery and anesthesiology, and veterinary sciences.

6911
Quastler, H. INFORMATION THEORY IN BIOLOGY. Contract DA 11 022 Ord 721; 1953, 273pp. Control Systems Lab., University of Illinois, Urbana, Ill.

This volume, in which the formalism of information theory and cybernetics has been applied to some basic biological problems, is a compilation of papers mostly dealing with the first stage of analysis, quantification. Section 1 is concerned with the definition and measurement of information: the Shannon-Wiener function and the Fisher function are considered; relations between information and physical entropy are discussed, and applications to living systems are made. Section 2 is devoted to the structural and functional analyses of fundamental biological units. In Section 3 are gathered the tentative beginnings of analysis of whole systems. (HEIAS)

Rockman, A.G., & Fussell, W.B. THE INFLUENCE OF FIELD OF VIEW ON THE TRANSMISSION OF LIGHT THROUGH TURBID WATER. NKL Problem H03-05, Proj. NR 663-050, Rep. 4708, March 1956, 7pp. Optics Div., Naval Research Lab., Washington, D.C.

6912
To determine the influence of field of view on transmission of light through clouded media, transmission through a seven-foot diameter tank of turbid water was measured in two ways: (1) with collimated light and a narrow field of view receiver (Macbeth Illuminometer), and (2) with uncollimated light and a wide field of view receiver (35 millimeter camera). A picture of a lamp bulb submerged in the water was analyzed to indicate the dispersion of energy around the source.

Madell, M.A. THE EFFECT OF VARIOUS LUMINANCE LEVELS AND TARGET CONFIGURATION ON THE REFRACTIVE STATE OF THE EYE. Contract AF 33(616)-2372, Proj. 7157, WADC TR-56-61, Feb. 1956, 30pp. Aero Medical Lab., WADC, ARDC, Wright-Patterson AFB, Ohio. (Los Angeles College of Optometry).

6917
To investigate night myopia and sky myopia, an infra red ophthalmoscope was used to measure the refractive state of the eye at increasing luminance levels from 0.05 foot lamberts to 300 foot lamberts. Various target configurations were employed in the first phase of the study in an effort to determine their relative efficiency in eliciting an accommodative response. In the second phase, a Snellen "E" and a flat white, homogeneous, unmarked wall were selected as targets to give data showing the extremes of accommodative response.

Tanner, W.P. Jr., & Swets, J.A. THE HUMAN USE OF INFORMATION. I. SIGNAL DETECTION FOR THE CASE OF THE SIGNAL KNOWN EXACTLY. Contract DA 36-039-sc-15358, EDO Tech. Rep. 4, 1956, 14pp. Vision Research Lab., University of Michigan.

6918
In this paper, a theory of visual detection is developed, based on the model provided by the theory of signal detectability, and, more generally, by the theory of statistical decision. Two experiments are reported which test some predictions of the theory for the case of the signal-known-exactly (frequency known). The predictions of the theory are compared with contrasting predictions of conventional sensory theory. Finally, two specific cases of signal detection involving uncertainty in the frequency of a sound signal are compared with the case of the signal-known-exactly.

Burnett, W.A., Adorno, D.A., Bogar, J.E., & Ross, W.C. PROCEDURES FOR ANALYSIS OF COMMUNICATION TRAFFIC ENGINEERING DATA. Contract DA 49-025-SC-150, DA Proj. 3-99-01-001, SC Proj. 102 E, SC Tech. Requirements SCEL-2101 E, HRB Inc. Proj. 57, Rep. 57-M-12, Feb. 1956, 48pp. Haller, Raymond and Brown, Inc., Pennsylvania State College.

6920

This report is concerned with procedures for the analysis of communication traffic data. Techniques are presented for developing delay predicting equations for busy periods selected on the basis of (1) call arrival process, (2) call length distributions, and (3) queue discipline. An example of an analytical solution to the single-trunk system is given, and an approximation method for the multi-channel problem. Comparison is made between analytical methods and simulation techniques. G. R 21

Doyle, F.J. METHODS FOR OBTAINING DIMENSIONAL INTELLIGENCE FROM SINGLE OBLIQUE AERIAL PHOTOGRAPHS. Contract AF 18(600) 90, OSURF Proj. 485, Tech. Paper 187, Dec. 1954, 67pp. USAF Wright Air Development Center, Air Research and Development Command, Wright-Patterson AFB, Ohio. (Ohio State University Research Foundation, Columbus, Ohio).

This report presents methods which may be employed by the photo interpreter in order to determine dimensional information about ground objects from measurements of their images on single oblique photographs. 3 simple computational methods and 2 semigraphical methods are developed with computing forms and examples for each. The semigraphical methods are based on overlays precomputed and predrawn for standard camera installations. A series of overlays are included with this report. Methods for determining the orientation of oblique photographs are described, and the accuracy of the solutions is investigated. R 4

6928

Money, J.F. DETECTION TECHNIQUES IN DOPPLER TRACKING SYSTEMS. FINAL REPORT. Contract DA 04 200 ORD 278, SRI Proj. 899, April 1955, 69pp. Ballistic Res. Labs., USA Aberdeen Proving Ground, Md.

A study of the detection problems involved in the reflection Doppler tracking system is reported. It is shown that, under the expected field conditions, detection errors due to noise may be made small compared to errors in field site surveying and errors due to unknown variations in the velocity of radio waves if suitable detection techniques are used. Interfering signals, particularly those due to multipath propagation, are considered to pose a principal problem of detection. It is suggested that selection of the desired signal from interfering signals may best be accomplished by an operator, since the decisions required involve the application of relatively complex information. Two data reduction techniques which utilize the capabilities of the operator in the selection of the desired signal have been proposed. The first is a frequency detection system in which the operator acts as the detector. The frequency vs. time characteristics of an estimate of the signal are adjusted by the operator to approximate those of the received signal in a series of convergent spectrographic presentations. The second technique provides visually supervised phase detection of the desired signal. Its use would normally follow the spectrographic analysis procedure. In this system, the operator is presented with a phase interference pattern of the desired signal with respect to the best estimated signal produced by the spectrographic process. Both of the data reduction techniques can be built around commercially available magnetic tape handling equipment. Laboratory experiments indicate that the visual frequency and phase detection operations proposed can be conducted successfully at signal and noise levels expected in a field installation of the reflection Doppler missile tracking equipment.

Straub, H.E., Gilman, S.F. & Konzo, S. DISTRIBUTION OF AIR WITHIN A ROOM FOR YEAR-ROUND AIR CONDITIONING, PART I. University of Illinois Engng. Exper. Station Bull. 435, July 1956, 52(82), 48pp. (University of Illinois, Urbana, Ill.).

This bulletin is a report of one phase of a research project on air distribution in an experimental room for year-round air conditioning which was conducted under the terms of a cooperative agreement between the Engineering Experiment Station of the University of Illinois and the American Gas Association. Engineering data were obtained for selecting the proper types of supply outlets at floor, baseboard, and sidewall locations only, which would give satisfactory air distribution in residential rooms during all seasons of the year. For this purpose the air temperature and air velocities were measured at 231 stations in the room for each different experimental arrangement. These data together with visual observations of the air motion by means of smoke provided a complete picture of the air distribution within the space. In spite of the fact that studies with almost 100 different experimental arrangements were conducted with the various outlets, only 4 distinct groups of room air patterns were obtained.

Adams, E.W., & Fagot, R.P. A MODEL OF RESELECTION DECISIONS. Prepared under Contract Nonr-225(17), Proj. 78 171-034, Tech. Rpt. 4, Aug. 1956, 65pp. Applied Mathematics and Statistics Lab., Stanford University.

6941

This paper presents a model for the explanation and prediction of individual decision making in situations of multiple choice, involving just two components. The model provides a method of measuring "subjective value" or "utility" which under some conditions leads to an ordered metric scale, and which still more restrictive conditions to an interval scale. Two possible extensions of the theory of decision making to wider classes of decision situations are considered. Finally, brief consideration is given to the problem of treatment of data.

6942

Stone, W.P. ALPHA-NUMERIC CHARACTER READER. MDC-78-56-194, June 1956, 13pp. Rome Air Development Center, AFMPC, Griffiss AFB, Rome, N.Y.

6943

This technical note describes a device, called the "Alpha-Numeric Character Reader," which rapidly converts hand- or machine-printed alpha-numeric characters into the standard tele-type code. With this aid for intelligence data processing, only thirteen bits of information are extracted from the latent information in a printed character, and despite slight recognition interpretation errors, virtually full content can be extracted economically.

Cooming, L.J., Jr. ELEMENTS IN AIRCRAFT SCHEDULING SCHEDULING. Res. Rep., Jan. 1956, 48pp. Graduate School, Syracuse University.

6947

The purpose of this report is to bring together some of the factors that combine to make aircraft maintenance scheduling effective. Periodicals served as the major source of material for the report and the discussion is organized under the following headings: organization and operation of the scheduling function, methods and tools for maintenance scheduling, methods of evaluating effectiveness, and, in an appendix, a general plan for the planning and scheduling of aircraft maintenance.

Wissinger, R.L., & James, T.M. A TECHNIQUE FOR DISPLAYING TASK ANALYSIS INFORMATION. Contract AF 25(520)-175, Proj. 7800, Rep. 56-11, March 1956, 5pp. AFMPC, Air Force Special Weapons Center, Griffiss AFB, N.Y.

6949

This report illustrates a new technique for displaying a large quantity of task analysis information in a limited space and in a manner such that job requirements may be examined in full or separately by type of requirement. A portion of an analysis of high speed interceptor mission is included as an example of the technique. Processes involved producing the display are discussed and described.

Elkins, A. PERSONNEL REPLACEMENT AND TRAINING RESEARCH DEVICES. Prepared under Contract Nonr-1413(00), Proj. A, Rep. 8, July 1956, 66pp. Courtesy and Co., Philadelphia, Penn.

6951

This study was designed to determine the extent of replacement and the personnel situation aboard destroyers in order to make suggestions for handling these situations more efficiently. Present orientation techniques and training approaches are analyzed and recommendations for improvement are made, even to the extent of evaluating training manuals.

T. I.

6952

Elkins, J.I. CHARACTERISTICS OF SIMPLE MANUAL CONTROL SYSTEMS. Contract AF 19(122)-458, Tech. Rep. 111, April 1956, 145pp. Lincoln Lab., Massachusetts Institute of Technology.

6953

This report presents a method for measuring and describing the characteristics of manual control systems. The method is applied in an experimental study of the characteristics of simple manual systems. The experimental results are discussed and analytic models are derived that approximate the measured characteristics. An analogue computer developed to present the measurement of the system characteristics is described.

Barr, N.L., & Macken, F.C. INVESTIGATION AND IMPROVEMENT OF SYSTEMS FOR SIMULATING INSTRUMENT CONDITIONS IN AVIATION INSTRUMENT FLIGHT TRAINING (INSTRUMENT FLIGHT TRAINING). Proj. No. 001 054.07.04, Jan. 1956, 154pp. Naval Medical Research Institute, National Naval Medical Center, Bethesda, Md.

6345
This report is concerned with an evaluation of available methods for simulating instrument flight, with special reference to optical and operational requirements and the report of two improved methods. Current devices were evaluated according to criteria derived from the opinions of instructors and pilots, as well as by operational and laboratory tests.

Gill, R.C. THE ATTENTION OF HUMAN BEINGS IN THE IRON AND STEEL INDUSTRY. Part II. PHYSICAL CONDITIONS OF WORK. Dec. 1955, Jan.-Feb. 1956, 24pp. Plant Engineering Division, The British Iron & Steel Research Association, London, England.

6350
This report is the second of two reports which show how ergonomics has been and can be applied to benefit the steel industry. It deals with the improvement of physical conditions in which operators have to work. Examples of available information, of the actual conditions prevailing, and of recommendations are given under five headings: a) seating, b) lighting, c) ventilation from dust, d) access to control panels, and e) heavy manual work. Details of the arrangements developed by the British Iron and Steel Research Association are given. Further work in basic design of cab structures and effects on work output of various types is needed.

Berkefire, J.R., & Lyon, T.W. PERFORMANCE IN NAVAL AIR TRAINING AS A PREDICTOR OF SUCCESS IN THE FLEET. PRELIMINARY REPORT: FOLLOW-UP STUDY OF GRADUATES SENT TO COMBAT. Special Rep. 56-14, April 1956, 11pp. USN School of Aviation Medicine, Pensacola, Fla.

6353
This report covers the first half of a follow-up study of graduates of naval air flight training to determine the degree of performance in training as a predictor of success in the fleet. Grades for various stages of training are related to the later success or failure of the (pilot) leading to recommendations for speed-training system standards of performance for certain critical phases of training.

Scharf, C. A TRANSLATION OF ERGONOMICS - A NEGLECTED PRODUCTION FACTOR. RE/5/10/55, March 1956, 11pp. Plant Engineering and Energy Division, The British Iron & Steel Research Association, London, England.

6353
A general survey is given of the importance of a detailed study of the workers positions and movements in the design of machines. Suggestions are made relative ways in which the construction engineer, the manufacturers and work-repair personnel, and the workers should be educated about this important production factor.

Anon. TEST OF THE STANDARD AND MODIFIED M5A1 COMBAT AND ES1R15 AND ES1R17 NONCOMBAT PROTECTIVE GAS MASKS. DPCR 168, Industrial Funding Proj. Order 6015, Jan. 1956, 35pp. Dugway Proving Ground, Utah.

6354
To compare the E 51R15 and E 51R17 non-combat protective gas masks with the standard and two modified models of the M 5A1 combat mask, each of the five masks were tested by 20 men while performing field training activities and the M 5A1 mask was worn by 18 men during 20 minute trials doing calisthenics and digging fox-holes. The masks were compared for suitability and ease of wearing under desert conditions and for need of modification in design.

Taylor, D.W. STUDIES OF PROGRAM DESIGNING. Prepared under Contract N600-11115, Proj. No. 150-149, Final Rep., Jan. 1956, 6pp. Stanford University.

6355
This report describes briefly a series of experimental studies concerned with problem-solving performed to cause possible more effective training of individuals in such processes. A list of the articles describing the research is appended, as well as an analysis of reports yet to be published.
E. 15

6357
Scharf, C. THE DESIGN OF A 100-TON LOOSE CRANE. RE/5/10/55, Jan.-Feb. 1956, 24pp. Plant Engineering Division, The British Iron & Steel Research Association, London, England.

6357
This report describes how the interior of the cab of a crane was laid out and discusses the human engineering factors underlying the particular layout. The aim was to provide a cab which could be used with ease and comfort by a variety of operators, and operated at the maximum of their capabilities. Factors considered are seating, controllers layout, positioning, location of controls, lighting, and visibility.

G'Connor, W.F., & Blair, J.T. ANXIETY AND
FLYING: II. MAJOR SOURCES OF ANXIETY AMONG
FIVE-SEVEN STUDENTS. Special Rep. 56-7, Feb.
1956, 13pp. The School of Aviation Medicine,
Pensacola, Fla.

6941
This is the second report of a study designed to assess the nature and extent of anxiety expressed by the normal pilot candidate in the early stages of flight training. Group interviews were conducted with 55 normal aviation cadets before (to assess expectations) and after their seventh instructional flight. After the second interview, the subjects were given a sentence-completion test designed to elicit their reactions to flight. The different content analyses were performed on the responses to the test, as well as analysis of the interview material.

6944
Knight, J. ACCURACY IN STOPPING A MOVING SECTION AS A FUNCTION OF THE SPEED OF THE SECTION. RESEARCH, Jan./Feb. 1956, 15pp. Flight Engineering Division, The British Iron & Steel Research Association, London, England.

6945
A frequent criticism leveled out by men engaged in controlling the movement and processing of steel ingots and sections is to stop the steel at some point. This experiment investigated the accuracy with which a section was stopped as a function of its speed and of the degree of visibility of the section. A laboratory situation was set up based on the real situation in which the steel comes toward the operator. The subject, on a raised platform, viewed a moving section and attempted to stop it at an exact mark. Six speeds from 0.38 to 2.33 feet per second and two situations (screen or bridge to provide different degrees of visibility of section) were used. Error data were analyzed.

Gorb, D., & Johns, R.J. EFFECTS OF ACETYLCHOLINE (ACh) AND CHOLINE ON KENOSYNTOMAL TRANSMISSION IN JOURNAL STRENGTHS. Contract DA 18-108-CML-5611, Proj. 4-59-12-007, CML Rep. 2002, March 1956, 8pp. Army Chemical Center, Md. (Johns Hopkins University).

6947
This report describes the probable function of acetylcholine (ACh) in nerve impulse transmission and its effects if present in excessive amounts at motor end plates. Also described are the vascular, stimulating, "prompt" depressant, and "late" depressant effects of ACh, the dose-effect relationship, and how neuromuscular transmission is effected if ACh is used either before or after other drugs. Similar information is given for choline itself.

6948
USA Quartermaster Food & Container Institute for the Armed Forces. IMPROVEMENT OF THE marginally ACCEPTABLE CANNED MEAT ITEMS. TERMINATION REPORT. Proj. 7 R 4 06 031, Jan. 1956, 6pp. USA Quartermaster Food & Container Institute for the Armed Forces, Chicago, Ill.

6949
This paper reports investigations conducted to study the improvements which could be applied to canned meat rations. Formula modification, reduction in the heat process used, and partial dehydration of the meat prior to canning were tried with varying success. The results with specific products are itemized.

6945
Hesse, W., Fies, D., Lieberman, B., & Dehols, J. RESEARCH ACTIVITIES DURING 1955. Prepared under Contract Nour-432(04), Annual Tech. Rep., Jan. 1956, 13pp. Boston University.

6946
This is an annual report on work done for the Office of Naval Research by the Division of Research at Boston University. The current status of various research studies is given with brief summaries of five studies also included. The focus of the research for the year was in the general area of opinion-attitude change, with emphasis on motivational factors as effective independent variables.

Bryson, G.L. ELECTRONICS TROUBLE SHOOTING: A SYSTEMATIC ANALYSIS. Prepared under Contract Nour-228(02), Proj. NR 153-095, Tech. Rep. 13, March 1956, 260pp. University of Southern California.

6952
In this lengthy report step-by-step protocol from four data sources are examined with the objective of developing a framework for behavioral analyses of electronics trouble-shooting. In an attempt to integrate various facets of such performances, qualitative segments are identified in each protocol, and reference is made to their frequency, position, consistency, and behavioral consequences. Separate treatment is given to redundancy, errors, time, and action rate. The generalizability of the results is stressed throughout.

Shepherd, R.J. CHANGES OF PHYSIOLOGY AND PSYCHOMOTOR PERFORMANCE DURING ACUTE HYPOXIA: SOME OBSERVATIONS WITH THE NULL-BALANCE DISCONTINUOUS PURSUIT METER. FFRS 963, March 1956, 16pp. RAF Institute of Aviation Medicine, Farnborough, Hants, England.

6970
Changes of physiology and psychomotor performance were studied during the acute exposure of ten normal subjects to an altitude of 20,000 feet for ten minutes. Arterial oxygen saturation, pulse rate, and respiratory minute volume were checked, and psychomotor performance was measured by the null-balance electrical pursuit meter. The response to hypoxia was evaluated in terms of general changes and inter-subject differences.

Dewick, M. A STUDY OF CONDITIONS AFFECTING COOPERATION. Prepared under Contract Number 2854101, Tech. Rep. 4, Feb. 1956, 26pp. Research Center for Human Relations, New York University.

6972
This paper reports part of a program of research on the conditions affecting cooperation. One of the studies included investigated the effects of motivational orientation, psychological similarity, and opportunity to communicate upon the development of mutual trust. Another reports on the influence of some types of power relationships on the development of trust, while the last two studies have to do with (1) the establishment of trust between two people via their relations with a third person, and (2) personality structure and interpersonal trust.

6973
Shuman, A.L., Radin, A.O., & Gmelin, W.C. A STUDY OF "THROW RIDE" CHARACTERISTICS OF CHAIRMAN CHAIRMAN VS. SUSPENSION TYPE SEATS IN MILITARY VEHICLES. Contract DA 11-022-ORD-1999, ORD Proj. 171-496, DA Proj. 57701001, Final Rep., March 1956, 60pp. Boeing Aircraft and Aberdeen Proving Ground, Aberdeen, Md. (Boeing Air Corp., Milwaukee, Wis.).

6974
To study the environmental factor of vibration as related to truck drivers, the 3-8 cycles per second acceleration and/or jerk component was measured (electronically) on the driver and on the truck cab in three directions: vertical, longitudinal, and transverse. Various terrains and speeds were used with two types of seats: standard and suspension. The effect of laboratory vibration studies on man in both types of seats was studied. The accelerations and frequencies were compared for field and laboratory studies and related to accepted tolerance levels reported in other studies. The efficiency of the two seats in reducing vibration was compared. Some theories are presented on man's expenditure of energy in attempts to reduce vibrations.

Quartermaster Food & Container Institute for the Armed Forces. ACCEPTABILITY OF IMITATION BLACK PEPPER. Proj. 7-34-15-007, Termination Rep., May 1956, 25pp. Quartermaster Food and Container Institute for the Armed Forces, Chicago, Ill.

6976
The acceptability of an apparently superior imitation black pepper was investigated in a field test at a large army post. Ten 6 ounce 10 ounce balls used the imitation pepper while 10 comparable new balls used natural pepper. The products were intentionally mislabeled for half of each group. Preference for 30 foods before and after the period was measured by a general food preference questionnaire administered to random samples of the men who regularly ate in the participating mess halls.

Thislethwaite, D.L., Kamenetzky, J., & Schmidt, H. FACTORS INFLUENCING ATTITUDE CHANGE THROUGH REPUTATIVE COMMUNICATIONS. Speech Monographs, March 1956, 23(1), 14-25. (Contract AF 33(033)-25726, Proj. 7705, AFTRC TX-56-54, June 1956. AFTRC, ARDC, Lackland AFB, Tex.).

6978
This paper is concerned with the most effective methods of presenting persuasive communications. In the first of two studies, explicitly refutative versus implicitly refutative communications were studied as well as one-sided versus two-sided communications. In the second, climax versus anti-climax order of presentation of explicit refutations were the concern - and the use of second-person versus third-person grammar in describing the source of the counterarguments refuted. Audience affective reactions to tape recorded speeches were measured and checked against opinion questionnaires.

Kasell, Dorothy M. RELATIONSHIPS BETWEEN ATTITUDES OF SQUAD CREWS IN TRAINING AND THEIR ATTITUDES AND PERFORMANCE IN COMBAT. Proj. 7713, AFTRC TX-56-48, April 1956, 44pp. Crew Research Lab., AFTRC, ARDC, Randolph AFB, Tex.

6980
Attitudes of members of 12 B-29 crews in training were compared with those they expressed later in the 1953 combat situation. The attitudes were assessed as predictors of the crews' combat performance ratings. Both attitude surveys were factor analyzed to find common factors suitable for prediction purposes. In addition, the item composition of the attitude scales was studied.

6981
Sorgatta, L.P. AWARENESS OF SOCIAL INTERACTION: ACTUAL, ROLE PLAYING, AND PROJECTIVE. J. Abnorm. Soc. Psychol., Nov. 1956, 51(3), 354-358. (Contract AF 33(033)-17726, Proj. 7730, Res. Rep. AFTRC TX-56-50, April 1956. AFTRC, ARDC, Lackland AFB, Tex. Russell Sage Foundation).

6982
This research concerns the relation of verbal statements about an action to the actual behavior. Data were collected for 125 enlisted men who participated as three-man teams in three situations (role playing, projective test requiring writing of a conversation, and actual behavior). Responses in these situations, scored in Baltes' 12 behavioral categories, were correlated with scores for military adjustment and popularity, and performance on the test of Primary Mental Abilities. Factor analysis was performed with the data and the results are discussed in relation to the problem of predicting social interaction of team members.

6983
Eby, T.B. SOCIOMETRIC INDEX MEASURES AS PREDICTORS OF MEDIUM-BOOMER CREW PERFORMANCE. Proj. 7713, AFTRC TX-56-48, April 1956, 12pp. Crew Research Lab., AFTRC, ARDC, Randolph AFB, Tex.

6984
To evaluate sociometric index measures as predictors of medium-boomer crew performance, conventional self-report data from 30 B-29 crews in training were analyzed from three standpoints (the inferred role behavior of the raters, the inferred attitudes of the raters, and interactions expected to occur between raters and rateres). Indices were developed from these approaches and correlated with each other and with performance measures and instructor ratings. The results with the technique are compared with results from conventional sociometric measures.

French, E.G. DEVELOPMENT OF A MEASURE OF COMPLEX MOTIVATION. Proj. 7704, AFTRC TX-56-48, April 1956, 10pp. Personnel Research Lab., AFTRC, ARDC, Lackland AFB, Tex.

6986
This paper describes the development of an independent measure of complex motivations for use in studies of the role of such motivations in systems operations. A projective test, constructed to measure achievement and affiliation motivation, was given to pre-flight cadets as a Test of Insight. A reliable scoring system was developed and validity testing initiated by correlating test scores with observer ratings, goal attainment, and questionnaire responses.

Getzels, J.W., & Gaba, E.G. ROCK CONFLICT AND INSTRUCTOR EFFECTIVENESS AT THE AIR COMMAND AND STAFF SCHOOL. Contract AF 15(600)-5, Proj. 7750, AFMTC IX-56-41, Feb. 1956, 57pp. Cy-ficer Education Research Lab., AFMTC, AFMTC, Maxwell AFB, Ala.

6977

To study the effect of role conflict on effectiveness as an instructor in a service school, instructors were given an inventory in which each item described a conflict situation. In answering each question they were to give an objective appraisal of how widespread each situation was in the school; in a second version they were to say how deeply they were disturbed by each conflict situation. The results were analyzed in relation to personal history questionnaires and ratings, by the other instructors, of their teaching effectiveness.

Ferguson, L.D., Bertman, A.B., Ransome, A.J., & Christensen, Margaret L. MEASUREMENTS, VARIABILITY AND RELIABILITY OF REGIONAL SWEATING RATES IN HUMANS AT CONSTANT AMBIENT TEMPERATURES. Contract AF 15(600)-96, Proj. 7155, WADC TR-56-39, Feb. 1956, 47pp. Aero Medical Lab., WADC, AFMTC, Wright-Patterson AFB, Ohio.

6982

This paper describes observations of sweating rate by the desalinating capsule technique on ten regions of the body surface of six male male subjects. The subjects were exposed to accurately controlled climates of 90, 100, 110, and 115 degrees constant dry bulb temperatures with one constant vapor pressure. The magnitudes, variability, and reliability of regional sweating rates are described. The implications of the results for future testing and for the design and use of ventilated clothing are discussed.

Nagel, M.W. ILLUMINATION, CONTRAST, SPECTRUM, AND COLOR CONDITIONS IN AN "AVERAGE" OUTDOOR SCENE AS FUNCTIONS OF GROUND REFLECTANCE, OBJECT ORIENTATION, AND VIEWING DIRECTION. Proj. 6472, Tech. Rep. 56 H, Aug. 1955, 43pp. Serial Reconnaissance Lab., Wright Air Development Center, Wright-Patterson AFB, Ohio.

In the report, an attempt is made to define the concept of an "average" outdoor scene for application to the development of photographic equipment and material. It consists primarily of a white sphere on a neutral gray or white ground under a clear sky at a sun altitude of 40 degrees. The distribution of illumination, reflection spectra, and color on the surface of such an object is investigated. The contrast (or exposure range) and the spectral uniformity of the illumination on the object are determined as a function of both the ground reflectance and the direction from which the object is photographed or viewed. Wicks, E.W. THE EFFECTS OF SIMULTANEOUS DECELERATION, TUMBLING AND WINDBLAST ENCOUNTERED IN ESCAPE FROM SUPERSONIC AIRCRAFT. Proj. 7218-71726, WADC TN-54-12, March 1956, 147pp. Aero Medical Lab., WADC, ARDC, Wright-Patterson AFB, Ohio.

6991

To investigate the effects of simultaneous deceleration, tumbling, and windblast encountered in escape from supersonic aircraft, two chimpanzees were ejected by ejection seats from a rocket travelling at Mach 1.1 and 1.5, both at 21,500 feet altitude. Information from three accelerometers, three rate gyros, and two electric monitors, as well as heart and respiration rates was recorded on magnetic tape during the ejection. Cures were mounted on the seat to photograph the effects of windblast. Film and tapes were recovered in usable form from the wreckage and results are analyzed in this paper. T. G. I. R 9

Euradio, A., Velasquez, T., Reynafarje, C., Lissano, R., Chavez, R., Salazar, E.A., Reynafarje, B., Sanchez, C., & Mancy, J. MECHANISMS OF NATURAL ACCLIMATIZATION: STUDIES ON THE LATE PRESENT OF MEXICO, PERU, AT AN ALTITUDE OF 14,900 FEET. Rep. 56-1, March 1956, 62pp. USAF School of Aviation Medicine, Randolph AFB, Tex.

6993

Investigation was made of the physiological characteristics, at rest and during physical activity, of the Indian native resident of Maricao, Peru, a mining town located in the Andean region at an altitude of 14,900 feet with an average barometric pressure of 116 millimeters of mercury (see Rep.). Comparative observations were carried out on healthy men living in Lima, which is at sea level. The study sought information on adaptive mechanisms in the respiratory, hematic, and circulatory functions. T. G. I. R 64

Drum, L.B. HUMAN ENGINEERING RECOMMENDATIONS FOR THE DESIGN OF A TIMING DEVICE. Ordnance Proj. T51-1000, DA Proj. 535-20-001, Tech. Rep. 2339, Aug. 1956, 15pp. Picatinny Arsenal, Dover, N.J.

6992

The human engineering aspects of a timing device to cover the range of .1 to 100 seconds accurately by intervals of .1 second were studied. Detailed recommendations are presented concerning the design of dial markings, pointer, adjusting knobs, and control-display relationships. The design of counter markings is also dealt with in detail. T. I. R 6

Johnson, C.E. AN ANALYSIS OF THE CONTENT OF LOW ALTITUDE HIGH SPEED PILOTAGE CHARTS. Contract AF 33(616)-2378, Proj. 555, Tech. Paper 202, June 1956, 34pp. Mapping and Charting Research Lab., Ohio State University Research Foundation.

6995

In an attempt to determine what should be the content of charts for low altitude high speed pilotage, ground features are discussed from the standpoint of their frequency, availability, time available for recognition, and their positions in relation to different types of flight paths. The problem of obstacles and their avoidance is considered. Various types of physical and cultural terrain features suitable for guidance are described in relation to their local environment. Finally, some general conclusions regarding pilotage charts are given. I.

See Clair, R.S. EVALUATION OF FLIGHT ATTITUDE INDICATOR MODEL NO. 1055 - SWAGERS GYROSCOPE COMPANY DOUGLAS SPEC. NO. 7545077. Contract 54-521, Rep. 26322, June 1956, 20pp. El Segundo Div., Douglas Aircraft Co., Inc., Santa Monica, Calif.

6996

To study the operational suitability of a moving aircraft symbol attitude indicator, ten Navy pilots flew a SNJ-5 airplane in which the new type of flight attitude indicator was installed. Flights were for two hours and consisted of time turns, slow rolls, barrel rolls, loops, spins, and recoveries from unusual attitudes. The pilots were interviewed immediately following their flights and the interviews analyzed for acceptability of the device and suggested design changes. I.

7009

Hughes, H.G.A. & Read, S. THE FILM AND FUNDAMENTAL EDUCATION. Pamphlet 1, 1950, 20pp. Film Centre, Ltd., London, England.

7009

The authors discuss the utilization of films and filmstrips as aids to fundamental education in terms of the utilization of this medium, the organization of a film program, and factors pertinent to the production of educational films. The problem of understanding through film is also discussed.
R 15

7010

Brinson, P. FILM AND FILMSTRIP PROJECTION IN FUNDAMENTAL EDUCATION. Pamphlet 2, 1950, 21pp. Film Centre, Ltd., London, England.

7010

The author discusses film and filmstrip projection in fundamental education in terms of their design, operation, and maintenance. Also discussed are some aspects of optical aids in general, such as the distinction between episcopic and discopic projection, the deficiencies inherent in the episcopic, and so forth. A specimen log book and a series of logbook charts are presented.

R 10

7011

Brinson, P. CHOICE AND CARE OF FILMS IN FUNDAMENTAL EDUCATION. Pamphlet 3, 1950, 21pp. Film Centre, Ltd., London, England.

7012

In a discussion of the choice and care of films in fundamental education, the author presents specific recommendations concerning maintenance and storage of films, suggestions for the improvement of film distribution programs, and remarks concerning the factors involved in selecting films for particular audiences. He also presents detailed information concerning sources of films in various parts of the world.

R 12

7012

Seser, G. CHOICE AND CARE OF FILMSTRIPS IN FUNDAMENTAL EDUCATION. Pamphlet 4, 1950, 19pp. Film Centre, Ltd., London, England.

7012

The author discusses the factors involved in the choice and care of filmstrips in fundamental education. He describes the various types of filmstrips (i.e., the narrative, instructional, and reference strips), techniques of producing filmstrips, and examples of and suggestions for the utilization of this educational medium. Also included is a guide to sources of filmstrips of potential value in fundamental education.

R 13

7013

Brinson, P. FILM DISCUSSION GROUPS IN FUNDAMENTAL EDUCATION. Pamphlet 5, 1950, 21pp. Film Centre, Ltd., London, England.

7013

The author discusses the role of film discussion groups in fundamental education in terms of the factors involved in the effective utilization of films with such groups. He defines the film discussion group and presents an example of the approach and problems encountered in using films with discussion groups in fundamental education.

R 13

7030

Cardwell, Irene. **ADULT READING IMPROVEMENT WITHOUT MACHINES.** Sch. & Soc., 1955, 82, 71-72.

7030

In an investigation of adult reading improvement without the use of mechanical aids, 20 Ss between the ages of 26 and 58 were given the California Achievement Test and other reading tests to ascertain the individual reading levels. Formal education of the group varied from incompletion of secondary school to achievement of technical degrees. The group met for 12 two-hour sessions of lectures, discussions, practice exercises, and tests. The group was retested at the completion of the course. The results were discussed in terms of the degree of reading improvement as a function of the course of instruction. Such variables as age, interest, formal education, etc., were also treated.

R 1

7031

Kelso, H.C. **CLASSROOM DISCUSSION VIA TELEVISION.** Sch. & Soc., 1955, 82, 120-122.

7031

This is a report of an experiment in which television was used as a technique to facilitate the teaching of a large class of students. A group of 87 students were placed into three discussion groups and taught a course by means of closed circuit television and open audio circuits. Additional arrangements to permit intergroup and group-instructor communication were employed. The results are described in terms of the relative effectiveness of this technique as observed both by participants and nonparticipants.

7033

Allen, K.M. **AUDIO-VISUAL LEARNING: A COMMENT ON RESEARCH.** Sch. & Soc., 1953, 78, 25-27.

7033

This is a reply to a critical evaluation of published audio-visual research studies (see 7034). The author denies reliance of contemporary studies on classical studies and presents evidence of the contributions being made to this area of research. He reviews studies dealing with such aspects of audio-visual instruction as applications of audio-visual aids, the influence of communication upon learning, and mentions the variety of factors being investigated by Army, Navy, and Air Force research programs.

R 11

7034

Erickson, K.M. **AUDIO-VISUAL LEARNING.** Sch. & Soc., 1953, 78, 197-203.

7034

In a review of audio-visual learning, the author cites and evaluates approximately 30 books dealing with many aspects of audio-visual instruction. A general criticism of the entire field of research is reflected in the author's belief that contemporary studies rely too much upon earlier classical studies.

R 12

7035

Dunbar, F. **EDUCATION PREPARES TO USE TELEVISION.** Sch. & Soc., 1952, 76, 374-376.

7035

This is a report on the effectiveness of television as an aid to education. The author cites the results of several investigations and analyzes these results in terms of the probable factors involved in the successful utilization of television. A brief survey of the television facilities being used throughout the country for educational purposes is also presented.

R-3.

7037

Jehring, J.J. **VISUAL COMMUNICATION IN THE CLASSROOM.** Sch. & Soc., 1952, 76, p. 75.

7037

In an attempt to answer certain questions raised concerning visual communication in the classroom (see Acc. Jo. 7039), the author presents an analysis of some of the dangers involved in the use of visual materials. The positive aspects of learning by means of visual materials are also discussed. The potential effects of both correct and incorrect use of such materials are considered.

R 1

7038

Millen, R.W. **TEACHING PSYCHOLOGY BY TELEVISION.** Sch. & Soc., 1952, 76, 133-134.

7038

The author describes his experience in teaching a psychology course by means of television in terms of the differences between this technique and the customary classroom techniques. In particular he speaks of adjustment to the atmosphere of a television broadcast, the teaching techniques required in teaching through television, and the applicability of visual aids such as slides, pictures, graphs, etc., to the television teaching medium.

7039

Casper, K. IS THERE DANGER IN THE USE OF VISUAL AIDS? *Sch. & Soc.*, 1951, 24, 58-59.

7039

The author discusses the potential dangers involved in the utilization of visual aids in teaching. He raises questions concerning such aspects as the tendency of visual aids to reduce reading competency, the amount of mental effort involved in comprehension of material presented in this manner, the potential effect on the imagination of learners, and so forth.

7040

Witty, P. TELEVISION AS AN AID TO INSTRUCTION. *Sch. & Soc.*, 1951, 24, 273-276.

7040

In this article on television as an aid to instruction, the author discusses the educational potentialities of television, the current status of television in elementary, high school, and college programs, and the use of television for special education, i.e., teaching deaf children. In addition, three types of educational program transmission are described and discussed.

Hoban, C.F., Jr. DETERMINANTS OF AUDIENCE REACTION: STATUS. *A-V Communication Rev.*, 1953, 1, 242-251.

7058
The author discusses status as a determinant of audience reaction. He cites a number of researches dealing with this aspect of audience and discusses in detail two studies reflecting the relation between film content and audience reaction as a function of such variables as social status, military status, amount of education, training rating of film, etc.
T, R 11

7060
Zuckerman, J.V. PREDICTING FILM LEARNING BY PRE-RELEASE TESTING. *A-V Communication Rev.*, 1954, 2, 49-56.

7060
This is an investigation of the degree to which film learning can be predicted by pre-release testing. Two comparable groups of Air Force trainees, reflecting a total of 90 subjects, were pretested on knowledge concerning the content of a film. Then one group was shown the regular film while the other group was presented with a film strip mocked-up to resemble the regular film. The subjects were retested and the results are treated in terms of the correlation of scores between the groups as indication of the film-strip's ability to predict amount of learning from the film.

- 7063
VanderWeer, A.M. COLOR VS. BLACK AND WHITE IN INSTRUCTIONAL FILMS. *A-V Communication Rev.*, 1954, 2, 121-134.
- 7063
To evaluate the relative effectiveness of color and black and white films in instruction, two experiments were conducted. In the first, 500 high school students were divided into two groups: one group was presented with five color films on five successive days; and the other with five black and white prints of the same films. In the second experiment an alternation technique was used in presenting the films. In both experiments subjects received intelligence tests prior to film showings and verbal and non-verbal learning tests following the showings. Results are discussed in terms of the relative performance of subjects viewing color vs. that of subjects viewing black and white films.

The author discusses the General Motors Driver Education Film Series as an educational aid for driver training. He lists the titles of the films and filmstrips contained in the series and evaluates the potential effectiveness of a program incorporating such audio-visual materials.

7101
Lewis, P. TV TAKES A TEST. *Educ. Screen.* 1950, 20(5), 196-198 & 203.

7101
This article describes several experiments concerned with the utilization of television in the classroom. The various factors investigated include the following: seating arrangement, viewing distance, viewing angle, interior illumination, size of screen, and so forth. The results of the experiments are presented and discussed in terms of the role of each factor in the television experience. Implications and specific recommendations for the utilization of television as a teaching aid are presented.

7102
Carpenter, C.R., & Greenhill, L.P. USING INSTRUCTIONAL FILMS EFFECTIVELY. *Educ. Screen.* 1950, 20(5), 331-333.

7102
This article presents a discussion on the effective use of instructional films. The factors of film utilization which are evaluated concern those aspects inherent in the instructional film itself, those pertinent to the viewing audience, and those relevant to the learning process. The authors present a summary of their recommendations for effective instructional film utilization.

7103
Koss, E.I. REAL DAYLIGHT LANTERN SLIDES. *Educ. Screen.* 1950, 20(10), 426-437.

7103
The author describes a technique for producing and projecting lantern slides under ordinary conditions of daylight room illumination. The practicality of this technique is discussed in terms of the factors involved in the production process itself and those pertinent to viewing this type of slide (e.g., the amount of glare present; the reduction of eyestrain, etc.).

7104
Jassiel, R.M. RETENTION OF LEARNING AND TRANSFER OF TRAINING. *Progressive Educ.*, 1953, 31:1, 26-29.

7104
In this discussion of learning the author is primarily concerned with retention of learning and transfer of training. In his analysis of the theoretical aspects of these two learning phenomena, the following theories are discussed: localization of brain function, identical component theory, Judd's generalization theory, Dunlap's negative transfer theory, and training for transfer theory.

7105
Trotter, Lella. SOME DO'S AND DON'T'S FOR AN AUDIO-VISUAL PROGRAM. *Educ. Screen.* 1954, 23(3), 48-49.

7105
The author presents an extensive list of suggestions concerning the effective use of audio-visual teaching aids. The suggestions are organized under the following three aspects of audio-visual instruction: 1) organization of the audio-visual program; 2) the proper equipment and facilities to be used; 3) the utilization of audio-visual aids.

7107
Merritt, H.A. & Schiller, C.E. AUDIO-VISUAL MATERIALS: THEIR MAKING AND USE. 1933, 344pp. Harper Bros., New York, N.Y.

7107
This is a textbook on the nature and use of audio-visual materials. Included are chapters on learning, the chalkboard, graphics, films, recordings, television, and other kinds of aids and techniques. Frequent reference is made to the results of research studies in the discussion of each area of audio-visual instruction.

Carpenter, R.C. & Schlosberg, H. MONOCULAR AND BINOCULAR INTENSITY THRESHOLDS FOR FIELDS CONTAINING 1-7 DOTS. *J. Gen. Psychol.*, 1950, 40, 81-94. (Johns Hopkins University, Baltimore, Md. & Brown University, Providence, R.I.).

2 Ss reported the number of black dots they saw when plates containing 1-7 dots were presented. All exposures lasted 32 msec. at an intensity of .55 ml. Each dot subtended a visual angle of 33' and all were within a field of 1°. Each S received 200 trials with each eye and 200 binocularly for each number of dots. The percentage of correct responses fell off as a function of the number of dots exposed. The monocular results were in agreement with the curve described by p^n (p = percentage of correct reports, n = number of dots). The binocular results conform roughly to properly compounded monocular probabilities. (MEIAS)

8002
Davis, A.C. MOTOR RESPONSES TO AUDITORY STIMULI ABOVE AND BELOW THRESHOLD. *J. Gen. Psychol.*, 1950, 40, 107-120. (Indiana University, Bloomington, Ind.).

The study aimed at finding muscular responses produced by auditory stimuli at or near threshold. Muscle action potentials were recorded from 4 body locations for 27 Ss while a series of near-threshold auditory stimuli was delivered. Muscular responses were found after stimulus onset as well as after cessation of the stimulus. Responses to unheard stimuli were smaller than to those heard. There was an increase in response with increase stimulus intensity, and with repetition of the stimulus. The results are interpreted by a scheme of 3 principles: that of motor response, partial forward displacement, and self-excited system. (MEIAS)

Rann, C.M. & Passey, G.E. THE PERCEPTION OF THE VERTICAL: V. ADJUSTMENT TO THE POSTURAL VERTICAL AS A FUNCTION OF THE POSITIVENESS OF POSTURAL TILT AND DURATION OF EXPOSURE. *J. exp. Psychol.*, 1951, 45, 108-113. (Yale University, New Orleans, La. & USAF Human Resources Research Center, Randolph Field, Tex.).

3 Ss were subjected to tilts of 5, 15, 25, 35, 45, and 55 degrees for periods of 0, 5, 15, 25, 35, 45, 55, and 65 sec. Each S was given 10 adjustments from each position; there were 10 experimental sessions. With increasing duration of exposure to tilt there was an increasing average error of adjustment and a shift of constant error of adjustment in the direction of initial tilt. The same were the effects of increasing amount of initial tilt. Results are related to previous work, and curves are fitted to the data. These curves are proposed as theoretical functions. (HEIAS)

Melnick, J.S. PURSUIT LEARNING AS AFFECTED BY SIZE OF TARGET AND SPEED OF ROTATION. *J. exp. Psychol.*, 1951, 41, 126-138. (University of Southern California, Los Angeles, Calif.).

8012
To investigate the relation between difficulty of task and amount of reminiscence after one interpolated rest period during practice, ten groups of 25 Ss were tested for 20 trials on a Kierth-type pursuit rotor, under five conditions of difficulty. Difficulty was controlled by variations in the rate of rotation or in size of target. Five experimental groups had one-min. rest periods between all trials; five control groups had a five-min. rest period between trials five and six. Scores for time on target as a function of trials are compared for the groups.

Mechberg, J.E., Triebel, W. & Seamon, G. COLOR ADAPTATION UNDER CONDITIONS OF HOMOGENEOUS VISUAL STIMULATION (GANZFELD). *J. exp. Psychol.*, 1952, 41, 153-159. (Cornell University, Ithaca, N.Y.).

A technique is described whereby spatially homogeneous illumination may be presented to the eye, and the results of some exploratory experiments, using homogeneous colored light, are presented. Koffka's hypothesis that a colored Ganzfeld would lose its color was tested with red and with green light. Complete disappearance of color was obtained. In most cases, despite considerable individual differences in the course of the adaptation process and in the phenomenal content during adaptation. However, the results of presenting colored light to one eye after the other eye had been adapted to light of the same color, and of introducing a shadow into the field, make it difficult to ascribe the disappearance of the color to its adoption as a general "chromatic neutral point" for the entire visual field.

8013
Honey, D.H. & Solomon, R.L. VISUAL DURATION THRESHOLD AS A FUNCTION OF WORD-PROBABILITY. *J. exp. Psychol.*, 1951, 41, 401-410. (Harvard University, Cambridge, Mass.).

Data from 2 experiments, using 75 words, show that the visual duration threshold of a word, measured tachistoscopically by an ascending method of limits, is an approximately linear function of the logarithm of the relative frequency with which that word occurs in the Thorndike-Lorge word counts. Product-moment correlations between the two variables range from -.68 to -.75 in the main experiment. Empirical corrections for certain physical characteristics of the words and their component letters were found to raise the range of these correlations to -.76 to -.83. Viewed as a correlation between language behavior in a highly specific situation (duration threshold determination) and in general usage (Thorndike-Lorge counts), these data are of significance for the experimental analysis of language behavior. In addition, they point to the necessity for operational interpretation of a large number of perceptual experiments, since the size of threshold is found to be a function of a property (relative frequency) of the responses (words) that operationally define perceptual threshold.

Birren, J.E., Casperson, R.C. & Botwinick, J. PAIN MEASUREMENT BY THE RADIANT HEAT METHOD: INDIVIDUAL DIFFERENCES IN PAIN SENSITIVITY, THE EFFECTS OF SKIN TEMPERATURE, AND STIMULUS DURATION. *J. exp. Psychol.*, 1951, 41, 419-424.

The purpose of the study was to determine the reliability of the Hardy, Wolff, and Good method of measuring pain sensitivity, the day-to-day variability in the pain threshold, and the influence of skin temperature and stimulus duration. A correlation of .91 was obtained between two successive determinations in routine pain measurements on 50 Ss. When stimulus duration was held constant at 3 sec., a significant variation in pain threshold was produced by varying the skin temperature. When skin temperature was held constant at 90°F, a significant relation was found between threshold and stimulus duration. The radiant heat method of pain measurement offers the advantage of an easily controlled and measured stimulus. (HEIAS)

Duncan, C.P. THE EFFECT OF UNEQUAL AMOUNTS OF PRACTICE ON MOTOR LEARNING BEFORE AND AFTER REST. *J. exp. Psychol.*, 1951, 42, 257-264. (Northwestern University, Evanston, Ill.).

8018

To determine whether the acquisition of discriminative verbal responses facilitates the acquisition of discriminative motor responses to identical stimuli, five matched groups of 15 Ss were required to learn a 12-unit paired-associate list of syllables and figures and then to learn motor responses to the figures. Initial learning proceeded to mastery for three groups and for one and four trials for the other two. One of the former groups underwent an interpolated-learning trial in which all verbal responses were followed by shocks; another was required to make the appropriate verbal response overtly during motor-learning. Comparisons of correct responses during the motor-learning trials are drawn between the various groups.

T. G. R

8025

To determine whether distributed practice produces superior learning, as well as performance, than massed practice when length of session (practice plus resting time) is held constant, 157 female Ss, four groups were required to perform on a pursuit-rotor through a five-minute pre-rest session, a ten-minute rest, and a five-minute post-rest session. Two groups worked under massed and two, under distributed practice during the pre-rest session; during the post-rest session, two groups worked under reversed conditions of practice. Percent time on target is compared for the groups.

VanKrevelen, Alice. THE ABILITY TO MAKE ABSOLUTE JUDGMENTS OF PITCH. *J. exp. Psychol.*, 1951, 42, 207-215. (University of Rochester, Rochester, N.Y.).

17 Ss, who satisfied Bachem's criterion for absolute pitch, performed in 2 experiments. In one they identified randomly presented oscillator tones. In the second experiment they adjusted oscillator frequencies to produce specified pure tones. No particular frequency was agreed upon by all individuals to correspond to a particular tone; but when judgments were pooled the greatest number of judgments coincided with the true physical standard for a given tone. Experience seems important in establishing the tonal norm for an individual. Even with the established individual norms the Ss differed in the consistency with which they could retain their own standards through a long series of judgments. The group average error for both methods was about .3 semitone, greater than Bachem's estimate of .1 semitone, for his Ss. (HEIAS)

Graybiel, A. & Niven, J.I. THE EFFECT OF A CHANGE IN DIRECTION OF RESULTANT FORCE ON SOUND LOCALIZATION: THE AUDIOGRAVIC ILLUSION. *J. exp. Psychol.*, 1951, 42, 227-230. (USN School of Aviation Medicine, Pensacola Air Station, Fla.).

An experiment was carried out in which 4 male Ss estimated the location of a source of sound while being subjected to a change in direction of resultant force with respect to themselves. A consistent error was made in terms of a non-visual vertical-horizontal frame of reference. The error amounted to about 70% of the angle ϕ and a linear relationship was found to exist between the two. This phenomenon has been termed the audiogravic illusion and it can be readily explained on the basis that the egocentric localization of the horizon, under the conditions of our experiment, accords with the change in direction of resultant force.

Cogg, L.W. FRACTIONATION OF TEMPORAL INTERVALS. *J. exp. Psychol.*, 1951, 42, 3-7-312. (University of Wisconsin, Madison, Wisc.).

A reliable time function was established for 5 temporal intervals of 400, 800, 1,600, 2,400, and 4,800 msec. by the method of fractionation. 36 Ss made 10 judgments each for each of the 5 intervals. The means of the median half-values for all Ss were overestimations of 2.00, 2.09, 1.16, 1.16, and 9.31 %. A scale of subjective time, the "temp scale", was constructed from the fractionation data, and the variables that probably influence the form of the scale were discussed.

Bilodeau, E.A. PERFORMANCE DECREMENT IN A SIMPLE MOTOR TASK BEFORE AND AFTER A SINGLE REST. *J. exp. Psychol.*, 1952, 43, 388-390. (USAF Human Resources Research Center, Lackland AFB, Tex.).

8031

In an investigation of response decrement and recovery in a simple motor task, 260 women students were required to lift weighted table-tennis balls from a cup at the base of a chute to the top of the chute. Three variables were combined factorially: 1) duration of an initial practice session (2, 4, 8, or 16 minutes); 2) duration of an interpolated rest period (1, 2, 4, or 8 minutes); 3) weight of the balls (21, 42, 84, or 166 grams). Rates of responding during initial practice and during final practice are analyzed as a function of the experimental parameters.

McNab, C.B. & McNab, J.E. FAMILIAR SIZE AND THE PERCEPTION OF DEPTH. *J. Psychol.*, 1952, 45, 187-194. (Cornell University, Ithaca, N.Y.).

The aim of the experiment was to compare "familiar size" which requires past experience, and "relative size", which does not, as cues for depth perception. Exp. I: On 2-dimensional "reversible-screen" drawings were drawn a man, 4 3/4 in. high, on one panel, and a boy of the same size and approximate contour, on the other. Each member of 4 groups of 15 college students viewed the figure monocularly through a reduction screen at a 70 cm distance, was shown its reversibility, and asked to allow the screen to reverse as it would and to let his gaze move freely. The results indicate that familiar size was ineffective in this situation. Exp. II: The procedure of Exp. I was repeated with the boy being on one panel, and a reduced version of the same boy on the other panel. The panel with the larger boy appeared nearer, suggesting the importance of relative size. Cogg, L.W. & Brogden, M.J. THE EFFECT OF SIMULTANEOUS VISUAL STIMULATION ON ABSOLUTE AUDITORY SENSITIVITY. *J. exp. Psychol.*, 1952, 43, 179-186. (University of Wisconsin, Madison, Wisc.).

Auditory thresholds were measured under 3 conditions of auxiliary visual stimulation. A small light patch was fixated by S and increases in the brightness of the patch of zero, .005, and .055 ml. were used. For each S 3 auditory thresholds were determined for each of these light conditions. 1 group of 18 Ss received instructions to report the presence or absence of the light as well as that of the tone; another group of 18 Ss made no specific response to the light and were instructed to report presence or absence of the tone only. The results showed a significant elevation of the auditory thresholds for the light increases when a specific verbal response was required to the auxiliary stimulus and a significant lowering of the thresholds as the brightness of the light increased, when no response to the auxiliary stimulus was required.

Exploratory experiments were carried out to test the texture-hypothesis, i.e. that depth depends in the first instance on the relative density of the texture. 4 different experiments relating to the hypothesis are reported; only a few observers took part in each. 2 tentative conclusions emerged: a) It is probably a mistake to assume that a phenomenal surface is an elementary impression of visual space; and b) The visual hardness of a surface does not seem to be in psychophysical correspondence with texture as such. The texture-hypothesis as usually formulated is inadequate. The formula of the steepness of gradients of luminous intensity between regions of the image gives promise of being valid. The problem of the stimulus conditions for an edge involves several variables. 3 basic ways are suggested for producing retinal images which arouse an edge. (MEIAS)

Ittelson, W.M. A NOTE ON "FAMILIAR SIZE AND THE PERCEPTION OF DEPTH". *J. Psychol.*, 1953, **35**, 235-240. (Princeton University, Princeton, N.J.).

In a recent paper, Hochberg and Hochberg state that they do not like theories which involve the concept of familiar size as a cue to depth perception, and argue that the evidence for the existence of this cue is questionable since most of it hopelessly confuses familiar size with relative size. They report an experiment in support of the latter argument and offer a theory of size-distance perception based on "an autochthonous tendency toward homogeneity." Reference is made to several experiments which are not considered in the paper by the Hochbergs. These experiments either successfully separate familiar size from relative size, or cannot be accounted for by an autochthonous tendency toward homogeneity, or both. The experiment reported by the Hochbergs is then discussed, and their conclusions are found to be unjustified both by their own criterion and on methodological grounds.

Gibson, J.J., & Cornsweet, Janet. THE PERCEIVED SLANT OF VISUAL SURFACES—OPTICAL AND GEOGRAPHICAL. *J. exp. Psychol.*, 1953, **44**, 11-15. (Cornell University).

8041

The phenomenon of perceived slant of visual surfaces is defined in terms of optical and geographical slant. To test the hypothesis that optical slant occurs as a function of the direction of increasing texture-density in the retinal image (when geographical slant accompanies but is not in correspondence with optical slant), each of ten subjects was presented with a textured surface which was slowly rotated around a vertical axis and required to judge when the surface reached either of two positions: perpendicular to line of sight and at 45 degrees to surround; or parallel to surround and at 45 degrees to line of sight. Standard deviations and constant errors of judgment were analyzed to evaluate the consistency and accuracy of judgments. The results are discussed as indicative of the nature of optical and geographical slant. T.

8047 Bilodeau, E.A. DECREMENT AND RECOVERY FROM DECREMENTS IN A SIMPLE WORK TASK WITH VARIATION IN FORCE REQUIREMENTS AT DIFFERENT STAGES OF PRACTICE. J. exp. Psychol., 1951, 41, 96-100. (USAF Perceptual & Motor Skills Research Lab., Lackland AFB, Tex.).

The Ss (N=40) practiced rotating a crank handle as fast as possible for 5 min. with either a light or heavy loading of the crank. One group practiced with the light load, a second group with the heavy load, and the third and fourth groups alternated between loads after each minute of practice but were not of phase. After a brief rest all groups practiced for 3 min. with the loading used just before the rest. During the first minute of practice, rate of responding dropped more rapidly with the heavy load than with the light load. Thereafter, differences between the loads remained fairly constant. After a brief rest both load groups recovered equally in terms of rate, but the heavy load group recovered more in terms of \dot{M} . When the two groups which had practiced under one load condition were instantaneously shifted to the other, rate output was approximately equal to that of the nonshifting groups. Furthermore, after rest both alternating groups spontaneously recovered to the level of their non-alternating controls as if unaffected by the alternation treatment of initial practice.

8049 Bilodeau, E.A. MASSING AND SPACING PHENOMENA AS FUNCTIONS OF PROLONGED AND EXTENDED PRACTICE. J. exp. Psychol., 1952, 44, 108-113. (USAF Perceptual & Motor Skills Research Lab., Lackland AFB, Tex.).

8049 To investigate the relation of 1) rate of responding early and late in a practice session and 2) amount of spontaneous recovery for relatively short and long rest periods to 1) amount and 2) distribution of previous practice, two groups of 26 airmen were required to practice cranking for eight min. on each of ten days; either continuously within each session or in two periods of four min. separated by a four-min. rest period. Mean numbers of revolutions per 20-sec. trials were plotted as a function of successive trials for different days; gain after rest was plotted as a function of successive recovery periods.

MacLeod, S. A CONSTRUCTION AND ATTEMPTED VALIDATION OF SENSORY SWEETNESS SCALES. *J. exp. Psychol.*, Nov. 1952, **44**(5), 316-323. (Hobart College, Geneva, N.Y.).

The present paper is an attempt to assess the validity of sweetness scales based on fractional judgments of one-half. The following conclusions may be drawn from the present experiment: a) Log concentrations of sucrose and glucose judged half bear a linear relationship to log concentrations of sucrose and glucose standards. In the case of glucose the equation describing this relationship is $\log I = .651 \log S + .043$; in the case of sucrose the equation is $\log I = .681 \log S - .110$. b) Log concentrations of glucose bear a linear relationship to equally sweet log concentrations of sucrose as given by the equation: $\log I \text{ glucose} = .681 \log I \text{ sucrose} + .439$. c) Inasmuch as hypothetically valid fractionation functions for both sugars could be fitted (within S-to-S variability) to the obtained fractionation values, it would appear reasonable to assume that the method of fractionation did, in this instance, provide data for valid interval scale construction.

Garvey, W.D. THE INTELLIGIBILITY OF SPEEDED SPEECH. *J. exp. Psychol.*, 1953, **45**, 102-108. (USN Research Lab., Washington, D.C.).

8069

In an investigation of intelligibility of speeded speech, 96 subjects were presented with taped accelerated speech produced by a drop-slice technique. Eleven experimental tapes representing various relations between the amount of removed and remaining segments of speech patterns were used. The results are presented and discussed in terms of the general effect of acceleration on intelligibility, the effect of the amount of speech pattern removed, and the size of the drop removed with acceleration held constant.

8079

Swartz, P. A NEW METHOD FOR SCALING PAIN. *J. exp. Psychol.*, 1953, 45(5), 288-293. (University of Rochester, Rochester, N.Y.).

An algometric technique using 60-cycle alternating current as the stimulus and the tooth pulp as the site of contact has been described. By this method 24 male and 21 female Ss successively bisected pain intensities. For both sexes curves plotted for successive bisections against fractions of fractionating range have the same shape regardless of the actual size of the range being fractionated. Reversing the order of stimulus presentations and the direction in which S changes the size of the stimulus, reverses the direction of acceleration of the curves. Compensating for differences in fractionating technique indicates that the relation between the intensity of the stimulus and the estimation of its painfulness approximates a straight line with a slope fairly close to 1. It is concluded that: a) Within the range of intensities employed in this study, there is a one-to-one relationship between the intensity of the stimulus and the estimation of its painfulness; b) there are no sex differences in pain scaling behavior.

Wertheimer, M. AN INVESTIGATION OF THE "RANDOMNESS" OF THRESHOLD MEASUREMENTS. *J. exp. Psychol.*, 1953, 45(5), 294-303. (Wesleyan University, Middletown, Conn.).

Successive measurements of auditory, visual, and pain thresholds were obtained at 6-sec., 1-min., 3-min., and 1-day intervals on a series of Ss. These psychophysical thresholds were subjected to 5 different kinds of analysis: autocorrelation, estimated power-spectrum transformation of the autocorrelation function, correlation of the thresholds of 2 modalities measured over the same period of time on the same S, correlation of the spectra of the thresholds of 2 modalities taken over the same period of time on the same S, and analysis of variance. The data obtained tended to confirm the hypothesis that the variations of thresholds in time, under normal conditions, are not "random". This evidence is: a) Reliable changes in thresholds can be shown to occur in S from day to day, b) changes in the thresholds of different modalities are slightly correlated, c) successive threshold measurements are not independent, d) some thresholds can be shown to undergo cyclical drifts, and e) the patterns of variation of thresholds of different modalities over the same time interval in the same S are not unrelated. The relevance of these findings for an approach to the total organism is discussed.

Hundy-Castle, A.C. & McKiever, B.L. THE PSYCHOPHYSIOLOGICAL SIGNIFICANCE OF THE GALVANIC SKIN RESPONSE. *J. exp. Psychol.*, 1953, 46(1), 15-23. (National Institute for Personnel Research, South African Council for Scientific and Industrial Research.).

The GSR's of 109 normal Ss were recorded while auditory stimuli were given at 30-sec. intervals. Recordings continued until adaptation occurred or until 35 stimuli had been presented. EEG's were independently recorded. GSR's were classified as labile, stable, and stable/labile. It was found that labiles tended not to adapt to the stimuli, whereas, stables did, their adaptation rate being significantly correlated with alpha frequency. Mean age of the labile group was significantly lower than that of the stable group. 2 factors were thought to have contributed to these results: a) A factor determining the relative strength of excitatory/inhibitory processes, which is also related to alpha frequency; b) Extent of cortical restraint over lower autonomic centers, this probably related to a maturation factor. 8090

Slack, C.W. SOME CHARACTERISTICS OF THE "RANGE EFFECT". *J. exp. Psychol.*, 1953, 46(2), 76-80. (Princeton University, Princeton, N.J.).

The study aimed at discovering the shape of the range-effect error curve and the shape of the distributions of response errors under conditions of varying speed stress resulting from increasing stimulus frequency. The shape of the range-effect curve for a particular sequence of stimuli was found to be S-shaped on the average. The distributions of error at each input amplitude were found to have modes near zero and to be skewed toward the mean of the input distribution. Under conditions of lower speed stress the range effect decreases, the error curves flatten out, the SD's of the distributions of response errors to extreme inputs decrease and the distributions tend to be less skewed. A model for the range effect proposed by Craig was discussed in the light of these results. (HEIAS)

Poulton, E.C. TWO-CHANNEL LISTENING. *J. exp. Psychol.*, 1953, 46(2), 91-96. (Applied Psychology Research Unit, Medical Research Council, Cambridge, England).

Selecting information from 2 simultaneous sources of speech was evaluated in terms of omissions (of which S was generally unaware) and mishearings, which were distributed independently. When relevant information was surrounded by irrelevant on the same channel, omissions exceeded mishearings. When it was covered by simultaneous irrelevant information on the other channel, mishearings predominated. Instructions to listen to both sources (distributed attention) gave more omissions than instructions to listen to one of them (restricted attention). This in turn gave more than instructions as to when and to what to listen (direct attention). Mishearings were independent of these instructions. Placing the speakers together increased both omissions and mishearings. Similarity of relevant material to irrelevant increased omissions; it also increased false selections, especially with the speakers together. When only one or neither source presented information continuously, omissions and mishearings were reduced, and none of these differences was significant. The results were discussed in terms of inattention and physical interference.

Riopelle, A.J. & Chow, K.L. SCOTOPIC AREA-INTENSITY RELATIONS AT VARIOUS RETINAL LOCATIONS. *J. exp. Psychol.*, 1953, 46(5), 314-318. (Emory University, Atlanta, Ga. & Yerkes Labs. of Primate Biology, Yale University, New Haven, Conn.).

Absolute scotopic thresholds were determined for 10 areas of stimulation at each of 5 different retinal locations. All thresholds were made monocularly with the naked eye following at least 30 min. of dark adaptation. The largest area (subtending 57 min. of visual angle) was 64 times larger than the smallest area. The locations of retinal stimulation were 4, 8, 12, 24, and 48 degrees above the fovea. Stimulus durations were 50 and 250 msec. The authors alternated as S and as E. The results may be summarized as follows: a) There was a significant difference in over-all threshold at the various retinal locations; b) The longer the duration of the test flash, the lower the intensity required for threshold; c) The larger the stimulus patch, the lower the threshold; d) Area-intensity curves obtained at different retinal locations were parallel, indicating that within the range of this experiment the area-intensity relation is invariant with respect to locus of its determination.

Mech, E.V., Schaefer, R.W. & Auble, D. THE EFFECTS OF "SET" ON GROUP PERFORMANCE UNDER STRONG AUDITORY STIMULI. *J. Psychol.*, 1953, 36, 187-194. (Institute of Educational Research, Indiana University, Bloomington, Ind.).

The purpose of the experiment was to study the effects of "set" upon group performance under noise. The following procedure was used. 3 high school groups of 13 Ss each worked at a routine coding task 20 minutes a day for 5 days under the following conditions. For 10 minutes of each session the groups worked under noise stimulation of 85 db, while for the remaining 10 minutes the groups worked under quiet conditions. Noise and quiet conditions were alternated in a simple ABBA sequence. One group was told only that they were serving in an experiment on the effects of noise. Of the remaining 2 groups, 1 was given a set to perform better under noise while the other was given a "set" to perform better under quiet. Analysis of the data indicated: a) The pre-task "sets" did not influence differential group results in the desired direction; b) Noise stimulation of an 85 db intensity level does not appear to have any effect upon routine performance.

Bilodeau, E.A. & Bilodeau, Ina McD. THE CONTRIBUTION OF COMPONENT ACTIVITIES TO THE TOTAL PSYCHOMOTOR TASK. *J. exp. Psychol.*, Jan. 1954, 47(1), 37-46. (USAF Perceptual and Motor Skills Research Lab., Lackland AFB, Tex.).

Data for 2 multidimensional tracking tasks analyzed by components and total task were presented in an introductory analysis of the relative contribution of components to the total task. Whether the total task represented 2 or 3 components, the analysis (by trials) suggested that, as a first approximation, time of scoring in one component was essentially independent of times of scoring in the remaining components. The hypothesis of independence was tested by multiplication of the separate proportions of time on target and comparing the resulting value with that obtained by observation of the proportion for the total task. The comparison showed that fairly accurate prediction of total-task means and variances can be made, although small but systematic deviations suggest the need for additional research. The analysis brought out the implication that total-task performance can be improved by a redistribution of the on-target component proportions. Thus, for example, for a 2-component task, raising the proportion for one relatively low component at the expense of the second will raise the proportion of the total or criterion. In this way it is suggested that overall proficiency on some tracking tasks might be improved without raising S's general skill level. Methods for bringing about redistributions are still untested.

SYSTEM IN DISCRIMINATING THE AMPLITUDE OF MOVEMENT. J. Gen.
Psychol., 1954, 47, 381-391. (Ohio State University,
Columbus, Ohio).

8104
Utilizing certain concepts of information theory,
this study attempts to relate the Weber function (vari-
ability of response as function of amplitude) to the phe-
nomenon of variability as a function of duration of re-
sponse. Specifically, three experiments are reported
which test the hypothesis that average duration of re-
sponse is directly proportional to minimum average amount
of information per response provided to the subject by
his own motor system in a particular task. A total of
fifty-two subjects were used in three experimental tasks
(recognition tapping, disc transfer, pin transfer) in
which amount of information available to the subject was
related to optimal motor performance. The constancy of
performance capacity of the human motor system is dis-
cussed. T. I. R 25

Poulton, E.C. TWO-ALTERNATIVE SPAN IN SIMPLE SERIAL
TASKS. J. Exp. Psychol., 1954, 47, 403-410.
(Applied Psychology Research Unit, Medical
Research Council, Cambridge, England).

8106
In an investigation of the psychological factors
which determine eye-hand span in simple serial tasks,
79 subjects performed a three-choice double-joint task
and learned step-tracking tasks under conditions
designed to (1) determine the limits of eye-hand span
range, and (2) reduce eye-hand span to .30 seconds (in
an eight response three-choice task). The results are
presented and discussed in terms of the variations in
eye-hand span range, the effect of display speed upon
span, the effect of varied response lag upon performance,
and the effects of the attempt to reduce eye-hand span
(i.e., number of errors, omissions, etc.).

Levitt, C.M. ERRORS OF INTERPOLATION IN INSTRUMENT READING AND SETTING. *J. appl. Psychol.*, 1952, 36, 49-52. (Lehigh University, Bethlehem, Penn.).

30 Ss of both sexes and of various ages and occupations were required to make interpolations between marks 10 mm. apart in 3 different situations: a) reading from a slide rule set by experimenter to exact tenths; b) setting the rule to tenths; and c) reading tenths from Miller cards. Each S made 304 interpolations in each of the 3 situations. Results showed large individual differences among Ss. Slide rule reading errors range from 0 to 87. Slide rule setting errors in excess of half a unit ranged from 6 to 134. Errors in reading Miller cards ranged from 0 to 77. Correlations between slide rule readings and the mean discrepancy in setting was .62, between slide rule readings and errors over .5 was .61, and between slide rule readings and Miller card readings was .37. In all 3 methods errors were made less frequently at position 5 than at any other. Readings at positions 1, 2, 8, and 9 showed an inward bias, possibly due to the use of the end lines as reference points. Readings at positions 3, 4, 6, and 7 showed an outward bias, possibly due to the use of an imaginary line at the center as a reference point.

Rubin, G., Von Trebra, Patricia & Smith, K.U. DIMENSIONAL ANALYSIS OF MOTION: III. COMPLEXITY OF MOVEMENT PATTERN. *J. appl. Psychol.*, 1952, 36, 272-276. (University of Wisconsin, Madison, Wisc.).

Due to the lack of experiments of a systematic nature which, with meaningful definitions and observations, demonstrate what conditions of complexity produce variations in efficiency of motion, this study was deemed necessary. Results indicate that variations in the complexity of a movement pattern in terms of the number of directional dimensions involved do not produce noteworthy changes in the efficiency of the manipulation and travel components of the movement. This study substantiates previous work in showing that it is mainly the manipulation component of a motion pattern that is influenced by practice and not the travel component. The present data point up a fundamental weakness of the traditional generalized approach to the study of psycho-motor learning, as well as concepts which have been derived from such an approach. The study suggests that a real problem of reliable measurement exists in the analysis of psycho-motor activity and that this problem may be avoided only by separate measurement of the unrelated components of the work task. The principles and techniques of motion study described here provide the basis for such new approaches to the study of reliability of performance in skilled movements.

Zaccaria, A., Jr. & Bitterman, H.J. THE EFFECT OF FLUORESCENT FLICKER ON VISUAL EFFICIENCY. *J. appl. Psychol.*, 1953, 36, 413-416. (University of Texas, Austin, Tex.).

The experiment here reported was designed to study the effects of fluorescent lamp flicker upon visual fatigue. Performance of a standardized visual task was measured for 2 30-min. periods under 20 ft-candles of fluorescent daylight illumination. During 1 of the periods the lamps were operated with direct current, while during the other period they were operated with alternating current. In this way spectral characteristics, brightness level, and distribution were constant, with flicker being the only variable. Performance did not differ significantly under the 2 conditions, but the A.C. condition produced a significantly greater drop in critical fusion frequency than did the D.C. Only 25% of the 26 Ss detected a difference between the 2 conditions of illumination, but those that did uniformly expressed a preference for the D.C. condition. It may be concluded that single-lamp, or in-phase, multiple-lamp fluorescent installations are undesirable. Further experimentation is needed for the evaluation of out-of-phase installations.

Parker, J.W. PSYCHOLOGICAL AND PERSONAL HISTORY DATA RELATED TO ACCIDENT RECORDS OF COMMERCIAL TRUCK DRIVERS. *J. appl. Psychol.*, Aug. 1953, 32(4), 317-320. (Tufts University, Medford Mass.).

This study has been concerned with studying the relationship of certain psychological and personal history data to the accident records of a sample of commercial truck drivers. The accident data used were of 2 types - preventable accidents and non-preventable accidents, and were equated for the number of miles driven. The Ss for the study were 104 commercial truck drivers employed by a large East Coast trucking concern. For each of the criterion groups 2 types of analyses were made: a) the significance of differences between the upper and lower halves of the accident group was computed; and b) the significance of differences between the accident and non-accident group was computed. In addition, a Sherry-Bohlittle Shrout-Multiple Coefficient of Correlation was computed for 4 of the variables and the criterion score based on the first analysis of significance of differences. From this study the following conclusions can be drawn: a) A difference seems to exist between preventable and non-preventable accidents. b) Psychological traits, as well as sensory capacities, are important in analyzing the accident liability for preventable accidents, while only personal history data and sensory capacities seem to be important in analyzing the accident liability for preventable accidents, while only personal history data and sensory capacities seem to be important in analyzing the accident liability for non-preventable accidents. This study also demonstrated the applicability of a technique for controlling exposure to accident hazard; that is, using the number of accidents per unit mileage rather than just the total number of accidents.

8126 Johnson, K.W. CHECK-READING AS A FUNCTION OF POINTER SYMMETRY AND UNIFORM ALIGNMENT. *J. appl. Psychol.*, Oct. 1953, 32(5), 407-411. (State College of Washington, Seattle, Wash.).

A tachistoscopic study in which simulated instrument dials were observed at short exposure was performed to determine efficiency in locating deviating dial pointers in 4 instrument panels employing the principles of uniform alignment, pointer symmetry, and sub-grouping of pointer pattern. A null hypothesis was stated that the 4 patterns would equally well facilitate check-reading. Ss totalled 48 naive male students. The results of the experiment allow a statement of the following tentative conclusions: a) Configurations in this experiment employing pointer symmetry facilitate check-reading equally as well as do panels with uniform alignment. There is reasonable evidence that one of the former type is superior to the latter in terms of number of correct responses, and that another might prove superior with practice. The null hypothesis was rejected. b) Panels employing pointer symmetry and uniform alignment are superior to sub-groups for check-reading. c) Check-reading improves with a relatively short amount of practice and some transfer exists between panels with differing pointer positions. d) It was suggested that the use of a rectangular sixteen-dial panel of aircraft engine instruments with rotatable dials would facilitate rapid check-reading, and that these principles might profitably be applied in other situations where multi-engine panels are used.

Rock, M.L. VISUAL PERFORMANCE AS A FUNCTION OF LOW PHOTOPIC BRIGHTNESS LEVELS. *J. appl. Psychol.*, Oct. 1953, 32(5), 412-427. (C.N. Hay & Associates, Inc., Philadelphia, Penn.).

A systematic investigation of performance in visual tasks as a function of low photopic brightness levels was attempted. 4 types of visual tasks were investigated: judgment of magnitude of an illusion, absolute threshold for motion, depth perception and a simple addition task. All tasks were investigated under 5 brightness levels in the range of .005 foot-lamberts to 1.00 foot-lamberts. In each of the experiments, critical brightness levels were found below which performance was increasingly poor. Increased brightness above the critical level improved performance relatively little or not at all. The critical level for motion threshold was .1 foot-lamberts; for the other tasks approximately .05 foot-lamberts. It was suggested that for maximum performance on visual tasks, with minimum brightness, illumination should be adjusted to yield brightness values of .05 to .1 foot-lamberts.

 Cohen, J., Vanderplas, J.H. & White, V.J. EFFECT OF VIEWING ANGLE AND PARALLAX UPON ACCURACY OF READING QUANTITATIVE SCALES. *J. appl. Psychol.*, Dec. 1953, 37(5), 482-486. (Antioch College, Yellow Springs, Ohio).

Two experiments were performed to evaluate and quantify the effects of decreased viewing angles and parallax upon accuracy of reading instrument scales. In the first experiment, viewing angles were varied, and subject-controlled tachistoscopic presentation of the stimulus was used. Dial photographs were used as stimulus materials to isolate effects of viewing angle from those of parallax. The results show that reading errors increased as viewing angle decreased from 90° to 25°. Reading time was unaffected by changes in viewing angle. In the second experiment the effect of parallax was studied by requiring the Ss to align a movable pointer with a mark. The apparatus was set at viewing angles between 90° and 25°, and 4 pointer-mark displacements were used. The average error of the settings increased as the viewing angles decreased. The increase is approximated by a function proportional to the cosecant of the viewing angle. The constant error tends to increase systematically with viewing angle. With increasing pointer-mark displacement the average error tends to increase, but the constant error is inversely related to the amount of pointer-mark displacement. The error curves in both experiments are approximated by a function proportional to the cosecant of the viewing angle. An interpretation in terms of a least discriminable visual angle is advanced to account for the results.

Harris, S.J., & Smith, K.U. DIMENSIONAL ANALYSIS OF MOTIONS. VII. EXTENT AND DIRECTION OF MANIPULATIVE MOVEMENTS AS FACTORS IN DEFINING MOTIONS. *J. appl. Psychol.*, 1954, 38, 127-130. (University of Wisconsin).

8135

This is a study of the effects of varying extent and direction of manipulative movements upon the component movements of travel and manipulation in the motion pattern. Utilizing an electronic motion analyzer (the analytic reactometer), 42 right-handed subjects were evaluated on performance of a repetitive switch-turning task under six varied experimental conditions (three extents of manipulation, 40, 80, and 120 degrees, and two directions of movement, clockwise and counterclockwise). Each subject performed one trial under each condition for seven consecutive days. Analysis of variance of the data for day one and day seven is presented along with learning curves for travel and manipulation components of motion. The relative effects of extent and direction upon performance are discussed in detail. T. G. R 6

Sidman, M., Keller, F.S., Kennedy, E.J. & Wilson, M.P. TEACHING MORSE-CODE RECEPTION WITH SIGNALS WEIGHTED IN FREQUENCY ACCORDING TO THEIR DIFFICULTY. *J. appl. Psychol.*, Feb. 1955, 39(1), 1-4. (Columbia University, New York, N.Y.).

8135

To determine whether the learning of Morse code is facilitated when frequency of signal presentation is weighted according to difficulty, two groups of 19 college students were required to practice receiving Morse code for 26 sessions. The experimental groups was presented with signals each with frequency roughly proportioned to its difficulty for beginners as determined in a previous study. The control group received all signals an equal number of times. The groups are compared with respect to error scores obtained on successive test runs. T. G. R 7

8136

Safety Maintenance & Production THE SAFEST CAR IN THE WORLD. *Safety Maint. Prod.*, Dec. 1957, 114(6), 18-20, 26.

8136

This article describes an automobile designed and constructed with the safety of the occupants as its unique goal. Developed by the joint efforts of the Liberty Mutual Insurance Co., and Cornell Aeronautical Laboratory, Inc., the design presents such safety features as the following: adjustable control panel which also functions to secure the driver in his seat, lever control rather than steering wheel, bucket seats, a windshield providing 150 degrees of vision, a redesigned instrument panel with a warning light on each instrument to indicate malfunction, and many other features including modification of the structural design of the automobile body. I.

8137

Safety Maintenance & Production. SKID-WARNING SYSTEM FOR AIRCRAFT. *Safety Maint. Prod.*, Nov. 1957, 114(5), 22-29.

8137

This article describes the Skid-Warning System which utilizes a foot-thumping warning device to provide the aircraft pilot with knowledge of an impending skid. This system is contrasted with the automatic anti-skid system which automatically controls excessive brake pressure but offers the pilot little or no information concerning which tires are skidding. The new system provides "feel" along with complete control of the aircraft. The types of evaluative tests being conducted with this system are briefly described. I.

8138

Anon. UNAP PROBES SYSTEMS MAINTENANCE. *Aviation Week*, July 29, 1957, 67(4), 64-70.

8139

This article describes the research program of the Maintenance Laboratory of the U.S. Air Force Personnel and Training Research Center at Lowry AFB, Colorado. Two primary types of research are described, a technical program investigating devices, methods and techniques for the utilization, training and evaluation of maintenance personnel, and an operational program for the development of Qualitative Personnel Requirements Information (QPRI) on systems and weapons maintenance and service. Specific automation devices are described along with the problems inherent in their application. I.

8139

Anon. LABORATORY SEEKS SOUND INDEX. *Aviation Week*, Aug. 5, 1957, 67(5), p.25.

8139

A brief description is presented of the Douglas Aircraft attempt to devise an Acoustical Comfort Index for turbojet airliners. Its goal is to arrive at a meaningful unit of measure of the annoyance experienced by a passenger and attributable to noise. The major components of the experimental laboratory include an audition room, anechoic chamber, reverberation room, stress fatigue test room, and an analysis room. The anechoic chamber is illustrated. I.

8140

Anon. RUNWAY PLANS DESIGNED TO SPEED TRAFFIC. *Aviation Week*, July, 1957, 67(3), p.45.

8140

This article presents a brief description and illustration of a runway plan proposed by the Civil Aeronautics Administration. The plan was designed to increase the acceptance rate of air traffic by redefining the location of exits, taxiways and runways and by ensuring positive identification of each of these. A recommendation for holding apron design is also made.

8141: Bendig, A.M. RATER RELIABILITY AND THE HETEROGENEITY OF THE SCALE ANCHORS. *J. appl. Psychol.*, 1955, 39(1), 37-39. (University of Pittsburgh, Pittsburgh, Penn.).

Raters (N = 200) used 5-category rating scales, which varied in the heterogeneity of the verbal anchors defining the end categories, to rate for preference value two lists of 10 foods. The food lists differed in the homogeneity of food stimuli on each list. Measures of individual rater reliability and rater bias were computed and analyzed as to the effect of scale and list differences. Reliability was significantly smaller for the more homogeneous list and increased linearly as a function of the heterogeneity of the end anchors. Rater bias was unaffected by either scale or list differences. R 8

Leavitt, H.J. SOME EFFECTS OF CERTAIN COMMUNICATION PATTERNS ON GROUP PERFORMANCE. *J. Abnorm. soc. Psychol.*, 1951, 46, 38-50.

8144

To evaluate the effects of certain communication patterns upon group performance, a total of 100 subjects divided into appropriate groups were presented the task of discovering a single common symbol from among several symbols (printed on cards). Each group (5 subjects) received 15 trials in a workspace so designed as to provide a measurement of time of solution and type of communication pattern. Four types of communication patterns were utilized; chain, wheel, y, and circle. Additional analysis of the data was provided by a questionnaire and message analysis. The results are presented and discussed in terms of the relation between the particular communication pattern and such variables as number of messages transmitted, number of errors, enjoyment of the task, etc. T. Festinger, L. & Thibaut, J. INTERPERSONAL COMMUNICATION IN SMALL GROUPS. *J. abnorm. soc. Psychol.*, 1951, 46, 92-99. (University of Michigan, Ann Arbor, Mich.)

The variables of a) amount of pressure toward uniformity existing in a group and b) the degree to which the members perceived the group as homogeneously composed, were manipulated experimentally in a laboratory setting of a discussion group to test certain hypotheses concerning the pattern of communication within the group and the amount of change in opinion which occurs. The results strongly support the theoretical hypotheses and may be summarized as follows: a) When there is a range of opinion in the group, communications tend to be directed towards those members whose opinions are at the extremes of the range. b) The greater the pressure toward uniformity and the greater the perception of homogeneous group-composition, the greater is the tendency to communicate to these extreme opinions. c) The greater the pressure toward uniformity and the greater the perception of homogeneous group-composition, the greater is the actual change toward uniformity which takes place.

Bruner, J.S. & Rodrigues, J.S. SOME DETERMINANTS OF APPARENT SIZE. *J. abnorm. soc. Psychol.*, 1953, 48(1), 17-24. (Harvard University, Cambridge, Mass.).

One group of Ss was presented a penny, a nickel, and a quarter to judge; another judged correspondingly sized nickel-colored metal discs; a third judged gray cardboard discs. 60 Ss were in the "coin group", and 30 Ss were in each of the "disc groups". The Ss were children and were assigned randomly. 1/2 of each group were set to think of the buying power of money, and 1/2 were set to think about accuracy of size judgments. 1/3 of each group used a variable 6-chorded light figure for matching the sizes of coins or discs. Another 1/3 used a 9-chorded light, and a last 1/3 used a circular light figure. Order of presentation of the different sized coins was randomized for each subgroup as was the size of the variable light figure from which a match began. Conclusions are: the value of objects does not unequivocally affect their judged size; the value of objects does affect their phenomenal appearance; an accuracy "set" seems to increase absolute overestimation of discs and coins; it is difficult to say any thing definite about the effect of the shape of the variable light patch used; new types of experiments are needed which get at basic processes in the areas of perception and judgment. Gibson, J.J. THE RELATION BETWEEN VISUAL AND POSTURAL DETERMINANTS OF THE PHENOMENAL VERTICAL. *Psychol. Rev.*, 1952, 59, 370-375. (Cornell University, Ithaca, N.Y.).

The purpose of this paper is to suggest that beliefs concerning space perception which depend upon a motor theory or a phenomenological theory of space perception cannot be decided one way or the other but need to be resolved instead. Comparisons are made between the 2 theories and suggestions are made as to possible methods of resolution. (HEIAS)

8166

Homes, D. A STATISTICAL THEORY OF THE PHENOMENON OF SUBCEPTION. *Psychol. Rev.*, 1954, 61(2), 98-110. (Aero Medical Lab., Wright-Patterson AFB, Ohio).

The assumptions made in this theory are consistent with the symbolic-report hypothesis. From them it is possible to deduce some 13 definite inequalities of GSR between the Lazarus and McLeary experimental categories, whereas only 1 inequality follows rigorously from the subception hypothesis itself. The present assumptions assign a definite significance to exposure time as a parameter of the inequalities of GSR. Exposure time will affect inequalities differently according to the categories being compared. They yield, in addition to the interpretation of GSR inequalities, quantitative deductions of syllable probabilities for lower-order reports. The subception hypothesis offers no interpretation of these data. These assumptions are subject to quantitative formulation on the basis of experimental data. The 2 basic relationships needed are: a) the function relating average strength of a syllable process to the duration for which the corresponding syllable is exposed, b) the function relating mean GSR to the average strength of the processes underlying shock syllables. All these advantages may be subsumed under the statement that the statistical form of the symbolic-report hypothesis possesses far greater potentiality for the analytic description of perceptual phenomena than does the subception hypothesis. Miller, G.A. WHAT IS INFORMATION MEASUREMENT? *Amer. Psychologist*, 1953, 8, 3-11. (Massachusetts Institute of Technology, Cambridge, Mass.).

The paper introduces basic concepts of information theory and points to their applications in psychology. Information theory provides a yardstick for measuring organization. Basic concepts, like "amount of information", "bit" are clarified. Transmission situations are described. The obvious psychological analogy to the transmission situation is between the S in experiment and a communication channel, between stimuli and inputs, and between responses and outputs. Another analogy arises in mental testing. It requires only a slight extension of this analogy to see the similarity between any process of measurement and the transmission situation. The sequential situation is described, the obvious analogy is verbal behavior. Taken together, the sequential and the transmission situations suggest a wide range of possible applications in psychology. A selected bibliography of 36 items is included.

Spiegelman, H., Terwilliger, C. & Fearing, F. THE RELIABILITY OF AGREEMENT IN CONTENT ANALYSIS. J. soc. Psychol., 1953, 37, 175-187. (Psychology Dept., University of California, Berkeley, Calif.).

After a discussion on the theory and methodology of reliability in content analysis, the paper reports an experiment carried out a) to investigate the effect of non-directed discussion of criteria upon agreement among judges when stimulus ambiguity and ambiguity of criteria are constant, and, b) to test the effect of such "training" when the ambiguity of the stimulus is also varied. 2 groups of 6 psychology graduate students each categorized a random sample of 49 comic strip characters on the basis of explicit criteria. The results indicated that non-directed discussion had no significant effect on reliability of agreement. The ambiguity of the material also had no effect. From a discussion of the current method for computing reliability, it was concluded that several different kinds of reliability should be applied in content analysis. (HEIAS)

Young, F.A. STUDIES OF THE PROJECTED AFTER-IMAGE: I. METHODOLOGY AND THE INFLUENCE OF VARYING STIMULATION TIMES. J. gen. Psychol., 1952, 46, 73-86. (State College of Washington, Seattle, Wash.).

The study aimed at determining whether or not variations in time of stimulation were related to size changes in the after-images, and, further, whether there would be an increasing amount of inability to maintain fixation with the longer stimulation which would result in differences in the size of the projected after-image. Stimulation times of .01, .10, 1.0, 5.0, 10.0, 15.0, 20.0, 40.0 were used with 2 or 3 practiced Ss at different times. No differences were found. Major conclusions: a) There is no significant variation in the size of the projected after-image with variations in the time of stimulation. b) Individual differences in terms of the size of the after-image are not to be explained by assuming variations in fixation during stimulation. c) The method used in the experiment is reliable. Edwards, A.S. A QUANTITATIVE STUDY OF VOLUNTARY VS. INVOLUNTARY MOVEMENT. J. gen. Psychol., 1952, 46, 93-99. (University of Georgia, Athens, Ga.).

2 kinds of involuntary movement were compared with measured results of certain voluntary activities by means of the coefficient of correlation and by measures of central tendency and of dispersion. 68 men and 51 women were measured a) for finger-tremor, b) for body sway c) by the Metfessel Pursuit apparatus and d) by the Purdue Peg Board. Conclusions: a) All relationships are small and some are negative. b) Body sway and scores on the rifle range showed the highest correlation, the second closest relationship was between the 2 kinds of involuntary movement. c) Women were less able than men to achieve high scores with a moving target, but were superior to men with the material that did not move. d) Men have more body sway and finger tremor than women. Young, F.A. STUDIES OF THE PROJECTED AFTER-IMAGE: II. THE PROJECTION GROUND AND THE PROJECTED IMAGE. J. gen. Psychol., 1952, 47, 195-205. (State College of Washington, Seattle, Wash.).

2 experiments were performed. The first experiment determined the relation between the level of illumination on the projection ground, with the changes in visual cues which vary with changes in illumination, and the size of the projected after-image. The second experiment utilized backgrounds of varying degrees of linear perspective to determine the relation between the size of the projected after-image and a structured projection ground. No variation in the size of the projected after-image was found when the illumination on the projection ground was varied through 5 log steps. A structured ground influences the size of the projected after-image. The size of the after-image varied from S to S for the same position on the background and from one background to another background for the position and the same S. No hypothesis was offered to explain these results. These experiments refute the interpretation that the same variables are responsible for size constancy results and the size of projected after-images.

Wiener, G., Salpeter, M.M., Tobach, E., Vineburg, E., et al. THE EFFECT OF THE EXPERIMENTAL SITUATION ON THE AMPLITUDE OF THE PSYCHOGALVANIC RESPONSE IN HUMANS. *J. gen. Psychol.*, 1952, 42, 213-225. (Payne Whitney Psychiatric Clinic, New York Hospital, New York, N.Y.).

In order to determine the effect of the experimental situation on the magnitude of the psychogalvanic reflex (PGR) and to determine the usefulness of innocuous stimuli as conditioned stimuli, 2 groups of 12 female college students each were tested in experimental and non-experimental situations with a yellow pilot light, a nonsense syllable, and a square of white light as stimuli. Findings: a) No significant differences between responses to the same stimulus in the experimental and non-experimental situations. b) PGR's to different stimuli were also not significantly different in the experimental room. c) Reversals in the expected adaptation curves of the responses took place in the cases of the syllable KAX and the yellow pilot light. d) Differences in intensity of the stimuli did not correlate with amplitude of PGR. The data suggest that the attitude of the S toward the experimental nature of the situation, rather than the experimental situation per se, is more instrumental in affecting the amplitude of the PGR. Torris, J.D. & Myers, C.K. EXPERIMENTS ON FLUCTUATION OF AUDITORY ACUITY. *J. gen. Psychol.*, 1954, 50, 87-109. (USM Medical Research Lab., New London, Conn.).

The auditory acuity of normal-hearing young men was tested by air and by bone conduction at each of 11 frequencies using the serial method of limits. The typical minute-to-minute fluctuation is of the order of slightly less than 21 decibel. There is no difference in threshold variability between air and bone conduction, or among frequencies. No trends are revealed for any hour of the day, or day of the week. The data at 8192 cps show more variability than at 1024 or 256 cps, probably as a result of a relative sensitivity of the initial section of the basilar membrane to any of a variety of (in this experiment) unknown physiological conditions. (HEIAS)

Edwards, A.S. THE RELATION OF INVOLUNTARY MOVEMENT TO CERTAIN PSYCHO-MOTOR ACTIVITIES. *J. gen. Psychol.*, 1954, 50, 111-127. (University of Georgia, Athens, Ga.).

Hand and arm steadiness and body sway were measured to throw some light on the relationships between types of involuntary movement. The studies included feeble-mindedness, skilled groups, seniles, schizophrenics, perception, attention with and without distraction, emotional states, smoking and inhalation, controlled breathing, practice, and the relation of certain voluntary activities to involuntary movements. Conclusions: a) Involuntary movement appears to be fundamentally related to organic conditions, but may be modified greatly by some functional changes. b) It is related to the development and integration of children, and to senility. c) Improvement of steadiness may appear with generally improved conditions (e.g. in improved schizophrenics). d) Surgeons and musicians are steadier than normals, but individuals with great unsteadiness may show excellent performance in skilled activities (e.g. shooting). e) The relatively small correlation between measurements of finger tremor and of body sway, suggest somewhat different systems of psychosomatic function. f) Improvement in techniques, insight, and intelligence, rather than amount of practice, appear responsible for improvement during practice. (HEIAS)

Miller, G.A., Bruner, J.S. & Postman, L. FAMILIARITY OF LETTER SEQUENCES AND TACHISTOSCOPIC IDENTIFICATION. *J. gen. Psychol.*, 1954, 50, 129-139. (Massachusetts Institute of Technology, Cambridge, Mass.).

An experiment was designed to test the hypothesis that, within reasonable limits, the total amount of information received by Ss familiar with the language is constant and unaffected by the redundancy of the language. Pseudo words were constructed representing different degrees of contextual constraint. The words were exposed tachistoscopically to 6 undergraduates who wrote what they saw. The total number of correct letters and the number of correct letters in the proper blank on the answer sheet were scored. Both scores were converted into percentages. Conclusions: a) The number of letters identified correctly increases when the stimulus sequence provides a context familiar to the observer. Thus it appears that context improves recognition. b) When the lower informational value of the contextually constrained sequences is considered, the corrected identification scores for familiar and unfamiliar sequences of letters become essentially equivalent. (HEIAS)

Osgood, C.E. THE NATURE AND MEASUREMENT OF MEANING. *Psychol. Bull.*, May 1952, 49(3), 197-237. (University of Illinois, Urbana, Ill.).

The first portion of this paper describes a behavioral conception of the sign-process as developed from a general mediation theory of learning. The remainder is concerned with the problem of measuring meaning. Various existing approaches to the problem--physiological, learning, perception, association, and scaling methods--have been evaluated against the usual criteria of measurement and have been found inadequate. The development of a semantic differential as a general method of measuring meaning is described. It involves a) the use of factor analysis to determine the number and nature of factors entering into semantic description and judgment, and b) the selection of a set of specific scales corresponding to these factors which can be standardized as a measure of meaning. Using this differential, the meaning of a particular concept to a particular individual can be specified quantitatively as a particular point in the multidimensional space defined by the instrument. Some of the possible uses of such a measuring instrument are briefly indicated.

Soar, R.S. STROKE WIDTH, ILLUMINATION LEVEL, AND FIGURE-GROUND CONTRAST IN NUMERAL VISIBILITY. *J. appl. Psychol.*, 1955, 39, 429-432.

8201

This study attempts to define the respective effects of stroke width, illumination level, and figure-ground contrast in numeral visibility. Forty subjects were presented with stimulus numbers under eight experimental conditions reflecting a combination of two stroke width to height ratios (1:4 and 1:16), two illumination levels (.5 and 500 foot-candles), and two modes of figure-ground contrast (black on white and white on black). Numeral were observed at three different distances and a subject's score reflected the estimated threshold distance at which he might be expected to read half of the numbers. An analysis of variance of the data was made. The results are discussed in terms of the effects of each of the variables and their interaction upon numeral visibility.

Sanders, J.W., Webb, I.B., & Baker, C.A. THE PERIPHERAL VIEWING OF DIALS. *J. appl. Psychol.*, 1955, 39, 433-436.

8202

To investigate the possible role of peripheral visual cues in the reading of instruments, four subjects were tested on an apparatus presenting simulated dials and so designed as to determine the extent of displacement of a particular dial from the subject's fovea. Dials reflecting four pointer designs were viewed monocularly for a total of 256 readings. The results are presented and discussed in terms of reading time and errors as a function of degree of foveal displacement. Implications for the design of instrument panels are noted.

DeNittis, G.L. RELATIVE EFFECTIVENESS OF TWO STANDARD COLOR-VISION TESTS. *J. appl. Psychol.*, 1955, 39(6), 437-441. (Fordham University, Washington, D.C.).

In this study a comparison was made between the commercial edition of the Illuminant-Stable (I-S) Color Vision Test, containing 12 plates, and the American Optical (AO) Color Perception Test, containing 18 plates. 10 color-blind and 40 normal male Ss were tested. Principal conclusions were: a) The I-S test was much more difficult than the AO test under all conditions of illumination; b) The types of illumination used in this experiment had no significant effect on the scores obtained; c) Within the range of the color temperatures used, the AO test is as stable as the I-S test. Tinker, M.A. PROLONGED READING TASKS IN VISUAL RESEARCH. *J. appl. Psychol.*, 1955, 39, 444-446. (University of Minnesota).

8204

Two experiments are presented to demonstrate the usefulness of prolonged reading tasks in visual research. Two approximately equivalent forms of a reading task were constructed. A total of 24 subjects were presented with this task in two experiments. In the first, roman type was compared with italic type, and in the second, lower-case type was compared with all capitals. The results are presented and discussed in terms of the relative effect of each type of typography upon speed of reading.

Lutz, Mary C. & Chapanis, A. EXPECTED LOCATIONS OF DIGITS AND LETTERS ON TEN-BUTTON KEYSSETS. *J. appl. Psychol.*, Oct. 1955, 39(5), 314-317. (Bell Telephone Laboratories, Murray Hill, N.J. & Johns Hopkins University, Baltimore, Md.).

300 Ss, stratified according to age, sex, and previous experience on keysets, were asked to write on diagrams of keysets either numbers or letters in the arrangements that they felt were most natural. Our results show: a) People expect to find numbers on keysets arranged in left-to-right order in horizontal rows starting with the top row, for all of the 6 configurations of keys. b) People expect to find letters on the keyset arranged in left-to-right order with 2 or 3 letters in order on each key, in horizontal rows, starting with the top row, for all of the 6 configurations of keys tested. c) With numbers already on the keyset: 1. People expect to find the letters arranged in horizontal rows, beginning with the top row, for those patterns in which the numbers are arranged that way. 2. When the numbers are arranged in patterns not having numbers in order in horizontal rows (beginning with the top row), people are equally divided between lettering arrangements following the numbering pattern and lettering as in 1. above even though this conflicts with the numbering arrangement.

Ross, S., Katchmar, L.T., & Bell, H. MULTIPLE-DIAL CHECK READING: POINTER SYMMETRY COMPARED WITH UNIFORM ALIGNMENT. *J. appl. Psychol.*, 1955, 39, 215-218. (University of Maryland).

8209

Two experiments are reported in this study of the differential effect of uniform and symmetrical pointer alignment upon multiple-dial check reading time and accuracy. The same 24 subjects were used in both experiments. In the initial experiments the subjects were tested on uniform (at 12 o'clock) and symmetrical aligned dial patterns with regard to ability to discern a deviating dial. The second experiment replicated the first and in addition presented the uniform alignment at 6 o'clock. The results are treated in terms of transfer effects, reading time, and reading accuracy as functions of the type of pointer alignment.

Green, B.F., & Anderson, Lois K. THE TACTUAL IDENTIFICATION OF SHAPES FOR CODING SWITCH HANDLES. *J. appl. Psychol.*, Aug. 1955, 39, 219-226. (MIT).

8210

Three experiments are presented on tactual identification of 16 differently shaped lever-switch handles. The first compares two methods of measuring confusability: a "learn" method--10 subjects learned to associate a number with each of the 16 handles; and a "find" method--10 subjects (blindfolded) were presented with "target" handle and were required to match it by tactually identifying an identical handle in the array of handles. The second compares 16 identically shaped but one-third smaller handles (14 subjects using learning method). In the final experiment, the learn method was used to evaluate two subsets of handles. The results are discussed in terms of the most effective measuring method, the ease and degree of transfer from one size handle to another, and the ease of learning an array when confusing handles are removed. Erikson, C.W. PARTITIONING AND SATURATION OF VISUAL DISPLAYS AND EFFICIENCY OF VISUAL SEARCH. *J. appl. Psychol.*, April 1955, 25(2), 73-77. (Johns Hopkins University, Baltimore, Md.).

The present study was concerned with the effect of several characteristics of visual displays upon speed of visual search. The time required to locate a constant number of signals in a square display was determined when: a) the number of irrelevant signals was varied (from 10 to 70) and b) the number of partitions of the display was varied by the use of grid lines. Grid lines were used to partition the display into a 5 X 5, a 13 X 13, and a 16 X 16 matrix. The results show that search time increases both when the number of irrelevant signals is increased and when the number of partitions is increased. An explanation was advanced for these effects in terms of the number of foveal fixations required for signal identification and the use that observers make of grid lines in their plan of search.

Tiffin, J., & Robideau, G.F. REDUCED TRIALS AND RELIABILITY OF VISUAL-ACUITY THRESHOLDS OBTAINED BY THE METHOD OF CONSTANT STIMULI. *J. appl. Psychol.*, June 1955, 22(2), 78-81. (Purdue University, Lafayette, Ind.).

A psychophysical investigation was made to find what effect a reduction in trials per stimulus has upon reliability of visual-acuity thresholds computed by the method of constant stimuli and Müller-Urbach curve-fitting method. A goal was to find a practical minimum in terms of number of trials. Visual-acuity thresholds were determined for 15 college students, who were each subjected to 2 successive measurement series of stimuli. Thresholds were computed, using 5 stimulus values and 5, 10, 20, 30, 40 and 50 presentations per stimulus. The target used was the Landolt ring. Retest reliabilities of .92 and higher were obtained for as few as 10 trials per stimulus (50 per threshold). The following conclusions are warranted: a) insofar as this kind of psychophysical measurement may be typical of previous work, classical psychophysical investigators probably utilized more judgments than are necessary for computation of reliable thresholds; b) for purposes of estimating absolute thresholds, the Müller-Urbach constant method with 5 stimulus sizes appears to yield satisfactorily reliable thresholds for purposes of practical applications, when as few as 10 trials per stimulus and 4-choice response categories are used. This conclusion applies only under the conditions of the present experiment. (NEIAS)

Simon, J.R., & Smader, R.C. DIMENSIONAL ANALYSIS OF MOTION: VIII. THE ROLE OF VISUAL DISCRIMINATION IN MOTION CYCLES. *J. appl. Psychol.*, Feb. 1955, 39, 5-10. (University of Wisconsin).

8223

This is a study of the effect of a specific visual discrimination upon the interrelation of component movements in a complex motion pattern. 24 subjects performed an assembly task consisting of four component movements - (assembly manipulation, grasp manipulation, loaded travel, and unloaded travel). A visual discrimination condition (a consistent color cue) a non-discrimination condition (inconsistent color cue) and three conditions of travel distance were manipulated. Motion analysis was accomplished by electronic methods. The results are presented and discussed in terms of the interaction and relative effect of each condition upon duration of motion with particular emphasis upon the role of visual discrimination.

Kempel, V.E., Jr. & Fleishman, E.A. A FACTOR ANALYSIS OF PHYSICAL PROFICIENCY AND MANIPULATIVE SKILL. *J. appl. Psychol.*, Feb. 1955, 39(1), 12-16. (USAF Personnel & Training Research Center, Lackland AFB, Tex.).

15 factors were identified to account for performance on the 46 experimental tests (17 manipulative apparatus tests, 6 printed tests, 23 gross physical performance tests). While the precise nature of several of the factors is yet uncertain, some general conclusions appear possible. The results indicate that the abilities contributing to performance on gross physical tasks are quite independent of those contributing to fine manipulative skill. No factors were found that overlapped these areas. Pending the identification of additional factors or clarification of the present ones, the factors identified suggest a possible justification of ability areas primarily involved on a wide range of motor tasks, especially those of a gross physical nature. They at least point up a way of organizing more meaningfully such tests generally used in evaluating physical proficiency. 5 factors identified in the physical performance tests appear to fit under the following categories: strength, flexibility, balance, gross body coordination, energy mobilization. 4 factors identified in the manipulative tests are: manual dexterity, finger dexterity, arm-hand steadiness, aiming. A non-verbal reasoning factor was identified in certain of the printed tests. (NEIAS)

Jones, L.V. & Thurstone, L.L. THE PSYCHOPHYSICS OF SEMANTICS: AN EXPERIMENTAL INVESTIGATION. *J. appl. Psychol.*, Feb. 1955, 39(1), 31-36. (University of Chicago, Chicago, Ill. & University of North Carolina, Chapel Hill, N.C.).

51 descriptive adjectives were presented as items on a successive-interval schedule to approximately 500 Army enlisted personnel, who were asked to indicate the meaning of each word or phrase. For each stimulus a scale value and a standard deviation of meaning were determined. From these 2 parameters, an attempt was made to reproduce the cumulative proportions of response for each of the nine categories on the questionnaire. The suitability of the successive-interval method of scaling is demonstrated by the small average error of reproduction of proportions, about .015 in this case. A further check upon the method was derived by analysis of distributions of responses over the scale continuum. For all but 6 of the 51 stimuli, these distributions did not depart appreciably from normality. Results are compared with those reported in a similar study by Mosier. From results of the present study, it is possible to select suitable descriptive adjectives for use as labels of successive intervals on subsequent preference schedules.

Witcott, R.C. VARIABLES AFFECTING THE ANGULAR DISPLACEMENT THRESHOLD OF SIMULATED AUDITORY MOVEMENT. *J. exp. Psychol.*, Jan. 1955, 49(1), 68-72. (Institute for Juvenile Research, Chicago, Ill.).

The angular displacement threshold of auditory movement simulated by a linear step-wise change in interaural time delay was determined under various conditions. Variables investigated were: a) signal noise bands of 106-1200 cps and 2400-3400 cps; b) movement originating at the median and lateral planes; and c) 6 different velocities of movement ranging from a perceptually slow to fast movement. Lower thresholds were obtained with the low frequency noise band, and for both noise bands lower thresholds were obtained for simulated movement from the median plane. The threshold is directly related to the velocity of movement; the threshold increases as the velocity of simulated movement increases.

Kunnepas, T.M. AN ANALYSIS OF THE "VERTICAL-HORIZONTAL ILLUSION". *J. exp. Psychol.*, Feb. 1955, 49(2), 134-140. (University of Stockholm, Stockholm, Sweden).

This study investigates the so-called vertical-horizontal illusion. Figures in addition to the L form and inverted T were analyzed systematically. 4 conditions were arranged according to the 4 directions of the dividing line. In each condition 9 different positions of the dividing line in relation to the divided line were used. The principal finding were: a) In the vertical-horizontal figures, 2 different illusions appear--the classical overestimation of the vertical line as compared with a horizontal line of equal length, and the overestimation of the dividing line. b) The main differences of these illusions are: the overestimation of the vertical line is always connected with the vertical whereas the illusion due to the division is independent of this direction; unlike the classical illusion, the latter is variable, it has a maximum at the midpoint position and 2 minima at the 2 end positions; the amount of the overestimation of the dividing line can be considerably stronger than the overestimation of the vertical line, depending on the distance from the midpoint section. c) Where the dividing line was vertical and the divided line horizontal, the 2 illusions operated in the same direction, and the amount of the total illusion was equal to their sum. Where the dividing line was horizontal and the divided line was vertical, the 2 illusions acted in opposite directions and the total effect was equal to the difference between their individual effects. Conrad, R. ADAPTATION TO TIME IN A SENSORIMOTOR SKILL. *J. exp. Psychol.*, Feb. 1955, 49(2), 115-121. (Applied Psychology Research Unit, Cambridge, England).

An attempt was made to explain the temporal accuracy with which a series of responses could be matched to a series of signals, by reference to the continuously changing temporal relationships between these events. Although approximately half of the responses were made too soon and half too late, this distribution was not fortuitous. The temporal position of a response in relation to the signal which initiated it was influenced both by the position of the previous response, and by the position of the signal for the next response. Not only did these events determine whether a response would be made early or late, but to a large extent they influenced the size of this error. Thus, while the character of the temporal structure of events around a signal determined the relative accuracy of the response, the mean signal speed in relation to the mean response rate determined the frequency with which particular temporal structures occurred. The underlying factors that actually determined the character of the response were shown to be masked when the effects on response of the signal speed variable were presented as mean accuracy.

McCollough, C. THE VARIATION IN WIDTH AND POSITION OF MACH BANDS AS A FUNCTION OF LUMINANCE. *J. exp. Psychol.*, Feb. 1955, 49(2), 141-152. (Olivet College, Olivet, Mich.)

The present experiment was designed to investigate the Mach band phenomenon quantitatively. A square stimulus field was used. Measurements of width of the apparent bright band were made at 5 different values for the log of maximum luminance of the field, over a range of 3.5 log units. Measurements were made for each of 2 gradients describing different rates of decrease of the log of luminance within the upper half of the field. When rate of decrease of log luminance is held constant, and the log of maximum luminance is increased, width of the band decreases according to a negatively accelerated function, and vice versa. The conditions giving rise to report of a contour dividing 2 fields of differing luminance may be described as a limiting case of that class of luminance gradients which, when the change of luminance is less rapid, gives rise to the report of Mach bands. 2 mathematical accounts of the band phenomenon, one by Mach and the other by Fry, fail to describe changes in width of band under the conditions giving rise to such changes in the present experiment. Archer, E.J., Bourne, L.E. Jr., & Brown, P.G. CONCEPT IDENTIFICATION AS A FUNCTION OF IRRELEVANT INFORMATION AND INSTRUCTIONS. *J. exp. Psychol.*, 1955, 49, 153-164. Contract AF 33(038)-23294, Proj. 7708, Task 77143, Rep. AFTRC-TN-55-50, Nov. 1955. AFTRC, Air Research and Development Command, Lackland AFB, Texas.

8245
Two experiments on the relation between concept formation and amount of irrelevant stimulus information were carried out. 1) Twenty-four Ss on each of three days worked a different problem in which a visual stimulus was defined by two out of three dimensions, with one to three bits of irrelevant information present. 2) Thirty Ss in two groups were presented with problems, on each of six days, in which two bits of information were relevant and one to five bits, irrelevant. One-half of the group was given special instructions on how to test a dimension for relevance. The results are presented as mean times to completion for the successive problems. T. G. R 17

Kendler, H.H. & D'Amato, M.F. A COMPARISON OF REVERSAL SHIFTS AND NONREVERSAL SHIFTS IN HUMAN CONCEPT FORMATION BEHAVIOR. *J. exp. Psychol.*, March 1955, 49, 165-174. (New York University, New York, N.Y.).

8246
To test the hypothesis that the presence of appropriate symbolic cues (from implicit responses to stimulus cards) facilitate concept formation and that thus reversal shift takes place more rapidly than nonreversal shift, three experiments using 112, 62, and 58 Ss were carried out. The conditions included card-sorting with or without stimulus cards, partial reinforcement effects being equated or not equated for reversal shift and nonreversal shift subgroups. Numbers of trials required by the subgroups to reach a criterion of learning are compared. T. R 5

Green, E.J. CONCEPT FORMATION: A PROBLEM IN HUMAN OPERANT CONDITIONING. *J. exp. Psychol.*, March 1955, 49, 175-180. (Harvard University, Cambridge, Mass.).

8247
To determine how concept formation is controlled by fixed-ratio schedules of reinforcement and by the length of time that discriminative stimuli are exposed, 45 college students were required to perform a key tapping response to visual stimuli. Correct responses were reinforced under a 1s1, 15s1, or 30s1 fixed ratio; stimuli were exposed for 3, 30, or 60 sec. Rates of responding to positive and negative stimuli during conditioning and extinction under the various experimental conditions are compared, as are total number of correct verbalizations. T. G. R 7

Goldstone, S. FLICKER-FUSION MEASUREMENTS AND ANXIETY LEVEL. *J. exp. Psychol.*, March 1955, 49(3), 200-202. (Duke University, Durham, N.C.).

This study involved 33 high-anxiety patients, 18 low-anxiety patients, 2 high-anxiety normals, and 21 low-anxiety normals. A flicker fusion test was administered to all Ss and the following reliable differences were found: a) Those groups designated high anxiety had a lower FET than those groups designated low anxiety, suggesting reduced sensitivity to flicker associated with high anxiety; b) Those groups designated high anxiety had a greater intrasubject variability of judgments than those groups designated low anxiety; c) Those groups designated high anxiety had a greater decline in sensitivity to flicker (FFT) associated with continued exposure to the flicker test than those groups designated low anxiety. Grant, D.A., & Kaestner, N.P. CONSTANT VELOCITY TRACKING AS A FUNCTION OF S'S HANDEDNESS AND THE RATE AND DIRECTION OF THE TARGET COURSE. *J. exp. Psychol.*, March 1955, 49, 203-208. (University of Wisconsin).

8250
This is a study of constant velocity tracking as a function of handedness and rate and direction of target course. Twenty-four subjects (16 right-handed and 8 left-handed) were required to track a target for five minutes with a unidimensional tracking device under each of eight experimental conditions which varied target rate (5.33, 2.67, 1.78, and 1.33 in./sec.) and direction (right-to-left vs. left-to-right). Performance scores were treated by analysis of variance. The results are presented and discussed in terms of the relative effect of each of the variables and various combinations of these variables upon tracking performance. T. G. R 7

Leibowitz, H.W. THE RELATION BETWEEN THE RATE THRESHOLD FOR THE PERCEPTION OF MOVEMENT AND LUMINANCE FOR VARIOUS DURATIONS OF EXPOSURE. *J. exp. Psychol.*, March 1955, 49, 209-214. (University of Wisconsin).

8252

This is a study of the threshold velocity for the perception of motion at a constant duration of exposure (referred to as the locomotor threshold velocity) with regard to determining the various luminance values and the nature of the function at five durations of exposure. Threshold velocities were obtained for three subjects by determining pairs of thresholds consisting of mean of movement thresholds for motion to right and left. These threshold velocities were determined at seven luminance levels (.016, .07, .16, .3, .5, .90, and 500 m). Five exposure times (1/8, 1/4, 1, 2, and 16 sec.) were employed. The results are presented and discussed in terms of threshold velocity as a function of luminance and duration of exposure.

Kruger, L. & Bonane, J.R. A RETINAL EXCITATION GRADIENT IN A UNIFORM AREA OF STIMULATION. *J. exp. Psychol.*, March 1955, 49(3), 220-224. (Yale University, New Haven, Conn.).

A method for testing excitation within a uniformly illuminated area is described, and intensity thresholds were obtained for a point source at 4 different horizontal positions within a large area in the dark-adapted human eye for the peripheral retina. A consistent relationship is shown between the intensity threshold and the distance from the center of the large area, for the point source, the threshold being lowest in the center of excitation. It is believed that the present experiment provides direct confirmation of Graham, Brown, and Mote's (4) hypothesis explaining the area-intensity relation in terms of neural convergence.

Nystrom, C.O., Morin, R.E. & Grant, D.A. EFFECTS OF AMOUNT, RATE, AND STAGE OF AUTOMATICALLY-PACED TRAINING ON SELF-PACED PERFORMANCE. *J. exp. Psychol.*, April 1955, 49, 225-230. (University of Wisconsin, Madison, Wisc.).

8257

In an investigation of the effect of automatically paced (AP) training on subsequent self-paced (SP) training, 11 groups of male students (120 in all) underwent training on the Multiple Serial Discriminator for a total of 17 blocks of trials with 25 stimulus patterns per block. Three aspects of AP training were varied: amount (0, 1, 4, or 10 blocks), rate (1.28 or 1.80 sec. per pattern), and stage of practice (early or late) at which it was given. Performances (in mean sec. to match a pattern) of the experimental groups are compared with each other and with the performance of a control group that underwent SP training throughout.

Anderson, W.H., Kresco, P.H., & Grant, D.A. EFFECT OF RATE OF AUTOMATICALLY-PACED TRAINING IN A MULTIDIMENSIONAL PSYCHOMOTOR TASK. *J. exp. Psychol.*, 1955, 49, 231-254. Contract AF 33(038)-23294. AFFTC, Lowry AFB, Denver, Colo. (University of Wisconsin).

8259

To determine the effect of rate of automatically-paced (AP) training on subsequent self-paced (SP) training in a multidimensional psychomotor task (with a general radar simulator), nine experimental groups received AP training on eight initial trials and subsequently received SP training on five test trials. For six groups, all initial training was at one of six constant rates of stimulus presentation (1.7 to 3.2 sec.). For three groups stimuli on successive trials were presented at faster rates. Each trial consisted of 40 stimulus patterns. Results are presented as time scores and errors in range, azimuth, and elevation obtained on the test trials by the experimental groups and by a control group that received SP training throughout.

8257

Battig, W.F., Voss, J.F. & Brogden, W.J. EFFECT OF FREQUENCY OF TARGET INTERMITTENCE UPON TRACKING. *J. exp. Psychol.*, April 1955, 49, 244-248. (University of Wisconsin, Madison, Wisc.).

Measures of proficiency of tracking on the Pedestal Sight Manipulation Test were obtained at frequencies of intermittent target presentation of 2, 4, 6, 8, 10, 12 and 14 cps and a steady state condition above fusion (16 cps). The brightness of the target was held constant for all conditions at .548 ml and the light-dark ratio for each of the frequencies was 50/50. 2 experiments were performed. In one, 10 Ss each received 8 trials of practice for one of the 8 conditions of target presentation. In the other, 2 Ss were selected at random from each of the 8 groups of the first experiment and these 16 Ss received 2 trials of practice on each of the 8 target conditions as determined by an 8x8 latin square. Although measures of tracking proficiency were obtained for azimuth (A), elevation (E), range (R), azimuth and elevation (AE), and azimuth, elevation, and range (AER), because of the similarity of results over these separate measures, only the AE and AER data were analyzed completely and presented. Analysis of variance demonstrated a significant effect of frequency of intermittent presentation of the target of tracking.

Noble, M., Fitts, P.H. & Warren, C.E. THE FREQUENCY RESPONSE OF SKILLED SUBJECTS IN A PURSUIT TRACKING TASK. *J. exp. Psychol.*, April 1955, 49(4), 249-255. (Ohio State University, Columbus, Ohio).

The efficiency of highly skilled Ss in tracking a target which moves in a simple harmonic motion pattern, as measured by root-mean-squared error and by time-on-target within 5% of the target amplitude, was found to decrease steadily as input frequency was increased. Examination of objective scores and analysis of graphic records of the problem input, S's output and tracking error indicate that 5 types of changes in motor behavior contribute to the decrease in performance proficiency: a) variability in phase relations between stimulus and response, b) variability of output amplitude, c) variability in the point of termination of successive flexor or of extensor movements, d) a constant error in matching response amplitude to the average input amplitude, and e) loss of synchronization between output and input frequencies, i.e., periods during which the output frequency was independent of the input frequency.

8260

Conrad, R. SOME EFFECTS ON PERFORMANCE OF CHANGES IN PERCEPTUAL LOAD. *J. exp. Psychol.*, May 1955, 49(5), 313-322. (Applied Psychology Research Unit, Cambridge, England).

An experiment was carried out using 12 practiced Ss in which the perceptual load was systematically varied. The aim of the experiment was to determine whether changes in serial performance as well as changes in score could be associated with the experimental variable. Increasing the number of pointers from 4 to 12 had the effect of increasing both the number and duration of errors. Results were: a) Errors occurred when signals requiring action were bunched. b) Errors occurred when Ss failed to determine the correct signal order. c) With load increases, errors were more likely to arise in event sequences of identical temporal structure, even when an essential element of the sequence was an event which occurred after the error. d) Recovery from error took longer with greater loads. e) Even under the condition of practice, stress, attention was apparently distributed strictly according to display demands rather than in accord with either a spatial or a signal-frequency pattern. Results are discussed in terms of their value as criteria of changes in skilled performance under stress. A constant load stress is postulated. Objections made from a consideration of eye movements are reviewed. (HEIAS)

Eriksen, C.W. & Hake, H.W. ABSOLUTE JUDGMENTS AS A FUNCTION OF STIMULUS RANGE AND NUMBER OF STIMULUS AND RESPONSE CATEGORIES. *J. exp. Psychol.*, May 1955, 49, 323-332. (Johns Hopkins University, Baltimore, Md.).

8261

In this study of the method of absolute judgments, an attempt is made to determine the effects of variation in stimulus range and response factors upon the accuracy of absolute judgments of visual size. Squares varying in size from 2 to 82 mm sq. and spread over two size ranges, 2-42 and 2-82 mm sq. were presented to 90 observers. The number of stimulus and response categories were equal (5, 11, or 21). Increment in size varied according to the number of stimulus categories. The results are presented and discussed in terms of the relative effect of each of the variables and their interaction upon absolute judgments.

Beck, J., & Gibson, J.J. THE RELATION OF APPARENT SHAPE TO APPARENT SLANT IN THE PERCEPTION OF OBJECTS. *J. exp. Psychol.*, Aug. 1955, 50, 125-33. (Cornell University).

8286

Three experiments are reported in this study of the relation of apparent shape to apparent slant in the perception of objects. The experiments were designed to evaluate each of the following aspects of the shape-slant relationship: (1) the effect on apparent shape of apparent slant when slant is not determined by stimulation (judgments of luminous shape in the dark); (2) the effect of illusory slant on apparent shape (judgments of shape against visible background); and (3) effect on apparent shape of apparent slant with stimulation provided for slant. The results of each of the experiments and all of the experiments as a whole are discussed in terms of redefining the relation between variables of apparent shape and apparent slant.

Diamond, A.L., & Gilinsky, A.S. DARK-ADAPTATION LUMINANCE THRESHOLDS FOR THE RESOLUTION OF DETAIL FOLLOWING DIFFERENT DURATIONS OF LIGHT ADAPTATION. *J. exp. Psychol.*, Aug. 1955, 50, 134-43. (Columbia University).

8287

This study is concerned with the course of dark adaptation (luminance thresholds) as a function of time in dark following varied durations of preexposure, level of visual acuity, and the relative effect of duration vs. luminance of preexposure. Utilizing a modified Hecht-Schlaer adaptationster, luminance thresholds were obtained for two subjects under varied duration of light adaptation (1 sec., 30 sec., 5 min. and 10 min.) and varied acuity values of grating used in the test field (.042, .083, and .62). The results are presented and discussed in terms of the course of adaptation at various acuity levels and following varied duration of light adaptation.

Diamond, A.L. FOVEAL SIMULTANEOUS CONTRAST AS A FUNCTION OF INDUCING-FIELD AREA. *J. exp. Psychol.*, Aug. 1955, 50, 144-52. (Northwestern University).

8288

Two experiments are reported in this investigation of foveal simultaneous contrast as a function of inducing field area. In the initial experiment, inducing field area was varied in terms of vertical dimension (0 to 33') and luminance (0 to 2.71 log m). Test field luminance was held constant at .60 log m. The distance between the near borders of the field was held constant while the second experiment differed in holding constant the distance between their centers. A binocular matching technique was employed in both experiments (total of three subjects). The results are presented and discussed in terms of test-field apparent brightness as a function of degree of increase in inducing-field area.

Eriksen, C.W., & Hake, H.W. MULTIDIMENSIONAL STIMULUS DIFFERENCES AND ACCURACY OF DISCRIMINATION. *J. exp. Psychol.*, Sept. 1955, 50, 153-160. (Johns Hopkins University).

8289

This is an investigation of accuracy of discrimination as a function of the number of dimensions along which stimuli differ. Six subjects were presented with seven series of stimuli differing in terms of number and kind of dimensional differences (size, hue, brightness, size and hue, etc.). The method of absolute judgment was utilized to determine discrimination accuracy. An analysis of the data compares the relative ease of discriminability as a function of dimensional differences. Also discussed is the predictability of multi-dimensional discrimination accuracy on the basis of knowledge of accuracy on the compounded dimensions.

Hake, H.W. & Eriksen, C.W. EFFECT OF NUMBER OF PERMISSIBLE RESPONSE CATEGORIES ON LEARNING OF A CONSTANT NUMBER OF VISUAL STIMULI. *J. exp. Psychol.*, Sept. 1955, 50(3), 161-167. (Johns Hopkins University, Baltimore Md.).

8290

This study is concerned with transfer in the learning of visual stimuli as a function of the degree to which the learner is able to specify a verbal label for the visual stimulus. Ninety-Ss received a series of visual patterns to identify by means of a set of labels. The number and kind of labels available to the S was varied among nine subgroups. Each S then received a transfer task in which the same patterns had to be identified with a new set of labels. Results are discussed in terms of the effect of number of labels upon the initial learning and transfer tasks.

Kunnappas, T.M. INFLUENCE OF FRAME SIZE ON APPARENT LENGTH OF A LINE. *J. exp. Psychol.*, Sept. 1955, 50, 168-170. (University of Stockholm).

8291

To investigate the effect of frame size upon apparent length of a line, ten subjects were presented with a series of white cardboard squares differing in size (length of sides: 7, 9, 12, 16 and 21 cm.) and placed two at a time on a sky-blue background. The 7 cm. square served as the constant square on which was drawn a line 50 cm. long whereas on the squares it was varied (interval of variation: 1 mm.). The subjects were required to compare the lengths of the lines. An analysis of these comparisons was conducted to evaluate the influence of the frame upon apparent length of the line.

Diamond, A.L., Scheible, H., Schwartz, E., & Young, R. A COMPARISON OF PSYCHOPHYSICAL METHODS IN THE INVESTIGATION OF FOVEAL SIMULTANEOUS BRIGHTNESS CONTRAST. *J. exp. Psychol.*, Sept. 1955, 50, 171-74. (Northwestern University).

8292

This study presents a comparison of three different psychophysical methods utilized in the investigation of foveal simultaneous brightness contrast with the aim of determining: (1) whether the characteristic effects are dependent upon the method of investigation; and (2) the most useful and reliable method. A total of six subjects were used in three experiments which compared the following methods: limits vs. constant stimuli, adjustment vs. constant stimuli, limits vs. adjustments. The general methodology entailed experimental matches with a 33' test field (at 0.6 log m), a match field, and an inducing field varied in luminance (0 to 2.71 log m). The results are treated in terms of the shape of the contrast curves as indicative of differences among methods.

Wyckoff, L.B., & Sidowski, J.B. PROBABILITY DISCRIMINATION IN A MOTOR TASK. *J. exp. Psychol.*, Oct. 1955, 50(4), 225-231. (University of Wisconsin, Madison, Wisc.).

8296

In an investigation of probability discrimination in the performance of a motor task, 60 Ss were given a tracking task which incorporated anticipation of the target as an element of optimal performance. The direction of the target across the screen occurred at a fixed percentage for each of five subgroups (25, 40, 50, 60, and 75 percent from right to left). The amount of time on target required for a hit was .3 sec. for half the Ss and .5 sec. for the other half. The results are presented and discussed in terms of the percent of correct anticipations demonstrated by the various subgroups.

Weiss, B., Coleman, F.D., & Green, R.P. A STOCHASTIC MODEL FOR TIME-ORDERED DEPENDENCIES IN CONTINUOUS SCALE REPETITIVE JUDGMENTS. *J. exp. Psychol.*, Oct. 1955, 50, 237-244. (University of Rochester).

8297

In order to determine a stochastic model for the time ordered dependencies in a bisection task, 20 subjects while blindfolded were required to make 120 bisections of an angle of 40° (after sampling the angle by turning a knob). Monetary bonuses were offered for accuracy but there was no knowledge of results during the experiment. The data were treated by spectral analysis and autocorrelations between two series of trials. On the basis of these results a stochastic model is presented and discussed in terms of accuracy of response prediction. The role of past experience in such a task is also discussed.

Garvey, W.D., & Mitnick, L.L. EFFECT OF ADDITIONAL SPATIAL REFERENCES ON DISPLAY-CONTROL EFFICIENCY. *J. exp. Psychol.*, Oct. 1955, 50, 276-82. (NRL, Washington, D.C.).

8301

The purpose of this study was to determine the effect of fixed reference lines upon the rate of response in a display-control system consisting of a matrix of display lights and an isometric matrix of response switches. Preliminary practice in operating the response switches corresponding to display signals occupying the analogous positions was given to eight naval enlisted men. The experimental tasks consisted of a 10 x 10 matrix and a 2 x 10 matrix. Half of the subjects worked on unmarked matrices and half on matrices subdivided by reference lines. The learning curves of the control and experimental groups are compared with respect to the response rate over a series of 36 trials. In a further experiment five subjects were tested on an 8 x 8 matrix with still more reference lines.
G. M. 3

G. M. 3

To investigate various aspects of methodology and characteristics of ratio judgments in the constant sum method of scaling, 2 experiments were carried out with 9 weights ranging between 108.5 and 919.8 gm. Exp. I involved 20 Ss who divided 100 points between pairs of weights to express ratio judgments, while Exp. II had 10 Ss express their ratio judgments of the same pairs directly, i.e., say how many times heavier the one weight felt in comparison to the other. The data were used to derive psychological scales for the 2 conditions. Results were: 1. Exp. I yielded a scale which fairly closely approximated the physical scale, but there was a tendency to overestimate heavier weights and underestimate lighter ones. 2. Successive multiplication in the procedure used in computing scale values from judgments data introduced an artifact which influenced final scale values. 3. Averaged judged ratios between adjacent stimuli in the series reflected the patterns of over- and under-estimation seen in the relationships between psychological and physical scales for both methods of reporting judgments. 4. Individual pair comparisons revealed that in both experiments judgments were biased by the similarity between stimuli within a pair and by whether the lighter or the heavier stimulus was lifted first. Gogel, M.C., & Harker, G.S. THE EFFECTIVENESS OF SIZE CUES TO RELATIVE DISTANCE AS A FUNCTION OF LATERAL VISUAL SEPARATION. *J. exp. Psychol.*, Nov. 1955, 50(5), 309-315. (USA Medical Research Lab., Fort Knox, Ky.).

2 experiments were conducted to investigate the change in the effectiveness of a size cue to relative depth as a function of the lateral separation of 2 differently sized objects. In one experiment, the 2 objects (playing cards) were viewed binocularly and in the other experiment the left card was viewed binocularly and the right card monocularly. 2 different amounts of lateral separation of the cards were used in each experiment. The change in the effectiveness of the size cue was determined by measuring the change in apparent depth between the 2 cards. The apparent depth between the 2 cards was measured by having the subject adjust a binocular disc to apparent distance equality with each of the cards. Controls were used to determine the effect of the increased lateral separation upon the apparent relative distance of the cards when both cards were the same size. It was found that the average apparent depth between the 2 differently sized cards increased as the lateral visual separation of the cards was increased. An equivalent change did not occur when one card was the same size. This happened both when the 2 cards were binocular and when one card was binocular and when one card was monocular. Under the condition of these experiments, the effectiveness of size cues to relative depth increased as the lateral separation of the differently sized cards was increased.

Krulac, G.K., & Weisz, A. STUDIES IN THE VISUAL DISCRIMINATION OF MULTIPLE-UNIT DISPLAYS. *J. exp. Psychol.* Nov. 1955, 50, 316-324. (Tufts University).

8304
This study investigated the relation between the discrimination of numerals and the amount of information transmitted by them. In experiment I the amount of information was held constant while its distribution varied amongst three positions in the display. In experiment II the amount of information in any one position was limited to 0 or 1 bit, while the total information was varied. In experiment III the restriction to ten categories, imposed by the use of arabic numerals, was removed by using an augmented alphabet of 32 letters. Experiment IV attempted to measure the effects of the amount of information transmitted while the inherent difficulty of discriminating the letter form was controlled. The first two experiments were performed with nine college students and the last two with 16 enlisted men. T.R. 3.

Leibowitz, H.W., Myers, H.A., & Grant, D.A. FREQUENCY OF SEEING AND RADIAL LOCALIZATION OF SINGLE AND MULTIPLE VISUAL STIMULI. *J. exp. Psychol.*, Dec. 1955, 50, 360-373. (University of Wisconsin).

8307
The frequency of seeing and the accuracy of localizing small circular patches of orange light 4.5° from the fixation point of the visual field are measured as a function of the number of lights presented simultaneously and their luminance and duration. In one experiment 30 subjects viewed stimuli with luminance of .02 to 3.12 millilamberts and durations of .02 to .20 seconds. The number of lights was fixed at one value between one and six for each of six subgroups of subjects. The position of the lights was varied at random. In a second experiment on six subjects the number as well as the position of the lights was randomized. The implications of the results for the interdependence of perceptual events are discussed. T. G. R. 6

Purdy, J., & Gibson, Eleanor J. DISTANCE JUDGMENT BY THE METHOD OF FRACTIONATION. *J. exp. Psychol.*, Dec. 1955, 50, 374-380. (Cornell University, Ithaca, N.Y.).

8308
The accuracy with which an unaided observer can fractionate a stretch of ground by viewing it from one position was determined by the methods of bisection and trisection. The observer indicated his judgment by instructing a bicycle rider, who served as the stimulus, to stop at the one-half or one-third point. The distances to be fractionated were selected so that the true division points were at intervals of 25 yards. The results were compared to those expected on the basis of the size of the retinal image. The effects of the direction of motion of the rider on the constant error were shown as well as the effects of knowledge of results. T. G. R. 5

Bakan, P. DISCRIMINATION-DECREMENT AS A FUNCTION OF TIME IN A PROLONGED VIGIL. *J. exp. Psychol.*, Dec. 1955, 50, 387-390. (New York University).

8310
This study is an investigation of the differential threshold for brightness as a measure of vigilance. A test spot 15 minutes in diameter was presented at a distance of nine feet to 20 subjects, 11 male and 9 female. The test spot had a steady luminance of 2.1 ft. lamberts and flashed once every second. The brightness of the flash was varied from 3.1 to 4.0 ft. lamberts following the method of limits during trials which were spaced irregularly over a period of 1 1/2 hrs. In between trials the brightness of the flash was always 3.1 ft. lamberts. The mean difference limit and the number of false responses are reported as a function of the elapsed time on watch. T. G. R. 5

Kennedy, J.L. SOME PRACTICAL PROBLEMS OF THE ALERTNESS INDICATOR. P 277, Feb. 1952, 3pp. The Rand Corporation, Santa Monica, Calif.

An alertness indicator could be based on brain waves; an alarm or alerting signal would come on when the frequency of the alpha rhythm of the brain waves changed. Experiments, however, showed great variability among individuals. Furthermore, some normal people did not show an alpha rhythm. Recording of electrical activity from the forehead appeared to be a reliable indicator of alertness, when muscle spike activity was translated into a moving average DC level. The device also contained a sensitive relay circuit to sound an alarm or activate a switch when the DC activity dropped below a certain level. Practical problems in using the alertness indicator in real life are discussed. (MEIAS)

Ernst, W.H., Summney, R. & Kennedy, J.L. EXPERIMENTS ON THE CORTICAL CORRELATE OF PATTERN VISION. P 447, Nov. 1952, 4pp. The Rand Corporation, Santa Monica, Calif.

The Kikler-Held experiment on DC potential shifts related to visual stimulation has been repeated, using 2 channels of DC recording. In a preliminary experiment, 11 Ss were given 538 exposures to a moving bar of light. 23% of the trials were successful, i.e., a DC response from an occipital electrode referred to a vertex electrode was observed. When records of 8 of the 11 Ss were scored during non-stimulus periods, 32% successes were observed. It is concluded that the DC responses are not necessarily related to the occurrence of the visual stimulus. A second experiment was conducted on 19 Ss with 2 channels of DC recording. These results suggest that the source of the DC changes may be the corner-retinal potential from eye movement or other areas of the brain rather than the occipital areas. It is concluded that the Kikler-Held phenomenon, although it may be recorded from all Ss, is statistically infrequent and the conditions under which it does appear are rather obscure. It is suggested that the name, "The Cortical Correlate of Pattern Vision," is premature. R 3

8313

Flood, N.H. THE INFLUENCE OF ENVIRONMENTAL NON-STATIONARITY IN A SEQUENTIAL DECISION-MAKING EXPERIMENT. P 345, Nov. 1952, 3pp. The Rand Corporation, Santa Monica, Calif.

This paper reports on a series of pilot experiments, and on their theoretical background, that were conducted to study the effect on human decision-making of a belief that the environment is changing when in reality it is constant. The results suggest that Ss tend to search more among poorer alternatives when they believe that the situation is changeable, and in conformity with mathematical models suggested by W.K. Estes and R.R. Bush to describe the 2 types of decision-making behavior.

8314

Flood, N.H. TESTING ORGANIZATION THEORIES. P 312, Nov. 1952, 2pp. The Rand Corporation, Santa Monica, Calif.

This paper proposes a class of mathematical models to represent the behavior of a group of one or more individuals engaged in a decision-making process. 3 broad theories are synthesized to yield an organization theory to relate to the dynamic valuation, learning, interaction, and decision processes observed in group decision-making. The decision model is defined for groups with 2 members. Experiments are proposed to provide the data for estimating the parameters in the ~~member~~ group model. (MEIAS)

Kirsch, J. COMMUNICATION BY VIBRATORY TACTILE STIMULI FOR MESCON SYMPOSIUM. Aug. 1955, 14pp. The Rand-Holdridge Corporation, Los Angeles, Calif.

This paper deals with an apparatus and method for communication whereby tactile vibratory stimuli replace or supplement the visual and auditory means. The basic system consists of a simple apparatus: the 5 fingers of the "speaker" rest on sensitive vibration sending diaphragms, and correspondingly, the 5 fingers of the "listener" rest on sensitive vibration receiving diaphragms. A duplicate reversed system allows the "listener" to become the "speaker". Experiments from the area of military communication relevant to the problem are discussed. The sensitivity of the skin to vibration is in the frequency range of 10 to 8000 cps. A system (FACT) is described for the study of communication by the sense of touch directly. Problems for future tests are outlined. (MEIAS)

Fiedler, F.E. THE INFLUENCE OF LEADER-DEPMAN RELATIONS ON COMBAT CREW EFFECTIVENESS. J. abnorm. soc. Psychol., Sept. 1955, 51, 227-235. (University of Illinois, Urbana, Ill.).

This study of interpersonal relations among members of military crews tests the hypothesis that the "emotional distance" of the leader from his crew is positively related to crew effectiveness. The measure of "emotional distance" is derived from a questionnaire in which the leader describes the attributes of persons whom he finds it easy to work with and persons he finds it hard to work with. The difference between these descriptions is taken to represent "emotional distance". The attitude of the leader toward the crew member occupying the most crucial role in the crew's operations was also measured by a sociometric questionnaire. Air Force bomber crews (70) and Army tank crews (25) were studied by this method and the results related to the objective criteria of the effectiveness of the crew in training operations.

Reidy, J.J. & Brury, H.F. SOME FACTORS IN THE EMOTIONAL ADJUSTMENT OF RADAR OBSERVERS IN JET FIGHTER INTERCEPTOR AIRCRAFT. SPECIAL REPORT 1. Proj. 22 1201 0000, Tech. Rep. 56, Nov. 1953, Top. USAF Arctic Aeromedical Lab., Ladd AFB, Alaska.

This report deals with the emotional adjustment of radar observers assigned to a jet fighter interceptor squadron based in the sub-Arctic. 2 groups were studied. The 13 reserve officers in the first group were older men, most of them with combat experience, several of them were large in body build. Most of them had many complaints about the pilots and aircraft, and displayed symptoms of alcoholism, fatigue and irritability. The second group of 6 reserve officers were younger, all except one lacked combat experience, they were short and slender and had few complaints. Each of them flew almost exclusively with the particular pilot with whom he was trained. After 5 months these men showed little change. Conclusions: a) the permanent assignment of each radar observer to a specific pilot was an important factor in the significantly better adjustment of the second group. b) the screening for size and body build is particularly important in climates where heavy clothing must be worn. c) the conditions resulting from the severe climate were a constant source of annoyance and complaints. (REIAS)

Simon, C.W. & Emmons, W.W. THE EEG, CONSCIOUSNESS, AND SLEEP. P 655, April 1955, 17pp. The Rand Corporation, Santa Monica, Calif.

Monopolar occipital and vertex EEGs were taken from 21 normal, male, alpha-dominant adults during an 8-hour sleep. Information was presented by means of a tape recorder during this period. Ss reported if they heard the information during stimulation and were later tested, upon rising, to see if they could recall it. These 2 variables were correlated with electroencephalographic patterns occurring during the information presentation. The following conclusions were drawn: a) The probability of remembering and responding to meaningful auditory stimulation increased as the quantity and quality of waking alpha within the immediate vicinity increased. b) The absence of alpha does not mean unconsciousness. c) The presence of delta is an indication of unconsciousness. Unconsciousness is directly related to delta amplitude, and inversely related to delta frequency. d) Several seconds of EEG scored by eye is a reliable measure of the state of consciousness. e) For any particular EEG pattern, persons who have been asleep prior to stimulation absorb and retain relatively less information than those who have been awake. f) Movements per se are not a good criterion of consciousness.

Aviation Week. USAF GETTING F-102A SIMULATOR. *Aviation Week*, July 1953, 53(1), p.69.

8334

This article describes the development by Link Aviation of a supersonic Convair F-102A interceptor flight simulator. A major deviation from usual simulators is reported as permitting more accurate computing over a greater range of aerodynamic variables and more precise and realistic simulation of certain flight characteristics. A picture and explanation of the training facility is presented.

Aviation Week. AUTOMATIC SAFETY BELTS FOR JET PILOTS. *Aviation Week*, Jan. 1953, 52(4), p.19.

8335

This article presents a brief description of a new automatic safety belt for bailouts at high speed and high altitudes being produced for the Air Force by Stanley Aviation Corp., Buffalo. Designed for use in conjunction with explosive ejection seats, it safeguards the jet pilot should he be knocked unconscious during bailing by actuating the seat release and the parachute ripcord.

8336

Anderson, D.A. TRAINERS EASE HUP COPTER SERVICING. *Aviation Week*, June 1953, 52(22), 30-36.

8336

This article describes the first mobile maintenance trainer for helicopters, designed and constructed for Piasecki Helicopter Corp. by Burton-Rodgers, Inc., being used to help train Navy ground crews who service Piasecki HUP copters. A detailed description of the composition and functions of the various components of the training unit (e.g., electrical system, longitudinal controls, tool panel, etc.) is presented along with a description of the training program itself.

I.

8337

Aviation Week. GROUND-BORNE MISSIONS READY PILOTS FOR COMBAT. *Aviation Week*, Dec. 1951, 52(25), p.53.

8337

This brief article presents pictures and a description of an Air Force trainer, the Sabre Fliteronic which simulates the North American F-86D all-weather fighter, and a Navy simulator, the F8F cockpit trainer which comprises a standard Grumman F8F Bearcat Link trainer and is designed to train pilots of all-weather squadrons.

I.

8338

Christian, G.L. PAN AM BUILDING DC-68 FLIGHT SIMULATOR. *Aviation Week*, Nov. 1951, 52(21), 56-59.

8338

Success with its electronic flight simulators has inspired Pan American World Airways to undertake construction of a "mock simulator" for the DC-68's. This article describes the contemplated design of this simulator and some of the aspects of the Stratocruiser electronic simulator (illustrated in the article). The assets of the latter simulator are discussed in terms of its operation, flight training efficiency, and the realistic conditions which it can achieve. The simulator provides training for all the crew of DC-68.

8339

Aviation Week. AUTOMATIC APPROACH EQUIPMENT TRAINER. *Aviation Week*, Nov. 1951, 52(19), p.68.

8339

This article presents a brief description of the development by Northrop Aircraft, Inc. of an automatic landing approach flight simulator designed to simplify training of Air Force personnel in maintenance of automatic approach equipment. The device duplicates the flight of a Northrop F-89 Scorpion all-weather fighter. Comments are made concerning the operation and design of the model.

8340

Aviation Week. AF TESTS TEMCO, BEECH TRAINERS. *Aviation Week*, Aug. 1951, 52(8), p.14.

8340

A description is presented of an Air Force flight training evaluation test of three Temco T-35 Buckaroo trainers against two Beech T-34 trainers. Three flying cadets selected on the basis of identical stanine tests were assigned to each plane and the planes were then given a series of evaluative tests. Comments are made concerning the results of the tests in terms of suitability to primary-basic training mission, instrumentation, radio and flight characteristics, response of the controls, and night flying suitability.

8342

Christian, G.L. LINK THRIVES ON SIMULATOR BOOM. *Aviation Week*, July 1951, 52(2), 43-44, 47-48.

8342

This article discusses the general development of flight simulators, pointing out the distinction between a flight trainer and simulator and the techniques being utilized by Link to evaluate the problems inherent in developing pilot proficiency. An automatic means of scoring a pilot's performance in an actual airplane is described as one of the methods being employed to improve simulated flight trainers. The Flex-Gunnery Trainer and some of the problems still existent in simulated trainers are also discussed.

I.

8343

Aviation Week. NEW RADAR TRAINERS FOR USAF. Aviation Week, June 1951, 54(25), 57-59.

8343

This article describes the development by Transducer Corporation, Boston, of two radar trainers, a gun laying trainer and a navigator-bomber trainer. From his control panel on the gun-laying trainer, the instructor can place blips representing attacking planes at various ranges and angles of elevation and azimuth on the gunner's radar screen and record the rounds fired and results. In the navigator-bomber trainer, a terrain map and radar antenna both submerged in water are two of the aspects of a device which can simulate navigational and bombing problems for the trainee.

8344

Aviation Week. WEAK EYES DO NOT MEAN POOR PILOTS. Aviation Week, Jan. 1951, 54(3), p.55.

8344

This article presents a brief summary of a study conducted by the Committee on Aviation Psychology of the National Research Council concerned with the relation of deficient eyesight to pilot efficiency. An analysis was made of the records of 194 pilots divided into three groups: normal vision, vision corrected to normal by glasses, and deficient vision not necessarily correctable to normal with glasses. The results are presented in terms of the comparable safety records of each of the groups.

8345

Aviation Week. USAF COPTER INSTRUMENT COURSE. Aviation Week, 1951, 54(4), 27-28.

8345

This is a description of the development and results of the Air Force's application of the hooded instrument flying technique to their helicopter pilot training course. It discusses the basic program which includes such maneuvers as instrument takeoff, autorotations, turns, etc., and presents the results of observation of a group of students utilizing the trainer in terms of the difficulties encountered in the training, e.g., overcontrolling, pilot fatigue, radio signal difficulties, and others. Modifications in the instrument to overcome such difficulties are described.

8346

Lee, B.S. TRAINER-X. Aviation Week, May 1952, 56(20), p.17.

8346

A new training plane, the Air Force Trainer-X, is considered as the prototype of a training craft which will embody the best features of both the North American T-6 "Texan" and its postwar replacement, the heavier T-28. This article describes the need for such a trainer and also the general need for trainers which are capable of topping an air speed of Mach 1. The implications of training at such speeds for the design of a trainer are made explicit (e.g., dual controls to enable instructors to coach the trainee in high speed techniques and maneuvers).

8347

Klass, P. LINK SIMULATOR BOOSTS B-47 POTENTIAL. Aviation Week, June 1952, 56(24), 65-70.

8347

This article describes Link Aviation's new B-47 flight simulator designed to provide pilot training for the B-47 jet bomber. Some of the aspects discussed are the reliability of the instrument's components, maintenance of the equipment, and such advantages of the trainer as close supervision of trainee, simulation of emergency conditions, flight realism, instructor control position, and others.

8350

Aviation Week. BREATHING PILOT SEAT EASES LONG FLIGHTS. Aviation Week, Dec. 1952, 57(25), p.15.

8350

This brief article describes a pulsating seat designed to relieve the strain on fighter pilots kept in the air for long periods of time. The pulsating seat uses a "breathing" action to relieve pressure and promote circulation. The operation of the seat and its effectiveness over a flight period as long as ten hours are both discussed.

8351

Aviation Week. REACTIONS STUDIED IN RADAR READING. Aviation Week, 1951, 54(12), p.39.

8351

This article presents a brief description of the radar-screen interpretation studies conducted at the Air Force School of Aviation Medicine, Randolph AFB, Texas. It mentions the human factors being investigated (e.g., visual acuity, eye movements, perceptual skill, etc.) during the current phase of the program in which untrained airmen are taken on simulated long flights over strange territory to check on the stimulus and human factors incident to radar observation. The determination of individual differences in observer interpretation of radar pictures is described as an essential aim of the program. The implications of the studies to training and improvement of equipment are examined.

8352

Aviation Week. NEW SAFETY HARNESS FOR AIRBORNE TROOPS. Aviation Week, May 1951, 54(19), p.50.

8352

This article presents an illustration and brief description of a "side saddle" safety harness designed to replace lap belts and provide greater crash protection to paratroopers and combat infantrymen. Stressed for an impact force of 32 gs and consisting of tough nylon mesh webbing and straps, the harness was tested on the human decelerator at Edwards AFB, California.

8368

Anon. COCKPIT VIEW VS. SCREEN IMAGE.
Aviation Wk., 1951, 54 (20), 32.

8368

This article presents a brief description of the research conducted by Dr. S.N. Roscoe, University of Illinois on the feasibility of eliminating a plane's wind-screen and substituting a viewing screen for pilot guidance on the aircraft instrument panel. The results of tests in which eleven pilots flew a plane without the windows covered and then with the windows covered, using various screen sizes and magnification, are presented in terms of optimal screen and magnification sizes to permit efficient flying ability. A suggestion is offered for conditions of blind flying in which television or optical systems do not provide a view ahead.

8369

Anon. HIGH LATITUDE NAVIGATION TRAINER.
Aviation Wk., 1950, 53 (26), 31.

8369

This article describes a special navigation trainer (D-2 High Speed, High Latitude Celestial Navigation Trainer) developed by Link Aviation, Inc. said to be capable of accurately reproducing polar region navigating problems. The trainer permits six students at a time to take sights from the observers' platform using periscopic sextants to remain in constant communication with the instructor, and also to furnish data to a larger group of students. The operation of the trainer, its potential application, and the variable at the instructor's disposal are also discussed.

8373 Kaden, S.E., Wapner, S. & Werner, H. STUDIES IN PHYSIOGNOMIC PERCEPTION: II. EFFECT OF DIRECTIONAL DYNAMICS OF PICTURED OBJECTS AND OF WORDS ON THE POSITION OF THE APPARENT HORIZON. J. Psychol., 1955, 39, 61-70. (Psychology Dept., Clark University, Worcester, Mass.).

The present study, consisting of 2 experiments, is a continuation of previous work designed to demonstrate that visual directional dynamics exists as a behaviorally measurable event. The first of these experiments showed that a figure with directional dynamics upwards or downwards has the effect of shifting the physical location of the apparent horizon (eye line), opposite the direction of the dynamics. The second experiment used visually presented verbal symbols connoting uprightness or downrightness, e.g., "rising" vs. "falling". Analogous to the findings with meaningful pictorial material used in the first experiment, the physical position of the apparent horizon shifted opposite the direction of the dynamics conveyed by the words. Thus, in addition to demonstrating that visual dynamics in the upward-downward direction can be measured behaviorally, the study shows that certain semantic aspects of words can be conceived and dealt with experimentally in a theoretical framework developed for problems of perception.

Beebe-Center, J.G., Rogers, M.S., & O'Connell, D.N. TRANSMISSION OF INFORMATION ABOUT SUCROSE AND SALINE SOLUTIONS THROUGH THE SENSE OF TASTE. J. Psychol., Jan. 1955, 39, 157-160. (Harvard University).

8374

The amount of information transmitted in absolute judgments of sucrose and saline solutions was measured for simple and compound solutions. The number of concentrations in an ensemble was varied from 3 to 17, but the range was always 100 gusts covered in equal log gust steps. The subject sipped the test solution from a shot glass, expectorated, and made his judgment in the form of a number from a pre-arranged scale. The experimenter gave him the correct identification after every response. Several experiments are reported, each involving from one to five subjects. The channel capacity of gustation for salt and sugar is estimated, and the effects of mixing stimuli on information transmission are described.

Green, R.F. TRANSFER OF SKILL ON A FOLLOWING TRACKING TASK AS A FUNCTION OF TASK DIFFICULTY (TARGET SIZE). *J. Psychol.*, April 1955, 39, 356-370. (University of Rochester).

8377
In a study of transfer of skill on a following tracking task as a function of task difficulty, 64 Ss were asked to perform on the SAM Two-Hand Coordination Test (CM101B). Task difficulty was defined by varying target size. Transfer was measured by having the S first perform on an easy (or hard) target and then on a hard (or easy) target. The results are presented and discussed in terms of the relative amount of transfer of training from a difficult to an easy task as compared to the amount of transfer from an easy to a difficult task.

Alexander, S.J., Cotzin, M., & Wendt, G.R. CHEMICAL INFLUENCES ON BEHAVIOR: I. THE EFFECTS OF A SMALL DOSE OF HYOSCINE ON PERFORMANCE. *J. Psychol.*, April 1955, 39, 389-402. (University of Rochester).

8378
To determine the effects of small doses of hyoscine on performance, 15 subjects were tested on each of six successive days after receiving 0.6 mg of hyoscine hydrobromide or a placebo of milk sugar. The performance tests used were complex coordination, rifle target shooting, addition, code substitution, parts of the Army Alpha and a recognition memory test. The order in which the tests were taken was counterbalanced between two halves of the group which had been matched for body weight. The extent of the impairment of the performance of active young men as indicated by these tests is assessed in relation to the military use of hyoscine as a motion sickness preventative.

Alexander, S.J., Cotzin, M., Hill, C.J., Jr., Ricciuti, E.A., et al. STUDIES OF MOTION SICKNESS: X. EXPERIMENTAL PROOF THAT AVIATION CADETS TELL THE TRUTH ON MOTION SICKNESS HISTORY QUESTIONNAIRES. *J. Psychol.*, April 1955, 39, 403-409. (Psychology Dept., University of Rochester, Rochester, N.Y.).

Questionnaires were given, under conditions which could be duplicated in the armed services, to 349 naval aviation cadets shortly after arrival at flight preparatory school. 14 of 42 questions were concerned with motion sickness in different circumstances. 1 to 10 weeks later they were interviewed to determine their face-to-face answers to the same items as had appeared on the questionnaire. The results show that 80% of the answers were identical. Changes of a magnitude large enough to be possibly indicative of falsehood occurred in 0.6% of the answers. It is concluded that this study gives no support whatever to the allegation that aviation cadets may be expected to falsify questionnaire answers. (HEIAS)

8380
Alexander, S.J., Cotzin, M., Kise, J.B., & Wendt, G.R. STUDIES OF MOTION SICKNESS: XIII. THE EFFECTS OF SICKNESS UPON RIFLE TARGET SHOOTING. *J. Psychol.*, April 1955, 39, 411-415. (Psychology Dept., University of Rochester, Rochester, N.Y.).

Tests of rifle fire accuracy at 25 ft. from the target have been administered to 117 Ss before and after exposure to motion on our vertical accelerator. The data were analyzed to determine whether those who became motion sick showed deficits in performance. The average deviation from the target center of shots by 26 sick Ss showed a mean deterioration of 0.1 mm in performance, whereas 91 who did not become sick showed a mean improvement of 1.6 mm. This difference is not statistically reliable, as shown by a critical ratio of only 0.5. Records of speed of firing indicated no tendency for sick Ss to slow down after wave-machine exposure. It was found that the sick Ss, when asked to predict their own post-exposure performance, tended to drop their estimates further below their pre-exposure performance than did the not-sick Ss. Other analyses showed that neither susceptibility to machine sickness nor past history of sickness bore any demonstrable relation to normal performance on the test administered before exposure to motion.

8381
Cotzin, M., Hill, C.J., Jr., & Wendt, G.R. STUDIES OF MOTION SICKNESS: XIV. SUBJECTIVE REPORTS OF THE APPARENT PATH OF MOTION ON A VERTICAL ACCELERATOR. *J. Psychol.*, April 1955, 39, 417-421. (University of Rochester, Rochester, N.Y.).

Ss exposed to wave motion on a vertical accelerator were asked to describe the apparent path of motion. Out of 267 Ss, 93 reported only one kind of motion, 122 reported 2 kinds, 44 3 kinds, 6 four, and 2 five kinds. Most of the reported motions other than the true vertical were ellipses or modified ellipses. The differences between Ss might have been due to small variations or differences in head position. Differences in perceived path of motion may be a causal factor in sickness, but it seems more likely that the perceptions were influenced by differences in attitude of susceptible and non-susceptible Ss and were thus less cause than effect. (HEIAS)

8382
Johnston, C., & Wendt, G.R. STUDIES OF MOTION SICKNESS: XVII. THE EFFECTS OF TEMPERATURE, POSTURE, AND WAVE FREQUENCY UPON SICKNESS RATES. *J. Psychol.*, April 1955, 39, 433-439. (Psychology Dept., University of Rochester, Rochester, N.Y.).

The study was designed to find how motion sickness rates on the vertical accelerator were affected by 2 temperatures, by 4 combinations of head and body posture, by 5 different waves and by 3 classes of susceptibility. 120 men were blindfolded and subjected to motion for 30 minutes (or less if vomiting occurred). Main findings: a) There was no difference of consequences between sickness rates at warm (86° F) and cool (65° F) temperatures. b) Sickness indices for different postures: seated with head upright, 47; seated with head back, 103; supine with head upright, 57; supine with head back, 53. c) A simple mechanical action of wave motion on blood distribution was not a factor in the production of sickness. d) The relation of sickness index to susceptibility was in the expected direction: susceptible, 100; intermediate, 65; non-susceptible, 30. e) Sickness indices corresponding to wave frequencies of 13, 16, 22, 26 and 32 cycles/min. were 54, 83, 92, 83, and 34 respectively. (HEIAS)

Jones, F.N. OLFACTORY ABSOLUTE THRESHOLDS AND THEIR IMPLICATIONS FOR THE NATURE OF THE RECEPTOR PROCESS. *J. Psychol.*, Oct. 1955, 40, 223-228. (University of California).

8385
This article is concerned with the implications of olfactory absolute threshold data for the nature of the receptor process. Using a "controlled-blast" technique, thresholds were obtained for 84 Ss and 20 substances (e.g., pyridine, benzene, fugenol, etc.). These data are treated as group results and discussed in terms of the problems of defining stimulus-receptor interaction and qualitative differentiation of stimuli. The process of adsorption receives major emphasis in the discussion of olfactory stimulation.

Heidbreder, Edna, & Zimmerman, Claire. THE ATTAINMENT OF CONCEPTS: IX. SEMANTIC EFFICIENCY AND CONCEPT-ATTAINMENT. *J. Psychol.*, Oct. 1955, 40, 325-336. (Wellesley College).

8386
To investigate the relation between systematic variation of semantic efficiency and attainment of concepts, 41 Ss were presented with 16 series of nine phrases, each phrase representing one concept. Semantic efficiency was varied by modifying both the degree of explicitness and the syntactic direction of a phrase. The results are treated in terms of the effect of each of the factors of semantic efficiency upon ease of concept attainment.

Angelino, H. & Mech, E.V. FACTORS INFLUENCING ROUTINE PERFORMANCE UNDER NOISE: II. AN EXPLORATORY ANALYSIS OF THE INFLUENCE OF "ADJUSTMENT". *J. Psychol.*, Oct. 1955, 40, 397-402. (University of Oklahoma, Norman, Okla.).

To investigate the potential relation between performance under noise and personality or "adjustment" measures, 28 subjects were selected from a total population of 150 college students on the basis of their scores on the California Test of Personality (i.e., the highest 14 and the lowest 14). Each of the subjects was required to perform a task involving simple addition under conditions of quiet and noise (a continuous tone of approximately 85 db). The results are presented and discussed in terms of the quantitative differentiation in performance between the two groups as indicative of the role of personality in performance under noise.

Green, R.F., Andreas, B.G., Norris, E.B., & Spragg, S.D.S. PERFORMANCE ON A FOLLOWING TRACKING TASK (THE SAM TWO-HAND COORDINATION TEST) AS A FUNCTION OF THE CONTINUITY OF THE PLANE AND DIRECTION OF MOVEMENT OF THE CONTROL CRANKS AND TARGET FOLLOWER. *J. Psychol.*, Oct. 1955, 40, 403-410. (University of Rochester).

8388
To evaluate the effects of the continuity of the plane and the direction of movement of the control cranks and target followed on performance of a following tracking task, a total of 84 subjects performed on a modified SAM Two-Hand Coordination Test under conditions of varied display-control arrangements. Where that crank location was known on the basis of previous experiments to produce poor performance, spatial continuity was introduced. The results are presented and discussed in terms of the relative effect of spatial continuity as contrasted to that of position of control cranks.

Green, R.F., Norris, E.B., & Spragg, S.D.S. COMPENSATORY TRACKING PERFORMANCE (MODIFIED SAM TWO-HAND PURSUIT TEST) AS A FUNCTION OF THE DIRECTIONS AND PLANES OF MOVEMENT OF THE CONTROL CRANKS RELATIVE TO MOVEMENT OF THE TARGET. *J. Psychol.*, Oct. 1955, 40, 411-420. (University of Rochester).

8389
This is a study of compensatory tracking as a function of directions and planes of movement of the control cranks relative to movement of the target. 32 subjects performed on a modified SAM Two-Hand Pursuit Test under varied conditions of direction and plane of controls movement. An analysis of variance of the data was conducted to determine the relative effects of each of the variables and their combinations, i.e., position, order, order and directions, etc. The results are discussed in terms of a comparison between effects of optimum display-control movement relationships on compensatory and following tracking.

Andreas, B.G., Green, R.F., & Spragg, S.D.S. TRANSFER EFFECTS IN COMPENSATORY TRACKING (MODIFIED SAM TWO-HAND PURSUIT TEST) AS A FUNCTION OF REVERSAL OF THE DISPLAY-CONTROL RELATIONSHIPS ON ALTERNATE BLOCKS OF TRIALS. *J. Psychol.*, 1955, 40, 421-430. (University of Rochester).

8390
This study was designed to assess the transfer effects in compensatory tracking which result from reversal of display-control relationships during a series of trials. 216 subjects performed a series of tracking trials with the modified SAM Two-Hand Pursuit Test (CM 8106) under conditions in which display-control relationships were reversed on alternate blocks of trials. Different patterns of alternation were applied for various subgroups. The results are presented and discussed in terms of the degree of facilitation and interference effects on performance as a function of the pattern of display-control alternation.

Hartzman, M., Seitz, C.P., & Orlansky, J. STABILITY OF PERSONALITY STRUCTURE UNDER ANOXIA. *J. gen. Psychol.*, Jan. 1955, 52, 66-74. (College of the City of New York).

8391

This study was designed to investigate the stability of personality structure under conditions of stress produced by severe anoxia. Two groups of 20 subjects each were tested at sea-level and a simulated altitude of 10,500 feet, with order of condition varied for each group. Group Rorschach tests were administered following a fifteen-minute exposure to each condition with the time interval between the two conditions averaging two weeks. Correlations between the tests were used as indices of personality stability. Specific effects of anoxia as reflected by change in Rorschach variables are noted and discussed.

Cotton, J.W. & Verplanck, W.S. THE DEPENDENCE OF FREQUENCIES OF SEEING ON PROCEDURAL VARIABLES: III. THE TIME-INTERVAL BETWEEN SUCCESSIVE STIMULI. *J. gen. Psychol.*, July 1955, 52, 59-66. (Northwestern University).

8399

In a study of the effects of procedural change on frequencies of response to weak visual stimuli, two experiments were conducted. In the first experiment, six subjects, experienced in visual experimentation, were tested for the effect of various inter-trial intervals (range of 3 to 12 sec.) upon the 50 percent visual threshold obtained in intensity-ordered stimulation (Hecht-Schlaer Model III Adaptometer). In the second experiment six subjects, with no previous experience, were used in an attempt to produce a more sensitive determination of the relation between inter-trial interval and 50 percent threshold. The results are discussed in terms of the relative lack of dependence of the 50 percent threshold on inter-trial interval.

Sheer, D.E. & Worchel, P. CONFIGURATIONAL CONSTANCY: I. THE EFFECTS OF CHANGES IN THE INTRINSIC ELEMENTS. *J. gen. Psychol.*, Oct. 1955, 52, 265-280. (University of Houston, Houston, Tex.).

The present study was concerned with determining whether there is a tendency for configurations to remain constant even though individual elements of the pattern are modified. 60 inspection stimuli, each consisting of one configuration containing 3 elements and a center reference point, were individually projected on a screen for 30 sec. to both an experimental and control group of 50 Ss each. After the exposure of each inspection stimulus, a series of 4 multiple-choice configurations were projected simultaneously on the screen and the S was required to indicate which one of the 4 corresponded to the preceding inspection stimulus. In the multiple-choice configurations for the experimental group, 15 items were changed in each of the following factors: form and size of the elements, orientation of the configuration and distance between the elements. In the control group, the multiple-choice configurations were not changed in any of these properties. The results of this study clearly indicate that changes in the form and size of the elements and distance between elements and orientation in the configuration produced a significant decrease in the ability to recognize configurations as compared with controls. A comparison of group means between experimental categories indicated a significant difference in the degree of decrement produced by each modification.

Horne, E.P. & Eschenbach, A.E. THE EFFECT OF LOCALIZED MONAURAL CUES ON A VISUALLY CONTROLLED TURNING MOVEMENT. *J. gen. Psychol.*, Oct. 1955, 53, 287-292. (University of Florida).

8404

To study the effect of an extraneous monaural stimulus upon the time required to introduce a 450 change of course in a Link trainer, an ICA Sigma Tone of approximately 600 cycles was occasionally presented either to the right or left ear of 10 subjects prior to the onset of a cockpit signal light (a danger signal and indicator for change of course). For half the subjects the trainer was set to turn at 6 revolutions per minute while for the remainder it was set at nine revolutions per minute. Position of monaural sound and signal light were varied. The results are presented in terms of the average reaction time for the slow-moving and fast-moving trainer groups under the various conditions of stimulus position. Performance on sound trials is compared with that on non-sound trials. T. R 2

Taylor, Jean G. (Ed.) SYMPOSIUM ON THE ROLE OF STRESS IN MILITARY OPERATIONS. 1 AND 2 MAY 1953. Tech. Memo. ORO-T-256, Dec. 2, 1953, 56pp. *Operations Research Office*, Johns Hopkins University.

8410

This is a report of a symposium on the role of stress in military operations. The first part presents the results of a study of combat stress in Korea along with a discussion of this study by the participants. The second part presents a conference of administrators and representatives of military, government, and private agencies concerned with the military stress problem. The field study in Korea entailed the psychological and physiological measurement of infantrymen in the actual combat situation. Discussed are the indicators of stress and the nature of the recovery phase.

Brody, S.I. PROBLEMS OF HIGH ALTITUDE FLIGHT. USN Naval Inst. Proc., Nov. 1951, 77(11), 1190-1195.

Because of the advantage of higher altitude in air to air combat operations, efforts are being made to extend the operational ceiling of modern military aircraft. Samples taken at an altitude where the atmospheric pressure is 1/10th that of sea level have shown the percentages of O₂, nitrogen and other gases to be the same as it is at low altitudes. However, there are great variations in the air temperature. A significant factor is the ram compression temperature on the surface of the jet or rocket ship. New airfoil concepts in design are necessary for adequate performance and maneuverability at high altitudes. Visual difficulties may arise at high altitudes because it is harder to detect relative motion. Physiological limitations include anoxia, bends (due to the dissolved nitrogen in the bloodstream). Pressurized flying-suits and better ejection-seats are being developed. (NEIAS)

This article presents a brief description of the development by the Army of armored clothing and a new plastic helmet. The design of the clothing and helmet are described in terms of the kind and amount of protection afforded by each.

8413

Dowdy, H.S. INTERIOR DECORATING FOR SUBMARINES. US Naval Inst. Proc., Nov. 1950, 76(11), 1182-1185.

Prolonged stay in submarines results in decreased efficiency, and a number of unpleasant physiological and psychological effects. Experiments were carried out leading to recommendations of designs, colors, and materials for improving submarine compartments as regards visibility, comfort, and habitability. Various shades of grey were found the optimal color. The problem of lighting was solved by the use of bed-lamps, fresh-colored lights in recreation areas, spot-lights for control gauges. Interior design included linoleum for covering the deck, plastic table covers, upholstered seats, and other features which help to create the effect of home. (NEIAS)

Lindsley, D.B. & et al. EXPERIMENTS IN TRAINING RADAR OPERATORS IN VISUAL CODE RECEPTION. Contract OEM sr 919, Proj. SC 70, NS 146, OSD Rep. 4811, Res. Rep. 16, March 1945, 15pp. Office of Scientific Research & Development, WADC, Applied Psychology Panel. (Verkes Laboratories of Primate Biology, Orange Park, Fla.)

The Bainbridge experiment showed that radar operators trained in code reception on blinker lights transferred readily to reception of code on oscilloscopes. Following transfer, the majority of the men regained their previous level of code reception in 3-4 hrs. of training. Good men learned the code quicker when training methods included the use of the whole method in contrast to the part method. The letter sending device was found preferable to the tape method in the use of blinker code learning. A comparison of learning when different character speeds were used showed that a group whose initial band speed was .244 sec. acquired the character-letter associations quicker in early stages of training than did a group whose band speed was .122 sec. The letters used differed greatly with respect to learning difficulty. Age, General Classification Test Scores and Radio Aptitude Test scores were correlated with achievement on blinker code after incomplete learning. Correlations between RCAT scores and achievement ranged from .45 - .57, indicating practical value of the RCAT in the selection of blinker code trainees. (NEIAS)

Bartlett, F., Broadbent, D.E., Pople, R.D. & Wilkinson, R.T. EFFECTS ON HUMAN PERFORMANCE OF VARIOUS STRESS CONDITIONS. *PPRC* 961, Jan. 1956, 6pp. *Flying Personnel Research Committee*, ARC, Unit for Research in Applied Psychology, Cambridge, England).

This report is a summary of three reports which in turn summarize the important conclusions that can be drawn from the effects on human performance of exposure to: a) noise; b) heat and humidity; c) sleeplessness. It was concluded that all three forms of stress may, under special precautions, be taken, seriously affect human behavior when great accuracy and speed are required. It was recommended that further experimental work be conducted concerning the further effects that may be produced when work has to be continued under these forms of stress for a relatively long period and under environmental conditions which are apt to change suddenly and unexpectedly. Wickens, R.J. & Peterson, G.W. FACTORS INFLUENCING DIAL OPERATION: THREE-DIGIT MULTIPLE-TURN DIALS. SC 3635(13), Santa Fe 51 0315, Feb. 1955. 65pp. Sandia Corporation, Albuquerque, N.M. (Psychology Dept., University of New Mexico, Albuquerque, N.M.).

Tests devised and conducted by the Psychology Department of the University of New Mexico to obtain data on the frequency of occurrence of errors in reading and setting multiple-turn dials of 5 different designs are described. Analysis of the data obtained from the tests lead to the conclusion that dial design has marked effects on speed and accuracy with which the dials may be set and read. The design of Dial 5 is recommended for use under the specifications for this study. The set-check system used in the experiments is found to have an error probability of 0.0015 for this dial. A double-set system, in which two persons set two automatically interlocked dials, is suggested and it is predicted that this system would reduce the probability of error for Dial 5 to the order of 0.00003.

Gillinsky, Albert S. THE RELATION OF PERCEIVED SIZE TO PERCEIVED DISTANCE: AN ANALYSIS OF GRUBER'S DATA. Amer. J. Psychol., 1955, 68, 475-480. (Columbia University, New York, N.Y.).

In a recent paper, Gruber presents data on perceptions of size and distance which he takes to indicate that perceived size is not related to perceived distance. Gruber performed 2 experiments. He rejects Exp. I for the purpose and offers Exp. II as a fair test of the hypothesis. In the experiment he obtained coupled observations of perceived size and perceived distance from 20 Os over a range of distances from 200 to 450 cm. Within this range 0 viewed a standard object at each of 5 different distances and so set a variable object that it appeared half-as-distant (1/2); equally distant (ES); equal in size (ES1/2) with the standard half as far from 0 as the variable; and equal in size (ESE) with the standard and variable equidistant from 0. Although unequivocal instructions are not reported, Gruber states that he instructed his Os to adopt a 'phenomenal' as opposed to an 'objective' attitude. The purpose of the present note is not to criticize Gruber's experimental procedure nor to question the validity of his results. Accepting his findings at face value, the question is simply: Do these results in fact reveal a situation in which relative size is underestimated when relative distance is overestimated—a size-distance paradox—as Gruber asserts? An alternative interpretation may better fit the facts and remove the paradox into which Gruber's discussion has plunged us.

Brown, M.K. & Fitzsimons, J.T. ELECTROCARDIOGRAPHIC CHANGES DURING POSITIVE ACCELERATION. (WITH A NOTE ON VECTOR-CARDIOGRAPHY). FPRC 1009, BR 103363, June 1957. 17pp. RAF Institute of Aviation Medicine, Farnborough, Hants, England.

In the human centrifuge 53 subjects have carried out 366 fully instrumented runs under positive accelerations of 3-5 g. The results were analysed for pulse rates, pulse rate intervals, and changes in the electrical axis. Some vector-cardiograms were also recorded. No abnormal rhythms have been found and the only abnormal pattern was in a subject who lost consciousness at 4 g. Differences in cardiovascular response to g were found between experienced and inexperienced subjects, these were maximal at low g values and disappeared as the g level increased. Unconsciousness causes muscle artifacts in the limb-leads and T-wave changes which, however, require cautious interpretation. Analysis of the electrical-axis has been carried out. There are definite trends under g but these are overshadowed by the effect of respiration. Positional changes are complex and cannot be dissociated from respiration. Vector-cardiograms were easily carried out and gave reproducible results but were of little value in studying the heart during positive acceleration.

Jones, G.M. AIRCREW FATIGUE IN LONG RANGE MARITIME RECONNAISSANCE: VI. GASTRIC ACTIVITY MEASUREMENTS. FPRC 907.6, Aug. 1956, 36-41, 8pp. RAF Institute of Aviation Medicine, Farnborough, Hants, England.

An investigation of gastric activity in one S during a week of high intensity operational flying is described. The method chosen involved the ingestion of a daily test meal, by means of which it was possible to determine both motor and secretory responses of the gastric muscularis mucosa. The gastric activity determined in this way appeared to be increased by the operational experiences encountered, and it is inferred that this increase may have been due in some measure to the stressful or fatiguing nature of those experiences. The results, although of limited value in themselves on account of the limited experimental data available, are considered sufficiently positive to encourage continuation of the investigation. It is concluded, however, that a technique more appropriate to a field investigation should be employed.

Jameson, Dorothea & Hurvich, L.M. SOME QUANTITATIVE ASPECTS OF AN OPPONENT-COLORS THEORY: III. CHANGES IN BRIGHTNESS, SATURATION AND HUE WITH CHROMATIC ADAPTATION. *J. opt. Soc. Amer.*, June 1956, 46(6), 405-415. (Eastman Kodak Company, Rochester, N.Y.).

A theoretical model for an opponent-colors theory of vision is used to predict and describe quantitatively changes in the brightness, saturation, and hue of colors with changes in chromatic adaptation. The systematic nature of such changes in color appearance is examined, and comparisons are made between specific theoretical predictions and results of experimental studies of chromatic adaptation.

Hurvich, L.M. & Jameson, Dorothea. SOME QUANTITATIVE ASPECTS OF AN OPPONENT-COLORS THEORY: IV. A PSYCHOLOGICAL COLOR SPECIFICATION SYSTEM. *J. opt. Soc. Amer.*, June 1956, 46(6), 416-421. (Eastman Kodak Company, Rochester, N.Y.).

A system for the numerical specification of colors is developed on the basis of a quantified opponent colors theory. The derived HSB (hue, brightness, and saturation) system permits the quantitative specification of colors in terms of their primary psychological (perceptual) attributes for various adaptations and illuminations.

8457
This paper describes the effects on post-flight vigilance of flying four fifteen hour sorties at night with one day's rest between each flight in Royal Air Force Coastal Command long range reconnaissance aircraft. The Fraser π -function technique was used with the eight subjects to measure variability of judgment under vigilance conditions. The amount of objective deterioration in post-flight vigilance is discussed as well as subjective reports of weariness.

Helson, H., Michels, W.C. & Sturgeon, A. THE USE OF COMPARATIVE RATING SCALES FOR THE EVALUATION OF PSYCHOPHYSICAL DATA. *Amer. J. Psychol.*, 1954, 67(2), 321-326. (University of Texas, Austin, Tex.).

It has been shown in previous studies that the absolute type of judgment commonly employed in rating scales may be utilized for psychophysical measurements as well as in the evaluation of responses which have no basically measurable stimuli. The question arises: can the quantitative theory found adequate for absolute judgments be extended to direct comparison of standard and variables as in the method of constant stimulus differences? If this can be done then the theory of absolute judgment may be applied to the comparative type of judgment. In an attempt to answer the question, an experiment wherein 12 Os were required to judge weights--ranging from 300 gm to 500 gm--following a standard of 350 gm or 400 gm. The study demonstrated that reliable comparative rating judgments may be made of stimuli when a standard is provided. It was concluded that the comparative rating scale has an advantage over the method of absolute judgment because it provides a stimulus-standard which helps to stabilize the adaptation-level and therefore the judgments of the stimuli. Michels, W.C. & Helson, H. A QUANTITATIVE THEORY OF TIME-ORDER EFFECTS. *Amer. J. Psychol.*, 1954, 67(2), 327-334. (Bryn Mawr College, Bryn Mawr, Penn. & University of Texas, Austin, Tex.).

The time-order error can be accounted for as being due to the role which adaptation-level plays in establishing PSE. The PSE is found to be a weighted mean of all stimuli, past or present, which affect the judgment. The standard, while exerting predominant influence, is only one of the determinative factors. Time-order errors have been studied by the use of a comparative rating scale. When the order of presentation of the standard and the stimulus is reversed, a new relation between stimulus and judgment is found. The only judgment that remains unaffected is that of a stimulus equal to the standard. If this stimulus evokes a judgment of equality, PSE or AL is equal to the standard and there is no TOE; if it evokes a higher judgment, TOE is negative; and if it evokes a lower judgment, TOE is positive. The average of the 2 PSE's obtained with the different time-order is not generally equal to the standard, although it may be in special cases.

Crumbaugh, J.C. TEMPORAL CHANGES IN THE MEMORY OF VISUALLY PERCEIVED FORM. Amer. J. Psychol., 1954, 67, 647-658. (University of Texas, Austin, Tex.).

The problem of temporally progressive memory-changes in visually perceived forms was studied by the method of identical stimuli, in which identical figures (standard and variable) both were repeated in each comparison made by O as in a typical psychophysical experiment on the time-error. Luminous stimuli on a milk-glass screen were used, standard and variable being presented on opposite sides of a fixation-point. Each of the 5 figures employed contained a degree of asymmetry which O judged to be greater or less in the variable as compared with the standard. The results provide clear evidence of temporally progressive changes in the traces of visually perceived forms. The changes observed, which suggest autonomous rather than assimilative effects, differ in their pattern of development according to the particular form perceived. The traces of some forms progress rapidly toward greater symmetry, while the traces of others show an initial tendency toward decreased symmetry which soon is reversed. The direction and pattern of change is influenced by quantitative as well as by qualitative variations in the perceived figure. While autonomous changes as yet undiscovered may occur over longer intervals, the present experiment reveals important effects within the first few sec. of the life of the trace.

Krauskopf, J., Duryea, R.A. & Bitterman, M.E. THRESHOLD FOR VISUAL FORM: FURTHER EXPERIMENTS. Amer. J. Psychol., 1954, 67, 427-440. (University of Texas, Austin, Tex.).

Foveal form thresholds were measured in terms of the intensity of illumination required to identify luminous figures briefly exposed in a dark room. Form threshold varies inversely with exposure-time, with magnitude of critical detail, and to some extent with area. The reciprocity of time and intensity is qualitative as well as quantitative; with short exposure-times distortions of form appear which are comparable to those obtained at low intensities of illumination. Brightness threshold, like form threshold, varies inversely with exposure-time and with area, but it is unaffected by extensive differences in configuration. Evidence is presented to show that O's knowledge of the forms employed may mask real differences in form threshold.

Krauskopf, J. FIGURAL AFTER EFFECTS IN AUDITORY SPACE. Amer. J. Psychol., 1954, 67, 278-287. (University of Texas, Austin, Tex.).

If the Köhler-Wallach theory of figural after-effects is conceived as a general theory of neural organization applicable to all perceptual dimensions which have a placewise representation, it follows that prolonged stimulation in any such dimension should yield alterations in spatial relationships. In the experiments here reported evidence of figural after-effects in auditory space was sought on the basis of a place theory of auditory localization. The following deductions were tested: a) that satiation in the medial plane should reduce the variability of subsequent determinations of the medial plane; b) that satiation at a point removed from the medial plane should shift subsequent settings of the medial plane in the direction of the satiating tone; c) that these displacements should exhibit a distance-paradox, that is, the effects should first grow as a function of the distance of the satiating tone from the medial plane, and then decrease; and d) that the distortions induced should decay with time. These expectations were confirmed, although only the rising portion of the curve of the distance-paradox was obtained. The data of Jones and Bresslar suggest, however, that the curve would be completed if the measurements were made over a larger range. The evidence strongly suggests that the Köhler-Wallach model is a general mechanism applicable to generalized perceptual systems.

Jareson, Dorothea & Hurvich, L.H. SOME QUANTITATIVE ASPECTS OF AN OPPONENT-COLORS THEORY. I. CHROMATIC RESPONSES AND SPECTRAL SATURATION. J. opt. Soc. Amer., July 1955, 45(7), 546-552. (Eastman Kodak Company, Rochester, N.Y.).

Saturation discrimination is assumed to be dependent on the ratio of chromatic to achromatic components in the sensory response to a given wavelength. The usual methods of measurement do not, however, permit independent control of the chromatic and achromatic variables. On the basis of an opponent-colors theory of vision, a method is described for measuring directly and separately the spectral distributions of the chromatic components. A series of experiments is reported in which this method was used to obtain measures of the paired chromatic responses associated with the four primary spectral hues. Results are reported for 2 observers, 1° foveal test field, for an equal brightness spectrum (10 nL), and a neutral state of adaptation (10 nL). The measured chromatic responses, together with achromatic (luminosity) functions measured earlier for the same Os, are used to predict the form of the spectral saturation discrimination function.

USN Air Applications Branch. VISUAL PRESENTATION PROBLEMS AND THE CARRIER LANDING TRAINER. Proj. 12 BK 5a, Sept. 1954, 7pp. USN Special Devices Center, ONR, Port Washington, N.Y.

Visual presentation is essential for many training situations. Its 3 basic categories are: a) direct viewing of scale models, b) optical projection, and c) television. A demonstration is given of wide angular visual display controlled by a synthetic trainer, which also contains a ship travelling independently within a moving background. The carrier landing device incorporates an operational flight trainer for a carrier-borne aircraft together with a visual presentation system which realistically reproduces to the student pilot the landing approach to the carrier deck. The visual presentation is a wide angle television chain technique. A description is given of the requirements and the 2 major systems of the device: electro-mechanical portion and television chain equipment. (HEIAS)

Tinker, M.A. PERCEPTUAL AND OCULOMOTOR EFFICIENCY IN READING MATERIALS IN VERTICAL AND HORIZONTAL ARRANGEMENTS. *Amer. J. Psychol.*, 1955, 68(3), 444-449. (University of Minnesota, Minneapolis, Minn.)

The purpose of this experiment was to investigate the effect of a limited period of practice in reading materials arranged in vertical columns upon speed and patterns of eye-movements while reading comparable materials in vertical and in normal horizontal arrangements. Equated passages of easy material were employed for initial and final tests. 12 similar passages were employed for the practice materials. Each of the practice selections was read in vertical arrangement 3 or 4 times over a period of 6 wk. which elapsed between the initial and final tests. The following results were obtained: a) At the initial testing, the vertical reading was 50% slower than the horizontal, but after practice it was only 21.8% slower. Speed of reading the horizontal did not change from initial to final testing but there was a significant gain of 17.8% in the vertical reading. b) The records of the eye-movements on the initial test revealed that the vertical reading required fewer fixations, fewer regressions, and longer pause-durations. Practice yielded an improvement in number of fixations and regressions in vertical reading in comparison with the horizontal.

Lightfoot, C. & Jerger, J.F. CUMULATIVE EFFECTS OF REPEATED BURSTS OF WHITE NOISE ON THRESHOLD FOR 4000-C.P.S. TONE PIPS. Proj. 21-1203 0001, Rep. 10, June 1955, 10pp. *USAF School of Aviation Medicine*, Randolph Field, Tex.

Results based upon 8 Ss, even though each one was tested a number of times, can only be regarded as bases for tentative conclusions. The data reported in the preceding section, however, definitely point to the reality of an increase in the effect of a 2-second burst of white noise upon the performance of normal ears when the burst is repeated regularly at the rate of 6 times per minute and its SPL is 90 db or greater. It would appear that the ability of an ear to hear a short pip of 4000 cps tone within the first second after such a burst is diminished with each successive burst--at least with each burst between the 15th and the 95th of a series. When burst-duration and repetition rate remain constant, it would appear that the level of the successive bursts is the main determinant of the rate of rise in the post-burst threshold. The accumulated elevation in threshold apparently disappears so slowly that the rate of accumulation is influenced little, if at all, by the amount of time between the end of the burst and the moment at which threshold is determined, provided that the measurement is made within a second of the burst's termination. There appear to be appreciable differences among individuals with respect to their reaction to the kind of serial stimulation under discussion. A fair proportion of persons exposed to a series of 110-db bursts may be expected to develop loss in acuity lasting several minutes and also abnormal sensations such as tinnitus.

Pollack, I. THE ASSIMILATION OF SEQUENTIALLY-ENCODED INFORMATION: V. BINARY-ENCODED MATERIALS. *HFORL Rep. TR 54-5*, Jan. 1954, 11pp. Human Factors Operations Research Labs., *USAF Air Research and Development Command*, Bolling AFB, Washington, D.C.

This report considers the immediate recall of binary-coded verbal materials--messages in which each unit could assume only one of 2 possible alternatives. Binary materials are of special interest because of the ease of recoding the materials into alternative units which, presumably, aid in their reproduction. The contribution of 4 variables, which were believed to influence the assimilation of binary messages, has been examined. Of these, 3 are significant: the length of the message--the number of binary units per message; the rate of presentation of the message--the number of binary units presented per unit time; and, the statistical restriction of the message source--the maximum length run permitted. In general, over the experimental conditions examined, the information transmitted increased as: the length of message increased, as the rate of presentation decreased, and, as the statistical restriction upon the message source decreased. More important, however, were the interactions among the several variables. These interactions may be accounted for by a few assumptions regarding the recoding operations reported by the subjects. While these assumptions are entirely reasonable, it is concluded that a further continuation of this type of indirect analysis of encoding operations will not be fruitful. Rather, a direct examination, of encoding operations e.g., as performed by Miller and Smith, appears to offer a more promising hope for elucidation of these operations.

Coonan, T.J. & Klemmer, E.T. INTERPOLATION AND REFERENCE MARKS IN READING A LINEAR SCALE AT BRIEF EXPOSURES. *AFCRC TR 55-3*, March 1955, 9pp. Operational Applications Lab., *USAF Cambridge Research Center*, Bolling AFB, Washington, D.C.

The study reported here was designed to investigate the relation between reading accuracy and the number of reference marks under conditions of brief exposure. Observers were asked to locate a point on a horizontal line with the aid of differing numbers of vertical reference marks. The scales used were line segments with 1, 2, 4, 8, 16 or 32 divisions indicated by vertical marks. The stimuli were presented tachistoscopically for exposure durations ranging from 0.02 sec. to 0.64 sec. The results may be summarized as follows: a) For 0.02 sec. exposure the addition of more than one reference mark does not materially increase scale reading accuracy. b) For exposure times of 0.04 sec. and longer the addition of quarter point marks improves accuracy over that for the scale with the center point only. c) At 0.04 and 0.16 sec. exposures the addition of eighth point or finer marks decreases accuracy from the level obtained with quarter point marks. d) At 0.64 sec. there was improvement in accuracy as scale marks were added through the addition of eighth point markers.

Pollack, I. & Klemmer, E.T. VISUAL NOISE FILTERING BY THE HUMAN OPERATOR: II. LINEAR DOT PATTERNS IN NOISE. AFRC Tech. Rep. 54-15, July 1954, 12pp. USAF Cambridge Research Center, Operational Applications Lab., Bolling AFB, Washington, D.C.

The filtering of information by the human operator was investigated. Ss had to detect vertical dot patterns (signal) which were presented with extraneous dots (noise) for controlled time durations. Findings: a) the precision of localization of the 2-dot pattern deteriorates as the number of noise dots added to the figure is increased. The function is approximately linear; b) improved performance resulted when the exposure duration was increased to 1-2 sec. or when 2 successive 1/40 sec. exposures were presented with a time separation between flashes of about 1 1/2 sec.; c) for a given number of noise dots, the response uncertainty decreases as the size of the signal pattern increases; d) the effect of internal grid lines was small. The experiment demonstrated that information transmission through noise may be improved by selecting noise resistant subclasses. It has also been shown that transmission obtained with any subclass will be less than that submitted by the parent class. (HEIAS)

Pollack, I. & Klemmer, E.T. THE ASSIMILATION OF VISUAL INFORMATION FROM LINEAR DOT PATTERNS. AFRC Tech. Rep. 54-16, July 1954, 11pp. USAF Cambridge Research Center, Operational Applications Lab., Bolling AFB, Washington, D.C.

The transmission of information from a simple linear display was investigated. The stimuli were patterns of filled and unfilled outlines (a binary or two-valued code) arranged along a line. These stimulus patterns were presented visually for short exposure durations to Ss who attempted to reproduce the pattern. Findings: a) the information transmitted with this linear display increased as the number of filled spaces was increased to 4 (out of a possible 8), and decreased thereafter; b) errors in the reproduction of the display were systematic rather than random; c) marked serial position effects were obtained for short exposures; d) as the duration of exposure of the display was increased, the information transmitted per stimulus presentation was increased; e) a comparison of the informational transmission obtained with simple linear and area displays suggests that the cardinality (i.e. the number of independent dimensions along which each element of the display varies summed over all independently varying elements) may determine the information transmitted under a given set of conditions. Mangelsdorf, J.E. VARIABLES AFFECTING THE ACCURACY OF COLLISION JUDGMENTS ON RADAR-TYPE DISPLAYS. Contract AF 33(616) 43, Proj. 5 (7 7192), Tech. Rep. 55-462, Dec. 1955, 51pp. USAF Wright Air Development Center, Wright-Patterson AFB, Ohio. (Aviation Psychology Lab., Ohio State University & Ohio State University Research Foundation, Columbus, Ohio).

The psychophysical method of adjustment was employed by 4 subjects who made a total of 4480 judgments. The task for a subject was to look at a pair of converging trials projected on an opal-glass screen and to adjust the position of one of the trials so as to produce a "collision" situation. The use of 3 variables (target speed, distance-to-go, and angle of convergence) resulted in 112 unique problems. Each observer made 10 successive judgments of each of these problems. Constant, average, and variable errors were calculated for each problem and were pooled for the 4 subjects. The resulting functions were markedly regular, and the constant and average error functions were nearly identical. A mathematical model was developed to relate variable error and the 3 experimental variables of speed, distance, and angle; this model provides a theoretical framework for relating the findings from several earlier empirical studies. Both general and applied aspects of the mathematical model are discussed.

Lathan, F. LINEAR DECELERATION STUDIES AND HUMAN TOLERANCE. FPRC-1012, NRL 106950, June 1957, 15pp. RAF Institute of Aviation Medicine, FPRC, Farnborough, Hants, England.

The limits of physiological tolerance to linear deceleration lasting 0.2 to 0.4 secs. have been assessed for Ss wearing 4 types of Service torso-restraining harnesses without limb restraint. A combined harness alone, which is proposed for use in Service aircraft, should give protection up to 17 g, but above this figure serious injury is likely. If additional leg-restraint is employed, it is considered that the safe limit may be raised to at least 20 g. Above this figure arm, leg and head restraint, and a jerkin harness should give protection up to 25 g. Attention is drawn to the possible mechanism of injury to the larynx, face and chest. Peak intra-abdominal pressures of 450 mm. Hg. at 12 g have been recorded in a test S. When the test Ss were relaxed prior to impact a protective extensor response in the lower limbs tending to brace the S against the rudder pedals was not detected less than 100 msec. after impact.

Craig, K.J.W. THEORY OF THE HUMAN OPERATOR IN CONTROL SYSTEMS. I. THE OPERATOR AS AN ENGINEERING SYSTEM. Brit. J. Psychol., 1947, 38, 56-61. (Applied Psychology Research Unit, Medical Research Council, University of Cambridge).

11
A series of preliminary experiments are presented which were designed to determine whether an operator responds to a continuous series of stimuli by utilizing intermittent or continuous control operations. Having found that operators respond intermittently, an experiment was designed to evaluate the psychological refractory period occurring with successive stimuli presentation. Twelve subjects performed a tracking task in which time interval and direction (of stimuli presentation) were varied. Theoretical results were plotted and compared to the actual results in terms of initial reaction time and the duration of interval between response to initial and subsequent stimulus. Conclusions are drawn concerning response oscillation as a function of refractory period. T. O. R 4

8508
Within the general context of the theory of the human operator in control systems, this article discusses the operator as an engineering system. The human operator's behavior is seen to parallel that of the intermittent correction curve. Primary intermittent corrections which consist of "ballistic" movements (i.e., movements with predetermined time pattern which are triggered off as a whole) are compared with those of the human operator. Counteracting processes which tend to make controls seem continuous and the stimulation of the human operator's behavior by means of electrical models represent two additional topics of discussion.

afford, E. & Hansel, C.E.H. THE IMPRESSION OF DEPTH IN PROJECTED PHOTOGRAPHS. Brit. J. Psychol., 1953, 44, 127-131. (University of Manchester, Manchester, England).

A series of 12 wooden blocks was made of square cross-section, varying in depth from 1/2 to 8 in., one of which was a perfect cube. The blocks were photographed in order of increasing size in an oblique position to the camera with a normal 2 in. Elmar lens and then with a 4 in. Triplet to give an image of the same size image on the screen. Positive film strips were made from these and used in the experiment. At each of the 5 viewing distances, 3, 6, 12, 18, 24 ft. from the screen, readings were taken using the limiting method of psychophysics to determine the point of subjective equality to a cube in the 2 series of photographs. From the data, the following were calculated: a) the percentage error of estimation of the depth of the cube; b) the interval of uncertainty; c) the movement or anticipation error. At 3 ft. from the screen the Ss experience considerable loss of depth, and this loss diminishes as distance from the screen increases. For an average audience viewing photographs taken with a normal angle lens, estimation of depth becomes reasonably accurate when viewing distance is greater than 12 ft.

Mansel, C.E.H. APPARENT MOVEMENT AND EYE MOVEMENTS. *Brit. J. Psychol.*, 1953, 44, 145-155. (University of Manchester, Manchester, England).

Apparent movement may be due to inability of the visual mechanisms to provide, under the stimulus conditions in which they are obtained, physiological cues which differ from those evoked by moving objects. Experiments have been carried out which show that intermittent excitation of a large area of the retina at a suitable frequency may produce inhibition of response on a small area intermittently illuminated at a similar frequency but out of phase. Such an inhibition effect is capable of reducing the physiological cues produced by real movement so that they are similar to those produced under stimulus conditions for apparent movement. It is postulated that not all the information provided by excitation of the retina under conditions of real movement is utilized by the brain. This seeming deficiency is thought to be due to a mechanism of use in providing increased efficiency of vision by suppressing signals from the retina which are produced during eye movements.

Broadbent, D.E. NOISE, PACED PERFORMANCE AND VIGILANCE TASKS. *Brit. J. Psychol.*, 1953, 44, 295-303. (Applied Psychology Research Unit, Cambridge, England).

A 5-choice reaction task was set to Ss under the same conditions as a vigilance task, that is with the S working alone in a monotonous environment without cigarettes or watch. One group of 9 Ss worked under these conditions 'unpaced'. Another group, of 6 Ss, worked 'paced'. It was found that in the paced condition the output of correct responses fell off after 10 min. work, while in the unpaced condition there was no decrement in output till nearly an hour had gone by. In the main experiment, 18 Ss worked at the task unpaced, for half an hour on each of 2 successive days. One day the room was quiet, while on the other day it contained a steady noise of high intensity. The previous results were confirmed for the first day under either condition but pauses ceased to show a decrement in performance with time on the second day; wrong reactions, however, continued to show one. Such errors were far more frequent in noise than in quiet, the average increase being more than half of the number occurring in quiet.

Graham, Morah Z. MANUAL TRACKING ON A HORIZONTAL SCALE AND IN THE FOUR QUADRANTS OF A CIRCULAR SCALE. *Brit. J. Psychol.*, Feb. 1952, 43, Part 1. (The Hufield Department of Industrial Health, University of Durham).

8519
To evaluate the role of choice of target in performance of tracking tasks which present the target on a circular scale, two experiments were conducted with a total of 42 subjects. Each subject was required to track a target by rotating a control knob. Each trial lasted 1 1/2 minutes. Target position was varied while all other aspects of the task were the same for both experiments. Speed and accuracy of tracking were evaluated as a function of position of target (in one of the four quadrants of the circular scale).

Argyle, M. METHODS OF STUDYING SMALL SOCIAL GROUPS. *Brit. J. Psychol.*, 1952, 43, 269-279. (University of Cambridge).

8521
The author presents an extensive review and discussion of the techniques utilized in the investigation of small social groups. The design of small-group experiments is treated in terms of the types of conditions varied and those held constant. Errors inherent in the process of generalizing the results of laboratory studies are specified. Finally, a brief survey of experimental research is presented and conclusions are drawn concerning the general status of small-group research.

Poulton, E.C. THE BASIS OF PERCEPTUAL ANTICIPATION IN TRACKING. *Brit. J. Psychol.*, 1952, 43, 295-303. (University of Cambridge).

8522
This article presents the results of experiments designed to investigate the source of information used in perceptual anticipation in tracking and to evaluate the deficiencies of the one-pointer display. Twelve subjects performing with a two-pointer display were given varied pre-exposures of the display to provide a cue in terms of speed of pointer movement. In experiment II speed cues were minimized and course anticipation emphasized. To evaluate the one-pointer display, subjects were required to counteract a harmonic stimulus movement using positional control with either one or two additional pointers being introduced during different phases of the task. The results are treated in terms of the primary aspects of information necessary for optimal perceptual anticipation and the principal deficiencies of one-pointer displays. III - 831

8523
Howarth, E. THE ROLE OF DEPTH OF FOCUS IN DEPTH PERCEPTION. *Brit. J. Psychol.*, 42 (1/2), 11-20.

An experiment to investigate the effects of varying the field illumination on the acuity of distance discrimination was attempted using 3 vertical white rectangles, with the central one movable towards and away from the observer who viewed them through a rectangular reduction tube. 12 OS were tested binocularly and it was found that, contrary to what might have been expected from visual acuity results, the lower illumination levels gave greater acuity of depth perception (smaller constant errors). An explanation in terms of depth of focus was put forward, i.e. that the small depth of focus (due to larger pupil aperture) produced in the lower illumination levels, caused the central movable rectangle to move more easily out of focus with the fixed side rectangles, so that distance differences were, on this count, more easily perceived. Visual acuities were also measured and the resulting rank correlations between V.A. and D.P. seemed to verify the main result in that they were largest (positively) in the central ranges. Visual acuity was measured both before and after the main depth perception task and slight, but clearly noticeable, decrements in visual acuity were found, due to the intervening optical work involved.

Graham, Morah Z., & Dexter, I.G. & Brown, R.C. MANUAL TRACKING IN RESPONSE TO THE DISPLAY OF HORIZONTAL, VERTICAL AND CIRCULAR SCALES. *Brit. J. Psychol.*, 1951, 42 (1/2), 155-163. (University of Durham, Hufield Dept. of Industrial Health, Durham, England).

An apparatus is described for studying the speed and accuracy of manual tracking in response to a displayed scale arranged either as a vertical or horizontal strip or as a circular dial. The scales are comparable in every respect except that of shape. The apparatus consists of a display and control panel, a cam follower which introduces disturbances of known and easily adjustable characteristics and a multiple ink recorder. The task is to sit in front of the control and display panel and to maintain the pointer setting on a given scale reading notwithstanding the disturbances which are introduced. The graphic record of speed and accuracy is converted into figures by a special mechanical device which measures the lengths of time for which errors of given magnitude are exceeded. It is concluded that in a tracking task of this nature, with a circular control knob, the speed and accuracy of the S's reaction is significantly better in response to the horizontal scale than to either of the other 2 displays. A record is kept of the number of times the control knob is turned the wrong way in the attempt to counteract a disturbance. Significantly fewer mistakes are made in response to the horizontal scale.

Gunter, R. BINOCULAR FUSION OF COLORS. *Brit. J. Psychol.*, 42(4), 363-372. (Medical Research Council, Vision Research Unit, London, England).

The experiments reported in the literature show great individual variations in the ability of observers to fuse colors and the results obtained seem in no small measure dependent on the experimental method. This paper reports several methods by means of which fusion was obtained. The following points emerge from the above investigations: a) Immediate binocular fusion of colours has been found to result on using appropriate methods, 3 of which are discussed in this paper. b) Yellow fusion could be obtained with ease in all Ss by using fields of less than 2°; conditioning to yellow light, using the galvanometer deflexion of the P.G.R. as an index; and by rhythmic binocular stimulation. c) The effects on yellow fusion of binocular stimulation with red and green lights has been investigated quantitatively by stimulating both eyes simultaneously; and by stimulating both eyes alternately. With this method, special regions of stimulus frequency were found which gave optimal fusion effects. The effect of stimulus size and stimulus intensity on these special stimulus frequencies was determined, and it was found that increase in both these variables had the effect of causing a rise in the frequency of stimulation at which colour fusion occurred.

8547 Hubbard, H.H. & Lassiter, L.W. SOME ASPECTS OF THE AIRCRAFT NOISE PROBLEM. *Aero. Engng. Rev.*, July 1952, 11, 28-33. (USAF Langley Aeronautical Lab., NASA, Langley Field, Va.).

Presented at a meeting on aircraft design, 3 aspects of the aircraft noise problem are considered: physical characteristics, effects on speech and hearing, and protection from noise. Propeller noise, noise from a pulsing flow, noise from jets, and noise from turbo-propeller units are analyzed and compared. Masking of speech is a common result of noise. Hearing losses may occur in persons who are working close to the noise source. Hearing loss is a function of intensity and duration of noise. Protection can be achieved by spatial isolation, soundproofing, and personal protection. (HEIAS)

Luft, U.C. PHYSIOLOGICAL ASPECTS OF PROLONGED FLIGHT AT HIGH ALTITUDES AND SURVIVAL IN EMERGENCIES. *Aero. Engng. Rev.*, 1953, 12(4), 56-60. (USAF School of Aviation Medicine, Brooks AFB, Tex.).

Presented at a meeting on aviation medicine. There is an astonishing degree of individual variation in tolerance to stress and in the range of adaptability. A temperature regulatory system is essential in aircraft to keep the temperature and humidity within the comfort zone. The following minimum cabin pressures are recommended: 10 lbs per sq. in. if the O₂ equipment cannot be used, 6 lbs per sq. in. when supplementary O₂ is used, and 3 lbs per sq. in. when pure O₂ is inhaled. The effects of decompression depend on the magnitude and rate of pressure change. Gases tend to expand affecting the intestines and the lungs. Hypoxia may lead to unconsciousness. The development of ejection seats poses a number of physiological problems. (HEIAS)

8554

Byrnes, V.A. VISION AT HIGH SPEED AND ALTITUDE. *Aero. Engng. Rev.*, 1953, 12(4), 61-64. (USAF School of Aviation Medicine, Brooks AFB, Tex.).

Presented at a meeting on aviation medicine. Visual problems at high altitudes and high speed are discussed. Above 120,000 ft. eye protection is necessary because of damaging rays in the 288-292 micron band. As one ascends, the greater the altitude, the less scattering of light there is. The sky appears darker, and there is less light on the instruments and inside the cabin. It becomes much more difficult to see another aircraft. Light-reflecting paint should be used in the cockpit to reflect the light that is present on the instruments. Also of benefit would be the use of high-intensity instrument lighting and filters in front of the eyes. Hypoxia should not interfere with vision but decompression may black out areas of the visual field. High speeds of up to 2000 mph may pose the following visual problems: a) effect of slanting optical surfaces, b) visual distortion produced by shock waves, c) vibration, d) lag in visual perception, e) effects of acceleration, f) high temperature, and g) high-speed escapes. These factors should be considered in the design and operation of high-performance aircraft. (HEIAS)

Connerwell, W.R. & Thomas, M.Y. ARMY'S TRAINING FILM PRODUCTION PROGRAM AND A DESCRIPTION OF U.S. NAVAL PHOTOGRAPHIC CENTER FILM REPORTING FACILITIES AVAILABLE TO COMMERCIAL FILM AND TELEVISION AGENCIES. *IN: J. L. SHER, Ed. 1952, 22, 49-57. (Naval Photographic Center, Annapolis Air Station, D.C.).*

3096

This article presents a detailed description of the Army's training film production program. Discussed are such topics as the need for training films and the technique of production, distribution and procurement of such films. Also included is a description of the facilities and services of the Navy Photographic Center which are available to the film and television industries.

3097

Hoban, C.F. & Moses, J.A. GAGE FILM PRODUCTION TECHNIQUE. *IN: J. L. SHER, Ed. 1952, 22, 195-204. (U.S. Photographic Service Div., Washington, D.C.).*

3097

This article describes the application of educational and psychological principles to the production of training films as a means of increasing the effectiveness of the film and at the same time reduce production time and costs. Discussed are such topics as story treatment, preproduction planning, and the Cameo technique (a method of film production). The results of applying these techniques to the production of an experimental film, "How to Operate the Army 16mm Sound Projector Set," are discussed in terms of film effectiveness and audience reaction.

Allee, E.F. SIGNAL CORPS MOBILE TELEVISION SYSTEM. *IN: J. L. SHER, Ed. 1952, 22, 462-471. (USA Signal Corps Photographic Center, Long Island City, N.Y.).*

3099

This article presents a brief description of the Signal Corps' mobile television system. A complete television unit capable of carrying the training and operational requirements of the Army is described in terms of each of its five components: a transmitter bus, a transmitter power bus, a receiver power bus, and a kinescope recording box. A description of an actual utilization of the unit to telecast a particular program is also included.

The filmograph, a film strip with synchronized commentary on a sound track, is described. Glass color transparencies for use at trade show exhibits and sales meetings are mentioned also.

8621

Sales Management. USE OF FILM. HOW TO SHOW...GIVE TO KITH & KIN. Sales Mgmt. Dec. 1950, 47, 42-43.

8621

This article presents a brief description of the utilization of charts as a technique of solving problems of communication and education in industry. Several illustrations are offered.

8622

McLure, R.F. COLOR INSERTS: THE BASIS FOR ADVERTISING ADVERTISING? Sales Mgmt. Jan. 1951, 46, 52-54.

8622

This article presents a brief description of the utilization of color inserts as a technique of focusing attention to advertisements. The results obtained with various types of color inserts (e.g., black and white vs. color, heavy vs. light paper, etc.) are discussed in terms of increase in readability.

8625

Sales Management. COLOR ADVERTISEMENTS GET WITH RECEPTION. Sales Mgmt. June 1954, 72, p.72.

8626

This is a brief review of a study conducted by National Analysis, Inc., and concerned with the effectiveness of color and black-and-white advertisements in achieving high readership. The effect of the position of the advertisement in a magazine is also discussed.

8628

Fuller, R.S. SLIDES AND FILMS: MULTI-PURPOSE TOOLS FOR MEETING. Sales Mgmt. April 1952, 48, 12-14.

8628

This article presents a brief description of the utilization of visual aids such as slides, filmstrips, and films in promoting commercial sales. Some of the specific effects discussed concern the communication of information about a product, the instruction of salesmen, the indoctrination of personnel, and so forth.

8629

Sales Management. THE RECORDER AND THE MOVIE ARE MODERN SALES TRAINING "EXERCISES". Sales Mgmt. June 1950, 46, 120-121.

8629

This article describes the application of wire recorders and movie films to the salesmanship training course at Rutgers University. The particular effects of each of these devices upon the general training program is briefly discussed in terms of facilitated achievement of training goals.

8631

Sales Management. TOOLS FOR SELLING: VISUAL AIDS GET FIRST AID. Sales Mgmt. Jan. 1954, 72, 62-64.

8631

A conference, attended by representatives of various manufacturing firms, on the improvement of visual aids in selling is described. Examples of benefits to sales provided by the conference are given.

8632

The Maddy Infotrainer. INFOTRAINER: DISTRIBUTION OF NEW YORK CITY SCHOOL. The Maddy Infotrainer, Feb. 1953, 148, p.486 & p.494.

8632

The use of the Infotrainer, a device that provides "behind-the-wheel" training in driving an automobile. In New York schools is discussed. A series of 22 films implement practice in the Infotrainer.

8633

The Maddy Infotrainer. AIDING THE STUDENT WITH SENSORY PERCEPTION. The Maddy Infotrainer, Inc. 1953, 148, p.486.

8633

The advantages of using the Infotrainer, a device for providing "behind-the-wheel" instruction in driving an automobile to 15 pupils simultaneously, are discussed. Training situations to be met by the driver are projected on a motion picture screen.

8634

Kiser, E. AUDIO-VISUAL AIDS AND ADDITIONAL TRAINING. The Maddy Infotrainer, Inc. 1952, 46, 225-232.

8634

The function of audio-visual aids (sound films, slides, sound films, and television) in various fields of vocational training: general education of apprentices, specialized training of adults, mental hygiene is discussed. Principles of use for optimal effect—e.g., verisimilitude, simplification—are delineated.

8635

Archives Forum. SOUND AND MOVIE FEATURES EQUIPMENT HAS A NEW PLACE IN EDUCATION: PROGRESS AT THE CLASSROOM LEVEL. Arch. Forum. Oct. 1949, 51, p.156 & p.234.

8635

The increasing use of audio-visual aids in the classroom is noted, and implications of this trend for the architecture of schools are detailed—e.g., the necessity of providing adequate electrical outlets, containing, central sound systems, ventilation systems.

8639

Moore, G. CURTISS-WRIGHT ELECTRONIC SIMULATOR. Aero Digest, Sept. 1952, 55 (3), 64-66. (Curtiss-Wright Corporation).

8639

The function of simulators in flight training is discussed. The Curtiss-Wright Debnel Flight Simulator is described, and the aircraft characteristics—e.g., attitude, airspeed, altitude—and emergency conditions—e.g., defective oil pumps, carburetor ice—that it duplicates are listed.

8653

Aero Digest. LINK FOR THE JETS. Aero Digest, Feb. 1950, 60, 36-37.

8653

The Linktronic (Link jet aircraft simulator) is described. Examples are given of simulated conditions that may be presented to the student pilot. The navigational aids that are available in the simulator are noted.

An all-weather radio-aid unit that simulates electronically VOR (radio-aid), DME (distance measuring equipment), and ILS (instrument landing system) is described. Special controls and indicators available to the instructor are listed.

8658
Aero Digest. TRAINING C-124A CREWS. Aero Digest, Jan. 1952, 62, 17-19.

8658
The training curricula and entrance qualifications for pilots, flight engineers, and loadmasters at the Heavy Transport Training Unit (which trains aircraft and maintenance personnel for the Douglas C-124 Globemasters) are summarized.

8660
Emerson, C.R. PRONE FLIGHT VISION. Aero Digest, May 1953, 66(5), 98-101. (Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio).

8660
This article describes the results of research on two aspects of prone position flight: physical discomfort and visual limitations. Particular emphasis is placed upon the problems and requirements of prone flight vision. Among the visual aspects, the following are discussed in detail: the extent of direct visual field available under prone flight conditions, the incidence and role of visual fatigue, and the physiological visual capacity of the person in the prone position.

8663
Meln, D.R. SELECTING AND TRAINING FORK-TRUCK OPERATORS. Mech. Engrg., Jan. 1952, 76, 568-572 & 1033-1034. (Myster Company, Portland, Ore.).

8663
This is a discussion of the selection and training of operators of fork trucks (self-powered lift trucks). Visual acuity scores and scores on the American Automobile Association tests as criteria for selection are noted. A five-day training curriculum—including, e.g., instruction in handling of materials, in preventive maintenance, and in basic procedures—is outlined. A list of suggested props—e.g., truck parts, scoring sheets, crates, graduation certificates—is presented.

8673
Wilkinson, G.D. APPLICATION OF STATISTICAL TECHNIQUES IN TIME STUDY. Mech. Engrg., Nov. 1951, 75, 906-909. (George D. Wilkinson and Company, Oceanport, N.J.).

Time study replaces subjective opinion with scientifically determined facts about rates of working. Mathematical methods are, however, neglected in both current methods: leveling and rating, and they lack scientific validity. Statistical techniques have been developed for use in time study. Its advantages are discussed and the application of the method is demonstrated. (MEIAS)

8675
Davis, L.E. HUMAN FACTORS IN DESIGN OF MANUAL MACHINE CONTROLS. Mech. Engrg., Oct. 1949, 71, 811-815, 837. (University of California).

8675
This study reflects an attempt to determine the essential factors relevant to optimum control and speed of usage of handwheels, cranks, and crossbars (under the specific condition of single settings of indicators within close tolerance limits). Data were collected on nine subjects who made settings with constant and accuracy of operation held constant while type of control device (handwheel, crank, or crossbar), size of control device, work load (torque), and control device location (in relation to operator) were varied. Both time and graphic records for each subject were obtained. The results are presented and discussed in terms of the relative accuracy of performance manifested under each of the varied conditions. Conclusions are drawn concerning the requirements of control size, type, etc., for optimal performance. T. O. I. R 7

8676
Bogolis, E.F. LIMITS OF FACTORS OF SAFETY IN THE HUMAN BODY. Mech. Engrg., July 1946, 68(7), 615-627. (Cornell University Medical College, New York, N.Y.).

This paper discusses man's physiological limits relative to the development and design of machines, particularly aircraft. Examples of the effects of speed, rapid pressure changes, forces, G supply and extreme temperatures are considered. (MEIAS)

8677
Randall, F.E. SEAT COMFORT. Mech. Engrg., Dec. 1946, 68, 1056-1058. (Office of the Quartermaster General, Washington, D.C.).

8677
In this article on seat comfort the author presents a discussion of the theory of seating (and its implications for seating design), the primary causes of fatigue, the design factors related to eliminating discomfort, the methods of seating analysis, the implications for seating of cockpit design, and the principles involved in meeting actual seating requirements. The contributions of seating research and the problems as yet not investigated are described in detail. Contemporary methods of research are seen as important factors in the resolution of problems of seating.

Knappe, C.J., & Whitson, L.S. POWER AND VELOCITY DEVELOPED IN MANUAL WORK. *Arch. Engrg.*, May 1943, 62, 383-389. (University of Minnesota, Minneapolis, Minn.)

8695
Mollipise, C.S., & Hood, J.D. THE SPEED OF THE SLOW COMPONENT OF OCULAR NISTAGMUS INDUCED BY ANGULAR ACCELERATION OF THE HEAD. *Proc. Roy. Soc. Lond., Ser. B.*, 1953, 151, 216-230. (Medical Research Council, National Hospital, Queens Sq., London, England).

8678
To determine the types of motions which permit maximal development of velocity and horsepower in manual work, six subjects ranging in age from 21 to 30 years were required to accelerate a series of weights (6, 9, 12, 15, 18 and 21 lb.) with their right hand. Determinations of velocity and horsepower were made along with an analysis of six types of hand motion (e.g., long forehand sweep from right to left with arm extended, etc.). Path and time of travel of weights were recorded electrically. A camera recorded motion paths. The resultant data are treated in terms of velocity and horsepower development as a function of weight accelerated, type of motion, and individual differences.
G. I. R I

8695
This study attempts an experimental determination of the slow component of ocular nystagmus (induced by angular acceleration of the head). Utilizing a revolving chair (of improved design) and the technique of flashing a small light spot (while seated in darkness), data were collected on subjects under varied conditions of acceleration. The experimental results are presented along with theoretical arguments in support of Graybiel's hypothesis, i.e., ocular nystagmus is dependent upon vestibular eye nystagmus. In addition, the data are applied to the physical theory of the cupular mechanism (Steinhausen).

8688
Schlanger, B. THEATER AUDITORIUM-SEATING PLANS FRESHLY CONSIDERED. *Arch. Engrg.*, June 1944, 62, 505/6.
Recommendations are made to improve seating plans in the design of new theaters. The deficiencies of current practice are discussed and illustrated. 2 longitudinal aisles are advocated. In addition, the spacing between 2 rows should be changed from 36 to 40 in. Alternate plans are given for cities where code interdictions would apply to the preferred plan. (HICIAS)

8697
Schott, L.O. SIGNAL TRANSLATION IN HEARING. *Bell. Lab. Res.*, Jan. 1953, 32, 2-8.

The hair cells of the inner ear behave like small generators that produce electric pulses when set in motion. The process involves chemical, mechanical and electrical operations. An electrical circuit analog of a single hair-cell unit was designed. It contains a saw-tooth oscillator which pulsates at a rate according to the intensity of the input signal. The adaptation of nerve fibers was simulated by using negative feedback. Having certain information about the general features of the overall pulse patterns sent toward the brain, and using the results of studies with the single analog hair-cell unit, it appeared possible to construct a detailed overall pulse pattern for each sound encountered. The processing employed in the ear evidently puts all of the salient information about a sound in terms of the occurrence positions of the generated uniform pulses. (HICIAS)

8696

Keller, A.C. SONAR DETECTION BY SONAR. Bell Lab. Rec., Feb. 1947, 25, 55-56.

The term sonar applies to underwater sound devices for listening, echo ranging, and locating obstacles. Acting as a listening device it can determine the bearing of a source of noise or signal within the frequency range from 10 to 30 KC. In addition, a trained operator, by listening to the sounds, can estimate the type, size, and speed of the source. By echo ranging, it can determine the range and bearing of submerged objects such as submarines. Its telegraph facilities permit it to communicate with nearby vessels provided with suitable equipment. A detailed description is given of an apparatus for the QM system. (M145)

Management Review. FACTORS IN EFFICIENT OFFICE LAYOUT. Manag. Rev., 1951, 42, 458-469.

8710

This article presents a brief description of a series of factors which are considered as important in planning an efficient office layout. Included are such aspects of space utilization as the following: width specifications for aisles or passageways, the utilization of wall partitions, desk placement, file arrangement, and so forth.

8717

Nistley, H.R. IS THERE AN IDEAL FACTORY CHAIR? Management Rev., March 1952, 41, 175-176.

8717

On the basis of a four-year study of various types of factory chairs, the author presents specifications for the ideal factory chair in terms of four primary considerations of chair design: comfort, safety, maintenance, and adjustability. An illustrative example of a chair meeting the requirements of all four factors is presented.

8715

Ryter, E.D. NOISE AND WORK PERFORMANCE: HEAT RESISTANCE HEARLY SECTS. Management Rev., 1950, 41, 511-12.

8718

This article presents a brief summary of the results of the relationship between noise and work performance. Included are the experimental findings concerning with the effect of noise on the following aspects of performance: reaction time, learning, intelligence tests, psychomotor tests, communications, subjective feelings, and physiological changes.

8721

Research Institute of America, Inc., New York, N.Y. APPRENTICE PROGRAM: TODAY'S BEST TRAINING TOOL. Manag. Rev., Feb. 1953, 42, 72-73.

8721

This article presents a brief discussion of the apprenticeship training program used in industry to solve the problem of skilled worker shortage. The advantages of such programs are presented along with incidental information concerning their establishment.

8723

Birren, F. COLOR: SOME FACTS ABOUT CONSUMER PREFERENCES. Management Rev., March 1953, 42, 166-167. (Monsanto Chemical Company).

8723

This article presents a brief discussion of several factors involved in consumer color preferences. Varietal fluidity, amount of sunlight, are some of the factors which are described. The effect of particular colors and the phenomenon of color trends are also discussed.

8730

Davis, L.E. & Josselyn, P.D. HOW FATIGUE AFFECTS PRODUCTIVITY: A STUDY OF MANUAL WORK PATTERNS. Personnel, July 1953, 39, 54-59. (University of California).

8730

To evaluate the effects of fatigue upon productivity, the performance of two experienced operators on a light assembly operation was recorded in terms of average daily production, speed of operation, and types of delays. Changes in these aspects of productivity are analyzed with reference to such aspects of fatigue as time of day, day of the week, introduction of rest period, etc. Three hypotheses concerning the physiological and psychological aspects of extended performance are offered. G. R. 5

8732

Kent, R.F. CONDITIONING EXPERIENCES FOR INCENTIVES. Manag. Rev., Feb. 1950, 39, 66-68. (Western Electric Corporation, Pittsburgh, Penn.).

8732

The author discusses the utilization of incentives in industry in terms of a need to condition employees for such programs. The primary objectives of such a process are presented along with specific recommendations concerning its institution.

8741

Management Review. USE OF COLOR IN CLERICAL WORK. Manag. Rev., Dec. 1950, 39, 703-704.

8741

This article discusses the role of color utilization in clerical work. Color is described as an effective means of reducing strain in perception, aiding retention, and, with specific reference to the clerical task, as a means of document differentiation, form identification, etc. Color is also seen as a technique for increasing legibility. Specific recommendations are presented with regard to the effective use of color outlines in clerical tasks. T

8746

Stevens, S.S. ON THE BRIGHTNESS OF LIGHTS AND THE LOUDNESS OF SOUNDS. Science, Nov. 1952, 118, 576. (Harvard University).

8746

The author presents a brief discussion of the brightness and loudness attributes of visual and auditory sensation in which he describes the techniques and results of experimentation concerned with the nature of these attributes. Similarities between brightness and loudness are noted.

8747

Hardy, J.D., Coocrell, Helen & Wolff, H.G. INFLUENCE OF SKIN TEMPERATURE UPON PAIN THRESHOLD AS EVOKED BY THERMAL RADIATION. *Science*, Aug. 1951, 114, 149-150. (Cornell University Medical College, Ithaca, N.Y.).

This paper summarizes 2 experiments performed to investigate quantitatively the matter of the phenomenon of cutaneous analgesia induced by reduced skin temperature. The first experiment involved 4 Ss and the second involved 2 Ss. The results indicated a linear inverse relationship between skin temperature and pain threshold as evoked by thermal radiation. The close relationship between tissue damage and noxious stimulation can be inferred from the experiments, thus significantly supporting the concept that the adequate stimulus for pain is tissue injury. (HEIAS)

Turk, A. & Bonnes, K. INADEQUATE STIMULATION OF OLFACTION. *Science*, Aug. 31, 1951, 114, 234-236. (V.B. Connor Engineering Corp., Danbury, Conn.).

Several workers in the field of olfaction have reported difficulties in obtaining test spaces for research purposes with an absolute zero level of odor. Such spaces are needed in olfactory research to serve as control rooms for comparison with test rooms of low odor levels, to act as reservoirs for the introduction of odors near threshold concentrations, and for the operation of odor test panels. The use of activated carbon as an air-cleaning device to remove all sources of olfactory stimulation from a test space can be successfully carried out provided certain precautions, as described, are taken. In the absence of such measures, a test space in which air has been purified by activated carbon sorbents may give rise to an odor variously described as "yeastlike" or "alcoholic", which, though not unpleasant and often even unnoticed by a lay observer, interferes with an olfactory research program. The theoretical implications of this phenomenon are of great interest. We have found that the olfactory stimulation in such cases is related to an inert aerosol, and hence is an "inadequate" stimulation of olfaction in the sense that no gas or vapor is involved. Experimental generation of the odor, examination of carbon for foreign vapors, and aerosol filtration are also discussed.

Cay, L.M. & Carliner, P.E. THE PREVENTION AND TREATMENT OF MOTION SICKNESS: I. SEASICKNESS. *Science*, April 8, 1949, 109, 339. (Johns Hopkins Hospital & University, Baltimore, Md.).

This paper describes briefly several cases wherein the administration of the drug Dramamine proved to be effective in curtailing the symptoms of motion sickness stemming from motion in automobiles and airplanes. (HEIAS)

8751

Strickland, B.A. & Hahn, G.L. THE EFFECTIVENESS OF DRAMAMINE IN PREVENTION OF AIR SICKNESS. *Science*, April 8, 1949, 109, 359-360. (USAF School of Aviation Medicine, Randolph Field, Tex.).

A procedure was devised whereby one-hour flights simulating flight through turbulent air in a C-47 (DC-3) airplane were utilized. Volunteers were obtained from among individuals stationed at Randolph Air Force Base who were not on flying duty. 12 flights of 18 individuals each have been carried out to date. On each flight conditions encountered in flying through gentle and moderately turbulent air were simulated. All variable factors were either controlled or "randomized." Each group of 18 men on a flight was subdivided into a group of 9 who received a 100-mg tablet of Dramamine and another 9 who received a placebo identical in appearance. The drug or the placebo was administered concurrently from 25 to 45 mins. before each flight. Seating arrangement in the airplane was carefully controlled in that an equal number of individuals who received the drug were distributed symmetrically in the forepart and the afterpart of the cabin. The same procedure was used in seating the individuals who received the placebo. Under the conditions described above 28.7% of those given Dramamine became ill as opposed to 55.6% among those given a placebo. Dramamine appears to decrease the incidence of airsickness.

Ludvig, E. & Kinsey, V.E. EFFECT OF LONG
ULTRAVIOLET RADIATION ON THE HUMAN EYE.
Science, Sept. 1946, 104, 246-247. (Harvard
University Medical School).

8754
To investigate the effect of long ultra-violet radia-
tion upon the human eye, seven subjects were required to
fixate (with one eye) a 1,000 watt mercury arc (visible
and ultraviolet radiation shorter than 320 mμ removed
by filter) at a distance of 30 cm. Pupil light-dif-
ference sensitivity and critical flicker frequency of
both eyes were measured at five minutes and one hour
following exposure. The results are presented and dis-
cussed in terms of the statistical analysis of differences
between both eyes as indicative of the effect of ultra-
violet exposure.

Mialak, H. DECREASE OF CRITICAL FLICKER
FREQUENCY WITH AGE. *Science*, May 1951, 113,
551-552. (Fordham University).

8764
To investigate the role of age in critical flicker
frequency, 319 subjects (male and female) ranging in
age from 7 to 89 years were tested for ten days on a
flicker apparatus (with number of readings ranging as
high as 80). The data were analyzed in terms of the
mean and variability of critical flicker frequencies
for the subjects divided into four-year age groups (e.g.,
7-11, 12-16, etc.). Interindividual variability and mean
differences are discussed as a function of the neurologi-
cal process of aging.

Miles, W.R. METHODS OF USING BINOCULARS.
Science, 1952, 115, 484.

8766
This article presents a brief description of the
effectiveness of two methods of utilizing binoculars:
1) keeping binoculars constantly at eyes, and 2)
loosening field with naked eye and then utilizing binocu-
lars. Five target areas at distances varying from 1/2
to 2 miles were observed by a group of subjects using
both methods. The relative effectiveness of the methods
is discussed in terms of promptness of judgments and
case of threshold resolution.

Ulett, G.A. & Gleser, G. THE EFFECT OF EXPERIMENTAL STRESS UPON THE PHOTICALLY ACTIVATED EEG. *Science*, 1952, **115**, 678-682. (Neuropsychiatry Dept., Washington University School of Medicine, St. Louis, Mo.).

The study was aimed at investigating changes in the photically stimulated EEG in subjects whose mental state was deliberately altered under laboratory conditions. One group of 30 stable individuals and another group of 25 psychiatric patients (with anxiety as predominant symptom) were placed under an experimental anxiety-producing situation. A control group of 41 Ss were subjected to photic stimulation only. The experiment showed that the occipital rhythms induced by intermittent photic stimulation are disturbed by emotional tension. The 2 groups of experimental Ss did not show a differential decrease of response. (NEIAS)

Malstead, V.C. CHRONIC INTERMITTENT ANOKIA AND IMPAIRMENT OF PERIPHERAL VISION. *Science*, June 15, 1955, **101**, 615-616. (University of Chicago, Chicago, Ill.).

In this study 20 male Ss were exposed in a low pressure chamber to a simulated altitude of 10,000 feet above sea level for 5 or 6 hours per day, 6 days a week, for a period of 4 to 6 weeks. Peripheral vision was systematically studied. During the third or fourth week of exposure, 13 of the 20 Ss developed a marked and progressive impairment of peripheral vision. The effect was not immediately reversible. Four subjects developed impairment of peripheral vision earlier. The frontal lobe seems to be implicated in this alteration of peripheral vision. (NEIAS)

Wald, G. ON THE MECHANISM OF THE VISUAL THRESHOLD AND VISUAL ADAPTATION. *Science*, June 1954, **119**, 887-892. (Harvard University, Cambridge, Mass.).

After a review of previous studies dealing with the relationship between visual threshold and the bleaching of rhodopsin, an experiment is reported. The results suggest that a high degree of light adaptation can be achieved with very little bleaching of rhodopsin. Exposure of the eye to millilamberts for 5 sec., in raising the threshold about 8.5 times, bleaches at most 1200 molecules of rhodopsin per rod. A hypothesis is offered for the mechanism of visual adaptation based on the compartmental structure of the rod. (NEIAS)

Motokawa, K. & Ebe, M. SELECTIVE STIMULATION OF COLOR RECEPTORS WITH ALTERNATING CURRENTS. *Science*, July 1952, **116**, 92-94. (Tohoku University, Sendai, Japan).

A number of experiments are reported relating to threshold strengths of alternating currents as a function of frequencies. The sensation of flickering phosphores aroused by the current was used as an index. The minima of the strength-frequency curves are physiological manifestations of the composite nature of the retina. The relation between the frequencies of alternating currents and the wavelengths of colored lights can be studied more precisely on the basis of the fact that each minimum deepens specifically under the action of characteristic colored light. Barron, C.I. & Poole, F.E. INDUSTRIAL NOISE: ITS EFFECT AND CONTROL. Amer. J. publ. Hlth. 1952, 42, 705-710. (Lockheed Aircraft Corp., Burbank, Calif.).

The undesirable effects of noise are: the effects upon the ear and hearing, changes in organs other than the ear, and interference with speech communication. High intensity noise may rupture the tympanic membrane, or lead to a temporary hearing loss. For every individual a critical level exists beyond which complete recovery will not ensue. The safe level is between 70-90 db for daily exposures of 2-8 hrs. Interrupted noise and one associated with strong vibrations are more harmful. In any given sound field, hearing loss varies directly with the duration of exposure. Tinnitus (ringing of the ear) is an early symptom of hearing loss. General effects of noise include headache, irritability, tremors, nausea, vertigo, insomnia, among others. Loud noise leads to a diminution in working efficiency of up to 50%. Interference with speech communication leads to increased accident rates, impairs cooperation, reduces efficiency, and lowers morale. Solution to the noise problem involves elimination of the source, use of sound-absorbing materials, structural isolation, ear-protectors, detection and transfer of employees with great susceptibility, regular audiograms every 6-12 months, and loudspeakers. Yaglou, C.P., Baetjer, Anna K., Machle, W., McConnell, V.J., et al. THERMAL STANDARDS IN INDUSTRY. Amer. Publ. Hlth Yearb. Part II, May 1956, 40, 131-143.

The purpose of this report was to study the effects of temperature, humidity, and air movement on workers, and to recommend thermal standards which will provide a minimum of comfort in operational zones devoid of contaminants. A floor area of 40 sq. ft. per person with an air space of 400 cu. ft., and an operable window area of 10% of the floor area are considered minimum space allotments in workrooms. Temperature should be kept between 68° and 72°F in workrooms (75°-80° in warm weather), humidity should be below 50%. Female workers prefer temperatures about 4° higher. Outside air supply should be not less than 500 cu. ft. per person per hour for light work (1200 cu. ft. for heavy work). An effective temperature of 95° is the ceiling limit for short periods of work in the heat. Engineering and medical methods of heat control are discussed. Exposure to cold should be alternated with recuperation periods in a warmer environment as soon as generalized shivering sets in. Selection and adaptation are essential for controlling cold hazards in industry. Face masks, loose-fitting and multi-layer clothing, and electrically heated garments are available. (NEIAS)

Von Gierke, H.E. SOUND ABSORPTION AT THE SURFACE OF THE BODY OF MAN AND ANIMALS. J. acoust. Soc. Amer., 1949, 21, p55. (USAF Aero Medical Lab., Wright-Patterson AFB, Ohio).

The results of measurements of sound absorption by the body surface of man and fur-bearing animals are reported for the frequency range 100 to 12000 cps. The acoustical impedances and the absorption coefficients of the surfaces were determined from the resonance characteristics of an air-filled tube. The absorption coefficient of the human body surface varies from 10% to 0.1% and decreases at higher frequency. The resistances per cu cm vary between 10^3 and 10^5 ohms and are dependent on the area of application and the pressure on the skin and muscles. The measurements on rats show that up to 1000 cps the absorption coefficient decreases, and then increases up to 6000. The behavior below 1000 cps is determined largely by the tissues beneath the skin while the increased absorption above 1000 cps is the result of the presence of the fur. These absorption coefficients permit the estimation of the sound energy absorbed by the whole animal. (NEIAS)

8851
Knudsen, V.O. ACOUSTICS IN COMFORT AND SAFETY. J. acoust. Soc. Amer., July 1949, 21, 296-301. (University of California, Berkeley, Calif.).

The author makes a plea for quiet surroundings where people live and work. A moderate amount of acoustical designing could reduce traffic noise by 10 db. With such a reduction the problem of constructing rooms so that the noise levels in them would not exceed acceptable values could be solved at reasonable cost. The layout of rooms in an apartment house in Sweden is shown which incorporates many commendable features of acoustical design. More data should be obtained to help communities in formulating sensible standards for the control of noise. (NEIAS)

Carruthers, W.W. & Loye, D.P. BUILDING TO THE ACOUSTICAL OPTIMUM NEW MUTUAL DON-LEE BROADCASTING STUDIOS. J. acoust. Soc. Amer., July 1949, 21(4), 428-434. (Studio Div., Don Lee Broadcasting System & Electrical Research Products Div., Western Electric Company, Hollywood, Calif.).

The acoustical design and construction of the new Mutual-Don Lee Broadcasting Studios in Hollywood were done under novel and very favorable arrangements. First, a careful check was made of the optimum acoustical characteristics to which it was decided to design the studios. Some of the best auditoriums for broadcasting were measured, and from these data as well as comments regarding the excellence and shortcomings of these auditoriums, the optimum characteristics for the new studios were determined. During the course of construction, acoustical measurements were made several times for the purpose of "tailor-making" the acoustical characteristics of the studios. On the basis of the measurements, it was found that only a few minor modifications in acoustic treatment were necessary, such as changing the mountings of the Acousti-Celotex materials in order to change the low frequency absorption characteristics as desired, and the areas used of these materials. The results are, close agreement between optimum and finally measured acoustical characteristics, and very satisfactory broadcast programs.

Bolt, R.H. & MacDonald, A.D. THEORY OF SPEECH MASKING BY REVERBERATION. J. acoust. Soc. Amer., Nov. 1949, 21(6), 577-580. (Acoustics Lab., Massachusetts Institute of Technology, Cambridge, Mass.).

A general statistical theory is developed for the masking effect of reverberation on the intelligibility of words. Speech is considered a series of discrete pulses distributed statistically over a 30-db range in sound pressure level in a given frequency band. The articulation index is calculated as a function of reverberation time, using preliminary values of speech pulse lengths and spacings obtained from Visible Speech spectrograms. The percent articulation for words is then calculated from the articulation index and is compared with Knudsen's experimental values. The theoretical values agree precisely with the measured values at reverberation times less than 2 seconds and differ by less than 17% out to 6 seconds. The calculations are extended to include a combination of background noise and reverberation.

Morrow, C.T. REACTION OF SMALL ENCLOSURES ON THE HUMAN VOICE. PART II. ANALYSES OF VOWELS. *J. acoust. Soc. Amer.*, July 1948, 20, 487-497. (Harvard University, Cambridge, Mass.).

When an oxygen mask or a gas mask is worn by a talker, the distortion is much greater than would be predicted from the amount of muffling. The reaction on the voice is in part mechanical (obstruction of the flow of breath and constraining of the facial muscles), in part acoustical (addition of a new cavity). An experimental analysis is given in this paper of the distortion produced by small enclosures, as well as an evaluation of present theories of vowel production. The predictions of the theory are compared with the experimental findings. In general, predictions from the present state of the theory of vowels give a useful qualitative picture of the nature of distortion by small enclosures, but are not in quantitative agreement with experiments. The conclusion is that some of the underlying assumptions of the theory need to be modified. (MEIAS)

Rudnose, H.W., Clark, K.C., Carlson, F.D., Eisenstein, J.C., et al. VOICE MEASUREMENTS WITH AN AUDIOSPECTROMETER. *J. acoust. Soc. Amer.*, July 1948, 20(4), 503-512. (Cruft Lab., Harvard University, Cambridge, Mass.).

The distribution of average power in various speech sounds as a function of frequency has been measured with an integrating audio spectrometer. This instrument divides the electrical signal into 14 frequency bands and simultaneously records the integrated square of the amplitude in each band over a measured time interval, usually 30 seconds. From these data and the known over-all calibration of the spectrometer channels one can compute the spectral distribution of average acoustic power at the location of the input microphone. The operation of the instrument and the procedure of measurement are described. Speech spectra are given which are average results for a trained crew of 7 men, speaking into a condenser microphone in an anechoic chamber.

Fletcher, H. A METHOD OF CALCULATING HEARING LOSS FOR SPEECH FROM AN AUDIOGRAM. *J. acoust. Soc. Amer.*, Jan. 1950, 22(1), 1-5. (Bell Telephone Laboratories, Murray Hill, N.J.).

In the present paper a formula is developed for calculating the hearing loss for speech from an audiogram showing the hearing loss for each of a series of pure tones. The formula is based upon studies of loudness, including the determination of the relative contributions of different frequency regions to the audibility of speech at or near the threshold level. The formula is tested for each of 165 ears involving a wide variety of hearing losses. In every instance an audiogram is available and also an independent observation of the hearing loss for speech. The formula yields a calculated value which generally is in closer agreement with the observation than is the value calculated by the familiar rule of averaging the losses at 500, 1000, and 2000 cps. The agreement is particularly better when the audiogram is not "flat". A simplified computational rule, indicated by the more complete formula, is found within indicated limits to be almost as reliable as the formula. This simplified rule is to examine the hearing losses measured by means of the audiometer at the 3 frequencies: 500, 1000, and 2000 cps and to take the average of the 2 smallest values of loss.

Fletcher, H. & Galt, R.H. THE PERCEPTION OF SPEECH AND ITS RELATION TO TELEPHONY. *J. acoust. Soc. Amer.*, March 1950, 22(2), 89-151. (Bell Telephone Laboratories, Murray Hill, N.J.).

The intelligibility of the speech received over a communication system is usually expressed in terms of one or another measure such as the vowel or the consonant articulation, the average speech sound articulation, the syllable articulation, the word articulation, or the sentence intelligibility. The present paper establishes relationships among several of these measures and the articulation index. Relationships based upon statistical considerations are compared with the results of observations. Functions are developed which permit the calculation of articulation index and hence of articulation for communication systems which include a wide variety of response versus frequency characteristics and of noise conditions, as well as several special types of distortion. Although the treatment is predominantly empirical, the functions and processes are closely related to various fundamental properties of speech and hearing. Four principal series of articulation tests are cited in detail.

Munson, W.A. & Gardner, M.B. LOUDNESS PATTERNS--A NEW APPROACH. *J. acoust. Soc. Amer.*, March 1950, 22(2), 177-190. (Bell Telephone Laboratories, Inc., Murray Hill, N.J.).

In the past loudness patterns have been based on the masking effect of one sound on another. For complex sounds having distributed energy spectrums this method appears to be valid. For sounds with single frequency components the method is thought to be in error due to the formation of beats and modulation products between the primary tone for which a pattern is desired and the probe tone which is used to determine the pattern details. To avoid these difficulties in the present tests, the probe tone was presented after the primary tone was turned off. The resulting residual masking patterns differ in a number of important respects from patterns based on the simultaneous masking procedure. A comparison between the loudness of a primary tone, as evidenced by the magnitude of its residual masking pattern, with the results of loudness judgment tests was made. This was done by replacing the physical scales of pressure level and frequency by the subjective scales of loudness and position. A reasonably good check of computed and measured loudness values was obtained. Patterns for a 1000-cycle tone were measured to show how the loudness of the standard reference tone is distributed and how this distribution changes as the level of the tone is increased.

Munier, W.F., Slapmaker, F.M. & Merrill, L.L. THE ACOUSTIC IMPEDANCE OF CLOSED RECTANGULAR SPEAKER ENCLOSURES. *J. acoust. soc. Amer.*, March 1950, 22(2), 266-276. (Research Div., Stromberg-Carlson Company, Rochester, N.Y.).

Direct-radiator loudspeakers are often mounted with the back of the diaphragm working into a completely enclosed space. Conventional theory states that when the maximum linear dimension of such an enclosure is small compared with the wave-length, the pressure is uniform throughout, and the acoustical impedance presented to the loudspeaker is $-j\omega(V/\rho c)$, where V is the enclosed volume. Although it has not been clearly established how small an enclosure must be before it is "small compared with the wave-length," the foregoing expression is generally used, at low audiofrequencies, to calculate the acoustical impedance of closed loudspeaker housings. It is shown here that while the acoustical impedance of a closed rectangular housing is capacitive at very low frequencies, it passes through zero as the frequency increases and becomes that of an inductance as the frequency of the first normal mode is approached. For a typical housing 11 in. X 22 in. X 22 in., the frequency at which the impedance presented to a very small speaker passes through zero is in the vicinity of 70 cps; at this frequency, the maximum linear dimension of the enclosure is less than 1/7 of the wave-length. These results are obtained by using the methods given by Morse for determining the pressure distribution in a room. A point-source loudspeaker is assumed and the pressure at the source is calculated as the summation of the pressures due to the normal modes of the enclosure, losses being neglected. Measurements of the pressure within the enclosure support this analysis. From measurements of the pressure distribution over the surface of the loudspeaker diaphragm, it may be deduced that the magnitude of the acoustical impedance which the enclosure presents to the loudspeaker diaphragm and the frequency at which the impedance becomes zero depend upon the dimensions of the loudspeaker diaphragm as well as the dimensions of the enclosure.

Rowley, H.E. & Hettler, A.M. THE APPARENT SOURCE OF SPEECH IN THE MOUTH. *J. acoust. soc. Amer.*, May 1950, 22(3), 365-369. (RCA Victor Div., Government Sound Engineering Section, Camden, N.J.).

Investigation of the sound pressure on the axis of the mouth indicates the existence of a point which may be represented as the source of speech sounds. The location of this point is dependent upon the particular speech sound, the intensity with which it is uttered, and upon the frequency components under consideration. Using young, average, male speakers, this apparent source of speech was located for 18 frequency bands covering the portion of the spectrum which contributes to speech intelligibility in each of 36 fundamental speech sounds.

Ranson, V.A. & Wiener, F.M. SOUND MEASUREMENTS FOR PSYCHOPHYSICAL TESTS. *J. acoust. soc. Amer.*, May 1950, 22(3), 382-386. (Bell Telephone Laboratories, Murray Hill, N.J.).

The results of psychophysical tests on the auditory sensory system usually show much more variability than experiments involving only physical measurements of sound waves. This has resulted in the general impression that the variance of measurements of the auditory threshold and other psychoacoustic measurements is largely due to the inability of the observers to give consistent responses. This paper reports the results of a series of threshold measurements made under carefully controlled conditions and accompanied by search tube measurements of the sound pressures in the ear canals of the observers. The small variances obtained under certain conditions suggest that the large variability often times experienced in psychophysical work is partly due to inadequate techniques for measuring the levels of the stimuli that activate the sensory system.

Schubert, E.O. THE EFFECT OF A THERMAL MASKING NOISE ON THE PITCH OF A PURE TONE. *J. acoust. soc. Amer.*, July 1950, 22(4), 497-499. (University of Michigan, Ann Arbor, Mich.).

When a pure tone and a masking noise are fed into the same ear simultaneously, the pitch of the pure tone is raised. The effect is more pronounced at low loudness levels and is progressively greater as the frequency of the tone rises. Apparently the phenomenon is not present if the pure tone is 20 db or more above its masked threshold. Nineteen graduate music students served as Ss in the experiment. Control measurements were made to estimate the effects of diplacusis and of the difference in intensity between the masked and the unmasked pure tone when they were matched in loudness.

Bolt, R.H. & Doak, P.E. A TENTATIVE CRITERION FOR THE SHORT-TERM TRANSIENT RESPONSE OF AUDITORIUMS. *J. acoust. soc. Amer.*, July 1950, 22(4), 507-509. (Acoustics Lab., Massachusetts Institute of Technology, Cambridge, Mass.).

Studies of the response of an auditorium to a short tone burst have indicated that the character of the first 20 or 30 db of sound decay, the "short-term" response, is closely related to the subjective "hearing quality" of the room. Recently Haas has investigated the effect of a single echo on the subjective hearing of speech. On the basis of some of Haas' results and other information on the hearing of speech in rooms, a tentative criterion for the short-term response has been formulated as curves of amplitude vs. time delay of each reflection relative to the direct sound. The criterion correctly rank-orders subjective quality observations reported by others, and agrees quantitatively with some subjective judgments reported here.

Loeb, J. SPEECH AND LANGUAGE. J. acoust. Soc. Amer., Nov. 1950, 22, 712-717. (Columbia University, New York, N.Y.).

(Presented at the Speech Communication Conference, MIT, 1950) Speech is a selection out of a code by a source, which results in several bands of information (a ribbon concept rather than a linear concept of speech). This paper concentrates upon a few remarks on the control problems of normal speech under normal circumstances. The author thinks that the thorough knowledge of the normal situation is essential to the correct selection of abnormal cases, such as distortion of frequency and amplitude in speech, hearing in excessive noise, pathological speech, distortion of speech transmission, etc., the investigation of which, on the other hand, has contributed substantially to our knowledge of speech in general. Language exists mainly through speech, and thus only a cooperative effort of the various disciplines, such as communications engineering and physics, medicine and physiology, psychology and linguistics can achieve the solution of the problems of human speech. Lawless, A. COMMUNICATION PATTERNS IN TASK ORIENTED GROUPS. J. acoust. Soc. Amer., 1950, 22, 725-750. (Massachusetts Institute of Technology, Cambridge, Mass.).

(Presented at the Speech Communication Conference, MIT, 1950) When the nature of a task is such that it must be performed by a group rather than by a single individual, the problem of working relationships arises. It may be demonstrated that for entire classes of tasks success depends upon an effective flow of information. Some of the problems with which this paper concerns itself are as follows: on what principles may a pattern of communication be determined that will in fact be a fit one for effective and efficient human effort; how may a fixed communication pattern affect the work and life of a group; do some patterns have structural properties that limit group performance; what effects can patterns, as such, have upon the emergence of leadership, the development of organization, the degree of resistance to group disruption, the ability to adapt successfully to sudden changes in the working environment. Burn, M.C. THE CALCULATION OF VOWEL RESONANCES, AND AN ELECTRICAL VOCAL TRACT. J. acoust. Soc. Amer., Nov. 1950, 22(6), 750-753. (Bell Telephone Laboratories, Murray Hill, N.J.).

Presented at the Speech Communication Conference, MIT, 1950. By treating the vocal tract as a series of cylindrical sections, or acoustic lines, it is possible to use transmission line theory in finding the resonances. With constants uniformly distributed along each section, resonances appear as nodes of vibration of the tract taken as a whole. Thus, the fundamental node of the smaller cavity may be affected considerably by a higher node of the larger; and in addition, higher resonances are found without postulating additional cavities. This is an advantage over the lumped constant treatment, where it is necessary to postulate a different cavity for each resonance, and where the interaction terms in the equation do not include the higher nodes of vibration. Under the distributed treatment, dimensions for each vowel may be taken from x-ray photographs of the vocal tract. The calculations then yield at least 3 resonances which lie in the frequency regions known for the vowel, from analyses of normal speech. Dependence of the different resonances upon the different cavities is discussed in some detail in the paper. An electrical circuit based on the transmission line analogy has been made to produce acceptable vowel sounds. This circuit is useful in confirming the general theory and in research on the phonetic effects of articulation movements. The possibility of using such a circuit as a phonetic standard for vowel sounds is discussed.

Vilgis, F. AN APPARATUS FOR SPEECH COMPRESSION AND EXPANSION AND FOR PLAYING VISIBLE SPEECH RECORDS. J. acoust. Soc. Amer., Nov. 1950, 22(6), 754-761. (USAF Cambridge Research Labs., Cambridge, Mass.).

Presented at the Speech Communication Conference, MIT, 1950. In speechband compression or expansion all the frequencies of the band are divided or multiplied in a certain ratio, but without changing the time dimension. This last requirement makes the problem very difficult because, if we could neglect the time aspect, we could record speech and simply play it back at slower or faster speeds. I have tried to solve this problem by 3 different methods: a) by transformation of the speech frequencies into an optical spectrum and retransformation by light modulation disk and photo-tube; b) by use of a string filter; and c) by use of an ultrasonic cell as a storage device.

Huggins, W.H. SYSTEM-FUNCTION ANALYSIS OF SPEECH SOUNDS. J. acoust. Soc. Amer., Nov. 1950, 22(6), 765-767. (USAF Cambridge Research Lab., Cambridge, Mass.).

Presented at the Speech Communication Conference, MIT, 1950. The analysis of speech sound is facilitated if the sound is considered to be the response of a slow-time varying linear system to appropriate excitations. The linear system is characterized by one or more system functions which may be represented most naturally as the sum of complex exponential terms having complex frequencies corresponding to the various formants. Thus, a generalized frequency analysis is made not of the speech wave itself but rather of the system function that shaped that wave. On the other hand, the excitation is best analyzed by autocorrelation methods.

Chung, S.W. PORTRAIT OF SOME ELEMENTARY STATISTICS OF SPEECH SOUNDS. *J. Acoust. Soc. Amer.*, 1950, 22, 768-769. (Northwestern University, Boston, Mass.).

(Presented at the Speech Communication Conference, MIT, 1950.) Recent investigation of pulse-code modulation has enabled the quantification of speech sounds and made discrete numerical representation possible. These schemes are all aimed at a detailed and faithful representation of speech sounds. In many applications, however, such as speech impression and sensory replacement, a much simpler representation is needed. This simple representation should retain intelligibility. It is, indeed, a basic hypothesis that there is redundancy in speech sounds, and that there is such a thing as an essential element for intelligibility. However, the word intelligibility is not clearly definable. In dealing with this problem, a statistical method is preferable because a definite knowledge regarding the mechanism of generation and perception of speech sounds is lacking. This paper discusses statistical methods relevant to the problem. (NEIAS)

Potter, R.K. & Steinberg, J.C. TOWARD THE SPECIFICATION OF SPEECH. *J. Acoust. Soc. Amer.*, Nov. 1950, 22, 807-820. (Bell Telephone Laboratories, Murray Hill, N.J.).

This is an interim report on studies of the specification of speech sounds from acoustical measurements. Methods based upon analysis, synthesis, and vocal tract models are described. Included are the results of preliminary measurements on the vowel sounds of 25 speakers. Some of the problems in specifying the vowel sounds as indicated by these results are discussed. Results of preliminary measurement have reacted upon the formulation of methods by indicating need for shift of emphasis or even different approach. They have tended to magnify the importance of more accurate aural identification of sounds. They have indicated a need for studies of ways in which the ear assigns position or spacings to formants, and how these positions are affected by formant shape, etc. In this work it has been advantageous to synthesize sounds so that the parameters may be independently controlled. Both audible form or relative positions of the formants, and position of the form in the pitch dimension are important in identifying the vowels. But it is believed to be the form and position at the cortical level rather than in the incident sound that is important. (NEIAS)

Martin, D.W. & Touger, M.L. LOUDNESS BALANCE METHODS FOR EARPHONE RESPONSE MEASUREMENTS. *J. Acoust. Soc. Amer.*, Nov. 1950, 22(6), 833-837. (RCA Victor Div., Government Sound Engineering Section, Camden, N.J.).

Simple procedures are given for the subjective measurement of earphone response by 2 methods. The first method, which is rather widely recognized, requires the S to match the loudness of an earphone tone to the loudness of a free-field reference tone of the same frequency. Interpretation of the data from this method is direct, but the facilities, technique and time required are considerable. A second method, less widely used, involves the loudness balancing of an earphone tone of variable frequency to that of an earphone reference tone of fixed frequency and level. This method is much simpler, and can be used to measure earphone response under circumstances where the first method is virtually impossible. However, the interpretation of the data is less direct. This paper is an analysis of the 2 methods which attempts to develop a correspondence between the data obtained by the 2 methods.

Jones, F. DESCRIPTION OF LANGUAGE DESIGN. *J. acoust. soc. Amer.*, Nov. 1950, 22(5), 701-706 (University of Wisconsin, Madison, Wisc.).

Presented at the Speech Communication Conference, MIT, 1950. Physicists describe speech with continuous mathematics, such as Fourier analysis or the autocorrelation function. Linguists describe language instead, using a discontinuous or discrete mathematics called "linguistics." The nature of this odd calculus is outlined and justified here. It treats speech communication as being a telegraphic structure. (Non-linguists normally fail to orient themselves in this field because they treat speech as analogous to telephony.) The telegraphic code structure of language is examined from top to bottom, and at each of its several levels of complexity (compared to the 2 levels of Morse code) its structure is shown to be defined by possibilities and impossibilities of combination among the units of that level. Above the highest level we find, instead of such absolute restrictions, conditional probabilities of occurrence: this is the semantic field, outside linguistics, where sociologists can work. Below the lowest level we find, instead of such absolute restrictions, conditional probabilities of phonetic quality: this is the phonetic field, outside linguistics, where physicists can work. Thus, linguistics is peculiar among mathematical systems in that it abuts upon reality in 2 places instead of one. This statement is equivalent to defining a language as a symbolic system, that is, as a code.

Franch, W.R. & Steinberg, J.C. FACTORS GOVERNING THE INTELLIGIBILITY OF SPEECH SOUNDS. *J. acoust. soc. Amer.*, Jan. 1947, 19(1), 30-119. (Bell Telephone Laboratories, New York, N.Y.)

The characteristics of speech, hearing, and noise are discussed in relation to the recognition of speech sounds by the ear. It is shown that the intelligibility of these sounds is related to a quantity called articulation index which can be computed from the intensities of speech and unwanted sounds received by the ear, both as a function of frequency. Relationships developed for this purpose are presented. Results calculated from these relations are compared with the results of tests of the subjective effects on intelligibility of varying the intensity of the received speech, altering its normal intensity frequency relations and adding noise.

Carhart, R. MONITORED LIVE-VOICE AS A TEST OF AUDITORY ACUITY. *J. acoust. soc. Amer.*, April 1946, 17(4), 339-349. (Deshan General Hospital, Butler, Penn.).

Statistical comparisons were made of the relation between binaural thresholds for speech reception and "better ear" thresholds for pure tones. Speech reception was tested by monitored live-voice; while pure tone thresholds were obtained with commercial audiometers. Data for the comparisons were gathered during clinical routines at Deshan General Hospital. One group of 129 patients was used to explore the correspondence between hearing impairment as measured by speech reception for the Bell Telephone Intelligibility Lists and as expressed by 8 different scores abstracted from the pure tone audiogram. 4 other groups, totaling 682 patients, were tested with the Harvard bi-syllabic words (spondees). The data for these groups were analyzed to determine the correspondence between hearing impairment as measured by speech reception and as expressed by the "better ear" average for 512-2048 c.p.s. A 5th group of 150 patients underwent a series of tests which allowed the reliability of speech reception (tested with words) to be compared with the reliability of the 512-2048 c.p.s. average. Reliability was also explored for composite scores derived from combining the pure tone and speech reception thresholds. (HE/AS)

Sabine, H.J. & Wilson, R.A. THE APPLICATION OF SOUND ABSORPTION TO FACTORY NOISE PROBLEMS. *J. acoust. soc. Amer.*, July 1943, 15(1), 27-31. (The Celotax Corporation, Chicago, Ill.).

This paper was presented at the 28th meeting of the Acoustical Society of America, May 14-15, 1943, New York, New York. It deals with the problems created by excessive noise levels in a factory. The range of noise levels found in various factories, reduction of noise level through acoustical treatment, the spreading effect of sound in a non-absorbent room, reduction of noise through proper machine layout were discussed. Observations made are as follows: a) In rooms whose smallest floor dimension is several times the ceiling height, and having a sound absorbent ceiling, the intensity level due to a single source or concentration of sources decreases at a constant rate in db. per foot over the entire area of the room regardless of its size. b) This constant rate of attenuation varies inversely with the ceiling height. c) These attenuation rates are established at a distance from the source somewhat less than the ceiling height. Within this distance the intensity rises much more rapidly at a rate determined partly by the inverse square law and partly by the distribution of the noise source elements. d) The attenuation in the case of untreated ceilings is not only smaller but has a different characteristic, being of the order of 3 db. per distance double. Miller, G.A. & Mitchell, S. EFFECTS OF DISTORTION ON THE INTELLIGIBILITY OF SPEECH AT HIGH ALTITUDES. *J. acoust. Soc. Amer.*, 1946, 18, p256. (Psycho-Acoustic Lab., Harvard University, Cambridge, Mass.).

Sounds spoken into the closed cavity of an oxygen mask at high altitudes differ substantially in quality and intensity from normal speech at sea level. The mask imparts a low, "booming" quality to the speech. Tests with a wide variety of frequency response characteristics show that low-frequency attenuation improves the apparent quality without modifying appreciably the intelligibility of the speech. Also, the intensity of the speech signal varies considerably as a function of altitude, and talkers exhibit large individual differences in their ability to compensate for altitude effects. The range of speech levels under all conditions of altitude and talker differences is between 20 and 30 db, and for most installations some form of compression should be used to reduce this range. Sharp, symmetrical limiting ("peak clipping") is the most satisfactory method, since it combines the advantages of compression with the advantages of premodulation peak clipping for AM radio-telephony.

Ruedi, L. S. Furrer, W. PHYSICS AND PHYSIOLOGY OF ACOUSTIC TRAUMA. *J. acoust. Soc. Amer.*, 1946, 18, 409-412. (University of Berne, Switzerland).

Certain instances of acoustic trauma are cited. Audiograms of a number of men working in a noisy factory room (105 phons noise level) showed a dip around 4000 cps. There is a striking discrepancy between the frequency spectrum of the physical excitation and the hearing loss. An audiogram from a case of ear injury following explosion of an anti-aircraft gun showed the same pattern of the "4000 cps dip". When human ears are deafened by pure tones, hearing loss begins just below the excitation frequency, then increases rapidly and reaches its maximum 1-2 octaves higher. When hearing loss is produced by complex tones, the 4000 cps is again observed. These observations seem to confirm the existence of "streamings" of the lymph in the cochlea. The ear defender protects the critical zone in the inner ear against excessive acoustical stimulation, without reducing hearing capacity too much. It gives good protection against explosions. Its range for conversation is at least 50 meters. (HEIAS)

Flanagan, J.L. EFFECT OF DELAY DISTORTION UPON THE INTELLIGIBILITY AND QUALITY OF SPEECH. *J. acoust. Soc. Amer.*, May 1951, 23(3), 303-307. (Acoustic Lab., Massachusetts Institute of Technology, Cambridge, Mass.).

Speech articulation and quality tests were made on an all-pass system capable of advancing or delaying one frequency band relative to the rest of the spectrum. Parameters in the investigation were a) width of the advanced or delayed band, b) amount of advance or delay, and c) position in the frequency spectrum of the advanced or delayed band. Data were taken at signal-to-noise ratios of 30 db and 0 db. The results indicate that maximum impairment of speech intelligibility and quality occurs when the delays and advances are of the order of 1/4 second, and when the band that is advanced or delayed is near the center of the speech spectrum and has an articulation index equal to 0.5. These findings are related to data from statistical studies of the timing of speech energy bursts.

Jacobson, H. INFORMATION AND THE HUMAN EAR. *J. acoust. Soc. Amer.*, July 1951, 23(4), 463-471. (Brookhaven National Laboratory, Upton, N.Y.).

Calculations of the informational capacity of the human ear are made by computing the number of discriminable sound patterns per second, and applying the Shannon information theory. A maximum of 10^4 bits/sec transmission is found. This is compared with the capacity of existing auditory channels and recording media, and with the rate of actual information perception from speech and music. It is shown that a capacity of upwards from 5×10^4 bits/sec, depending on the informational match to the ear, is necessary for high fidelity transmission or recording. It is also shown that the brain can utilize less than 1% of the information transmitted by the ear. Finally, an average capacity of about 0.3 bit/sec, or of 40 tones/sec, is calculated for an individual cochlear fiber.

Peterson, E. FREQUENCY DETECTION AND SPEECH FORMANTS. *J. acoust. Soc. Amer.*, Nov. 1951, 23(6), 668-674. (Bell Telephone Laboratories, Murray Hill, N.J.).

This study is aimed primarily at evaluating the utility of axis-crossing detectors in tracking speech formants. Detectors of the usual type are found subject to an error, fundamental in nature. To remove this source of error speech is modulated up in frequency as a single sideband before limiting and detecting processes are applied. Experimental results with this carrier type of detector on a small number of speech samples are presented and compared with spectrograms. Conclusions are that the average axis-crossing rates cannot be trusted in general to follow specific formants, whether the speech is normal or differentiated. But when the formants are sufficiently localized by frequency selectivity, prospects of tracking the lower formants look promising.

Chang, S.M., Pihl, G.E. & Thirun, J. THE INTERVALGRAM AS A VISUAL REPRESENTATION OF SPEECH SOUNDS. J. acoust. soc. Amer., Nov. 1951, 23(6), 675-679. (Northeastern University, Boston, Mass.).

The points of zero crossing and the points of zero slope of the oscillograms of speech sounds are considered to contain the essential information for intelligibility. The intervals between zero crossings θ_z , and the intervals between zero slopes θ_s , are plotted as points in rectangular coordinates. The ordinate of the dot is a function of θ (θ_z or θ_s), and the abscissa is a function of the time of occurrence t of the particular θ . The resulting intervalgram gives a half-tone picture (consisting of dots) of speech sounds. The patterns may be proportioned to show either a detailed or general representation of the variation of the interval distribution. One type of pattern portrayed at the speech rate on a cathode-ray oscilloscope with a screen of long persistence has been found quite similar in certain respects to the patterns obtained using the sound spectrograph as described in the book Visible Speech by Fetter, Kepp, and Green. The equipment involved in obtaining the intervalgram, however, is much simpler.

London, J. PRACTICE RECOMMENDED PRACTICE FOR LABORATORY MEASUREMENT OF AIRBORNE SOUND TRANSMISSION LOSS OF BUILDING FLOORS AND WALLS. J. acoust. soc. Amer., Nov. 1951, 23, 686-689. (US National Bureau of Standards, Washington, D.C.).

This recommended practice is intended to cover the random incidence or reverberant sound method for laboratory measurement of airborne-sound transmission loss of large-scale building floors and walls and other elements of building construction such as doors, windows, etc. While generally applicable to large specimens such as building constructions, this recommended practice is also applicable to smaller specimens, such as airplane panels. This recommended practice covers only measurements of airborne-sound transmission loss, where airborne sound refers to sounds which originate within a room, are carried through the air, and then are transmitted through the test specimen as a result of the sound field excitation. It is not applicable for measuring the sound insulation of a test specimen for impact or tapping sounds such as are caused by direct mechanical contact with the specimen. (NEIAS)

Moore, C.R. AN EXPERIMENTAL STUDY OF SUBJECTIVE TONES PRODUCED WITHIN THE HUMAN EAR. J. acoust. soc. Amer., Oct. 1942, 13, 159-166. (Physics Dept., University of Southern California, Los Angeles, Calif.).

Quantitative measurements are reported on the intensities of subjective tones produced within the human ear under single and dual tone excitation. The measurements are made by the exploring tone method. The intensities of the subjective harmonics from each of 2 frequencies, 690 and 950 cycles were determined. The primary tones were presented to each ear of 3 Os. A total of 110 readings was made at each intensity level. The even and odd subjective harmonics show some differences, indicating that the organ, or set of organs, producing non-linearity is not the same as the source of asymmetry. The intensities at which these 2 distorting effects first appear are not the same. The subjective summation tones are, in general, weaker than the corresponding difference tones of the same order. These differences are to be expected if auditory masking is a process occurring within the hearing mechanism.

Parkinson, J.S. & Jerk, W.A. A RE-EXAMINATION OF THE NOISE REDUCTION COEFFICIENT. J. acoust. soc. Amer., Oct. 1941, 13, 163-169. (Johns-Manville Research Laboratories, Manville, N.J.).

It is the present practice to call the average of the sound absorption coefficients at 256, 512, 1024 and 2048 cycles the noise reduction coefficient, in an effort to assign a single figure to an absorbing material which will be useful in judging its performance in a noise quieting problem. This is recognized as a makeshift, as no single figure can represent correctly the reduction obtained. Typical noise spectra are presented and analyzed for reductions that can be expected in each frequency band. It appears that if a single figure is to be assigned the absorption coefficient at 4096 should also be considered. This is particularly true of office quieting, which is an important field of commercial noise control. In factories where heavy machinery is operating, it appears advisable to give some weighting to 128 cycles.

Rosenblith, W.A. INDUSTRIAL NOISES AND INDUSTRIAL DEAFNESS. J. acoust. soc. Amer., Jan. 1942, 13, 220-225. (University of California, Los Angeles, Calif.).

A survey was conducted in France in 1938 on the effects of industrial noises. In several factories noise levels were measured, noises were analyzed, and several hundred audiograms were taken. In addition various physiological and psychotechnological data were collected. Measurements on the intensity and the frequency distribution of industrial noises and the hearing losses of industrial workers show: a) some degree of correlation between the average noise level and the temporary and permanent hearing losses; b) an almost complete localization of the permanent hearing loss in the region above 1500 cycles (with a maximum of 6000 cycles), while the most important components of industrial noises are practically always below this frequency-limit; c) some correlation between the amount of temporary and permanent hearing losses for high frequencies; d) a very small permanent hearing loss for low frequencies with a very rapid recuperation from temporary loss in this region.

Ford, A. DYNAMIC AUDITORY LOCALIZATION. I. THE BINAURAL INTENSITY DISPARITY LIPEN. *J. acoust. Soc. Amer.*, April 1952, **22**, 367-372. (Lehigh University, Bethlehem, Penn.).

In order to measure the binaural intensity disparity lipen an apparatus was designed to reproduce an intensity function as the S rotated his head. Changes in phase relations of the 2 receivers were eliminated. The position of intensity equality could be set at any place in a 360° circle. The S was instructed to rotate his head to find this position. Frequencies of 200 and 2000 cycles were used. The angular errors were recorded. Results demonstrated that pure tone localizations on the basis of intensity disparity yielded errors 10 times as high as found under natural conditions. There must be some other cue for localization than pure intensity effect. This conclusion was verified by the introspective evidence of Ss. (HEIAS)

Fry, W.J. ACTION OF ULTRASOUND ON NERVE TISSUE--A REVIEW. *J. acoust. Soc. Amer.*, 1953, **25**, 1-5. (University of Illinois, Urbana, Ill.).

This review is concerned with a) changes in the tissues of the central nervous system (CNS) caused by high level ultrasound, and b) investigations into the physical mechanisms underlying these changes. The effect of irradiation on the cell bodies of neurons in the CNS is a loss of function which may be reversible or irreversible depending on the dosage; the latter is accompanied by structural changes. Larger neurons are more susceptible than smaller ones. The dose can be adjusted to cause irreversible neuron damage without harming the vascular and supporting tissue elements. This effect is used in neuroanatomy to study intracellular structure and function. Studies were done on the physical basis for the biological effects of ultrasound. The following aspects of temperature have been analyzed and rejected: a) high average (space) level, b) interface heating, c) rapid time rate of change, d) temperature changes resulting from cavitation, and e) heating at gas nuclei. The phenomenon of cavitation was also shown to play no essential direct role in producing the effects. (HEIAS)

Herrick, J.F. TEMPERATURES PRODUCED IN TISSUES BY ULTRA SOUND: EXPERIMENTAL STUDY USING VARIOUS TECHNIQUES. *J. acoust. Soc. Amer.*, 1953, **25**, 12-16. (Mayo Clinic, Rochester, Minn.).

This paper reports experiments carried out to investigate ultrasound as a possible therapeutic agent. The frequency of the ultrasonic energy employed was either 800 kilocycles or 1 megacycle. Convincing evidence for the selective heating of nerve by ultrasound was derived from histological study of muscle after exposure to ultrasonic energy. Experiments on animals showed that high temperatures could be produced in bones, bone growth was inhibited, and fractures could be produced by ultrasound. The high temperatures produced in bone by a stationary source of continuous ultrasonic waves can be reduced to levels acceptable for therapy by either pulsing the stationary ultrasonic energy or by a to-and-fro movement of the continuous ultrasonic energy over the selected region. Using ultrasound for reversible blocking of nerves is impractical because the margin of safety between conditions for irreversible and reversible block is too narrow. (HEIAS)

Lehmann, J.F. THE BIOPHYSICAL MODE OF ACTION OF BIOLOGIC AND THERAPEUTIC ULTRA-SONIC RE-ACTIONS. *J. acoust. Soc. Amer.*, Jan. 1953, **25**(1), 17-26. (Mayo Foundation, University of Minnesota, Rochester, Minn.).

A review is presented of numerous biophysical studies concerning the action of ultrasound on living matter, with particular reference to therapeutic applications. On the basis of the experiments described, involving various physical, physiochemical, and chemical effects, it is concluded that selective heating caused by the radiation plays the major role quantitatively under therapeutic conditions. However, ultrasound also produces a mechanical effect. The diffusion layer at an interface is decreased by stirring, and thus exchange of metabolites is augmented.

House, A.S. & Fairbanks, G. THE INFLUENCE OF CONSONANT ENVIRONMENT UPON THE SECONDARY ACOUSTICAL CHARACTERISTICS OF VOWELS. *J. acoust. Soc. Amer.*, Jan. 1953, **25**(1), 105-113. (Speech Research Lab., University of Illinois, Urbana, Ill.).

The consonant environments of vowels were varied by forming nonmeaningful stimulus syllables consisting of 72 combinations of 6 vowels and 12 consonants. The syllables were spoken by Ss, and the duration, fundamental frequency, and relative power of the vowels were measured. 10 male Ss were selected who showed no aberrations of speech. Each spoke 72 different consonant-vowel-consonant syllables in each of which the vowel was both preceded and followed by the same consonant. All 3 factors varied significantly in response to changes of the consonant environment. The variations were systematically related to the attributes of the consonants, the most powerful attribute being the presence or absence of vocal fold vibration, followed by manner of articulation and place of articulation, in that order.

Miller, R.L. AUDITORY TESTS WITH SYNTHETIC VOWELS. *J. acoust. Soc. Amer.*, Jan. 1953, **25**(1), 114-121. (Bell Telephone Laboratories, Murray Hill, N.J.).

The results are given for a series of phonetic evaluation tests which were made by means of synthetically produced vowel sounds. By employing synthetically produced sounds, a number of the significant parameters could be varied in an independent and systematic manner without encountering the uncertainties and limitations of the human speech mechanism. The types of parameter changes which were investigated by this means were those of fundamental frequency or pitch, formant frequency and amplitude, and, finally, the number of formants important to a sound. The results of the tests indicate that all of these parameters are important in the evaluation of the sound. In particular, there is a shift in the phonetic evaluation which can be attributed to pitch alone.

Morton, J.Y. THE IMPEDANCE OF THE HUMAN MASTOID. Letter in J. acoust. Soc. Amer., Jan. 1953, 25(1), p159. (Post Office Engineering Dept., Research Station, Dollis Hill, London, England).

In reference to Mr. Ernst K. Franke's article, "The Impedance of the Human Mastoid," which appeared in the July issue, if the experiments had been continued beyond 1800 cps it would have been found that the skin covering the mastoid process behaved as a series resonant system. Measurements made at this establishment, over the frequency range 400 to 4000 cps, show the average of 13 normal male mastoids to have a compliance of 0.75×10^{-8} cm/dyne, a resistance of 16×10^3 dyne/cm/sec, and a mass of 0.73 g. The measurements were made with a measuring surface of 0.7 in. in diameter, corresponding to the mean area of a number of commercial receivers, and applied with a force of 440 g in weight. The resonance of individual mastoids occurred as low as 1200 cps for fatty flesh covering a flat mastoid and as high as 4000 cps for leathery flesh covering a ridged mastoid. Though we have no experimental proof, it is thought possible that the continued pressure of a receiver on the flesh of a deaf S may permanently reduce its fluid content, causing it to be stiffer and to have less effective mass.

Bolt, R.H. THE AIRCRAFT NOISE PROBLEM. J. acoust. Soc. Amer., May 1953, 25(3), 363-366. (Massachusetts Institute of Technology, Cambridge, Mass.).

Aircraft noise presents a system problem which to date has been attacked mainly at the level of individual components. The system includes: a) aircraft as noise sources; b) atmosphere and terrain as influences on sound propagation; c) people, under several classes and conditions, as responders to noise; d) physical components for controlling noise; e) operating procedures for reducing noise exposure in communities; f) public relations; g) aviation planning policies and economics; and h) many organizations concerned with characteristics and consequences of aircraft noise. The nature of these components is reviewed in a general way, with emphasis on their inherent interrelations. This discussion provides a framework for unifying the several Ss included in the present Aircraft Noise Symposium.

Benson, R.W. & Hirsh, I.J. SOME VARIABLES IN AUDIO SPECTROMETRY. J. acoust. Soc. Amer., May 1953, 25(3), 499-505. (Central Institute for the Deaf, St. Louis, Mo.).

Measurements of the long-time average spectrum of speech are reported with the purpose of pointing out the roles of several variables. 3 different sampling times of 3 different types of speech material are analyzed with several band-width intervals. The speech of 5 young men and 5 young women contributes to the averaged results. No significant differences are found among the 3 types of speech material nor among the 3 different sampling times of 30, 60, and 90 secs. Octave, half-octave and equal-mel intervals appear to yield the same results. The only important difference between male and female speech appears in the octave 75-150 cps. The shape of the long time spectrum remains fairly constant from person to person while the over-all level contributes most to interpersonal variability. A discussion of the meaning of "over-all level" in this and previous reports is given. A relatively simple system for obtaining these measurements is described.

Meyer, M.F. IS LISTENING TO A TELEPHONE A PSYCHOLOGICALLY NORMAL WAY OF HEARING? Letter in J. acoust. Soc. Amer., May 1953, 25(3), p575.

In reporting his experiments on pitch discrimination J. Donald Harris (J. Acoust. Soc. Am., 24, 754 (1952)) expresses a surprise in the following words: "The incredibly precise sensitivity as early reported by...Meyer...is not corroborated. On the other hand, much of Meyer's testing of the ability of Professor Stumpf may be valid." The surprise can be lifted. Stumpf was comfortably seated with his back to the variable fork and free from all head contact. He then intentionally assumed his most favorable attitude. If a speaking telephone had been pressing on 1 of his ears and a dummy telephone on the other, and the tests had proceeded machine-like as described by Harris on page 751, Stumpf's attention would have been greatly disturbed. The question raised is answered simply and negatively: Listening to a telephone is not a psychologically normal procedure for a highly sensitive musical observer of phenomena of hearing. Consequently, physiological conclusions drawn therefrom are unreliable.

Bogert, B.P. ON THE BAND WIDTH OF VOWEL FORMANTS. Letter in J. acoust. Soc. Amer., 1953, 25, 791-792. (Bell Telephone Laboratories, Murray Hill, N.J.).

A study on the band widths of the speech formants is reported. Each of 33 male speakers uttered each of the 10 vowels once, making 330 utterances. 100 of them were selected for investigation picked at random. The spectrograph sections of the vowels chosen were obtained, and the envelopes of the formants were drawn over the sections. The band widths 3 db down from the peak were recorded, as well as the center frequency and the relative level of the maxima. The results show that the band widths of the formants are relatively invariant and independent of the particular vowel. (HEIAS)

Harris, C.M. A STUDY OF THE BUILDING BLOCKS IN SPEECH. J. acoust. Soc. Amer., Sept. 1953, 25(5), 962-969. (Acoustics Lab., Columbia University, New York, N.Y.).

Identification of the information-bearing elements of speech is important in applying recent thinking on information theory to speech communication. One way to study this problem is to select groups of building blocks and use them to form standardized speech which then may be evaluated; a method having the advantage of simplicity is described. Individual recordings of the building blocks were made on magnetic tape and then various pieces of tape were joined together to form words. Experiments indicated that speech based upon one building block for each vowel and consonant not only sounds unnatural but is mostly unintelligible because the influences on vowel and consonants are missing which ordinarily occur between adjacent speech sounds. To synthesize speech with reasonable naturalness, the influence factor should be included. Here these influences can be approximated by employing more than one building block to represent each linguistic element and by selecting these blocks properly, taking into account the spectral characteristics of adjacent sounds so as to approximate the time pattern of the formant structure occurring in ordinary speech. There is no a priori method of determining how many building blocks are required to produce intelligible standardized speech. This can only be determined from experiments involving listening tests. Such tests are described.

Harris, C.M. A SPEECH SYNTHESIZER. J. acoust. Soc. Amer., Sept. 1953, 25(5), 970-975. (Acoustics Lab., Columbia University, New York, N.Y.).

"Standardized speech" constructed from building blocks called speech modules has been described; it was synthesized by piecing together bits of magnetic tape containing recorded speech sounds. An electromagnetic device, a "speech module synthesizer", is described here which performs the synthesis automatically. When buttons on a keyboard are pressed, a sequence of corresponding speech modules are automatically recorded on tape exactly in tandem. The modules are selected from a group "stored" on a rotating magnetic drum. The pressing of a button causes an electrical signal corresponding to a module to be reproduced - the electrical switching is so arranged that only 1 complete module is reproduced for a single button-pressing. This electrical signal is amplified, biased, and then fed into a constantly rotating head which makes contact with stationary magnetic tape and records the signal on it. A 10-kc signal superposed on each stored speech module controls an electromagnet clutch which a) measures the length of the recording accurately, and b) advances the tape at the completion of the recording by the correct amount so that the next recording forms a connected sequence with it. The same module may be used any number of times and in combination with different stored modules, thereby introducing wider experimental control in standardized speech studies. The principle of this type of device could be applied to other classes of problems involving communication of information, as the conversion into speech of typing or of electronically-read printed matter.

Corliss, Edith L. & Burkhard, M.D. A PROBE TUBE METHOD FOR THE TRANSFER OF THRESHOLD STANDARDS BETWEEN AUDIOMETER EARPHONES. J. acoust. Soc. Amer., Sept. 1953, 25(5), 990-993. (US National Bureau of Standards, Washington, D.C.).

To establish threshold standards for various types of earphones, from a set of threshold standards that has been determined for one particular type of earphone by a hearing survey, an empirical relationship must be found giving the sound pressures in the calibrating coupler corresponding to equal sound pressures in the ear. This has previously been accomplished by means of loudness balancing between earphones. The method described in this paper makes use of a direct probe measurement of the sound pressure developed by an earphone at the entrance to the ear canal. The experimental process is described and the results of tests to establish the equivalence of the probe method and loudness balancing are given. In addition, several of the conditions under which loudness balancing is carried out were investigated by the probe method. Equal loudness sensation was found to correspond to equal sound pressures at the ear, within the limits of experimental error.

Michels, V.C. AN INTERPRETATION OF THE BRILL SCALE OF SUBJECTIVE BRIGHTNESS. *J. Opt. Soc. Amer.*, Jan. 1954, 44(1), 70-74. (Bryn Mawr College, Bryn Mawr, Penn.).

The Brill scale, obtained from extensive experimental data by Hanes, represents an attempt to establish a subjective scale of brightness by the determination of particular luminances which produce specific ratios of brightness. This scale, like other scales obtained from fractionation data, necessarily assumes a one-to-one correspondence between intensity of stimulus and magnitude of response - an assumption in conflict with known facts regarding adaptation. It is shown that the reformulation of the Fechner law proposed several years ago, aided by results obtained from rating-scale techniques, can predict quantitatively all of the data used for the construction of the Brill scale. Since this theoretical treatment takes explicit account of adaptation, it follows that each of the ratios determined by fractionation techniques has meaning by itself, but that the combination of these ratios into a scale of wide range is not justified. The fallacy involved in such combination is the assumption that a given stimulus is psychologically equivalent to itself when it is presented under different conditions, and, therefore, under different states of adaptation.

Sumbly, V.H. & Pollack, I. VISUAL CONTRIBUTION TO SPEECH INTELLIGIBILITY IN NOISE. *J. Acoust. Soc. Amer.*, March 1954, 26(2), 212-215. (Human Factors Operations Research Labs., Washington, D.C.).

Oral speech intelligibility tests were conducted with, and without, supplementary visual observation of the speaker's facial and lip movements. The difference between these two conditions was examined as a function of the speech-to-noise ratio and of the size of the vocabulary under test. The visual contribution to oral speech intelligibility (relative to its possible contribution) is, to a first approximation, independent of the speech-to-noise ratio under test. However, since there is a much greater opportunity for the visual contribution at low speech-to-noise ratios, its absolute contribution can be exploited most profitably under these conditions.

Pollack, I. & Ficks, L. INFORMATION OF ELEMENTARY MULTIDIMENSIONAL AUDITORY DISPLAYS. *J. Acoust. Soc. Amer.*, 1954, 26, 155-158. (Human Factors Operations Research Laboratories, Washington, D.C.).

The purpose of the study was to explore the potentiality of informational transmission with elementary auditory displays of high-order dimensionality. The task of the study was to identify the conditions, or state, of each stimulus aspect of a multivariable display. Transmissions were averaged over individuals. The most striking finding was that the amount of information transmitted with these multidimensional elementary displays greatly exceeded that obtained with unidimensional displays. There was proportionately little improvement in information transmission as each dimension was subdivided more finely; this improvement depended on the proficiency of the Ss. A further increase in the number of stimulus dimensions produced a still further gain in information transmission. (JELIAS)

Collins, D.A. & Hall, H.J. LABORATORY EVALUATION OF FIELD MEASUREMENTS OF THE LOUDNESS OF TRUCK ENGINE NOISE. *J. Acoust. Soc. Amer.*, March 1954, 26(2), 215-220. (Arner Research Foundation of Illinois Institute of Technology, Chicago, Ill.).

Simple loudness judgment tests were performed by a jury of 15 observers on the recorded noises of approximately 100 highway trucks. The loudness of the noises calculated by a modification of the equivalent tone method proposed by Beranek and co-workers ranges from about 20 to 200 sones. Observers were instructed to rank the noise in 6 loudness classes and were allowed to listen to a sample of class 1 and class 6 after each 20 recordings. The calculated loudnesses were then divided into 6 classes with class limits set by a 4dB loudness increase per class. Although the subjective tests were conducted with no elaborate controls, a correlation coefficient of 0.94 was found between the average judgment of the group and the calculated loudness class. The correlation coefficient between average judgment and total sound pressure level was 0.70, whereas the correlation coefficient between the average judgment and the level on the A-network of the sound level meter was 0.83. Experimental techniques and the capabilities and limitations of the loudness-calculation methods are discussed.

Spilach, M., Curtis, J.F. & Webster, J.C. RESPONDING TO ONE OF TWO SIMULTANEOUS MESSAGES. *J. Acoust. Soc. Amer.*, May 1954, 26(3), 391-396. (USN Electronics Lab., San Diego, Calif.).

20 operators were given a task which required answering 1 of 2 simultaneous voice messages. The task was performed under a variety of conditions produced by combinations of 4 experimental "aid" variables: horizontal spatial separation of the sound sources, aural shaping filters which made the tone quality different in each channel, visual cues which indicated the channel about to call the operator, and facilities to "pull down" a desired message from the initial source into a headphone or a loudspeaker near the operator's ear. It was found that the use of horizontal separation and/or the filtered messages greatly improved the operator's performance. Visual cues had no apparent effect on ability to answer the message except when used with pull down facilities. The pull down facilities aided the operator to some extent. Some speculations are advanced about the nature of recognizing and attending to a message in the presence of another message.

Cherry, E.C. & Taylor, W.K. SOME FURTHER EXPERIMENTS UPON THE RECOGNITION OF SPEECH WITH ONE EAR AND WITH TWO EARS. *J. acoust. Soc. Amer.*, July 1954, 25(4), 554-559. (Electrical Engineering Dept., Imperial College of Science and Technology, London, England).

The experiments described here continue a series reported in this Journal earlier. A number of objective tests are described, directed towards the general problem concerning the faculty we possess of perceiving only 1 acoustic world under normal conditions (in spite of having 2 ears) and yet, if our ears be stimulated by different signals, artificially, we can attend to 1 or the other of them. The tests have been made with continuous speech (readings from light fiction) and the results assessed statistically. The first tests aim at measuring the reaction time t required to "switch the attention" from 1 ear to the other, as assessed by perception of the words of the message. A second set of tests show that we perceive only 1 speaker, as a "gestalt", when the ears are stimulated by similar messages but with a delay between them exceeding 20 times that ever experienced in real life by virtue of binaural directivity.

Burkhard, H.D. & Corliss, Edith L.B. THE RESPONSE OF EARPHONES IN EARS AND COUPLERS. *J. acoust. Soc. Amer.*, Sept. 1954, 26(5), 679-685. (US National Bureau of Standards, Washington, D.C.).

Applied voltage responses of 7 earphones on both ears of 14 people were obtained with the aid of a probe tube microphone inserted into the volume enclosed by the earphone. Treatment of the response data by the method of analysis of variance allowed separation of variation effects due to error in repeated measurement, dissimilarity between a given person's ears, and differences among individuals. The latter are found to be the most important effects to contend with in audiometric practice. Effects of application force on sound pressure output of an earphone are examined. Comparisons between the average response on ears and on 3 superficially different couplers are presented. Responses on ears were substantially different from responses on couplers over parts of the frequency range. Recommendations are given for improving the reliability of audiometric measurements by instrumental refinements.

Korn, T.S. EFFECT OF PSYCHOLOGICAL FEEDBACK ON CONVERSATIONAL NOISE REDUCTION IN ROOMS. *J. acoust. Soc. Amer.*, Sept. 1954, 26(5), 793-794. (Acoustics Lab., University of Brussels, Brussels, Belgium).

In many cases when sound absorptive treatment has been applied to rooms, the effective noise reduction has been found larger than that predicted by the conventional formula. It is shown that this discrepancy appears in cases where conversational noise is predominant, and that it is the result of a phenomenon which may be termed "psychological feedback," which increases the conversational noise reduction (expressed in decibels) by a factor of about 1.6.

Stevens, K.W. FREQUENCY DISCRIMINATION FOR DAMPED WAVES. *J. acoust. Soc. Amer.*, Jan. 1952, 24(1), 76-79. (Massachusetts Institute of Technology, Cambridge, Mass.).

Measurements of frequency discrimination for single damped waves are reported for frequencies between 200 and 5000 cps, and for values of the damping σ between 0 and 500 sec^{-1} (σ is the reciprocal of the time constant of the envelope of the damped wave). There is an increase in the difference limen for frequency as the damping increases, or as the effective duration decreases. The increase in the difference limen is accompanied by a loss in the pitch character of the stimulus, and there is usually a sharp deterioration in discrimination above a certain value of damping, i.e., above a certain band width of the stimulus. The results are related to existing data on the perception of short sinusoidal stimuli.

Mintz, F. & Tyzzer, F.G. A LOUDNESS CHART FOR OCTAVE-BAND DATA ON COMPLEX SOUNDS. *J. acoust. Soc. Amer.*, Jan. 1952, 24(1), 80-82. (Armour Research Foundation of Illinois, Institute of Technology, Chicago, Ill.).

The equivalent-tone method of Beranek, Marshall, Cudworth, and Peterson has been used as a basis for developing a loudness chart for octave-band data on noise. The loudness chart consists of contours of equal pressure level in octave bands which are superimposed on a loudness grid. The procedure is based on octave-band data, since octave-band filter sets are readily available commercially and are being widely used in noise measurement. Good agreement is shown with loudness values for various noises determined by Beranek et al., using 300 and 600-mel bands, and there is, therefore, good agreement with existing psychological data. The loudness chart not only facilitates the calculation of loudness but provides graphical loudness curves for comparison of noise and for the evaluation of various noise reduction measures.

Stanfield, R.L. USAF REPORTS REARWARD SEATING SAFER. *Aviation Week*, Feb. 1957, 66(5), p.91.

8963

This article reports the results of an Air Force study of injuries in USAF transport aircraft accidents in relation to seating. Data were collected over a period of two and a half years and are presented in terms of number and degree of injury incurred under the following seating conditions: facing front, facing rear, facing sides, seating unknown, and standing. Approximately 3500 passengers provide the basis for the assessment. Passenger tie downs are discussed along with the general problem of determining relevant factors in accidents. Conclusions are drawn concerning the optimal seating arrangement.

Pollack, I. COMFORTABLE LISTENING LEVELS FOR PURE TONES IN QUIET AND NOISE. *J. acoust. Soc. Amer.*, March 1952, 24(2), 158-162. (USN Electronic Lab., San Diego, Calif.).

The most comfortable listening level and the range of comfortable listening levels for pure tones were determined for a group of normal (nonclinical) listeners in the quiet and against various levels of background noise. In general, the most comfortable listening level contour has the general shape of the equal-loudness contour at intermediate loudness levels - lowest intensity at the middle frequencies and highest intensity at the lower frequencies. The range of listening levels considered "comfortable" against a quiet background varies from about 20 db at the lowest frequencies to about 35 db at the middle frequencies. The variability of the mcl is larger at high frequencies than at low frequencies and it is about the same magnitude as the variability of heterophonic equal-loudness matches. The effect of noise is primarily to raise the lower limit of the range of comfortable listening levels and only secondarily to raise the upper limit. As a result, the range of comfortable listening levels is decreased in noise. The possible use of the comfortable listening level test as a gross diagnostic tool in the detection of nerve-type deafness is discussed.

Gierke, H.E. von, Parrack, H.O., Gannon, W.J., & Hansen, R.G. THE NOISE FIELD OF A TURBO-JET ENGINE. *J. acoust. Soc. Amer.*, March 1952, 24(2), 169-174. (USAF Aero Medical Lab., Wright-Patterson AFB, Ohio).

The noise fields generated by a standard turbo-jet aircraft engine have been measured for 3 different power settings. Measurements were made at points on circles around the engine having radii of 25 and 50 ft. For the 50-ft. distance the directional characteristic is presented for the over-all sound pressure and for the noise in the different octave bands starting at 37.5 cps. From these measurements the total acoustic power radiated from the engine is calculated to be approximately 69 kw at full engine power. The distribution of this power over the different frequency bands and space angles is shown. The highest total energy per cycle and the highest sound levels are found at frequencies near 100 cps for the higher power settings of the engine. Above that frequency range the total energy per cycle drops approximately as the reciprocal of the square of the frequency. The data should help us understand qualitatively the jet engine as a sound source and are therefore discussed in that respect. On the other hand, the data have practical significance with respect to the design of test facilities for adequate protection of personnel. They are equally important with respect to problems of noise control on an airport.

Guelke, R. & Helm, H. THE ANOMALOUS BEHAVIOR OF THE THRESHOLD OF HEARING IN RELATION TO THE EQUAL LOUDNESS CONTOURS. *J. acoust. Soc. Amer.*, May 1952, 24(3), 317-322. (University of Capetown, Union of South Africa).

It is shown that for a 100-cycle note the well-known compression of the loudness contours at low frequencies is no longer valid near threshold. Measurements are carried out on 38 Ss in a free field test, and on 10 Ss in a monaural test to show that the intensity jump from threshold to 10 phons is greater at 100 cycles per sec than at 1000 cycles per sec. This is contrary to experience at higher intensities where the intensity jump is smaller at 100 cycles than at 1000 cycles. A possible explanation for the effect is put forward involving the middle ear muscles.

Robbins, J.G. THE ACOUSTIC SIGNIFICANCE OF THE AMPLITUDE AND PHASE OF HARMONICS PRESENT IN A SOURCE OF SOUND IN A ROOM. *J. acoust. Soc. Amer.*, July 1952, 24(4), 380-383. (Hendrix College, Conway, Ark.).

In order to obtain some further measure of the acoustic properties of a rectangular room, a brief subjective study is made of listener response to sounds having various degrees of modulation on their decay curves and to alternate sounds which differ only in the phase relation of a harmonic in the source with respect to the fundamental frequency. The data show that the average listener finds the decay of sounds pleasant in inverse proportion to the amount of modulation on the decay curves, and that a large majority of listeners cannot distinguish between 2 steady-state sounds, alike except that in 1 sound the phase of a harmonic is changed with respect to that of the fundamental frequency. Also, an objective study is made of the modulation on decay curves. A switching device is used to insure a smooth cutoff at any predetermined phase of the fundamental frequency. The data show that, if the source includes the fundamental frequency and a harmonic at equal amplitudes, the modulation of the decay curve consists of 2 superposed modulations. The phase relations and amplitudes of these modulations are dependent on the phase relations and amplitudes of the driving frequencies which produce them.

 DeVries, G.L. BROWNIAN MOTION AND THE TRANSMISSION OF ENERGY IN THE COCHLEA. *J. Acoust. Soc. Amer.*, Sept. 1952, 24(5), 527-533. (Rijks University, Groningen, The Netherlands.)

It is shown that Brownian motion at the eardrum is only partly due to noise of the air. (This part has been calculated by Sivian and White.) The main part is due to Brownian motion of the eardrum itself. The apparent flow of energy is close to the absolute threshold of the ear; it is reduced to one-half when the ear is provided with an exponential horn. The discussion of the Brownian noise in the inner ear reveals a serious discrepancy; considering 1-individual cell it proves to be very difficult to reconcile the low threshold with the thermal agitation. A mechanism is suggested for the excitation of the sense cells by which the disturbances by Brownian motion are appreciably suppressed; in this model the microphonic activity plays an important part. The model is based on some recent measurements of the microphonic activity of the lateral line organs of fishes, which are shortly summarized. It follows from these measurements that the microphonic potentials are related with the tension of the hairs on the sense cells.

 Pollack, I. ON THE EFFECT OF FREQUENCY AND AMPLITUDE DISTORTION ON THE INTELLIGIBILITY OF SPEECH IN NOISE. *J. Acoust. Soc. Amer.*, Sept. 1952, 24(5), 538-540. (Harvard University, Cambridge, Mass.)

The effect upon the intelligibility of speech in noise of the interaction of sharp frequency limiting and severe peak clipping was studied. The results are compared with previously reported results of similar tests with frequency-limited speech signals that were not subjected to amplitude distortion. The intelligibility of unclipped speech, relative to that of the peak-clipped signal under corresponding experimental conditions, is a function of the signal-to-noise (S/N) ratio under test and is, to a rough approximation, independent of the frequency range of the speech signal passed. At high S/N ratios, the intelligibility of the unclipped speech signal is higher than that of the severely peak-clipped signal. Under low S/N ratios, however, the intelligibility of the latter is considerably higher than that of the unclipped signal.

 Huggins, W.H. A PHASE PRINCIPLE FOR COMPLEX FREQUENCY ANALYSIS AND ITS IMPLICATIONS IN AUDITORY THEORY. *J. Acoust. Soc. Amer.*, Nov. 1952, 24(6), 582-589. (USAF Cambridge Research Center, Cambridge, Mass. & Research Lab. of Electronics, Massachusetts Institute of Technology, Cambridge, Mass.)

A filtering scheme that utilizes the phase-frequency characteristic of a filter is shown to have certain advantages for analyzing signals, such as speech, which are produced by shock or noise excitation of a physical system having one or more resonances. The phase principle is shown to be particularly well suited to neural mechanisms of inhibition and facilitation, and evidence is presented that such a principle may be used by the ear to achieve its analysis of the sound that it receives.

Fischer-Jorgensen, E. THE PHONETIC BASIS FOR IDENTIFICATION OF PHONEMIC ELEMENTS. *J. acoust. Soc. Amer.*, Nov. 1952, 24(6), 611-617. (University of Copenhagen, Denmark).

Phonemic analysis must be based to a large extent on considerations of phonetic similarity and difference. For this purpose various stages of the speech event may be chosen, in particular the articulatory, the acoustic, and the auditory stage. It does not seem irrelevant which stage is chosen, for the analysis may give different results in each of the 3 stages. However, it is usually not possible to state general reasons for preferring 1 stage over another. In a given language functional reasons may in some cases decide the choice.

Davis, K.H., Biddulph, R. & Balashek, S. AUTOMATIC RECOGNITION OF SPOKEN DIGITS. *J. acoust. Soc. Amer.*, Nov. 1952, 24(6), 637-642. (Bell Telephone Laboratories, Murray Hill, N.J.).

The recognizer discussed will automatically recognize telephone-quality digits spoken at normal speech rates by a single individual, with an accuracy varying between 97 and 99%. After some preliminary analysis of the speech of any individual, the circuit can be adjusted to deliver a similar accuracy on the speech of that individual. The circuit is not, however, in its present configuration, capable of performing equally well on the speech of a series of talkers without recourse to such adjustment. Circuitry involves division of the speech spectrum into 2 frequency bands, 1 below and the other above 900 cps. Axis-crossing counts are then individually made of both band energies to determine the frequency of the maximum syllabic rate energy within each band. Simultaneous two-dimensional frequency portrayal is found to possess recognition significance. Standards are then determined, 1 for each digit of the 10-digit series, and are built into the recognizer as a form of elemental memory. By means of a series of calculations performed automatically on the spoken input digit, a best match type comparison is made with each of the 10 standard digit patterns and the digit of best match selected.

Hardy, H.C. TENTATIVE ESTIMATE OF A HEARING DAMAGE RISK CRITERION FOR STEADY-STATE NOISE. *J. acoust. Soc. Amer.*, Nov. 1952, 24(6), 756-761. (Illinois Institute of Technology, Armour Research Foundation, Chicago, Ill.).

The probable shape of a limiting spectrum for noise in a working environment where there is long daily exposure is determined by reasoning from previously determined data of the hearing mechanism. It is assumed that hearing loss is due to a progressive fatigue phenomenon, the fatigue being a direct function of the energy stimulus in the inner ear. From the characteristics of this stimulus as a function of frequency, it is shown that the most sensitive region for loss is around 3000 cps, the low frequencies being as much as 20 db less sensitive than this region. The 4000 cps "notch" in audiograms of industrial workers is thereby explained. The limiting spectra are essentially equal-loudness contours for broad-band noise when the noise spectrum is plotted in octave bands. 2 limiting loudness curves and their corresponding spectra are tentatively suggested as damage risk criteria.

Kock, E.W. & Miller, R.L. DYNAMIC SPECTROGRAMS OF SPEECH. *J. acoust. Soc. Amer.*, 1952, 24, 783-784. (Bell Telephone Laboratories, Murray Hill, N.J.).

In studies of speech which are undertaken to determine in what factors the information is contained, one is soon impressed with the fact that a large number of the phonemes are intimately associated with rapid changes in the spectrum content of the sound. This is particularly true of the diphthongs, plosives, glides, and influence regions. Also pointing to the suggestion that perhaps these changes in spectrum are important is the observed fact that steady sounds tend to lose their meaning if they are prolonged. A means of portraying these changes has recently been developed, which involves minor changes in a conventional sound spectrograph. In essence this involves the differentiation of the time-amplitude pattern for different points in the spectrum, rather than the use of the time-amplitude function directly. This method is described in the paper. (MEIAS)

Brittain, F.H. LOUDSPEAKERS: RELATIONS BETWEEN SUBJECTIVE AND OBJECTIVE TESTS. J. Brit. Inst. Radio Engrs., 1953, 12, 105-109. (Research Laboratories, The General Electric Co., Ltd., Wembley, England).

The advantages and disadvantages of both subjective and objective tests are discussed. It is shown that both types of test are necessary. In order to devise an objective test which bears some relation to the subjective test, it is necessary to take cognizance of both the physiological and the psychological processes involved in the latter. Some common acoustic tests are then considered in detail, and it is shown that, for simple, single attribute tests, fair agreement is possible between the subjective and the objective results. Where a multiplicity of attributes are tested simultaneously, the subjective form of test is the only one possible.

Goldmark, P.C. FLICKER AND COLOUR FRINGING PHENOMENA IN COLOUR TELEVISION. J. Brit. Inst. Radio Engrs., 1950, 10, 208-217. (Columbia Broadcasting System Inc., New York, N.Y.).

In a sequential color television system, flicker becomes an important factor when the color changes occur after each field period. Scarcity of space in the radio spectrum makes it desirable to reduce to an absolute minimum the bandwidth required for color television. This is possible by operating the field sequential color television system with a color frame frequency of 48 per sec., rather than 60. The implications of the Ferry-Porter Law, which states that the critical fusion frequency is proportional to the logarithm of the apparent luminosity, are discussed. Investigations are described on threshold flicker and maximum tolerable flicker. Color fringing is discussed. It is the intensity of leading and trailing color fringes which determine the subjective effect of color fringing. A large variety of tests with the field sequential color television system have proved that color fringing is a rare phenomenon and occurs far less frequently than stroboscopic effects in motion pictures. (NEIAS)

9010 Goldmark, P.C. BRIGHTNESS AND CONTRAST IN TELEVISION. J. Brit. Inst. Radio Engrs., 1950, 10, 219-225. (Columbia Broadcasting System Inc., New York, N.Y.).

The American Standard Association recommends a motion picture screen brightness of 10 ft-L without film, and 8 ft-L with clear film. Many present day black-and-white receivers should not be viewed in rooms where the surrounding illumination is much in excess of 1 ft-L. Examples are cited to show that for adequate image recognition, contrast range is more important than mere brilliance. The capacity for visual acuity varies with brightness. Other factors, such as contrast discrimination, flicker recognition and color discrimination, also grow with brightness. Solutions are proposed for producing adequate contrast range in television pictures. (NEIAS)

Smedley, C.A. SPECIFICATION OF COLOR IN FINISHES. Machine Design, Oct. 1953, 25(10), 187-192. (Glidden Company, Cleveland, Ohio).

Designers who wish to utilize the advantages of color must keep the basic factors governing color selection well in mind. They might be summarized as: a) choosing a color that is acceptable in the normal environment of the machine; b) making the machine striking and appealing in sales areas by use of color; c) considering the effect of service conditions, such as wear, disfiguring conditions or heat, on the color; and d) weighing the importance of covering surface defects or blemishes with a finish. Relative importance of each of these factors differs with each product. It is up to the designer to consider each carefully and choose the finish that meets all the fundamental criteria successfully.

9023

Malcolm, D.G., & Marshall, G.L. HUMAN FACTORS IN MACHINE INDEXING. Machine Design, Nov. 1953, 25 (11), 143-145.

9023

To determine the optimum speed (index rate) for a machine fed at intervals by a human operator, 12 untrained subjects dropped two 11/16 inch balls into holes in a plate during a momentary pause (the dwell time) in its rotation. The index rate was varied from 40 to 100 per minute and the dwell time from 1/3 to 2/3. The results are discussed in terms of the effects of practice and the optimum index rates and dwell times for maximum production.

Boyden, R.E., & Oldenburg, K.F. DESIGNING FOR SPEED IN ADDING MACHINES. Machine Design, June 1951, 23(6), 110-115. (Clary Multiplier Corporation, San Gabriel, Calif.).

This paper reports developments in operator facility and mechanical design of adding machines. Highest operator speed could be attained with the system of entering groups of numbers simultaneously into the keyboard. To provide an easy means of "add" function control, an add bar was provided along the front of the machine. Design will have to consider overthrow protection at higher speeds. Positive transfer assures correct sequence. The increased wear in operating parts resulting from higher speeds is reduced by heat treating any parts having friction surfaces, either by carburizing or by the use of cyanide. (HEIAS)

 Perry, Scott, Ruby. THE VISIBILITY OF SMALL ECHOES ON RADAR PPI DISPLAYS. *Proc. I.R.E.*, Feb. 1948, 36, 180-196. (Council for Scientific and Industrial Research, Chippendale, N.S.W., Australia).

A theory of visibility on an intensity-modulated display is developed. From it is derived a mathematical formula for visibility on a PPI display, and this formula is confirmed by experimental investigations. It is shown that, under favorable conditions, received signals whose power is 15 db below noise level can be observed. Replacement of a linear detector in the receiver by a square-law detector will, under some conditions, produce a further improvement of 3 db. In the visibility formula all the system variables have been grouped into 4 parameters, and thus it has been possible to provide nomograms enabling the rapid calculation of the minimum visible signal under any set of conditions.

 Hoeff, A.V. MINIMUM DETECTABLE SIGNAL AND ITS DEPENDENCE UPON PARAMETERS OF RADAR SYSTEMS. *Proc. I.R.E.*, 1946, 34, 857-861. (USN Research Lab., Washington, D.C.).

This paper presents results of an early study of the influence of parameters of a pulse radar system on its sensitivity. More specifically, it describes an experimental determination of the absolute value of minimum pulse signal visually detectable through random noise with a probability of 50% for a wide range of the following parameters: pulse-repetition rate r , pulse length t , intermediate-frequency bandwidth B , and video bandwidth b . The following empirical formula expresses the results of the investigation with considerable accuracy: $V_{min} = \frac{1}{2} E_n \sqrt{1 + \frac{1}{Bb}} \left(\frac{1670}{r} \right)^{1/5}$ where V_{min} is the minimum detectable pulse voltage and E_n is the noise voltage per unit intermediate-frequency bandwidth of the receiver. The application of the results to the design of search radar systems is briefly discussed.

Dunke, P.R., Himmelfarb, Sylvia & Whittenberger, J.L.
THE EFFECT OF THE RESISTANCE TO INSPIRATION IMPOSED BY
THE COMBAT GAS MASK CANISTER ON THE ABILITY OF SOLDIERS
TO DO EXHAUSTIVE WORK IN TEMPERATE AND IN SIMULATED TROP-
ICAL CONDITIONS. Medical Div. Rep. 9, Nov. 1944, 15pp.
USA Chemical Warfare Service, Edgewood Arsenal. M.

9123

This study was designed to determine "the effect of
the resistance to inspiration imposed by the combat gas
mask canister on the ability of soldiers to do exhaustive
work in temperate and in simulated tropical conditions".
Thirty subjects were trained to ride the bicycle ergo-
meter while wearing the combat gas mask under the follow-
ing conditions: (1) daily for three weeks with 70 degrees
Fahrenheit temperature and 50 per cent relative humidity;
(2) exercised to exhaustion with valve and canister pres-
sures varied; and (3) graded exercises at 95 degrees
Fahrenheit and 87 per cent relative humidity. Heart
rate, pulse rates and volume of respiration were measured.
Results are discussed in terms of the specific and
general effects of wearing gas mask canister upon ability
to perform normal and exhaustive work. T. R. 6

Lewis, R.E.F. & Humphries, M. MEASUREMENT OF PILOT BE-
HAVIOR: COMPARISON OF DAY AND NIGHT APPROACH AND LANDING
TECHNIQUES. DRML Proj. 206, Rep. 206 2, Nov. 1956, 12pp.
Defence Research Medical Labs., Toronto, Ontario, Canada.

9125

This study makes an initial attempt to obtain objec-
tive pilot performance measures with regard to general
pilot behavior and the specific behavior in day and night
approach and landing procedures. Eight pilots made a
series of day and night landings (ten of each). A spe-
cial apparatus, the M2 Recorder, was employed to record
airspeed, altitude, longitudinal and vertical accelera-
tions, and several time measures. Results are presented
in terms of the simple averages of each of the variables
under day and night conditions, the average as a function
of certain variables, and the relative consistencies of
differences between day and night flying behavior. Rec-
ommendations for further studies are offered.

Edgerton, H.A. SHOULD THEORY PRECEDE OR FOLLOW A "HOW-TO-DO-IT" PHASE OF TRAINING. Contract
NORR 1722(00), Dec. 1956, 49pp. Richardson, Bellows, Henry & Co., Inc., New York, N.Y.

This study was undertaken to determine whether theory should precede or follow a "how-to-
do-it" phase of training. The experimental design of the study was as follows: the subject
matter of a selected course or school was presented in 2 different ways. The presentations
differed in the sequence of presentations of the "how-to" aspect of the course and the "ex-
planation" aspect. All trainees in the experiment were given the Chicago Test of Primary
Mental Abilities as a basis for identifying them by aptitude. Learning was measured by the
scores on the course examination. There were 139 trainees in the "how-to" class and 112 in
the "explanation" class. It was concluded that: a) the sequence of presentations has some
effect on the learning of trainees; b) the aptitude pattern of a trainee seems to govern the
effect of the sequence of presentations on learning; c) those who learned their theory before
their "how-to", learned their theory better; d) those who learned their "how-to" before their
explanation did better on the more routine parts of the course. (HEIAS)

Hopkinson, R.G. & Longmore, J. ATTENTION AND DISTRACTION IN THE LIGHTING OF WORK-PLACES.
Ergonomics, Aug. 1959, 2(4), 321-334. (Scientific & Industrial Research Dept., Building
Research Station, Garston, Watford, Hertfordshire, England).

General lighting with a uniform level of illumination over the working plane was intro-
duced and adopted in the inter-war period. Before this, local lighting over the work itself
had been customary. It was found, however, that general lighting was not always satisfactory
for work which demanded high degrees of visual skill and attention, and in many cases a re-
turn to local lighting, together with some general lighting was favoured. It is generally
accepted that the attention is held by objects which contrast strongly with their environ-
ment, either by their brightness, colour, texture or form. Equally the attention can be dis-
tracted by a bright or highly coloured object in the field of view a little away from the ob-
ject of regard. Experiments have been made in 'human phototropism', employing apparatus
which enabled a simultaneous cine-photographic record to be made of the visual scene together
with the eye movements of an unsuspecting observer viewing the scene. A count of the number
and duration of these eye movements revealed that sharp, intensely bright points of light dis-
tracted the attention in a series of jerky eye movements, whereas less bright but larger areas
caused more eye movements of longer duration. Different behaviour patterns of different ob-
servers were noticed, 2 rather distinct groups being recognized which bear many striking al-
liances to the 'postural-clue' and the 'visual-clue' personality groups recognized by
Witkin (1950). Some applications of the results to the lighting of work-places are suggested.
The results argue in favour of preferential lighting of the work, possibly by local lighting.

Rosenberg, S. A LABORATORY APPROACH TO INTERPERSONAL ASPECTS OF TEAM PERFORMANCE. *Ergonomics*, Aug. 1959, 2(4), 335-348. (Bell Telephone Laboratories, Murray Hill, N.J.).

This paper brings together and re-appraises a number of studies, mostly already published elsewhere, from a laboratory research programme to deal in an experimental fashion with certain problems of team performance. An attempt has been made to be sufficiently comprehensive to anticipate a variety of team performance problems observed in the Air Force and other work-group settings. Research to date in this programme has dealt primarily with team training, although one may also note implications in this work for the problems of the distribution of displays and controls among team members. The conceptual approach adopted is traceable to contemporary stimulus-response theories in psychology. Basic concepts and methods are briefly described followed by an analysis of stimulus-response arrangements in dyads. Feedback (reinforcing) stimuli in social settings are first given social attention when they seem central to almost any training problem. Experiments are summarized which deal with parameters relevant to socially affected feedback. A number of task parameters are also given experimental consideration. Finally, initial studies of discrimination learning within a team context, and the effects of individuals' past histories on a discrimination task, on these determining team outputs, are also described.

Davis, B.L. & Cooley, Patricia A. ACCIDENT-PRONENESS IN MOTOR VEHICLE DRIVERS. *Ergonomics*, May 1959, 2(3), 239-246. (Medical Psychology Lab., University of Cambridge, Cambridge, England).

Motor-vehicle drivers were examined at interview and on visual tests. Each was classified as 'accident-prone' or 'safe' on the basis of his known accident record and the distance he said he had driven, those with a rate of 3 or more accidents per 100,000 miles being classified as 'accident-prone', those with a lower rate as 'safe'. On this criterion there were 74 'accident-prone' drivers to be compared with 74 'safe'. All those who gave a history of definite nervous or mental illness were 'safe'. Those who had had grammar-school education or its equivalent tended to be 'safe'. The unmarried men tended to be 'accident-prone'. A larger proportion of the 'accident-prone' had been convicted of traffic or other offences. No differences were found between the 'accident-prone' and the 'safe' in the incidence of physical disabilities, eye or ear defects or psychosomatic complaints, or in personal qualities so far as these could be rated. Plans for further research into accident-proneness are briefly discussed.

9083

Hodgkiss, A. PHYSIOLOGICAL BASES OF TRAINING. *Ergonomics*, Feb. 1959, 2(2), 133-142. (Physiology Dept., School of Medicine, University of Leeds, England).

(Presented at a symposium on training.) The paper reviews the problem of athletic training in terms of the physiological background. The aim of training is to increase skill, endurance and strength. Attention to such factors as length of stride, speed of movements, lead and posture can lead to more economical use of the body. Often the most economical rate of performance is that naturally chosen. Improvements in the efficiency of the body often result from training by repetition, or from the use of auxiliary movements. Strength and endurance are developed only by exercises at or close to the limit of performance. In development training the scheme of training is progressively adjusted to the maximum performance attainable at the different stages of training. Some examples of this are cited in the paper. In regard to oxygen uptake and heart output, recent work shows that the difference between the trained and untrained man is that the former is able to increase his heart output and transport oxygen to his muscles at a higher rate than the latter. In modern training schemes, economy of effort and strengthening of the heart are achieved by progressive and long continued training. An example is given, based on training for a 4-min. mile.

King, S.D.M. THE OPERATOR AS A SET-REGULATING SYSTEM: A FACTORY EXPERIMENT. *Ergonomics*, Feb. 1959, 2(2), 171-179. (Organization & Training (Consultants) Limited, London, England).

In industry it is not unusual for the performance of ex-training of ex-trainees to fall after entering the production department. During training the trainee is treated, from a cybernetic viewpoint, as a self-regulating system. In the normal production department, however, the operator finds his role restricted to performing tasks, the control of which is largely vested in the supervisor. In the experiment described here the setting up of a training department was combined with the re-organization of the associated production department. This re-organization provided the conditions in which the operators, after re-training could continue to act as self-regulating systems. It coincided with a marked improvement in performance.

Kuoronen, M.J. PROBLEMS OF TRAINING OF THE CARDIOVASCULAR SYSTEM. *Ergonomics*, Feb. 1959, 2(2), 207-215. (Institute of Occupational Health, Helsinki, Finland).

(Presented at a symposium on training.) Training of the cardiovascular system may effect several structural, chemical and functional changes. Some of the functional changes become manifest only during exercise, others are observable also at rest. To some extent changes due to training are independent of each other, and depend on the type of training. For example, a decrease of the pulse rate during standard exercise is obtained only by training at high pulse rate levels. Training may reduce the mechanical work of the heart at rest. It increases the performance capacity of strenuous exercise. In submaximal work it may reduce the effort needed. Training of the cardiovascular system is not known to produce detrimental effects on health. The longevity of trained athletes is equal to or even longer than that of other comparable groups. The serum cholesterol level of athletes in training may be lower than that of the general population. In women, signs of a trained cardiovascular system are associated with reduced incidence of premature births. Training of the cardiovascular system has much to recommend it because of its effects on performance capacity and health.

Crozier, W.J., & Wolf, E. THEORY AND MEASUREMENT OF VISUAL MECHANISMS. IV. CRITICAL INTENSITIES FOR VISUAL FLICKER, MONOCULAR, AND BINOCULAR. J. gen. Physiol., 1941, 24, 505-534. (Harvard University, Cambridge, Mass.).

Comparison of monocular and binocular critical flash intensities for recognition of flicker, using a centrally fixated square image subtending ca. 6.13° on a side (white light) shows that for the cone segment of the response contour the inflection point of the probability integral correlating flash frequency F (for symmetrical flicker) and log mean critical flash intensity I_m is with the binocular measurements exactly intermediate between those for each eye separately. For the measurements in the predominantly rod region the binocular data are more or less intermediate. The rod curves result, however, from the integrative interplay of rod and cone effects for which the intrinsic curves overlap. For binocular, as for unocular excitation, the normal probability summation provides an efficient general description, under diverse conditions of size and location of retinal image, wave-length composition of light, light-time cycle-fraction, and kind of animal. It is pointed out that this is the only function abstractly likely to exhibit this kind of efficiency. That a summation of veritable effects independently generated by simultaneous, symmetrical unocular excitation does occur in the recognition of flicker is specifically demonstrated by the fact that for a given mean critical flash intensity the associated variation is lower for binocular than for either or the average of the single-eyed presentations, and in the ratio not statistically different from 1:1.4; the relative scatter of the binocular indices of dispersion is also reduced below the unocular.

Crozier, W.J., & Wolf, E. THEORY AND MEASUREMENT OF VISUAL MECHANISMS. V. FLASH DURATION AND CRITICAL INTENSITY FOR RESPONSE TO FLICKER. J. gen. Physiol., 1941, 24, 635-654. (Harvard University, Cambridge, Mass.).

The relation between flash duration and mean critical intensity (white light) for threshold recognition of visual flicker, as a function of flash frequency, was investigated by means of measurements at 5 values of the light-time fraction: 0.10, 0.25, 0.50, 0.75, 0.90, with flash frequencies of the interrupted beam ranging from 2 to 60 per sec. A square area, 6.1 x 6.1°, centrally fixated, was viewed monocularly; the discriminator used provided automatically an artificial pupil 1.8 mm. in diameter. Except for the slight day-to-day fluctuation in the magnitudes of the parameters, the data for the observer used are shown to form an essentially homogeneous group. As for other animals tested, the $F - \log I_m$ curve is enlarged and moved toward lower flash intensities as the light-time fraction is decreased. The low intensity segments are composites, their shapes determined by the summation of the lower part of the high intensity curve with an overlapping low intensity population of effects. Both the rising and the declining branches of this latter assemblage suffer competitive partial suppression by the effects in the high intensity population. The detailed analysis shows that these results are consistent with the theory of the central, rather than peripheral, location of the dynamically recognizable elements in the determination of flicker.

Haig, C. THE COURSE OF ROD DARK ADAPTATION AS INFLUENCED BY THE INTENSITY AND DURATION OF PRE-ADAPTATION TO LIGHT. *J. gen. Physiol.*, 1940-1941, 24, 735-751. (Medicine Dept., College of Physicians and Surgeons, Columbia University, New York, N.Y.).

An increase in the degree of light adaptation causes a decrease in the slope of the subsequent rod dark adaptation function and a displacement of the function to the right on the time axis. Over a wide range, these changes occur to the same extent whether the increase in the degree of light adaptation is produced by raising the intensity or by prolonging the exposure. Within these limits, the Bunsen-Roscoe reciprocity law applies to the intensity and duration of pre-exposure. Over a still wider range, dark adaptation has the same course following brief exposure to a bright light as it has following prolonged exposure to a dim light, provided the degree of light adaptation is the same in both instances (as indicated by identical initial dark adaptation thresholds).

Crozier, W.J. ON THE VISIBILITY OF RADIATION AT THE HUMAN FOVEA. *J. gen. Physiol.*, 1950, 34(1), 87-136. (Harvard University, Cambridge, Mass.).

Seeing-frequency functions determined unocularly for small brief images at the thoroughly dark-adapted human central fovea take the form of log-Gaussian integrals for intensity or for exposure-time as the independent variable. The properties of r' , the abscissa of inflection in the log-Gaussian integrals, and of the SD are discussed in relation to customary determinations of spectral visibilities and agreements and certain necessary divergencies are considered. A preliminary test of photosensitization has been made by the use of mixed monochromatic lights. The total energy is empirically the significant quantity, although the separate effects of the wavelengths are sharply exhibited. For the central fovea, where resistance to anoxia is at a maximum, the presence of an enzyme system, consisting mainly of cytochromes, is a reasonable assumption. (NEIAS)

Mueller, C.G. FREQUENCY OF SEEING FUNCTIONS FOR INTENSITY DISCRIMINATION AT VARIOUS LEVELS OF ADAPTING INTENSITY. *J. gen. Physiol.*, 1950, 34(4), 463-474. (Columbia University, New York, N.Y.).

9231

In a study of the relation of the frequency of seeing function to the intensity of the adapting stimulus, two subjects were tested in a series of twenty-three experimental sessions. Each session involved testing the subject's perception of stimulus differences at two levels of adapting intensity. Detection of the increment in intensity was determined as a function of magnitude of increment and magnitude of stimulus (to which increment is added). Five frequency of seeing curves were obtained at each level of adapting intensity (ranging from -1.45 to 4.45 log photons). The results are discussed in terms of the relation between the frequency of seeing curve and the intensity of the adapting stimulus.

Neeb, F.A. & Poppel, A.J. THE EFFECT OF VARYING THE INTENSITY AND THE DURATION OF PRE-EXPOSURE UPON FOVEAL DARK ADAPTATION IN THE HUMAN EYE. *J. gen. Physiol.*, 1951, 34(5), 657-674. (Emory University, Atlanta, Ga.).

The course of foveal dark adaptation was studied as a function of the intensity and duration of pre-exposure. 4 intensities (11,300, 5,650, 1,130, and 565 m μ) and 4 durations (100, 150, 30, and 15 secs.) were used in all combinations of intensity and duration. The threshold-measuring instrument was a monocular Meeht-Schlaer adaptometer and the threshold measurements were recorded in log micromicrolamberts. There were 2 Ss and each went through the complete series of intensities and durations 5 times. The 5 logarithmic values obtained for each threshold were converted into a geometric mean and these means were the data used in the analysis of the results. The chief results were as follows: a) For each S the final steady threshold value was in the region of 7.0 log μ l. b) As the intensity, or duration, or both, were increased the initial foveal dark adaptation threshold rose, the slope of the curve decreased, and the time to reach a final steady threshold value increased. c) For those values of pre-exposure intensity and time for which the product, $I \times t$, is a constant it was found that for the 2 higher intensities and 2 longer durations and also for the 2 lower intensities and 2 shorter durations, dark adaptation curves were the same. For other values of $I \times t = C$ the curves were generally not the same.

McFarland, R.A. & Halperin, H.H. THE RELATION BETWEEN FOVEAL VISUAL ACUITY AND ILLUMINATION UNDER REDUCED OXYGEN TENSION. *J. gen. Physiol.*, 1950-1951, 23, 613-630. (Fatigue Lab., Harvard University, Boston, Mass. & Ophthalmology Dept., Long Island College of Medicine, Brooklyn, N.Y.).

The foveal visual acuity of 11 Ss was studied in relation to illumination under normal atmospheric conditions and at simulated altitudes of 10,000 ft. (14.3% O $_2$) and 18,000 ft. (10.5% O $_2$). A mask was used to administer the desired mixtures of oxygen and nitrogen. At the end of each experiment, measurements were made while inhaling 100% oxygen from a cylinder. A red filter (No. 70 Wratten) was used so as to study only the behavior of the cones of the retina. The logarithm of illumination was plotted horizontally (abscissa) and the logarithm of visual acuity vertically (ordinate). The reduced oxygen tensions resulted in a shift of the curve to the right, along the intensity axis, the extent of the change being 0.24 of a log unit at 14.3% O $_2$ and 0.47% of a log unit at 10.5% O $_2$. These effects were completely counteracted within a few minutes by inhaling oxygen. As a consequence of the shape of the curve, such a shift to the right resulted in a relatively large decrease of visual acuity at low illuminations. At increasing light intensities anoxia produced less and less change, until at very high illuminations the decrease was negligible. Thus with 10.5% O $_2$ the visual acuity at 0.144 photons decreased an average of 0.344 of a log unit, to 45% of its normal value. At 1320 photons, however, it decreased only 0.026 of a log unit, to 94% of its normal value for that intensity.

Wald, G., Harper, P.V., Jr., Goodman, M.C. & Krieger, H.P. RESPIRATORY EFFECTS UPON THE VISUAL THRESHOLD. *J. gen. Physiol.*, 1942, 25, 891-903. (Harvard University; Cambridge, Mass.).

Measurements are reported of the effects of respiratory stresses upon the absolute threshold of peripheral (rod) vision. Some Ss were kept wholly dark adapted and the photochemical system of the rods therefore stationary, the changes recorded may be assumed to have originated more centrally. To this degree the measurements provide a quantitative index of central nervous imbalance. Breathing room in a 32-36% oxygen at about double the normal rate causes the visual threshold to fall to approximately 1/2 the normal value within 5-10 min. This change is due primarily to alkalosis induced by the hyperventilation, and can be abolished or reversed by adding CO₂ to the inspired mixtures. Normal or rapid breathing of 2% CO₂ causes no change in threshold, with 5% CO₂ the threshold is approximately doubled. Breathing 10% O₂ at the normal rate also approximately doubles the threshold. This effect is compensated in part by rapid breathing. When 10% O₂ is breathed at twice the normal rate, the threshold usually falls at first, then slowly rises to supernormal levels. Due primarily to variations in their breathing patterns, Ss yield characteristically different responses on sudden exposure to low O₂ tensions with breathing uncontrolled. The threshold may either rise or fall to normal or subnormal levels. The threshold adjusts to anoxia rapidly; exposures lasting 5 to 6 hrs. do not produce greater or more persistent changes than those of much shorter duration.

Hecht, S., Hendley, C.D., Frank, S.R. & Haig, C. ANOXIA AND BRIGHTNESS DISCRIMINATION. *J. gen. Physiol.*, 1946, 29, 335-351. (Biophysics Lab., Columbia University, New York, N.Y.)

Brightness discrimination was studied in 8 individuals breathing O₂ concentrations of 7 different altitudes between sea level and 17,000 ft. The brightnesses were 0.1, 0.01, and 0.001 m. Involving only daylight (cone) vision. Findings: a) Brightness discrimination begins to deteriorate at fairly low altitudes, and becomes obvious at 8,000 ft.; b) Impairment of brightness discrimination varies inversely with the light intensity; c) The thresholds of night (rod) vision and day (cone) vision are affected equally by anoxia; d) The quantitative form of the relation between brightness discrimination $\Delta I/I$ and the prevailing brightness I remains the same at all O₂ concentrations; and e) In the retina the conversion of photochemical change into visual function is impaired in such a way that the conversion factor varies as the 4th power of the arterial O₂ saturation. Glaser, E.M. & Hervey, G.R. FURTHER EXPERIMENTS ON THE PREVENTION OF MOTION SICKNESS. *Lancet* (London), March 1952, 1(10), 490-492. (University of Cambridge, Cambridge, England).

2 groups of a total of 150 soldiers were placed on a rubber raft, exposed to artificial waves (6 days, for 1 hr. every 48 hrs.) in a large swimming pool, and given a number of drugs as well as inactive substances for comparison. Nausea, vomiting, and other symptoms were recorded. Chi-square tests showed that hyoscine hydrobromide (1 mg.), or hyoscine hydrobromide (0.6 mg.) mixed with promethazine (15 mg.) were more effective in preventing seasickness than promethazine hydrochloride (Phenergan, 35 mg.). Dry mouth was a common symptom, even after taking the dummy pill. Glyceryl trinitrate did not prevent vomiting. Given 5-10 min. before the motion started, hyoscine (1 mg.) was still effective but less so than 1-1 1/4 hr. beforehand. (HEIAS)

Kinsler, L.E. IMAGING OF UNDERWATER OBJECTS. *Amer. J. of Physics*, Aug. 1945, 13, 255-257 (US Naval Academy, Annapolis, Md.).

This paper discusses experimental and theoretical proofs relating to the position of underwater objects when viewed from the surface. The refracted rays are not homocentric. The new center of the refracted rays is above the source by such an amount that the ratio of the true depth to the apparent depth equals the refractive index of the water. The mathematical treatment of the problem is illustrated. It is shown that a serious error is made if the incorrect apparent position is used in drawing conclusions as to the true location of underwater objects. (MEIAS)

Grether, W.F. OBTAINING READABILITY IN INSTRUMENT DIALS. *Prod. Engng.*, April 1950, 21(4), 109-112. (Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio).

9322

In this discussion of the problem of obtaining readability in instrument dials, the author notes the types and causes of dial reading errors (e.g., comprehension and precision errors, reading difficulty as a function of design), and presents specific recommendations concerning scale numbering, zero point location, and changes in scale values. In addition, he discusses the design of dials for check reading and multi-revolution instruments and the requirements for dial visibility and lighting.

Product Engineering. FITTING MACHINES TO MEN. *Prod. Engng.*, March 1952, 23(3), 164-167.

9328

This article describes the human engineering approach to the problem of fitting the machine to the operator. Analysis of the particular operation and objectives of a man-machine relationship is discussed in terms of the utilization of one of the general methods of human engineering, i.e., activity analysis, model analysis, and controlled experimentation. Also discussed are the problems of selection of relevant factors to be studied and the integration of equipment into systems.

Mackworth, N.H. THE BREAKDOWN OF VIGILANCE DURING PROLONGED VISUAL SEARCH. *Quart. J. exp. Psychol.*, 1948, 1, 6-21. (Applied Psychology Research Unit, Medical Research Council, Cambridge, England).

9342

This is a study of the breakdown of vigilance during prolonged visual search. The Clock test was devised to present the subject with a visual search situation of the following sort: a black pointer moved clockwise on a white background once every second (100 movements completed the circle). Approximately 150 subjects were instructed to observe the pointer and mark the double-length movements (twice the usual distance) by pressing a key. The subjects were divided into groups of two-hour, one-hour, and half-hour watches; and two-hour watches while receiving a telephone message. The results are discussed in terms of the average error scores for each of the different groups.

Vince, M.A. CORRECTIVE MOVEMENTS IN A PURSUIT TASK. *Quart. J. exp. Psychol.*, 1948, 1, 85-103. (Applied Psychology Research Unit, Medical Research Council, Cambridge, England).

9343

Five experiments are reported on the role of corrective movements in a pursuit task. Subjects were tested with a pursuit apparatus under conditions designed to investigate the following aspects of corrective movements: (1) hand reaction time to kinesthetic stimulus (joint and muscle); (2) effect of duration of large corrective movement upon its accuracy; (3) definition of the least duration of a movement which can be guided by visual cues; (4) the role of the kinesthetic sense in checking a movement (ballistic hypothesis); (5) effect of removal of visual stimulus upon accuracy; and (6) definition of minimal stimulus exposure (without accuracy impairment). The results are discussed in terms of the role of such factors as those investigated in speed and accuracy of tracking movement. T. G. I. R 9

Carpenter, A. A COMPARISON OF THE INFLUENCE OF HANDLE LOAD AND OF UNFAVORABLE ATMOSPHERIC CONDITIONS ON A TRACKING TASK. *Quart. J. exp. Psychol.*, 1950, 2, 1-6. (Applied Psychology Research Unit, Medical Research Council, Cambridge, England).

9344

To investigate the relative influence of handle load and unfavorable atmospheric conditions upon performance of a tracking task, twelve subjects were tested on a pursuitmeter under varied conditions of handle load (2, 8, 16, 24, 32, and 40 lb.) and environmental temperature (85°/75°, 90°/80°, 95°/85°, 100°/90°--F. dry bulb/F. wet bulb). An analysis of variance of the data was utilized to evaluate the relative effect and interaction of handle load and temperature upon tracking efficiency. Additional data are presented on the subjective appraisals of the experimental conditions by the subjects and the physiological changes (body temperature and weight) incurred during the experiment.

Fraser, D.C. THE RELATION BETWEEN ANGLE OF DISPLAY AND PERFORMANCE IN A PROLONGED VISUAL TASK. *Quart. J. exp. Psychol.*, 1950, 2, Part 4, 176-181. (Psychological Laboratory, Cambridge, England).

9345

To evaluate the relation between angle of display and performance in prolonged visual tasks, seventeen subjects were given the Clock Test with the test presented in display surface positions (vertical, angle of 45° to horizontal, and horizontal). Each subject was tested in each of the three conditions of clock position for a period of one hour (following 5 minutes of practice). The data were treated by analysis of variance and the results are presented in terms of the average number of errors occurring with each condition of position and also in terms of number of errors committed during first half-hour as compared to number occurring during second half-hour at each position.

Mitchell, M.J.H., & Vince, M.A. THE DIRECTION OF MOVEMENT OF MACHINE CONTROLS. *Quart. J. exp. Psychol.*, 1951, 3, 24-35. (Applied Psychology Research Unit, Medical Research Council, Cambridge, England).

9346

A series of experiments is described in which direction of movement of a control and display was varied to determine the most efficient relationships for the operator. A continuous pursuit task and a task utilizing intermittent stimuli were used in these experiments. The utilization of one vs. both hands, preferred vs. non-preferred hand, expected vs. unexpected directional relationship, and so forth, were evaluated along with the role of awareness of response. The results are compared with those in the literature and conclusions are drawn concerning optimal display control relationships.

Gibbs, C.B. TRANSFER OF TRAINING AND SKILL ASSUMPTIONS IN TRACKING TASKS. *Quart. J. exp. Psychol.*, Aug. 1951, III(Part 3), 99-110. (Applied Psychology Research Unit, MRC, Cambridge, England).

9347

Transfer of training was studied using a compensatory tracking and a serial pursuit task. For the first task, 70 Ss divided into groups learned to track on the standard and one of four modified arrangements of the handle-winding apparatus. These modifications were: pointer direction, pointer size, winding direction, and handwheel size. For the second task, ten females and ten males learned to track on both an easy and difficult course. Learning scores on all pairs of task conditions and sequences were compared by t-tests. The results were considered in terms of task difficulty, expectations based on previous experience, and different levels of required ability.

Poulton, E.C. & Gregory, R.L. BLINKING DURING VISUAL TRACKING. *Quart. J. exp. Psychol.*, 1952, 4, 57-65. (Applied Psychology Research Unit, Cambridge, England).

In order to determine the incidence of blinks during visual tracking, their effect, and the nature of this effect, 2 experimental arrangements were used. In one the S had to keep a pen upon a moving line, his blinks being recorded without his knowledge both electronically and by 2 observers. In the second he had to keep 2 pointers in line using a positional control, the display being occluded intermittently in one part by a wheel tachistoscope. In another by his own voluntary blinks. It was found that the blink rate was raised when the S expected the tracking to start, and again after tracking. During tracking it was reduced, particularly initially. The lowest blink rates were recorded during or immediately before the difficult periods of the course. It was not possible to predict the blink rate while tracking from a knowledge of the true "resting" blink rate. Although blinks were infrequent when the course was difficult, it was here that they caused the largest errors, especially when anticipation was not possible. This effect was due partly to interference with vision, but only temporary inattention could account for the delayed deterioration following blinking. It has been suggested that the blink rate might serve as an index of attention, blinking being one of the earliest signs of inattention.

9356 Chesman, G.H. & Hayne, Stella. THE INFLUENCE OF ADAPTATION ON ABSOLUTE THRESHOLD MEASUREMENTS FOR OLFACTORY STIMULI. *Quart. J. exp. Psychol.*, 1953, 5, 22-30. (Reading University, Reading, England).

A simple group test method of determining the absolute olfactory threshold for a test stimulus is described. Probit analysis is used to calculate the threshold concentration corresponding to 50% positive responses. This method of threshold measurement is used to determine the change in sensitivity to the test stimulus due to different concentrations of the masking stimulus. When the results for a pair of stimuli are plotted on a graph whose axes represent the log10(A) (log10 masking stimulus concentration) and log10(M) (log10 threshold concentration), the experimental points lie on a straight line. In the 3 cases examined where the test and masking stimuli are identical -- homogeneous pairs -- the slope of this line is -0.7. For the 6 heterogeneous pairs investigated, i.e. test and masking stimuli different, the slope of the line varies from -0.2 to -1.0. This slope may be considered as a measure of a degree of community of odour-property between the pair of substances.

Wells, G.L. THE BASIS OF NIGHT VISION. *J. Illum. Engng. Soc.*, 1944, 29, 93-111. (Bausch & Lomb Optical Company, Rochester, N.Y.).

Dark adaptation is a process during which a photoresponsive system automatically increases its sensitivity to light when the illumination is lowered. In vision the photochemical substances are brought back to maximal concentration from some lower level to which a higher illumination has pushed them. The changes which occur in the rods and cones of the retina are described. The role of rhodopsin is discussed. The photopic and scotopic curves are compared and the Purkinje shift explained. The effects of avitaminosis A and hyperventilation are described. (HEIAS)

Bald, L., Berrien, F.K., Price, J.B. & Sprague, R.C. ERRORS IN PERCEIVING THE TEMPORAL ORDER OF AUDITORY AND VISUAL STIMULI. *J. appl. Psychol.*, 1942, 26, 382-388. (Psychological Lab., Colgate University, Hamilton, N.Y.).

The present experiment has been designed to answer 3 questions: a) Is there a predisposition to judge either light or sound as appearing first when the 2 stimuli follow each other in rapid succession? b) What effect has the observer's position on his ability to make such judgements? c) What is the effect of obscuring the sound source from view? The judgments were made by a class in elementary psychology consisting of 30 to 32 college men in a large acoustically treated room. The data for the total group indicate: a) that more errors of judgment occur when the order is sound-flash, than when the order is flash-sound at short intervals of time; b) that obscuring the sound source from view increases the errors at the time intervals examined; c) the best situated group made more errors when the order was flash-sound than when the order was sound-flash, while the poorly situated group conformed in general with the total group results. The practical implications of this experiment have been developed.

9431 Zerbe, J.E. JOB ANALYSIS: A RESUME AND BIBLIOGRAPHY. *J. appl. Psychol.*, 1943, 27, 249-267. (Social Security Board, Bureau of Employment Security, Washington, D.C.).

Job analysis helps to cope with labor shortage in industry. Job analysis is a method of gathering pertinent facts about the worker and his work. The methods of job analysis are described. The role of the U.S. Employment Service is pointed out. Finally, 20 uses are listed for job analysis information. A bibliography of 401 is included covering the period 1911-1941 and dealing with job analysis literature. (NEIAS)

9433 Tinker, H.A. EFFECT OF VISUAL ADAPTATION UPON INTENSITY OF ILLUMINATION: PREFERRED FOR READING WITH DIRECT LIGHTING. *J. appl. Psychol.*, 1945, 29, 471-476. (University of Minnesota, Rochester, Minn.).

The purpose of the experiment was to determine the effect of visual adaptation upon illumination intensities preferred for reading under direct lighting that is strictly local. 60 Ss adapted to 20 foot-candle at one sitting, to 50 foot-candle at the second sitting. After adaptation, each S chose between the standard to which he was adapted and each of 5 other intensities on the basis of the intensity preferred for easy and comfortable reading. Findings: a) Visual adaptation at time of choice influenced the choice only moderately. b) There was a marked tendency to prefer intensities at and above the brightness to which the S was adapted. This resulted in frequent choice of high intensities. c) Since, in direct lighting such as used here, bright intensities make a bad situation worse from the viewpoint of hygienic vision, preferences for illumination intensities for reading yield unsatisfactory data for prescribing lighting for the individual. Seltz, C.P. & Rosenthal, C.H. THE EFFECT OF OXYGEN DEPRIVATION AND STRYCHNINE ON THE RELATIVE BLIND AREAS OF THE EYE. Psychol. Bull., 1940, 37, p462. (University of Alabama, University, Ala.).

This study was concerned with the changes in the relative blind areas of the eye under conditions of oxygen deprivation when strychnine was administered directly to the conjunctive. The control visual fields (35°) of the 4 Ss were mapped at frequent intervals. A definite decrease in the blind area was noted in the eye treated with 1% strychnine, while the eye which had not been treated showed widening of the blind areas, the usual effect of oxygen deprivation. The results clearly demonstrate the effectiveness of a small local application of strychnine in counteracting the effect of oxygen deprivation equivalent to an altitude of 17,500 ft. (MEIAS)

Lovell, G.D. PHYSIOLOGICAL AND MOTOR RESPONSES TO A REGULARLY RECURRING SOUND. Psychol. Bull., 1941, 38, p715. (Northwestern University, Evanston, Ill.).

Physiological and motor responses to a recurring tone of 60 cycles indicated relaxation (rise in palmar skin resistance above basal), tendency of breathing rate to approach that of the tone, and presence of motor rhythms simultaneous with the tone rate. These objective results were checked by a control group and questionnaire.

9465

Birron, J.E. STATIC EQUILIBRIUM AND VESTIBULAR FUNCTION. J. exp. Psychol., 1945, 35, 127-133. (USN Medical Research Institute, Bethesda, Md.).

Observations of body-sway and rail-walking tests were made on a 19-year old male who had lost all VIIIth nerve functions (vestibular). This S manifested marked body-sway during the first trial period, but improved greatly so that after one month his record could not be classed as pathological. During neither session could he score above zero on the rail-walking test. Postrotational nystagmus time and body-sway measurements were made on 45 male Ss. None of the correlation coefficients differed significantly from zero. The findings indicate that man may maintain stable posture despite loss of vestibular function, and that measurements of body-sway cannot be used to detect vestibular defects. (MEIAS)

Sharp, L.H. EFFECTS OF RESIDUAL TENSION ON OUTPUT AND ENERGY EXPENDITURE IN MUSCULAR WORK. J. exp. Psychol., July 1941, 29(1), 1-22. (University of Illinois, Urbana, Ill.).

The course of residual tensions in the resting but previously reacting arm is cyclical in character. A rather sharp initial loss in muscular tension is followed by a gradual rise to a much higher level at 15 minutes, then a subsequent slow decline to the pre-work level at 30 minutes. There are indications that the course of residual tensions provides a unitary basis for predicting the direction and relative magnitude of so-called "rest-pause" effect in muscular work. Optimally spaced double work periods show significantly greater output with significantly less energy expenditure in the second work period. It seems likely that the facilitative effects of increased proprioception are involved in simultaneously induced tension effects. (MEIAS)

 Grant, V.W. ACCOMMODATION AND CONVERGENCE IN VISUAL SPACE PERCEPTION. *J. exp. Psychol.*, Aug. 1942, 31(2), 89-104. (Northwestern University, Evanston, Ill.).

The effect of accommodation and convergence on distance perception, exclusive of the operation of other visual factors, was studied by means of an optical system providing unified control of image size and of the surface detail of the test target. Changes in the apparent distance of the target were measured and found to correlate in a systematic way with variations in the accommodative and convergent adjustments of the eyes. The differences between the mean distance judgments of 30 Ss were statistically reliable. When the apparent distance of the target was varied by increasing and decreasing accommodation and convergence, a group of 34 Ss gave correct perceptions ranging from 73% to 80% as compared with 33% correct by chance. Reports on apparent size changes of the target showed that increasing accommodation and convergence not only reduces the distance but diminishes the size of the visual image. (NEIAS)

 Read, L.C. THE INFLUENCE OF SIZE OF TEST STIMULI, INTERPUPILLARY DISTANCE AND AGE ON STEREOSCOPIC DEPTH PERCEPTION. *J. exp. Psychol.*, 1943, 31, 148-158. (Tufts University, Medford, Mass.).

23 stereograms, with 3 rows of 10 characters on each card, were viewed by 57 male Ss whose average age was 19.9 years and whose average interocular distance was 65.2 mm. The stereopsis angle and the size of numbers and letters were varied. Stereopsis scores were obtained by recording the number of correct responses; these were correlated with the other variables. For a given degree of binocular retinal disparity, the percentage of correct "nearer" judgments was directly related to the size of the test object; but the largest stimuli elicited a disproportionately greater number of incorrect "nearer" judgments than the smaller sizes of stimuli. No significant intercorrelations were found between number of incorrect responses, age, and interocular distance. The correlation between age and stereopsis score was reliable but not large. The perception of apparent depth in a test of this type is considered to be a highly specific and unique type of response, and only partially related to the natural type of depth and distance perception in free visual space.  Ferrus, C.E. & Read, C. A COMMENT AND PRACTICAL MEANS FOR STUDYING LIGHT AND COLOR MINIMA IN ANY PART OF THE RETINA. *J. exp. Psychol.*, 1940, 26, 28-52. (Research Laboratory of Physiological Optics, Baltimore, Md.).

The purpose of the paper was to describe an attachment to the Ferrus-Read Perimeter for determining light and color minima in any part of the field of vision. The limitations of the method of limits and the usefulness of the method of minima are discussed. The use of the attachment is described. It has particular value when a detailed study is needed, when great sensitivity is required. When quantitative knowledge is wanted of the relationship of the sensitivity in the central retina to the sensitivity at any point in the peripheral retina, where knowledge is wanted under different intensities of illumination. In eye diseases it is a means of showing what parts of the retina are apt to be affected. (MEIAS)

 Smith, F.O. A STUDY TO DETERMINE THE RELATIVE EFFECTIVENESS (VISIBILITY) OF RED, ORANGE, YELLOW, GREEN AND BLUE UNDER CERTAIN SPECIFIED CONDITIONS. *J. exp. Psychol.*, 1940, 26, 124-129. (Marshall State University).

To determine the relative effectiveness (visibility) of red, orange, yellow, green, and blue under conditions of distance of illumination, 22 subjects were required to make 30 comparisons of having colored paper with illumination reduced to .25 foot candle. To evaluate the effect of contrast, strips of black, white, and orange were pasted across each of the original five colors. The results are presented and discussed in terms of the relative effectiveness of each of the colors under conditions of distance of illumination and with and without contrast effect. Implications are presented for the utilization of the data for the design of road signs. T. R

 Andrews, T.G. THE EFFECT OF BENZEDRINE SULFATE ON SYLLOGISTIC REASONING. *J. exp. Psychol.*, 1940, 26, 423-431. (University of Nebraska, Lincoln, Neb.).

20 Ss were given a syllogistic reasoning test at 4 different experimental sittings. At two of the sittings, the Ss were under the influence of 10 mg of benzedrine sulfate; the other two sittings involved a placebo capsule of lactose. Accuracy, time, power scores, physiological indices were taken on the tests at each sitting. Conclusions: a) The drug had no statistically significant effect on reasoning scores, although slight changes occurred in favor of benzedrine--(women being more affected than men); b) The Ss who were lighter in weight obtained a slight increase toward significance due to the benzedrine; c) There was a significant rise in systolic blood pressure due to the effects of benzedrine. In general, all scores were improved by benzedrine. This "summation effect" indicates that benzedrine tends to increase the scores on a syllogistic reasoning test. Higher dose is suggested for a future experiment. (MEIAS)

 Broadbent, D.E. THE ROLE OF AUDITORY LOCALIZATION IN ATTENTION AND MEMORY SPAN. I. *J. exp. Psychol.*, 1954, 47, 191-196. (University of Cambridge).

Two experiments are reported in this study of the role of auditory localization in attention and memory span. To determine the relative efficiency of different types of localization, 76 subjects were divided into six groups with each group required to answer verbal messages presented under various conditions (e.g., two simultaneous messages, fused vs. localized recording, differing speaker location, etc.). Data are treated in terms of accuracy of answers as a function of condition of message transmission. The second experiment examined the limits of immediate memory on two separate channels. Utilizing the two-channel ferrograph, 24 subjects were tested for memory span with a list of digits presented simultaneously. The results are treated in terms of the type of order of response imposed by the subject under conditions of binaural presentation. T. G. R 13

 Hochberg, J.E. & Beck, J. APPARENT SPATIAL ARRANGEMENT AND PERCEIVED BRIGHTNESS. *J. exp. Psychol.*, 1955, 57(4), 263-266. (Cornell University, Ithaca, N.Y.).

In order to determine whether perceived brightnesses can be brought into one-to-one correspondence with stimulus illumination relationships any more than with absolute illumination intensities, Ss made judgments of the brightness of a target which, under constant or controlled conditions of illumination, was made to appear to be either perpendicular or parallel to the apparent direction of illumination. Since substantially the same illumination distributions produced different perceived brightnesses, analyses of brightness constancy in terms of stimulus illuminations cannot at present be considered complete explanations.

 Falk, J.L., & Bindra, D. JUDGMENT OF TIME AS A FUNCTION OF SERIAL POSITION AND STRESS. *J. exp. Psychol.*, 1954, 47, 279-282. (McGill University, Montreal, Canada).

9497
 To evaluate the function of serial position and stress in judgment of time, 40 subjects were required to judge a 15-sec. interval by the production method (5 marks interval by pressing and releasing a key). Half of the subjects (experimental group) were told of and received mild shock at the end of certain trials while the other subjects (control group) were unaware of and did not receive shock. The results are treated in terms of the relative effects of stress and the nature of the serial position gradients. Time-order error and improvement in ability to judge time are discussed with regard to their role in the production of serial position gradients.

 Hisslak, H. AGE AND SEX DIFFERENCES IN CRITICAL FLICKER FREQUENCY. *J. exp. Psychol.*, 1947, 37, 318-332. (Fordham University, New York, N.Y.).

The foveal critical flicker frequency (cff) for both eyes was determined for 100 Ss on 3 consecutive days. Half the Ss were 19-30 years old, the other half from 61-87 years. The sexes were equally represented. Conclusions: a) There is a significant decrease in the cff in old age for both eyes, dominant and non-dominant. It is probably due to the degeneration of the optic nerve and cerebrum; b) There are no sex differences; and c) The range of cff values is greater in old age. The cff test can be useful in gerontological studies. (MEAS)

 Doughty, J.V., & Garner, W.R. PITCH CHARACTERISTICS OF SHORT TONES. I. TWO KINDS OF PITCH THRESHOLD. *J. exp. Psychol.*, 1947, 37, 351-365. (Johns Hopkins University).

9504
 In a study of the relationship between pitch and the duration of a tone, two experimental subjects, selected for accuracy in threshold judgments from an original group of six, were asked to make a series of judgments of click-pitch (tone heard as click with some pitch character) and true pitch (definite pitch character) thresholds under conditions of varied tone duration and frequency (125 to 8000 cps) and under conditions of varied tone duration and intensity (90 to 30 db). A vernier setting was made by the subject when he felt he had determined the threshold. The results are presented and discussed in terms of the degree of variation of the click-pitch and tone-pitch thresholds as a function of frequency and intensity and in terms of pitch discrimination as a function of tone duration.

Nance, R.B. THE EFFECTS OF PACING AND DISTRIBUTION ON INTERCORRELATIONS OF MOTOR ABILITIES. *J. exp. Psychol.*, Dec. 1947, **32**(6), 459-472. (Milwaukee State Teachers College, Milwaukee, Wisc.).

The study was concerned with the effects of pacing and distribution of practice when using the S.A.M. rotary pursuit test. The rotary pursuit test and a complex coordination test were given to 400 male Ss. With both tests pacing produced lower initial scores. The distributed-paced group alone showed rapid improvement which did not level off at the end of 4 minutes. The hypothesis concerning an increase in the correlations between the 2 tests was not supported. It is concluded that equating the pacing and distribution variables for 2 motor tests carries, under the experimental conditions, no implications for a general motor ability. (NEIAS)

Baker, R.A. & Osgood, S. DISCRIMINATION TRANSFER ALONG A PITCH CONTINUUM. *J. exp. Psychol.*, 1954, **48**(4), 241-246. (Massachusetts Institute of Technology, Cambridge, Mass.).

4 groups of 10 Ss were trained on pairs of tones differing only in frequency. All groups received an equal number of reinforced training trials on a given discrimination and were subsequently tested on a difficult series. 1 group was trained throughout on the test series; a second was trained on an easy discrimination and then shifted to the test; a third approached the test discrimination through a series of graduated steps; a fourth group received no practice and served as a control. All groups were administered the difficult discrimination test prior to training. When these groups were compared in terms of improvement on the difficult discrimination test, it was found: a) the only significant evidence of learning was obtained for Ss who approached the test discrimination through a series of graduated steps; b) performance on the test discrimination appeared to deteriorate for those Ss trained on the very easy discrimination and abruptly shifted to the test discrimination. The decrement in performance was not, however, statistically significant. (NEIAS)

Corathewahl, S.J. CONSPICUITY OF FLASHING LIGHT SIGNALS OF DIFFERENT FREQUENCY AND DURATION. *J. exp. Psychol.*, Oct. 1954, **48**(4), 247-251. (USAF School of Aviation Medicine, Randolph Field, Tex.).

The experiments reported here have produced evidence that when S is engaged in a very complex psychomotor task, and does not know when and where a light signal may appear, its efficacy as a warning or indicator is determined not by the luminance of a single flash alone, but by the conspicuity of a series of flashes. The results suggest that, if the brightness contrast is 1.00 or 7/16, i.e., according to our previous findings, close to or larger than 1.00, S will respond to a series of light flashes in a complex situation with about the same speed whether the flash becomes visible only once each second for 1/2 sec., 2 times for 1/4 sec., or whether it occurs 4 times per second only for 1/8 sec. At the low contrast, however, the fast flashing light of short duration seems to be more conspicuous than the slow flashing signal of a longer duration.

Motokawa, K. RETINAL TRACES AND VISUAL PERCEPTION OF MOVEMENT. *J. exp. Psychol.*, June 1953, 45(6), 369-377. (Physiology Dept., Tohoku University, Tohoku, Japan).

A physiological aftereffect of a moving retinal image was investigated by the method of electrostimulation. Aftereffects at a series of points in the retinal pathway were measured and plotted against distances to obtain the "trace-curve". The trace-curve increases in height with increases in distance from the start, giving rise to a gradient in the direction of motion. The higher the velocity, the higher the trace-curve, and its initial gradient is greater. A trace-curve for a large figure is low and its initial gradient small. A trace-curve for a horizontal line moving in the horizontal direction is higher than that for the one oriented at right angles to it. The apparent velocity is little changed by reducing the linear dimensions of the moving field and the objective velocity to one-half of the original ones; but the retinal gradient becomes steeper. The physiological mechanisms of retinal traces is discussed in terms of the known properties of retinal induction. (HEIAS)

Motokawa, K., & Ebe, M. THE PHYSIOLOGICAL MECHANISM OF APPARENT MOVEMENT. *J. exp. Psychol.*, 1953, 45(6), 378-385. (Physiology Dept., Tohoku University, Tohoku, Japan).

Retinal induction caused by stroboscopic stimuli was measured by the method of electrostimulation. The retinal induction caused by a first stimulus is changed in character and magnitude by the action of a second successive stimulus. With an adequate interval between two stimuli, the induction lying in the field between the retinal areas exposed to the stimuli acquires the same quality as the induction at the site of stimulation so that the two stimuli become fused as retinal processes. A gradient of retinal induction directed from the first stimulus to the second is established by conversion. The interval for optimal conversion decreases with increasing stimulus intensities, and increases as the distance between 2 stimuli increases. These relations correspond to Torte's laws of apparent movement. (HEIAS)

Keller, Margaret. THE RELATION BETWEEN THE CRITICAL DURATION AND INTENSITY IN BRIGHTNESS DISCRIMINATION. *J. exp. Psychol.*, 1941, 28, 407-418. (Butler Hospital, Providence, R.I.).

A method is described for examining the influence on foveal intensity discrimination of variations in the duration (r) of ΔI , the increment added to the basic intensity I . In foveal intensity discrimination the Bunsen-Roscoe law ($\Delta I \cdot r = \text{constant}$) holds for exposures of ΔI up to the limit of a critical duration (r_c) at all levels of the basic intensity, I . Beyond the critical duration, intensity discrimination is independent of duration and $\Delta I = \text{Constant}$. The critical duration decreases as the basic intensity increases according to an empirical relation of the form $r_c = kI^{-p}$, where k and p are constants. A further analysis shows that, with durations of ΔI greater than r_c , failure to consider the influence of the critical duration may alter the form of the intensity discrimination function in such a way as to produce a rise at high intensities. This observation may partially resolve some disagreements in the work of earlier investigators.

Yacorzynski, G.K., & Brown, M. STUDIES OF THE SENSATION OF VIBRATION. I. VARIABILITY OF THE VIBRATORY THRESHOLD AS A FUNCTION OF AMPLITUDE AND FREQUENCY OF MECHANICAL VIBRATION. *J. exp. Psychol.*, 1941, 28, 509-516. (Northwestern University Medical School).

9519

This study is concerned with the elaboration of two specific aspects of vibratory threshold: (1) specification of the number of threshold determinations necessary for acquisition of a stable threshold measure; and (2) determination of degree of fluctuation of such a threshold over time. Utilizing an apparatus to produce and record vibratory sensations, the thresholds of the right index finger-tip were determined for 20 subjects. Stability of threshold was measured by computing Pearson correlation coefficients between the initial five and the last five threshold determinations. Thresholds were determined at each of four frequencies (200, 400, 600, and 800 d.v.). The results are presented and discussed in terms of number of determinations necessary for a stable measure and the variability of individual thresholds over time. T. G. I. R 8

Feinberg, R. & Vint, S.E. VISUAL ACUITY IN RELATION TO ILLUMINATION IN THE ORTHO-RATER. *J. appl. Psychol.*, 1947, 31, 406-412. (Purdue University, Lafayette, Ind.).

Visual acuity, right eye, of 100 college students was measured in the Ortho-Rater with different levels of illumination over a range of about 33" to 1 for the far tests and 25 to 1 for the near tests. There was no apparent learning or fatigue factor to bias the results, and the sequence of tests was varied systematically to neutralize any constant error. Mean visual acuity decreased approximately 16% (far) and 22% (near) for reduction in brightness in the ratio of about 2 to 1 from standard brightness. Intercorrelations of acuity at different levels of brightness over a range of 10 to 1 are .80 to .90 for the far tests and .70 to .80 for the near tests -- not much lower than the test-retest reliability. These relations were demonstrated only for photopic levels of illumination in the Ortho-Rater with the checkerboard test object. Similar relations may be true also for other types of acuity tests with standardized illumination, but for letter tests, or other shape characters, they would need to be demonstrated independently. Paterson, D.G. & Tinker, M.A. READABILITY OF NEWSPAPER HEADLINES PRINTED IN CAPITALS AND IN LOWER CASE. *J. appl. Psychol.*, 1946, 30, 161-168. (University of Minnesota, Minneapolis, Minn.).

3 studies were carried out relating to the problem of relative legibility of headlines. The first study dealt with 5-word single-column headlines set in 24 point bold face, half in upper case and half in lower case, to be read by tachistoscopic exposure at the normal reading distance of 15 inches. The results disclosed an 18.9% difference in favor of the lower case headlines. The second study used the same single-column headlines but exposed them at a distance of 5 1/2 ft. This time both kinds of headlines were shown to be equally legible. The third study used multi-column or banner headlines set in 60 point bold face. At 6 ft. the legibility of the lower case was 5.3% greater, at distances from 10 ft. to 14 ft. both were equally legible, at 17 ft. the upper case headlines proved more legible. The writers recommend that headline writers should abandon the use of upper case headlines. (HEIAS)

Fisher, M.B. & Birren, J.E. STANDARDIZATION OF A TEST OF HAND STRENGTH. *J. appl. Psychol.*, 1946, 30, 380-387. (Fresno State College, Fresno, Calif. & Northwestern University, Evanston, Ill.).

The paper deals with a test procedure for the hand dynamometer which is satisfactory for inclusion in a battery of performance tests. S squeezes the dynamometer every 3 sec., starting with a grip of 27 kg., and increasing his grip 3 kg. with each attempt. The split-half reliability coefficients, preferred vs. non-preferred hand, were 0.91 and 0.92 for the first and second tests, respectively (N=72). The retest reliability of the test, administered twice within 2 days, was 0.87 (N=72). Mean improvement in the early periods of practice for 40 Ss was 0.31 kg. per-period. Several groups of data involving various stress conditions indicate that the test has some degree of validity, in that test scores parallel the cardiovascular and respiratory responses and reported general fatigue of Ss under such conditions. Peterson, G.G. & Tinker, M.A. THE RELATIVE READABILITY OF NEWSPRINT AND BOOK PRINT. J. appl. Psychol., 1946, 30, 454-459. (University of Minnesota, Minneapolis, Minn.).

The purpose of this investigation was to compare the readability of newsprint and book print. Speed of reading 10 point Cheltenham book type was compared with speed of reading 8 point Opticon newsprint and with 7 point Ionic No. 5 newsprint. Both kinds of newsprint were read significantly more slowly than the book print. The slower rate of reading newsprint is apparently due to the greater difficulty of discriminating the printed characters in comparison with the book type which is larger and which involves greater brightness contrast between print and paper. The 10 point book print and the 8 point newsprint are judged to be about equally legible, but the 7 point newsprint is considered to be far less legible. The book print is judged to be most pleasing, the 8 point newsprint next most pleasing, and the 7 point newsprint least pleasing.

Peterson, G.G. & Tinker, M.A. INFLUENCE OF LEADING UPON READABILITY OF NEWSPAPER TYPE. J. appl. Psychol., 1947, 31, 160-163. (University of Minnesota, Minneapolis, Minn.).

The purpose of this investigation is to determine the influence of leading on the readability of newsprint. Speed of reading 7 point Ionic No. 5 newsprint in a 12 1/2 pica line width set solid was compared with speed of reading text typographically identical except for leading which varied in the different comparisons as follows: set solid (control group), 1, 2, 3, 4, 5, 7, and 9 points. All material with leading was read faster than text set solid. In comparison with set solid material, the 4 and 5 point leading produced differences with the highest significance (beyond the 1% level). One point leading is as effective in improving readability as larger amounts of leading except for 4 and 5 points. 9 point leading is less effective than most of the lesser amounts of leading. Text with 4 and 5 point leading is judged to be most legible. This agrees with the speed of reading results. Material set solid is judged to be least legible. In view of practical considerations, readability and readers' judgments, 1 point leading is indicated for 7 point newspaper type in a 12 1/2 pica line width. This would also hold for a 12 pica line width since unpublished data of the writers show that variations in line width from 12 to 12 1/2 to 13 picas do not significantly affect readability of newspaper type.

Solandt, D.Y. & White, R.E. THE EFFECT OF SPECTRAL COMPOSITION OF ILLUMINATION ON VISUAL
PERFORMANCE. Illum. Engng., N.Y., 1951, 46, 467-468. (University of Toronto, Toronto,
Canada).

The present work was undertaken to assess separately and compare the visual effectiveness
of white light produced by a source with a continuous spectrum and white light produced by
mixing complementary spectral colors of narrow band width with their relative intensities
adjusted to yield white light. Visual acuity was measured using 2 mixtures of monochromatic
lights adjusted to give the sensation of white light and the results were compared with those
obtained using the white light from a concentrated (zirconium) arc lamp, and from a fluores-
cent (white or daylight) lamp. The spectral distribution curve for the zirconium arc lamp
is continuous, and that for the fluorescent lamp shows peaks of the mercury spectrum super-
imposed on the relatively continuous spectrum of the various fluorescent materials in the
phosphor. That of the dichromatic illumination showed 2 peaks and the trichromatic three,
in accordance with the filters used.

Putnam, R.C., & Fausett, R.E. THE THRESHOLD
OF DISCOMFORT GLARE AT LOW ADAPTATION LEVELS.
Illum. Engng., N.Y., 1951, 46, 505-510.
(Case Institute of Technology).

9588
To determine the threshold of discomfort glare,
fifteen subjects were given momentary exposures to a
glare source and were required to adjust a variac con-
trolling the brightness until in their judgment the com-
fort-discomfort borderline was attained. Eye position
was fixed and the brightness of the adaptation field was
held constant by the experimenter. A total of 3139 ap-
praisals was recorded. The results are compared to those
obtained by other researchers using similar and different
techniques. Conclusions are drawn concerning the tolera-
bility of brightness as a function of the source (i.e.,
small vs. large light sources).

Jones, J.R. & Weidhart, J.J. COEFFICIENTS OF UTILIZATION FOR LUMINAIRES WITH CONCENTRATING
DISTRIBUTIONS. Illum. Engng., N.Y., Dec. 1951, 46, 601-609. (Westinghouse Electric Corp.,
Bloomfield, N.J.).

The currently used Lumen Method of calculating interior illumination was developed by
Harrison and Anderson during the period between 1915 and 1920. It is an empirical method
based upon the results of experiments with typical luminaires of that time in rooms of vari-
ous sizes and surface reflectances. The need for additional accurate data has long been re-
cognized and other studies have been initiated to provide information that is applicable for
all distributions. One of these has resulted in the Interreflection Method, which has been
used as the basis for computing the data for the reflected components presented in this paper.
The real need is for a method of calculating coefficients of utilization that more fully re-
cognizes differences in distribution of light flux from present day equipment. It would then
be possible to provide more accurate coefficients of utilization for use in the familiar
Lumen Method formulas. To satisfy this need the authors are proposing a method of calculat-
ing coefficients of utilization that considers the ultimate disposition of the flux from
every 10° zone instead of using an arbitrary wide zone of 40° as a criterion. The flux in
each 10° zone (0°-10°, 10°-20°, etc.) that strikes the work plane directly is determined, and
to that is added the flux that reaches the work plane by interreflection. The ratio of the
total flux reaching the work plane to the lamp lumens is the coefficient of utilization.

Kavern, G.M. EFFECT OF SOURCE SIZE UPON APPROACH LIGHT PERFORMANCE. Illum. Engng., N.Y., 1950, 45, 96-98. (Wright Air Development Center, Dayton, Ohio).

An investigation was initiated to determine the most practical solution to the following problems, utilizing presently available information: a) Determination of the effect of apparent source size upon the visual range of lamp assemblies used as approach and runway lights during low visibility conditions; b) Determination of suitable source size requirements for inclusion in specifications covering high intensity approach and runway lamp assemblies. It is evident that when runway and approach lighting systems are being designed, the effect of source size can no longer be ignored. A simple and convenient method of evaluating lamp assemblies with respect to effective source size has been developed and is presented. This method is admittedly approximate, but more exact methods are not feasible until more information is obtained by basic research on the following points: a) Background brightnesses during daylight fogs; b) Correlation of laboratory and practical pilot visual thresholds; c) Effect of non-circular shapes; d) Effect of non-uniform brightnesses; e) Effect of grouping 2 or more small sources.

Blackwell, R.R. BRIGHTNESS DISCRIMINATION DATA FOR THE SPECIFICATION OF QUANTITY OF ILLUMINATION. *Illum. Engng.*, N.Y., 1952, 47, 602-609. (University of Michigan).

9627
This article presents experimental data concerning the quantity of illumination necessary for the most adequate discrimination of brightness differences. Two subjects were presented the task of detecting a disc target produced by adding a brightness increment to a screen of uniform brightness. A total of 162 experimental sessions were conducted with each session consisting of 250 target presentations at various levels of target brightness increment and under varied conditions of target size, target duration, and background illumination. The results are presented in terms of optimal performance as a function of quantity of illumination. A discussion of this article is included.

Kahler, M.M. (Chm.). RECOMMENDED PRACTICE FOR SUPPLEMENTARY LIGHTING. Illum. Engng., Nov. 1952, 47, 623-635. (Subcommittee on Supplementary Lighting, Illuminating Engineering Society, New York, N.Y.)-

9628
This is a report prepared by the Subcommittee on Supplementary Lighting of Committee on Lighting Study Projects in Industry of the Illuminating Engineering Society and designed as a guide to solution of lighting problems requiring supplementary lighting illumination. The following aspects of supplementary lighting practice are included: the definition of supplementary lighting, analysis of the seeing task (e.g., factors in visual perception, fundamentals of visibility such as size, contrast, etc.), description and definition of supplementary lighting equipment (e.g., directional type, uniform brightness type, etc.), and a detailed classification of visual tasks and corresponding lighting techniques.

9631
Eeck, H.E. POSITIONING OF DIRECTIONALLY ADJUSTABLE LUMINAIRES. Illum. Engng., 1953, 48, 175-181. (Westinghouse Electric Corp., Cleveland, Ohio).

9631
Following a brief description of the various types of adjustable luminaires (e.g., searchlights, industrial concentrators, etc.) the author discusses the problem of positioning such luminaires in order to obtain a desired result. The principles of light pattern formation are presented along with an application of these principles to a specific problem, thus demonstrating a method of achieving desired lighting results with adjustable luminaires. A discussion of this article is included.

Guth, S.K., Eastman, A.A., & Rodgers, R.C. BRIGHTNESS DIFFERENCE: A BASIC FACTOR IN SUPRATHRESHOLD SEEING. Illum. Engng., N.Y., 1953, 48, 233-239. (General Electric Co., Cleveland, Ohio.)

9632
This article presents a discussion of the role of brightness difference in suprathreshold seeing. Utilizing a test composed of a standard E at four contrasts, data were collected concerning visibility and thresholds with eleven subjects who made a series of observations of the threshold illumination. The results are treated in terms of the relationships among contrast, brightness difference, and threshold and suprathreshold visibility. A discussion of this article is included.

Hopkinson, R.G. VISUAL REQUIREMENTS FOR CHALKBOARD LIGHTING. Illum. Engng., N.Y.; June 1953, 48, 325-333. (Department of Scientific and Industrial Research, Building Research Station, Hertfordshire, England).

9635
This article is concerned with the problem of defining adequate chalkboard lighting on the basis of the visual requirements inherent in the school environment. Data is presented on the visual acuity of some one hundred school children under chalkboard conditions with varied levels of chalkboard illumination. A subsequent study with young adults on the effect of contrast on visual acuity and ease of reading is presented along with data on the effect of color on visual acuity. The results are discussed in terms of the specific effects of each of the factors upon visual acuity and reading ease. Conclusions are drawn concerning the implications for chalkboard lighting.

9638
White, C.E. HOW LOUD IS SILENCE. Audio Engng., 1956, 40 (3), 17-19, 68.

9638
This article reviews physical, physiological, and psychophysical research findings and inferences from theory regarding minimum sound fields which might be distinguished by the human ear. Topics discussed include calculations of Brownian Motion, threshold of audibility, detectability of Brownian Motion, and the role of normal bodily noises which tend to mask minimal auditory stimuli. The author concludes that the probability of aural detection of Brownian Movement is remote.
C. R 15

9639
Villchur, E.M. ROOM ENVIRONMENT. Audio Engng., 1956, 40 (7), 22-23, 44-45.

9639
This article, one of a series pertaining to the design and utilization of high-fidelity sound reproducing systems, concerns itself with various aspects of the acoustics of rooms as they affect fidelity and efficiency of such systems. Among the topics discussed are: position of the speaker system, compensation of speaker placement, room "liveness", absorption coefficients of materials commonly found in rooms, treble dispersion, and acoustical resonances of listening rooms.

Stordehl, K.E., & Christensen, C.M. THE EFFECTS OF STUDY TECHNIQUES ON COMPREHENSION AND RETENTION. J. educ. Res., 1956, 49 (8), 561-570. (University of Illinois, Ill.).

9641
To determine the effect of four study techniques (underlining, outlining, summarizing, reading and re-reading) four groups of AAF Trainees (Total N = 200) were given immediate and delayed tests of retention on training material learned under one of the four study procedures. Discussion of the obtained data are related to the effectiveness of the four study procedures and the importance of practice in the use of such techniques if they are to be used more effectively.

9642
Standlee, L.S., & Fattu, N.A. NAVY VOCABULARY. J. educ. Res., 1956, 49 (7), 551-554. (Indiana University, Bloomington, Ind.).

9642
Recognizing the need for relevant basic word lists for use in Navy Illiteracy Training Programs, the authors prepared word frequency lists from four basic Navy Training Publications. Using a total of 121,931 counted words the authors prepared lists of the 500 most frequently used words and total frequency indexes for each of the four publications. Discussion relates the findings to Large-Thordike and Marine word lists and the utility of the desired list of 500 most frequently used "Navy words" to Navy Training programs and training materials.

9644
Davis, S.W. STRESS IN COMBAT. *Sci. Amer.*, 1956, 154 (3), 31-35. (Operations Research Office, Johns Hopkins University, Baltimore, Md.).

9644
This article describes a study of human behavior under actual conditions of combat stress. Three groups of men, an attacking company, a defending company, and a control group assigned a rear guard function, were given a series of psychological and physiological tests prior to and following combat. The results are discussed in terms of the function of stress in human behavior as reflected in pre- and post-combat measures. The relative accuracy of the measures and the effect of testing conditions are also discussed.
T. R 2

9645
Keilly, J.B. HEAT, COLD, AND CLOTHING. *Sci. Amer.*, 1956, 154 (2), 109-115.

9645
This article deals with the role of clothing in body temperature maintenance. The author briefly reviews the phenomenon of "normal" temperature maintenance and presents data concerning the amount of body heat lost as a function of type of clothing and environment. The results of several experimental studies are presented in the discussion of the protective value of various types of clothing in both hot and cold climates.

9652
Noble, Rosalie. EFFECT OF NOISE ENVIRONMENT OF AN ENGINE TEST LABORATORY ON AUDITORY ACUITY. *J. Aviat. Med.*, 1956, 27 (5), 482-485. (Air Crew Equipment Laboratory, Naval Air Experimental Station, NASC, Philadelphia, Penn.).

9652
In order to determine the effect of a high intensity noise environment, such as that of an engine test laboratory, upon auditory acuity, the audiograms of twenty-six men are compared. Each subject was tested prior to, at various intervals during, and following exposure for a period of approximately eight years to varying amounts of high intensity noise. The results are presented and discussed in terms of the degree of change in auditory acuity manifested by this group as compared to acuity changes evidenced in a normal population. The data are treated primarily in a qualitative rather than a quantitative fashion.

Lawrence, D.E., & Leberge, D.L. RELATIONSHIP BETWEEN RECOGNITION ACCURACY AND ORDER OF REPORTING STIMULUS DIMENSIONS. *J. exp. Psychol.*, 1956, 51 (1), 12-18. (Stanford University).

9653
To investigate the effect of instructions on accuracy of reporting stimulus dimensions, four groups of subjects (20 each) observed stimulus objects (differing in color, form, and number) by tachistoscopic presentation. Instructions for observing and reporting were to give (1) equal attention to and record all dimensions, (2) primary attention to one dimension but record all, (3) primary attention to and record one dimension, and (4) none as first concept. Order of recording was specified immediately after observation. Accuracy of report scores was computed and statistical significance determined by analysis of variance. The results are discussed in terms of selective effect of instructions on perceptual factors versus memory and response factors.

9654
Green, B.F., & Anderson, Lois K. COLOR CODING IN A VISUAL SEARCH TASK. *J. exp. Psychol.*, 1956, 51 (1), 19-24. (Lincoln Laboratory, MIT).

9654
To investigate the effectiveness of color coding in a visual search task, two experiments were run using twenty U. S. Air Force enlisted men each. The display (matrix of ten rows and six columns of two-digit numbers) was varied as to number of relative symbols of each color (0 to 60) and number of colors (1, 2, or 4.) Conditions of search: 1. target number and color were announced, and 2. target number only was given. Average search time was analyzed as a function of the relative number of symbols (density) of each color and of the number of different colors used. Differences due to conditions of search are discussed in terms of redundancy of information.

9655
Zuidema, O.D., Cohen, S.I., Silverman, A.J., & Riley, M.B. HUMAN TOLERANCE TO PROLONGED ACCELERATION. *J. Aviat. Med.*, 1956, 27 (6), 469-481. (Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio).

9655
This study was designed to investigate human tolerance to prolonged acceleration stress such as that which will be imposed by high speed aircraft of the future. Five subjects were given nine runs at various g levels (2.5, 4, and 0.4 g below blackout level) for various time durations. Physiological and psychological effects were recorded. The results are presented and discussed in terms of the effects of stress as reflected in visual symptoms, pulse rate, blood pressure, electrocardiogram changes, subjective feeling, performance of continuous and discontinuous tasks, and subjective judgment of each task performance.

9656

Haymaker, W., Johnston, A.D., & Downey, V.W. FATAL DECOMPRESSION SICKNESS DURING JET AIRCRAFT FLIGHT. *J. Aviat. Med.*, 1956, 27 (2), 2-17.

9656

This article presents a detailed investigation of two nearly identical cases of fatal decompression sickness in flight. Complete case reports are presented along with the results of post-mortem examination. The similarity in the clinical features of both cases is discussed in an effort to establish an explanation of the fatalities in terms of the environmental and jet flight characteristics. Included in this discussion are some of the physiological factors which appear to play a role in decompression sickness, e.g., obesity.

Shaw, W.A. FACILITATING EFFECTS OF INDUCED TENSION UPON THE PERCEPTION SPAN FOR DIGITS. *J. exp. Psychol.*, 1956, 51 (2), 113-117. (University of Pennsylvania).

9658

To investigate the effects of different amounts of induced muscle tension upon the perception span for digits, thirty subjects repeated series of digits (5, 6, 7, and 8) exposed tachistoscopically while pulling weights adjusted to zero, $1/4$, $1/2$, and $3/4$ of their maximum pull. The experiment was repeated after a two-month interval. Number of digits correctly reproduced was recorded and the variances attributable to tension, task difficulty, individuals, and replication were evaluated. The optimal tension as related to task difficulty and ability of subjects (performance under zero weight conditions) was further analyzed. These results are discussed in relation to previous studies of performance under induced tension.

Ammons, R.B., & Willig, I. ACQUISITION OF MOTOR SKILL: IV. EFFECTS OF REPEATED PERIODS OF MASSED PRACTICE. *J. exp. Psychol.*, 1956, 51 (2), 118-126. (University of Louisville).

9660

To determine the effects of repeated periods of highly massed practice of rotary pursuit on work decrement 104 subjects (four groups of 26) practiced on a pursuit rotor for 90 minutes (training period) followed by 20 minutes (test period) under two basic conditions: (1) 10-minute practice, 20-minute rest, and (2) 1-minute practice, 2-minute rest. These conditions were reversed for the test period for one half of the subjects thus creating four conditions. Performance data (percent of time on target) were analyzed in terms of warm-up decrement, temporary work decrement, and permanent work decrement for each of the four practice-test conditions. These results are related to theoretical formulations of motor skill learning.

Corvin, V. INDIVIDUAL BEHAVIOR IN SOCIAL SITUATIONS: ITS RELATION TO ANXIETY, NEUROTICISM, AND GROUP SOLIDARITY. *J. exp. Psychol.*, 1956, 51 (2), 161-166. (University of Toronto).

9661

To investigate the relation of social behavior and three variables--anxiety, neuroticism, and group solidarity--an experiment was designed and predictions derived from a generalized behavior theory based on Hull and Pavlov. Subjects (64) were selected on the basis of extreme (high and low) anxiety ratings. Two basic situations were experienced by all subjects in groups of three (one subject and two assistants): (1) solidarity or social approval, and (2) dissolidarity or social disapproval. Response latency, degree of participation, and shift of opinion were analyzed to find differences due to the variables. The usefulness of this procedure for experimental study of social situations is discussed.

9662

Edelberg, R., Henry, J.P., Maciolek, J.A., Salzman, E.W., & Zaldema, G.D. COMPARISON OF HUMAN TOLERANCE TO ACCELERATIONS OF SLOW AND RAPID ONSET. *J. Aviat. Med.*, 1956, 27 (6), 482-489. (Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio).

9662

In an investigation of human tolerance to high speed acceleration of slow and rapid onset, thirty-two subjects were given a total of eighty series (usually three or four runs) of centrifuge rides under conditions of gradual and rapid approach to peak accelerations. In order to evaluate the role of the g-suit, experimental runs were conducted with and without the use of the suit and under varied conditions of suit inflation. The results were assessed in terms of comparisons of physiological indicators of g-tolerance under conditions of rapid versus gradual acceleration and g-suit versus non-g-suit protection.

9663

Bolles, R.C., & Bailey, D.E. IMPORTANCE OF OBJECT RECOGNITION IN SIZE CONSTANCY. *J. exp. Psychol.*, 1956, 51 (3), 222-225. (University of California).

9663

To investigate the role of object recognition in size estimation, five subjects made two sets of size judgments of a representative sample of familiar objects: non-visual, based on verbal description, and visual based on free-field observation. Each S made a Q sort for the objects on basis of manipulative familiarity; the experiments sorted on the basis of homogeneity of size of stimulus object in relation to its class. The data (size, judgments, errors of judgment) are analyzed in terms of relations between visual and non-visual judgments estimated and actual size, and degrees of familiarity. Discussion related the results to size constancy.
T. G. R 3

9665
Kurtz, K.H., & Novland, C.I. CONCEPT LEARNING WITH DIFFERING SEQUENCES OF INSTANCES. *J. exp. Psychol.*, 1956, 51 (4), 239-243. (Yale University).

9665
To study the effect of order of presentation upon rate of concept learning, two groups of subjects (13 each) performed twice under two conditions: 1. all instances of a given concept were presented in succession, and 2. instances of all concepts were presented in an intermixed order with no one appearing twice in succession. Concept materials were geometric designs varied in color, size, shape, and position with each concept defined by a combination of two properties and identified by nonsense names; eight instances of four concepts comprised the training lists, two instances in a test list. The data (correct identifications on test and scores on verbal description test) are analyzed for differences in learning due to order of presentation.
I. T. R 7

9666
Arnoult, M.D. FAMILIARITY AND RECOGNITION OF NONSENSE SHAPES. *J. exp. Psychol.*, 1956, 51 (4), 268-276. (Skills Components Research Laboratory, Air Force Personnel and Training Research Center).

9666
To study the quantitative relationship between familiarity of an object and frequency of stimulation, nonsense shapes were presented with varied frequencies (0 to 25) to subjects (seven groups of 100 each) who later rated the stimuli on a five-point scale of familiarity. Delay periods (0, 1, 2, 3 or 5 hours) were interposed between familiarization and rating. Recognition was measured by a further rating of stimuli into familiar and unfamiliar categories. Judgments of familiarity are analyzed as a function of frequency of experience and the effects of delay on familiarity and recognition are studied. These results are related to the larger problem of the role of past experience in perception.

9667
Leibowitz, H., & Bourne, L.E. Jr. TIME AND INTENSITY AS DETERMINERS OF PERCEIVED SLOPE. *J. exp. Psychol.*, 1956, 51 (4), 277-281. (University of Wisconsin).

9667
To analyze the role of exposure duration and luminance as determiners of the extent to which shape constancy occurs, the subjects (49) viewed a disc at various angles to line of vision and matched it with one of 22 comparison shapes. Exposure durations were varied from .01 to 1.00 seconds and luminance values from .005 to 10 mls. Eye-movement records were made to determine duration of viewing disc. Average axis ratios of matched ellipses are analyzed as functions of duration of exposure and luminance. Discussion relates the results to theoretical considerations of shape perception.
I. T. G. R 16

9668
Katchmar, L.T., Ross, S., & Andrews, T.G. DIRECTION AND MAGNITUDE OF RESPONSE ERRORS IN A HORIZONTAL DISPLAY-CONTROL PATTERN. *J. exp. Psychol.*, 1956, 51 (4), 282-286. (University of Maryland).

9668
To investigate the direction and magnitude of response errors in a display-control pattern, subjects (36) observed a horizontal panel of lights (varied as to number, 5, 9, or 11, and space between lights, 3, 5, and 7 inches) and identified the position of a signal flash either verbally or by pressing a key corresponding to the position of the signal light. The data (number of errors made to each signal position, direction of errors to left or right, and magnitude of direction errors) were analyzed as functions of number of lights on the display, distance between lights, and type of response made (verbal or motor).
T. G. R 15

9669
Vallé, L.D., Andrews, T.G., & Ross, S. PERCEPTUAL THRESHOLDS OF CURVILINEARITY AND ANGULARITY AS FUNCTIONS OF LINE LENGTH. *J. exp. Psychol.*, 1956, 51 (5), 343-347. (University of Maryland).

9669
To determine the minimum directional change (either curvilinear or angular) of horizontal lines which can be perceived, ten subjects judged a series of lines as "straight" or "not straight." The stimulus lines were curved (diopter values of 0, .37, .75, 1.12, 1.5 and chord lengths of 30, 40, 50, 70, 90, 1.10 millimeters) or angular (area above angle approximated area above curve for base length equaling chord length); distance of presentation was 10.5 feet; level of illumination 4.5 foot-candles. Thresholds were computed using diopters, length of radius, length of sagitta, and length of "adjusted" sagitta. These data are analyzed in terms of the functional relationship between base length (chord length) and the discrimination of curvature or angle.
T. G. R 5

9670
Conrad, R. THE TIMING OF SIGNALS IN SKILL. *J. exp. Psychol.*, 1956, 51 (6), 365-370. (Applied Psychology Research Unit, Medical Research Council, Cambridge, England).

9670
To observe whether timing (temporal "layout") of a series of responses in a complex sensori-motor task as controlled by the operator changes the temporal structure of a random series of signals in an advantageous fashion, 18 subjects were tested under two conditions on a multifidial display which presented signals at approximately random time intervals. Condition 1, a control for changing intervals between signals was used; condition 2, control eliminated and signal-interval presented at rate determined in (1) with inherent temporal structure remaining random. The two distributions of the interval between signals and of the performance scores were compared. Discussion stresses the role of timing in skilled performance.
G. R 9

9671
Battig, W.F. TRANSFER FROM VERBAL PRE-TRAINING TO MOTOR PERFORMANCE AS A FUNCTION OF MOTOR TASK COMPLEXITY. *J. exp. Psychol.*, 1956, 51 (6), 371-378. (University of Wisconsin).

9671
To study the effect of complexity of a motor task on amount of transfer from verbal pretraining, twelve groups of subjects (20 each) received 20 one-minute trials on a finger-positioning task at one of four levels of complexity (one to four fingers) following training conditions of (1) relevant-S, pronouncing nonsense words formed from letters corresponding to stimulus lights, (2) relevant S-R, describing verbally the correct finger positions, or (3) control, no training. Performance scores (mean number of matches per trial) were studied by analysis of variance for effects and interactions of task complexity and type of pretraining. Percent transfer scores were computed and analyzed. Possible applications to training situations are discussed.
I. T. G. R 16

9672
Noble, M.E., & Bahrick, H.P. RESPONSE GENERALIZATION AS A FUNCTION OF INTRATASK SIMILARITY. *J. exp. Psychol.*, 1956, 51 (6), 405-412. (Ohio State University (Noble); Ohio Wesleyan University (Bahrick)).

9672
To investigate the effects of intratask response similarity upon response generalization, a psychophysical scale of force similarity was constructed. The subjects (50) were then trained to exert different amounts of force on a semirigid control in response to number stimuli. Two versions of the task were used differing in the degree of separation between required adjacent force responses (intratask similarity). Responses were measured on a continuous scale for seven response points (interpreted as empirical gradients of response generalization) and discussed in terms of learning theory. The average amount of information transmitted per response was computed and related to problems of response coding.
I. T. G. R 14

9674-
Beaumont, C.A. SAMPLED-DATA TRACKING: SAMPLING OF THE OPERATORS OUTPUT. *J. exp. Psychol.*, 1956, 51 (6), 429-436. (Human Factors Group, International Business Machines Corporation).

9674

To study tracking performance in the situation where an operator closes a control loop by his tracking behavior, the usual analog loop was altered by sampling the operator's output in three experiments (7 subjects each) using a non-aided compensatory tracking task (hand-controlled joystick; display--small spot on cathode ray oscilloscope provided with cross hairs and three concentric markers). Variables were: (1) sampling rates (2 to 8 cps plus a continuous condition), (2) delay and no delay between response and presentation on display, (3) control display ratios (from 1.0 to 4.0), and (4) tracking task (discretely displaced target and continuously displaced target). Recovery times and fifty per cent limits were analyzed to determine the importance of the variables on performance. I. T. G. R 8

9675

Davidson, W.Z., Andrews, T.G., & Ross, S. EFFECTS OF STRESS AND ANXIETY ON CONTINUOUS HIGH-SPEED COLOR NAMING. *J. exp. Psychol.*, 1956, 52 (1), 13-17. (University of Maryland).

9676

To determine effects of stress and anxiety on performance, 54 subjects were selected on basis of high and low scores on a modified Taylor Anxiety Scale. The task, high speed color naming, was performed under conditions varied to give three levels of failure stress (verbal instructions and electric shock), and three levels of task-induced stress (speed of presentation--75, 85, and 100 per minute). Errors of omission were used as measures of performance and were studied for two portions of the data: 1. after warning of potential failure, and 2. after shock indicating failure. Differential effects of anxiety, failure stress, task-induced stress and their interactions on performance are noted with attention given to individual differences. T. R 17

9678

Mandler, G., & Heinemann, Shirley H. EFFECT OF OVERLEARNING OF A VERBAL RESPONSE ON TRANSFER OF TRAINING. *J. exp. Psychol.*, 1956, 52 (1), 39-46. (Harvard University).

9678

To investigate transfer of training as a function of overlearning, sixty subjects learned three-place consonant combinations in response to single number integers in both a training and a transfer task. Five degrees of training (from 0 to 100 errorless trials) were used (12 Ss in each group). Four conditions of learning were tested in the transfer task: 1. new response to old stimulus, 2. old response to new stimulus, 3. old response to old stimulus, not previously paired, and 4. new response to new stimulus (control for warm-up). Transfer data (frequency of correct responses during first twenty trials and logarithm of ratio of transfer to control in terms of trial on which first correct response occurred) are analyzed in terms of degree of original training. T. G. R 13

9679

Gewirtz, J.L., Jones, L.V., Waerneryd, K.-E. STIMULUS UNITS AND RANGE OF EXPERIENCED STIMULI AS DETERMINANTS OF GENERALIZATION-DISCRIMINATION GRADIENTS. *J. exp. Psychol.*, 1956, 52 (1), 51-57. (University of Chicago).

9679

To investigate the effect of psychological versus physical stimulus units and central tendency (determined by earlier experience with stimulus dimension) upon generalization-discrimination gradients, forty subjects were trained to respond "same" or "different" to a stimulus dimension of visual angle followed by a test for response to stimuli symmetrically positioned about training stimulus. Two tasks were used: (1) response to zero-angle dimension and (2) response to non-zero angle dimension either to left or right of zero. The data (mean number of "same" responses) are analyzed as functions of stimulus position and order of experience. T. G. R 12

9681

Liberman, A.W., Delattre, P.C., Gerstman, L.J. & Cooper, F.S. TEMPO OF FREQUENCY CHANGES AS A CUE FOR DISTINGUISHING CLASSES OF SPEECH SOUNDS. *J. exp. Psychol.*, 1956, 52 (2), 127-137. (Haskins Laboratories, New York City).

9681

To investigate tempo of frequency change as a cue for perceived differences among speech sounds (stop consonants, semivowels, and vowels of changing color), two experiments were performed using synthetic speech-like sounds which subjects (168, 38) were asked to identify by first letter of sound. The stimuli represented transitions from stop consonants to semivowels to vowels of changing color, and were varied in duration of transition (ten to 300 milliseconds) and rate or frequency (500 to 2500 cycles per second). The judgments data were analyzed as functions of transition duration and transition rate. Results are related to other dimensions that have been found to be of importance for the discrimination and identification of individual speech sounds. I. G. R 8

9682

Edwards, W. REWARD PROBABILITY, AMOUNT, AND INFORMATION AS DETERMINERS OF SEQUENTIAL TWO-ALTERNATIVE DECISIONS. *J. exp. Psychol.*, 1956, 52 (3), 177-188. (Operator Laboratory, AFTRC, Lackland AFB, San Antonio, Tex.).

9682

To investigate probability of reward, amount of reward, and nature of information available about reward patterns as factors in probability learning, subjects operated a two-alternative slot machine for real money. The three factors were varied systematically in two experiments using seven groups of six subjects each, on nine and eight days, 150 trials per day. The data are studied by analysis of variance and by information-theory techniques to determine the relative influence of the three factors of reward in this type of decision-making wherein the learner must decide about the situation by observing the result of his decisions. Generalizations are derived from the data and related to learning theory. T. G. R 20

9683

Slack, C.W. FAMILIAR SIZE AS A CUE TO SIZE IN THE PRESENCE OF CONFLICTING CUES. *J. exp. Psychol.*, 1956, 52 (3), 194-198. (Princeton University).

9683

To investigate the effect of familiar size upon apparent size in a situation where many other size cues are present, an experiment was conducted in which chairs of varying sizes (small, normal, and large) and three sticks of comparable heights were presented at 20, 30, and 40 yards. The subjects (1) made size judgments by the method of reproduction with a steel tape manipulated by the experimenter. The experiment was conducted outdoors in an open field with binocular vision. The apparent-size judgments were analyzed and related to theories of size constancy and the role played by past experience. T. R 6

9684

Squires, P.C. STEREOPSIS PRODUCED WITHOUT HORIZONTALLY DISPARATE STIMULUS LOCI. *J. exp. Psychol.*, 1956, 52 (3), 199-203. (U.S.N. Medical Research Laboratory, Naval Submarine Base, New London, Conn.).

9684

To determine whether stereoscopic depth can be evoked by stimulus configurations phenomenally disparate, four pairs of targets (an illusion pattern--Hofler, Zollner, Poggendorf, Muller-Lyer--with a corresponding pattern of its chief lines only) were viewed through a troposcope (five subjects). The illusory figure was presented to one eye and the nonillusory figure to the other. Judgments were made of the character of the depth experience accompanying fusion--immediacy, compellingness, and tendency to disintegrate under prolonged fixation. The results are discussed in terms of necessary conditions for the production of stereo-depth and related to earlier studies of Gestalt disparation. I. R 6

9685
Adams, J.A. VIGILANCE IN THE DETECTION OF LOW-INTENSITY VISUAL STIMULI. *J. exp. Psychol.*, 1956, 52(3), 204-208. (Operator Laboratory, AFTRC, Lackland AFB, San Antonio, Tex.).

9685
To study vigilant or attentive behavior, 61 subjects were required to flick a toggle switch whenever they detected a blip of light appearing aperiodically in the center of a five-inch screen (Vigilance Test). Conditions of testing were: (1) brightness levels of stimulus (.029 and .015 apparent foot-candles), (2) duration of stimulus (1.0 and 2.0 seconds), (3) 11 trials, each a presentation of ten stimuli over a ten-minute period; a ten-minute rest followed by one trial. Correct detection was scored if target was noted within five seconds after onset. Detection scores are analyzed to evaluate the effects of stimulus brightness, stimulus duration, and rest. The results are discussed in relation to theoretical concepts. T. G. R 6

9686
Mabe, H.W., & Eriksen, C.W. ROLE OF RESPONSE VARIABLES IN RECOGNITION AND IDENTIFICATION OF COMPLEX VISUAL FORMS. *J. exp. Psychol.*, 1956, 52(4), 235-243. (Johns Hopkins University).

9686
To study the role of response variables in recognition and identification of visual forms, subjects (eight experimental groups) were given practice in using alphabet letters (labels) as discriminating responses to geometric forms or photographs prior to learning to associate them with a standard set of unfamiliar visual forms (both experimental and four control groups). All groups were then required to identify the standard forms when mixed with unfamiliar forms. Number of labels used varied from two to 12; 120 trials of practice, 120 trials of learning and six trials for identification. Correct labeling responses and number of recognitions are analyzed as functions of prior practice in use of responses and of number of responses practiced. I. T. G. R 9

9687
Zimny, G.H. EFFECT OF VARIOUS MOTIVATIONAL TECHNIQUES UPON LEARNING AND PERFORMANCE TASKS. *J. exp. Psychol.*, 1956, 52(4), 261-257. (University of Minnesota).

9687
To study some aspects of motivation and its effect upon human performance, two experiments were performed. In the first, four groups of subjects (25) learned a list of 12 nonsense syllables under conditions of (1) incentive of an excused classroom assignment, (2) threat of electric shock, (3) statement that task was a measure of intelligence, or (4) statement that task afforded additional practice (control group). In the second part, two groups (20) sorted ten decks of cards, one under control and one under incentive conditions. Performance scores (number of trials to criterion; sorting time, and number sorted in a two-minute interval) were studied for differences attributable to motivational technique and to type of task. T. R 10

9688
Surwillo, W.W. PSYCHOLOGICAL FACTORS IN MUSCLE-ACTION POTENTIALS: EMG GRADIENTS. *J. exp. Psychol.*, 1956, 52(4), 263-272. (Allan Memorial Institute and McGill University).

9688
To investigate the effect of incentives on EMG gradients (progressive increase of electrical activity in muscles from beginning to end of a task), 16 subjects performed two tracking tasks--compensatory and pursuit. The factors of incentive, difficulty, and goal structuring were used to weight one task "high" and one "low"; both required almost identical forces and patterns of muscular response. Muscle-action potentials were recorded from four muscle groups and EMG gradients were derived from the records. The data were analyzed for slope gradients attributable to the factors varied. The study was repeated with a new group of subjects, a third doubly-rewarded task, reduced muscular effort, and reduced goal structuring. Similar analysis were made of the data. G. R 27

9689
Solley, C.M. REDUCTION OF ERROR WITH PRACTICE IN PERCEPTION OF THE POSTURAL-VERTICAL. *J. exp. Psychol.*, 1956, 52(5), 329-333. (The Hummer Foundation).

9689
To investigate the effect of practice on perception of the postural vertical, two groups of subjects (9 each) were used, one group was tilted 30 degrees laterally to the right and the other to the left. The task was to return to point of perceived vertical; thirty trials were given. Visual cues were eliminated by blindfolding and use of darkened room; somesthetic cues were controlled by use of a biteboard, constant amount of tilt and by returning S to vertical by a series of random movements. The average number of degrees perceived vertical was off true vertical and time required to make adjustments were analyzed as functions of practice. The results are discussed in relation to procedures in like perceptual experiments. T. G. R 10

9690
Poulton, E.C. LISTENING TO OVERLAPPING CALLS. *J. exp. Psychol.*, 1956, 52(5), 334-339. (Applied Psychology Research Unit, Medical Research Council, Cambridge, England).

9690
To determine the effect of two competing messages, presented simultaneously from different loud speakers, on accuracy of listening performance, subjects were required to write down all three figure numbers preceded by their particular call signal. In one experiment, pairs of calls were given (two or four loudspeakers) either in synchrony or overlapping and responses were called for by both or only one message. In another experiment, conditions were similar except that conversation concerning aircraft was broadcast between calls and subjects were required in one subgroup to track the planes. Error scores (omissions and wrong numbers) were analyzed for effects of masking by competing messages, and by conversation, distraction of irrelevant task, and number of channels monitored. T. R 2

9691
Newman, S.E. EFFECTS OF CONTIGUITY AND SIMILARITY ON THE LEARNING OF CONCEPTS. *J. exp. Psychol.*, 1956, 52(6), 349-353. (Northwestern University, Evanston, Ill.).

9691
To investigate the effect of temporal contiguity and similarity on concept learning, six groups (twenty subjects each) learned a practice list (combinations of sizes and shades in simple geometric figures) and one of six experimental lists (line and dot combinations identified by azimuth and position of dots; distractors were color of lines and number of dots). Three variations in similarity (azimuth differences) and two in contiguity (dot cluster differences) were employed. Number of concepts learned and number of intrusions during learning were analyzed and discussed with regard to the generalization hypothesis in learning. T. R 5

9692
Riopelle, A.J., & Rogers, J.P. TRANSFER OF TRAINING TO ORTHOGONAL DIMENSIONS. *J. exp. Psychol.*, 1956, 52(6), 367-369. (Emory University).

9692
To determine whether the range of stimuli in one dimension to which S responds can be increased or decreased by training in another dimension, twelve experimental groups were trained to respond by releasing a telegraph key to any one of seven lights (half of the groups responded to lights appearing in the horizontal and half to the vertical dimension) and then were tested on their responses to lights appearing in the opposite dimension. Control groups (twelve) were trained to respond only to a center light and half were tested along the vertical and half along the horizontal dimension. Speed of response was analyzed for differences due to training and related to the concept of generalization. G. R 5

9693

Schipper, L.M. PREDICTION OF CRITICAL EVENTS IN CONTEXTS OF DIFFERENT NUMBERS OF ALTERNATIVE EVENTS. *J. exp. Psychol.*, 1956, 52 (6), 377-390. (Ohio State University).

9693

To study some factors influencing prediction of critical events, nine groups (14 subjects each) predicted the occurrence of the left-most light in a horizontal row of two, four or six event lights. Probability of occurrence was varied ($1/2$, $1/4$ or $1/6$); also the number of alternative event lights (one, three or five). The rate of omission of positive responses (predictions) was analyzed as a function of the relative occurrence of the critical event and the number of alternative noncritical events. Frequencies of correct predictions are discussed in relation to expectations based on statistical learning theory.

Batteraby, W.S., Kahn, R.L., Pollack, M., & Bender, M.B. EFFECTS OF VISUAL, VESTIBULAR, AND SOMATOSENSORY-MOTOR DEFICIT ON AUTO-KINETIC PERCEPTION. *J. exp. Psychol.*, 1956, 52 (6), 398-410. (Mt. Sinai Hospital).

9694

To study the effects of visual, vestibular, and somatosensory-motor deficit upon autokinetic movement, subjects were chosen from hospital patients who exhibited one or the other of these deficiencies and control subjects from a normal population exhibiting no deficiencies. The conditions of stimulation were: (a) control, (b) head alone turned to one side, (c) trunk alone turned to one side, (d) both head and trunk deviated to same side, (e) Barany rotation. The extent and direction of autokinetic movement (apparent movement of stationary light in dark surroundings) were recorded and analyzed for differential effects of the various deficits.

9695

Dumas, P. THE RADIAL ILLUSION. *Amer. J. Psychol.*, 1956, 69 (1), 118-121. (Montana State University).

9695

This note describes a perceptual effect that occurs when the observer is in motion relative to discrete, moving stimuli, e.g. riding in a car on a dark night through the rain, the raindrops appear to be radiating from a center rather than falling vertically. Changes in illusory effects with different speeds are described and illustrated. Observations were made to verify the perception as illusory rather than being a direct observation of physical factors.

Gaydos, H.P. INTERSENSORY TRANSFER IN THE DISCRIMINATION OF FORM. *Amer. J. Psychol.*, 1956, 69 (1), 107-110. (Quartermaster Research and Development Center).

9696

To study intersensory transfer of form discrimination two groups of subjects (86) learned to associate a series of stimulus shapes with names either through visual presentation or by handling them (with names given orally) to two errorless trials and then attempted to identify the same shapes through the other sense modality. Transfer test was carried to one errorless trial. Performance was recorded in number of trials and errors with transfer calculation as percent savings (trials and errors) on the relearning task. Qualitative factors involved in the learning process are noted in addition to most effective order of learning and relearning.

9697

Ryan, T.A., & Schwartz, Carol B. SPEED OF PERCEPTION AS A FUNCTION OF MODE OF REPRESENTATION. *Amer. J. Psychol.*, 1956, 69 (1), 90-98. (Cornell University).

9697

To study the comparative effectiveness of different methods of representing critical characteristics of three-dimensional objects, three objects (hand, group of electrical knife switches, and steam engine valve) each in four different positions were represented by photographs, shaded line drawings, line drawings, and cartoons. Each illustration was projected on a screen, in a series of increasing exposure durations, until the subject could identify the crucial relationship. Threshold data (in seconds) were obtained from 15 subjects and studied for significant differences for time of perception due to mode of representation. The methodology of this study is discussed and evaluated.

9698

Wallach, H., Weiss, A., & Adams, Pauline Austin. CIRCLES AND DERIVED FIGURES IN ROTATION. *Amer. J. Psychol.*, 1956, 69 (1), 48-59. (Swarthmore College (Wallach); Tufts University (Weiss); University of California (Adams)).

9698

To study perceptual changes in the appearance of figures as they change in spatial orientation, a series of observations was made of rotating circles, spirals, and ellipses. An explanation was formulated in terms of subjectively identical points along the contours arising in relation to absolute directions of visual space. Stereo-kinetic phenomena resulting from monocular observation of these illusions were compared with the kinetic depth-effect (obtained when the shadow of a solid object in rotation is observed) for occurrence without suggestion and irrespective of set.

Crosbie, R.J. DIRECTIONAL CONTROL OF ACCELERATIVE FORCES IN CENTRIFUGE BY SYSTEM OF GIMBALS. *J. Aviat. Med.*, 1956, 27 (6), 506-511. (U.S.N. Aviation Medical Acceleration Laboratory, HADC, Johnsville, Penn.).

9699

This article describes the utilization of a two-gimbal system in centrifuge as a means of controlling the direction of acceleration with regard to the subject. The use of this system is compared to that of the freely swinging platform in terms of control of tangential acceleration, subjective effects of oculogyral illusions, degree of equipment flexibility, the type of acceleration simulation afforded, and so forth. Human reactions to gimbals movements are reported on the basis of a series of experimental runs in the equipment by a number of subjects under varied conditions of acceleration patterns.

Postman, L., & Rosenzweig, M.R. PRACTICE AND TRANSFER IN THE VISUAL AND AUDITORY RECOGNITION OF VERBAL STIMULI. *Amer. J. Psychol.*, 1956, 69 (2), 209-226. (University of California).

9701

To investigate the effects of preliminary training on visual and auditory discrimination of verbal stimuli, a series of nonsense syllables was chosen for initial ease of discrimination (half of high and half of low usage frequency). Different syllables received varying frequencies of exercise (from zero to 15). Two groups of subjects had visual training followed by either visual or auditory testing and two had conditions in reverse order. A control group had no training. Testing consisted of recognition-thresholds: (1) tachistoscopic presentation of syllables under varying intensities of illumination, or (2) in conjunction with varying degrees of masking noise. Analyses were made for effects of frequencies of past exercise, of sensory modality, and of transfer

9702

Thompson, R.F., Voss, J.F., & Brogden, W.J. THE EFFECT OF TARGET-VELOCITY UPON THE TRIGONOMETRIC RELATIONSHIP OF PRECISION AND ANGLE OF LINEAR PURSUIT MOVEMENTS. *Amer. J. Psychol.*, 1956, 69 (2), 258-263. (University of Wisconsin).

9702

To investigate the effect of target velocity and angle of movement from the body upon precision of linear pursuit movements, 80 subjects, with styles in right hand, tracked a target moving at velocities of 2.5, 3.0, 3.5, 4.0 and 4.5 centimeters per second at angles from the body of 0, 30, 45, 60, 90, 120, 135, and 150 degrees. Each subject tracked all eight angles but at only one velocity. Analysis of variance of the standard error scores and adjusted scores (divided by trial duration) was made for differences due to angle of movement and target velocity. The trigonometric relationships are shown and discussed.

9703

Thomas, G.J. EFFECT OF CONTOURS ON BINOCULAR CFF OBTAINED WITH SYNCHRONOUS AND ALTERNATE FLASHES. *Amer. J. Psychol.*, 1956, 69 (3), 369-377. (University of Illinois).

9703

To test a hypothesis that addition of contours to the stimulus-patches which fall on corresponding retinal areas would enhance the Sherrington effect (superiority of flicker-sensitivity when flashes are delivered synchronously to the two eyes as compared to that obtained with alternate flashes), two observers made binocular threshold determinations (flicker) with both in- and out-of-phase flashes in the two eyes over a range of six log-units of flash luminance. In one condition the stimulus patch for both eyes was identical; the second used stimulus-patches perpendicular to each other. Threshold data were analyzed for effect of arrangement of contours, and synchronous versus alternate flashes on critical flicker frequency. Results from an earlier study with larger contours are compared with these results. T.G.R 22

Day, W.P. SERIAL NON-RANDOMNESS IN AUDITORY DIFFERENTIAL-THRESHOLDS AS A FUNCTION OF INTER-STIMULUS INTERVAL. *Amer. J. Psychol.*, 1956, 69 (3), 387-394. (Johns Hopkins University).

9704

To study non-randomness of responses to long series of threshold stimuli, the length of time between successive members of the stimulus series was varied under conditions generally associated with this effect. A continuous 1000 cycle per second tone was presented non-audibly to five subjects who responded to detection of increment by pressing a key. Increments in intensity (from 300 to 600, each 0.1-second duration, of differential threshold magnitude) were added to continuous tone at five interstimulus intervals, 1.6-10.6 seconds. Responses (yes or no) were analyzed for non-randomness as a function of inter-stimulus interval. In discussion of results, emphasis is placed upon probability of a number of factors underlying the "serial effect."

9705

Bilodeau, Ina McD. ACCURACY OF A SIMPLE POSITIONING RESPONSE WITH VARIATION IN THE NUMBER OF TRIALS BY WHICH KNOWLEDGE OF RESULTS IS DELAYED. *Amer. J. Psychol.*, 1956, 69 (3), 434-437. Proj. 7707, Task 77130, Res. Rep. AFPTTC-TN-57-49, April 1957, Skill Components Laboratory, AFPTTC, Lackland AFB, San Antonio, Tex.

9705

To determine the effect of temporal delay in knowledge of results (KR) on accuracy of a simple positioning response, two experiments were designed to make such a delay analogous to lag in a continuous tracking task by delaying KR over a number of trials (0, 1, 2, 3, and 0, 2, and 5). The task was to learn to make a lever-displacement of 33.57 degrees of arc; one pull on the lever constituted a trial; number of KR trials (trials preceded by KR) were held constant for each delay group (16 and 30); KR was given on a visual display with pointer indicating score. Positioning errors in degrees of arc are analyzed as a function of number of KR trials and lag or delay in knowledge of results.

9706

Chiselli, E.E. DIMENSIONAL PROBLEMS OF CRITERIA. *J. appl. Psychol.*, 1956, 40 (1), 1-4. (University of California).

9706

This paper examines problems connected with the dimensionality of the criteria used for describing worker's performance quantitatively. Three types of dimensionality are discussed--static, dynamic, and individual. Static dimensionality includes the problem of how to handle criteria that are multidimensional; dynamic dimensionality deals with types of change in job performance with time and the resultant effect on prediction; and individual dimensionality concerns different criteria, all of which lead to successful job performance by different individuals. It is suggested that these problems must be solved before criterion validity can be established.

Mahinsky, I.D. THE INFLUENCE OF CERTAIN TYPOGRAPHICAL ARRANGEMENTS UPON SPAN OF VISUAL COMPREHENSION. *J. appl. Psychol.*, 1956, 40 (1), 37-39. (University of Minnesota).

9707

To investigate the relationship between span of comprehension and typographical arrangement, 30 subjects (six groups, five each) were presented, tachistoscopically, with three arrangements of words (conventional, spaced-unit, and square-span or double-line blocks) in counter-balanced order. Words perceived were reported immediately after a 100-millisecond exposure; the score was the number of words correctly reported. The comprehension score in words per sentence was analyzed for differences due to typographical style. Over-lap scores are studied for additional comparisons. Implications for advertising are discussed in addition to "straight" reading situations.

Chernikoff, R., Birmingham, H.P. & Taylor, F.V. A COMPARISON OF PURSUIT AND COMPENSATORY TRACKING IN A SIMULATED AIRCRAFT CONTROL LOOP. *J. appl. Psychol.*, 1956, 40(1), 47-52. (USN Research Lab., Washington, D.C.).

9709

To compare the relative effectiveness of a pursuit and a compensatory tracking display in a simulated one-coordinate aircraft control loop, two experiments were conducted differing only in ranges of course frequencies of the tracking problem. In each experiment five subjects tracked a target (with spring-centered joystick) on both types of displays for six one-minute trials on twelve days. Four courses, each a complex of three sine waves, were made to vary in difficulty by increasing the frequencies of recurring cycles. Integrated error scores (total cumulative error integrated overtime) are analyzed as functions of type of display and difficulty of course. Implications for engineering design are discussed.

9711
Hall, M.S. INTERNAL RELATIONS OF ELEMENTAL MOTIONS WITHIN A TASK. *J. appl. Psychol.*, 1956, 40 (2), 91-95. (Dunlap and Associates, Inc., Stamford, Conn.).

9711
To study the extent of interaction of work elements in an actual factory operation, micro-motion samples of an industrial operation were taken eight times during the work day, Monday through Friday. A frame-by-frame analysis was made by the customary micro-motion techniques and a simo-motion chart of work elements (therbligs) constructed. Average times of individual elements within a sample (15 cycles) were paired and analyzed by correlational methods to study internal relationships among work elements. Productions records (average pieces produced per minute) for all samples were compiled and compared with variations in time of individual elements of work cycle. Discussion stresses an atomistic versus an integrated concept of human behavior.

Fleishman, E.A. & Hempel, W.E. FACTORIAL ANALYSIS OF COMPLEX PSYCHOMOTOR PERFORMANCE AND RELATED SKILLS. *J. appl. Psychol.*, 1956, 40 (2), 96-104. (USAF Personnel and Training Research Center, Lackland AFB, Tex.).

9712
To provide additional insight and possible leads about the organization of abilities in perceptual-motor skills, a factorial analysis of data from the wartime Air Force classification research program (published in 1952) was made. Included were 23 test variables of which 16 were apparatus psychomotor tests and seven were printed tests; the criterion of pilot success was added. All data were based on over 1000 Navy pilot candidates. Brief descriptions of each test are given. Ten factors were extracted from the inter-correlations and factor loadings were obtained. The rotated factors were interpreted for psychological meaningfulness and discussed in relation to motor skills. Areas for further investigation are indicated.

Anderson, W.H., Grant, D.A., & Wylstrom, C.O. THE INFLUENCE OF THE SPATIAL POSITIONING OF STIMULUS AND RESPONSE COMPONENTS ON PERFORMANCE OF A REPETITIVE KEY-PRESSING TASK. *J. appl. Psychol.*, 1956, 40 (3), 137-41. (University of Wisconsin).

9716
To investigate operator efficiency in a key pressing test as a function of spatial positioning, nine possible combinations of stimulus panel and response keyboard (left, right or in front of operator) were used with two modes of stimulus presentation (red lights on panel matched by green lights activated by pressing key): (1) self-pacing, stimulus patterns succeeding each other as fast as they were matched, and (2) automatic pacing, presentation at six-second intervals. The data were response times; number of key presses (error index); and latencies (in automatic pacing) for the last 15 stimulus patterns out of a block of 25. Analyses of results stressed performance as a function of angle between display and control units for both modes of presentation.
T. G. R 10

9717
Taylor, Jean G., & Smith, Patricia C. AN INVESTIGATION OF THE SHAPE OF LEARNING CURVES FOR INDUSTRIAL MOTOR TASKS. *J. appl. Psychol.*, 1956, 40 (3), 142-49. (Johns Hopkins University & Cornell University).

9717
To determine whether there is a "typical" learning curve for industrial motor tasks of varying degrees of complexity, seventy learning curves from operators on twelve power sewing-machine operations were obtained. Incentive conditions were the same for all operators--piece-rate system plus minimum guaranteed wage. The twelve operations increased in complexity from tasks of fixed motor sequence to those requiring continuous and varied adjustments. Using the period of initial plateau as a criterion of learning, modified Vincent curves were established for each job, and separate composite curves for each of two groups including half the jobs. Suggestions concerning change in requirements of task during learning are made to account for the shape of the curves.

Poley, P.J. EVALUATION OF ANGULAR DIGITS AND COMPARISONS WITH A CONVENTIONAL SET. *J. Appl. Psychol.*, 1956, 40 (3), 178-180. (Defence Research Medical Laboratory, Toronto, Canada).

9718

To evaluate a new set of digits (Lansdell) designed to make maximum use of easily discriminated forms, and to compare them with conventional design (Machworth), four experiments were conducted. Procedures common to all: digits presented singly by slide projection; viewing distance, 20 feet; recognition task. Experiments: (1) 300 presentations Lansdell digits for .6 second; rate one every three seconds; illumination, ten foot candles. Confusion errors given. (2) Lansdell digits, black on white and white on black; illumination of 10-50 foot candles. Errors analyzed for effect of contrast. (3) and (4) Lansdell and Machworth digits, black and white; illumination of 10-50 foot candles; viewing angles varied. Comparisons of legibility were made. I. R 7

Baishamp, Janet, Swander, R.C., & Smith, K.U. DIMENSIONAL ANALYSIS OF MOTION: II. COMPARISON OF VISUAL AND NONVISUAL CONTROL OF COMPONENT MOVEMENTS. *J. Appl. Psychol.*, 1956, 40 (3), 181-186. (University of Wisconsin).

9719

To determine the role of perceptual factors in the determination of component movements in a skilled pattern of motion, two groups (24 subjects) were matched on pre trials of a panel control knob-turning task, then given ten days of practice (12 trials per day) with vision or blindfolded, followed by one practice period of reversed conditions. Durations of manipulation and travel components of movements were measured electronically. Differences between the visual and blind groups are analyzed and discussed in relation to 1. skilled performance on the final day of practice, 2. acquisition of skill as a function of practice, and 3. transfer effects. Implications of the results for motion analysis studies in industry are pointed out. T. C. R 4

9720

Lookman, R.F. A NOTE ON MEASURING UNDERSTANDABILITY. *J. Appl. Psychol.*, 1956, 40, 195-196. (Bureau of Naval Personnel).

9720

To assess prose intelligibility or "understandability" an experimental rating scale of seven categories (very easy to very difficult) was devised. The uses for such data are illustrated by an experiment in which Naval Aviation Cadets rated a series of test directions for understandability. Comparisons were made with Flesch Reading Ease style descriptions by using rank correlations. The discussion points up the need for an "understandability" score in addition to ease of reading. R 3

9721

Hecker, D., Green, D., & Smith, K.U. DIMENSIONAL ANALYSIS OF MOTION: X. EXPERIMENTAL EVALUATION OF A TIME-STUDY PROBLEM. *J. Appl. Psychol.*, 1956, 40 (4), 220-227. (University of Wisconsin).

9721

To investigate the extent to which component movements (or therbligs) in patterned motion are interdependent, 48 subjects manipulated a series of controls, each control being separated by a constant distance of 24 inches. Eight different types of manipulations were practiced for four different periods. Travel times and manipulation times were measured electronically. Variations in duration of travel of a movement of constant length were analyzed as a function of the type of manipulation associated with it. The effect of learning upon travel time was further studied. These results are related to industrial time-and-motion study and to the general problem of integrating component movements in skilled motion. T. C. R 8

9722

Graham, Morah E. THE SPEED AND ACCURACY OF READING HORIZONTAL, VERTICAL, AND CIRCULAR SCALES. *J. Appl. Psychol.*, 1956, 40 (4), 228-232. (The Huxfield Department of Industrial Health, University of Durham).

9722

To study the speed and accuracy of reading comparable horizontal, vertical, and circular scales, 50 subjects were given practice and then tested on their ability to make readings (30) from pictures of the scale settings flashed on a screen at ten-second intervals, exposure time 1/2 second. Error scores were by analysis of variance techniques for differences attributable to scale shape, to segment of scale in which error occurred, and to subjects. These results are discussed in relation to previous studies and interpreted in terms of a physiological basis. T. I. R 6

9723

Kurke, M.I. EVALUATION OF A DISPLAY INCORPORATING QUANTITATIVE AND CHECK-READING CHARACTERISTICS. *J. Appl. Psychol.*, 1956, 40 (4), 233-236. (U.S. Army Ordnance Human Engineering Laboratory, Aberdeen Proving Ground).

9723

To evaluate the design of a dial incorporating quantitative and check-reading characteristics, the speed and accuracy of check-reading three different designs were measured by use of a card sorting experiment. Dials were alike in size, numbering, and pointer but varied in representation of danger: (1) reading alone, (2) red line marking danger area, and (3) contrasting colored wedge exposed for danger conditions. Speed scores were corrected for practice and motor activity effects by scores of an initial and final card sort on basis of color discrimination alone whereas the experimental sorts were on the basis of "safe and normal" and "danger conditions." The analysis was made in terms of the most effective design and the validity of the design principle used. I. C. R 5

Webb, W.E., & Wallon, E.J. COMPREHENSION BY READING VERSUS HEARING. *J. Appl. Psychol.*, 1956, 40, 237-240. (U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Fla.).

9724

To compare comprehension of narrative prose by reading and by hearing, two comparable sets of materials were developed using tales from Greek mythology. True and false questions were used for testing comprehension following (1) auditory, (2) read through once, (3) read-study during time equal to verbal presentation, or (4) simultaneous auditory and reading conditions. Testing was repeated after 24 and 43 hour intervals. Comprehension scores were analyzed for differences due to methods of presentation and the results discussed in terms of practical usage. T. R 2

Merrill, W.J. Jr., & Bennett, C.A. THE APPLICATION OF TEMPORAL CORRELATION TECHNIQUES IN PSYCHOLOGY. *J. Appl. Psychol.*, 1956, 40 (4), 272-280. (International Business Machines Corporation, Endicott, N.Y.).

9725

This paper defines and gives computation procedures for various temporal correlation techniques. Serial correlations for discrete data and correlation functions for continuous data are examples of these techniques. Specific descriptions of computational procedures for autocorrelations for temporal relatedness within one series of data and crosscorrelations for such relatedness between two series are given. Through such procedures both cyclical and noncyclical temporal phenomena may be discovered. Applications of temporal correlation techniques to psychological data are discussed. G. R 29

Stoll, Alice M. HUMAN TOLERANCE TO POSITIVE G AS DETERMINED BY THE PHYSIOLOGICAL END POINTS. *J. Aviat. Med.*, 1956, 27 (4), 356-367. (U.S.N. Aviation Medical Acceleration Laboratory, MADC, Johnsville, Penn.).

9726
This article describes a new method of analysis of human tolerance to positive g. Essentially the method consists of plotting the data of reaction to positive g as a strength-duration curve of maximum g versus total time of exposure to g. To evaluate this technique, comparisons were made with comparable independent data. The effectiveness of the technique is appraised on the basis of the amount of agreement with independent data. Potential applications of this technique are also discussed.

Shepherd, R.J. A NULL-POINT DISCONTINUOUS ELECTRICAL PURSUIT METER. *J. appl. Psychol.*, 1956, 40 (5), 287-294. (RAF Institute of Aviation Medicine, Farnborough, Hants, England).

9727
A null-balance electrical pursuit meter based on a Wheatstone bridge circuit is described. The task is one of producing settings in a voltmeter (by use of a control knob) which correspond to readings in a second voltmeter in rear panel. Two evaluation studies are reported: (1) Six subjects operated the machine under normal rest conditions for five-minute periods on six days. Initial and total response times were analyzed for reliability of measurements; and (2) nine subjects operated the machine under stress of high-pressure breathing and under normal rest (control). The data are analyzed for changes due to stress. Possible uses of the meter in psychomotor research are discussed.

Simon, J.R. THE DURATION OF MOVEMENT COMPONENTS IN A REPETITIVE TASK AS A FUNCTION OF THE LOCUS OF A PERCEPTUAL CUE. *J. appl. Psychol.*, 1956, 40 (5), 295-301. (University of Wisconsin).

9728
To study the inter-relation of perceptual processes and work movements, an assembly task consisting of inserting forty metal pins into an assembly plate was used. Locus of the perceptual cue was varied by special techniques to appear in each component of the work cycle (unloaded travel, grasp, loaded travel, and assembly). Two control conditions involving no perceptual cues were used. Thirty subjects performed under all conditions with latin-square design for control of individual differences and order of condition; 5 days of testing. Durations of the four component movements were measured by electronic methods and were analyzed for effect of locus of cue. Implications for time-and-motion studies are discussed in terms of the role of perceptual processes in human motion. I. T. G. R 13

9729
Baker, C.A., & Vanderplas, J.M. SPEED AND ACCURACY OF SCALE READING AS A FUNCTION OF THE NUMBER OF REFERENCE MARKERS. *J. appl. Psychol.*, 1956, 40 (5), 307-311. (Aero Medical Laboratory, WADC, Wright-Patterson AFB, Ohio).

9729
To investigate the speed and accuracy of determining target position on a polar coordinate display as a function of the number of scale rings, twelve subjects observed a series of displays projected on a screen and made estimates of target range to the nearest ten yards. The displays varied in number of scale rings (0, 2, 4, 9, 19, and 39) and size (5, 7, 9, and 11 inches diameter). The data were time scores and yards of range reports converted into error scores: (1) gross errors (misidentification of scale rings), (2) interpolation errors (in percentage of total range of display), (3) and constant errors. Analysis was in terms of effect of number of rings, size of display, and position of target on speed and accuracy. Practice effects are noted

9730
Churchill, A.V. THE EFFECT OF SCALE INTERVAL LENGTH AND POINTER CLEARANCE ON SPEED AND ACCURACY OF INTERPOLATION. *J. appl. Psychol.*, 1956, 40 (6), 352-361. (Defence Research Medical Laboratories, Toronto, Canada).

9730
To study some factors affecting speed and accuracy of interpolation between scale marks, single-scale intervals were prepared in six sizes: (from 0.25 to 2.0 inches) with pointers of varying clearances (from 0.0 to 2.0 inches) between tip and scale reference line. Ten subjects read pointer positions for two conditions of exposure: (1) self-paced and (2) at 0.3 second exposures. Error frequencies and time scores were analyzed as a function of scale interval length and pointer clearance. Trends in directional errors are discussed.

9732
Simon, J.R., & Smith, K.U. THEORY AND ANALYSIS OF COMPONENT ERRORS IN AIDED PURSUIT TRACKING IN RELATION TO TARGET SPEED AND AIDED-TRACKING TIME CONSTANT. *J. appl. Psychol.*, 1956, 40 (6), 367-370. (University of Wisconsin).

9732
To determine how variations in target speed and aided-tracking time constant (rate of cursor movement automatically generated by a motor system as operator adjusts hand control) affect type of errors made, an aided pursuit tracking task (aligning cursor with moving target by means of handwheel control) was used. Variables were target speed (23, 30 and 37 r.p.m.) and aided-tracking time constant (.25, 0.5, and 1.0 seconds). The data consist of tracking records for 27 practiced subjects on each of the nine combinations of variables. Errors are classified on basis of duration and extent as short, intermediate, and long wavelength and are analyzed as functions of target speed and time constant. Results are discussed in relation to applied problems of tracking aid and to tracking theory. T. G. R 8

9733
Bridgman, G.S., & Wade, E.A. OPTIMUM LETTER SIZE FOR A GIVEN DISPLAY AREA. *J. appl. Psychol.*, 1956, 40 (6), 378-380. (University of Wisconsin).

9733
To investigate the maximally visible size of letters inscribed in space limited by high-contrast borders, visual acuity determinations were made using single lines of block capital letters. Three ratios of letter size to field size (vertical dimension of background)--1.0, 1.4, and 5.5--were used at two luminance levels--8.45 and 0.084 ml.--observation distance 20 feet, 40 subjects. Criterion was "ease of reading" as size was increased. Threshold data were analyzed as functions of the surround or field to letter size ratios. Further study of the data in terms of the over-all size of the field required to provide threshold letters was made. Discussion relates the results to practical considerations of letter sizes when display space is a consideration.

9734

Briggs, G.E., Fitts, P.M., & Sahrlick, W.P. TRANSFER EFFECTS FROM A SINGLE TO A DOUBLE INTEGRAL TRACKING SYSTEM. Contract AF 18(600)-1201, Proj. 7716, Tasks 77292 & 57050, AFTRC-TN-56-135, Dec. 1956, 17pp. Operator Laboratory, AFTRC, Randolph AFB, Tex.

9734

To investigate the effect of training on a single integration to performance with a double integration tracking system, four groups (53 subjects) practiced on a two-dimensional compensatory tracking task simulating fire-control system of an aircraft. Amount of practice on the single integration was varied from 0 (control group), 10, 30, 50 trials of 40 seconds each before transferring to the double integration system (total of 90 trials). Performance (time on target for final three seconds of each trial) on the transfer task was evaluated by comparing initial levels, levels at time of transfer, and number of trials required to attain a given proficiency level for the experimental and control groups. Implications of the findings for training programs and for learning studies are discussed. T. G. I. R 11

9735

Luft, U.C., & Bancroft, R.W. TRANSTHORACIC PRESSURE IN MAN DURING RAPID DECOMPRESSION. *J. Aviat. Med.*, 1956, 27 (3), 208-220. (Lovelace Foundation, Albuquerque, N.M.).

9735

In a study of the dynamics of rapid decompression as reflected in transthoracic pressure, experiments were conducted with a rigid model (a bottle) and man. The effect of pressure upon the rigid model is reported as a function of the absolute pressure differential (of the decompression cabin) and the fractional differential of decompression. Human subjects placed in the decompression cabin under various degrees of decompression (150 mm. Hg to 502 mm. Hg) were measured for transthoracic pressure peaks. The results are discussed in terms of transthoracic pressure as a function of the fractional differential and the absolute differential of decompression. T. G. I. R 24

Johnson, W.H. HEAD MOVEMENT MEASUREMENTS IN RELATION TO SPATIAL DISORIENTATION AND VESTIBULAR STIMULATION. *J. Aviat. Med.*, 1956, 27 (2), 148-152. (Defence Research Medical Laboratories, Toronto, Canada).

9736

This article reports an investigation of head movements in which 500 flight cadets were tested on a turntable device simulating aircraft flight movements. The direction and magnitude of resultant vestibular sensations were measured by attaching miniature rate gyroscopes to the subject's head. In addition, airsick vs. non-airsick crews were evaluated. The results are discussed in terms of the relation between time for recovery from laboratory-induced vestibular stimulation and the incidence of incapacitating airsickness among flight crews. G. I. R 4

9737

Webb, W.B. THE PREDICTION OF AIRCRAFT ACCIDENTS FROM PILOT-CENTERED MEASURES. *J. Aviat. Med.*, 1956, 27 (2), 141-147. (U.S. Naval School of Aviation Medicine, Naval Air Station, Pensacola, Fla.).

9737

This article reviews several studies pertinent to the problem of selection and elimination of individuals who are highly likely to have aircraft accidents. Utilization of such criteria as aptitude, performance measures, and accident histories, is evaluated along with criteria of a more transitory nature, i.e., the individual's mood, attentiveness, temporary physiological state, level of training, etc. On the basis of these studies, conclusions are drawn concerning the general problem of predictability and the particular problem of prediction of pilot error accidents. R 8

Hendler, E., & Wurzel, E.M. THE DESIGN AND EVALUATION OF AVIATION PROTECTIVE HELMETS. *J. Aviat. Med.*, 1956, 27 (1), 64-70. (U.S. Naval Aeronautical Medical Equipment Laboratory, Philadelphia, Penn.).

9738

The authors present a detailed discussion of the research methods employed in the design and evaluation of aviation protective helmets. The design of such helmets is discussed in terms of the physiological factors which must be taken into consideration, e.g., the amount of load, force distribution, and so forth. The authors also describe a new rebound test device designed to provide more accurate measurements of location of force application to helmets, overall pressure distribution, pressure variation, etc. G. R 12

9739

Kitses, G. CABIN AIR CONTAMINATION PROBLEMS IN JET AIRCRAFT. *J. Aviat. Med.*, 1956, 27 (1), 53-58. (Aero-Medical Laboratory, WADC, Wright-Patterson AFB, Ohio).

9739

The incidence of air pollution problems in turbo-jet aircraft has led to a series of investigations to determine the cause and effects of cabin air contamination. An experimental evaluation of non-toxic engine oil is reported by the author. The toxic effects of the decomposition products of this oil upon laboratory animals are discussed in terms of rate of decomposition, exposure time, and temperature of decomposition. The implications for human performance in high speed aircraft are discussed in terms of the potential health hazard and performance decrement. T. G. I. R 6

9740

Strughold, H. THE US AIR FORCE EXPERIMENTAL SEALED CABIN. *J. Aviat. Med.*, 1956, 27 (1), 50-52. (USAF School of Aviation Medicine, Randolph AFB, Tex.).

9740

Technical, thermodynamical, and toxicological difficulties reflect the unsuitability of the conventional pressurized cabin for high altitude flight. This article presents a brief description of the U.S. Air Force experimental sealed cabin, a cabin designed to replace the conventional pressurized cabin. The two primary problems being investigated with this sealed cabin are: (1) the effect of cabin occupants upon various climatic factors, and (2) the extent to which such changes may be counteracted by physical, technical, and biological means. I. R 20

Dempsey, C.A., Greiner, T.H., Burch, N.R., Chiles, D., & Steel, J. THE HUMAN FACTORS IN LONG RANGE FLIGHT. J. Aviat. Med., 1956, 27 (1), 13-22. (Aero Medical Laboratory, Wright-Patterson AFB, Ohio).

9744
In an investigation of the human factors in long-range flight, subjects were confined to a grounded F-84 aircraft for a period of fifty-six continuous hours. The total time was divided into three phases of relative activity or performance; low performance, continuous performance, low performance. Such measures as heart rate, brain wave, blood samples, skin resistance, etc., were recorded along with a reaction time test and an alertness measure (British clock test). Cockpit noise level was controlled along with food intake and repeated subjective evaluations of clothing and seat discomfort were made. The results are discussed in terms of the qualitative and quantitative aspects of performance deterioration and cockpit habitability under simulated conditions of long-range flight. G. R 7

9745
Hilding, A.C. LABYRINTHINE STIMULATION. Amer. J. Ophthalm., 1956, 42 (4), Part 1, 621-629. (St. Luke's Hospital, Duluth, Minn.).

9745
The author reports two studies pertinent to the role of labyrinthine stimulation in visual axes deviation. In the first study, nine subjects were used to study the effects of prismatic lenses on vertigo. A series of seven tests (e.g., line-walking test, Hallpike test, Barany test, etc.) were used to measure the effect of the prism. In the second study, a group of subjects was used to evaluate the degree of deviation of the visual axes following vestibular stimulation by means of the Barany turning tests. The results of both studies are discussed in terms of the relative effect of prism upon vertigo and the effects of vestibular stimulation upon visual axes deviation. Also included are the results of experimental destruction of one labyrinth in cats. T. R 13

9746
Schmidt, T. EQUIPMENT FOR OBJECTIVE DETERMINATION OF VISUAL ACUITY ACCORDING TO GOLDMANN. Amer. J. Ophthalm., 1956, 42 (1), 123-126. (Freiburgstrasse 8, Bern, Switzerland).

9746
The author presents a description of a testing device to be employed with the Goldmann method of determining visual acuity. The primary characteristic of this method is the utilization of an involuntary physical reaction by the subject as the criterion of acuity. Such physical reactions may be eye movements, optokinetic nystagmus, or optokinetic pendular movements. The latter are employed in the Goldmann technique. The new apparatus presented induces such movements by utilizing a testing board with a checkered stripe on a uniform background. The ability to perceive the checkered stripe as a checkered stripe under variable conditions of stripe size, illumination, etc., reflects visual acuity.

9747
Berk, M.W. A LIGHTING SYSTEM FOR A TWO-METER TANGENT SCREEN. Amer. J. Ophthalm., 1956, 42 (3), 456-487. (University of Pittsburgh School of Medicine).

9747
The author describes a new fluorescent lighting system for a two-meter tangent screen which was developed to facilitate greater accuracy in central field examinations. The system utilizes two F96T12 Slim-Line fluorescent bulbs placed within two aluminum tubes. Simple rotation of a tube presents one of three color filters (red, green, and blue). Some of the additional advantages noted are the even distribution of light over the entire screen, the possibility of varying intensity without changing the quality of the light, and the fact that such a system requires the use of only white test objects (since the color is built into the system).

Van Itallie, T.B., Sinisterra, L., & Stare, F.J. NUTRITION AND ATHLETIC PERFORMANCE. J. Amer. med. Ass., 1956, 162 (12), 1120-1126. (Harvard School of Public Health).

9750
This article presents a general discussion of the role of nutrition in athletic performance in terms of the psychological, physiological, and metabolic considerations. Among the psychological factors, motivation is treated as a function of subjective reaction to the tests of the diet and reaction to pre-performance dietary supplement. Sources of energy required during athletic performance, the rate of digestion, and the influence of particular aspects of diet (e.g., carbohydrates, fat, etc.) are topics which receive discussion. General conclusions are drawn in terms of the "best" diet for the athlete.

Karpovich, P.V., & Hale, C.J. EFFECT OF WARMING-UP UPON PHYSICAL PERFORMANCE. J. Amer. med. Ass., 1956, 162 (12), 1117-1119. (Springfield College).

9751
Three experiments are reported in this study of the effects of warming-up upon physical performance. In the first experiment, seven track athletes were required to run a total of 60 test runs of 440 yd. each following three types of warm-up: 20 runs following deep massage, 20 following preliminary exercise, and 20 following digital stroking (as a control for psychological effect). In the second experiment, five subjects ran the same distance following conditions of no warm-up and digital stroking. In the final experiment, performance on the bicycle ergometer was compared under conditions of no warm-up and preliminary exercise. The results are discussed in terms of the general effectiveness of warm-up in improving performance and the specific effect of each of the pre-trial conditions upon performance. T. R 6

Learner, R.B., & Allard, R.I. COMPARISON OF FOUR METHODS OF EXPOSING SUBJECTS TO NOISE WITH CONYX LINE-EXPOSITION SHIELD. Summary AF 33(64)-3012, Proj. 7182, Tech. Note 34-685, Nov. 1954, 11pp. WAC, Wright-Patterson AFB, Ohio. (Ohio State University).

9753
To investigate the psychological feasibility of employing coding systems based on conyex line-detection signals for conveying information that might require as many as 70 unique signal categories, four groups (20 subjects each) decoded elevation information that had been encoded by the use of four different codes. Binary, decimal, and clock codes were based on eight lines radiating at 45-degree angular separation from the left, whereas the clock code consisted of a circle and two lines each of which could be positioned like the hands of a clock. The speed and accuracy with which 50 symbols in each test were decoded were studied for differences attributable to the type of code. Findings are discussed in terms of stimulus-response compatibility. T. G. I. R. H.

9754
Allphin, W. HOW TO FIX EXHAUSTION CRACKS. Factory Maintenance and Maintenance, 1956, 114 (5), 75-76. (Cynthia Electric Products, Inc., Salem, Mass.).

9755
The author presents specific suggestions for the most effective selection of colors with regard to workplace design. The role of lighting, work atmosphere, color preferences, is discussed along with such techniques as color coding, color selection systems, and the utilization of the color wheel. T.

9756
Fodolsky, E. USING COLOR TO BOOST OUTPUT IN FIVE PLANTS. Factory Maintenance and Maintenance, 1956, 114 (7), 124-125.

9757
The author presents a general discussion of the utilization of color to increase worker efficiency. Two primary aspects are presented: (1) the psychological effect of various colors, and (2) the most appropriate objects for which color is applicable. Under the latter heading the author suggests techniques for color application with tools, equipment, work being processed, and workplace environment.

9758
Wilkins, R. MAXIMIZING HEARING PROTECTION? Noise Control, 1956, 2 (4), 71, 68. (North American Aviation, Inc.).

9759
Following a brief presentation of the historical background of North American Aviation's hearing conservation program, the author describes the techniques used to deal with the specific problems encountered in one manufacturing building. A booklet on noise and hearing problem was issued to the employees along with a questionnaire designed to evaluate employee attitudes toward a hearing conservation program. A summary of results is presented together with the company's plans for utilizing these results in the formulation of a conservation program.

9760
Mass, R.B. A GUIDE FOR AN INDUSTRIAL AUDIO-METRIC MEASUREMENT PROGRAM. Noise Control, 1956, 2 (4), 64-67, 38. (Employers Mutual Liability Insurance Company).

9761
In discussing the development of a hearing conservation program the author cites four primary factors: "(1) pre-employment hearing measurements; (2) medical control; (3) ear protection program; (4) noise-level surveys; and (5) engineering control." Among the considerations concerning audiometric testing, the author includes the utilization of trained personnel, the location and design of the testing room, and the type of equipment and audiometric methods to be utilized in evaluating hearing thresholds. I.

9762
Wheeler, D.L. SOME FACTORS IN THE SELECTION OF HEARING INDUSTRIAL AUDIOMETRIC INSTRUMENTS. Noise Control, 1956, 2 (4), 61-63, 57.

9763
The author discusses the primary role of noise in the location of an industrial audiometric site and in audiometric evaluation. Acoustical, electrical, noise, and sufficient site are presented as determinants in the selection of an audiometric testing area. Also discussed are the techniques and objectives of ambient noise measurement and a method of noise control treatment, i.e., the probabilistic method. C.

9764
Stratynski, S. PLANT PLANNING FOR NOISE CONTROL. Noise Control, 1956, 2 (4), 37-44, 55.

9765
The author presents a detailed description of his approach to the task of evaluating the various sound-control requirements of two turbo-jet engines (Pratt and Whitney J40J-7) and J40J-7A). The general approach of analysis includes the calculation of sound-control criteria, analysis of the noise source, development of data obtained in noise source analysis, formulation of noise source criteria, and the development of specifications for muffler attenuation. Among the subjects covered are the following: body reaction to sound, noise annoyance factor in human behavior, noise effects on performance, etc. T. G. I. R. 32

9767
A quick method of automatic audiometry is described. Thresholds are determined at discrete frequencies by recording the first rise response after a threshold crossing on an IBM punched card.

9768
von Gierke, E.E. PERSONAL PROTECTION. Noise Control, 1956, 2 (3), 37-44. (WAC, Wright-Patterson AFB, Ohio).

9769
Devices for protecting individuals who must work in excessively noisy industrial or military environments, from noise-induced deafness are discussed. The theoretical limitations of earplugs, earmuffs and sound-proof helmets are outlined, and the actual performance of commercially available ear defenders is described. The criteria for determining when a noise is hazardous are reviewed, and the deficiencies of the available information pointed out. Practical problems of fitting earplugs and of instructing personnel to use them correctly are discussed.

9770
McMurray, R.P., & Rumsos, W. AN AUTOMATIC AUDIOMETER FOR INDUSTRIAL MEDICINE. Noise Control, 1956, 2 (1), 33-36. (Southern Methodist University).

9771
The design of an automatic audiometer for use in determining hearing loss among industrial employees is described. Its principal features are: the subject controls the level of the test tone; the operator may override the subject's control; hearing loss is measured at the discrete frequencies (500, 1000, 2000, 3000, 4000 and 6000 cps) customarily used in assessing industrial deafness; and a permanent record card is made of the threshold.

9765

To determine the effects of propofol on methyl ether (ME) upon subjective feelings in normal healthy crew personnel under realistic operational flying conditions, tests were arranged in conjunction with a 15 to 18 hour training exercise, 12 in actual flight. A battery of tests measuring subjective feelings of anxiety, irritability, and fatigue were given to 100 crew members and instructors immediately upon landing. The drug or a placebo was then given and crew finished their mission after which testing was repeated. A follow-up questionnaire was given the following morning. A comparison of pre- and post-test scores was made for changes attributable to sedation, and of experimental and control groups on follow-up questionnaire.

9773

Zajackowska, A. EXPERIMENTAL DETERMINATION OF LUNEBERG'S CONSTANTS σ AND K . *Quart. J. exp. Psychol.*, 1956, 9 (2), 66-73. (University College).

9773

According to Luneberg's theory, subjective visual space is hyperbolic with a constant negative curvature. The subjective visual space of any observer is determined by two personal constants— σ indicating the degree of depth perception, and K indicating the degree of curvature characteristic of that individual. These constants were determined for 30 observers, children or untrained adults, by Luneberg's 3- and 4-point method. The implications of the results for the validity of this geometric model of visual space are discussed.

Jeffress, L.A., Blodgett, H.C., Sidel, T.T., & Wood, C.L. MASKING OF TONAL SIGNALS. *J. Acoust. Soc. Amer.*, 1956, 28, 416-426. (Defense Research Laboratory, University of Toronto).

9775
The principal facts of monaural and binaural masking are reviewed in relation to two proposed theoretical models: the model for monaural listening is a narrow band-pass filter followed by a detector sensitive to changes in level; the model for binaural listening is a series of coincidence detectors associated with a delay network capable of matching an interaural stimulus delay with a contralateral neural delay. Original data from three listeners employing a variety of methods in alternative interaural phase relations are presented in support of the utility of these models. The prediction of many of the phenomena of masking from the properties of these two models is illustrated.

9779
This study is a part of a group of investigations of simultaneous listening to multiple messages. Two series of 3 digits each were presented simultaneously to one eye and to one ear. The subject was required to reproduce both series in their correct order. In the control group all six digits were presented successively to one eye or to one ear. In another experiment two sets of three digits each were presented simultaneously either binaurally or dichotically. The voice speaking one set of digits was high-pass filtered with a cut-off frequency of 225 or 1200 cps and either mixed with the other voice or presented to the opposite ear only. The experimental groups were composed of 12 subjects in each case. The implications of the results for a theory of attention are discussed. R 6

Ogilvie, J.C. THE INTERACTION OF AUDITORY PATTERN AND CFF: THE EFFECT OF BRIGHTNESS. *Canad. J. Psychol.*, 1956, 10 (4), 237-240. (Defense Research Medical Laboratories, Toronto, Canada).

9780
The effect of auditory flutter on the critical flicker frequency was determined as a function of the luminance of the visual stimulus and the phase relation between it and the fluttering notes.

9781
Riley, P.J. EFFECT OF BACKGROUND ON THE CRITICAL FLICKER FREQUENCY. *Canad. J. Psychol.*, 1956, 10 (4), 230-236.

9781
The effects of the size and brightness of background illumination on the critical flicker frequency were determined for three background brightnesses and six background sizes. The implications of the results for the theory of retinal interaction are discussed.

9782
Kooner, C.M. CLOSURE WITH NEGATIVE AFTER IMAGES UNDER FLICKERING LIGHT. *Canad. J. Psychol.*, 1956, 10 (4), 191-199. (Defense Research Medical Laboratories, Toronto, Canada).

9782
Perceptual closure of incomplete pictures of human heads was studied under a condition permitting a long viewing period with only one fixation point. This condition was secured by inducing a negative after-image of a photographic negative flashed under a light flickering at 2-10 cps. The optimum flicker frequency for a clear after-image was determined. The effects of the flicker and prior viewing of the negative on the ease of closure were examined to validate the technique.

9783
Loveless, J.E. DISPLAY-CONTROL RELATIONSHIPS ON CIRCULAR AND LINEAR SCALES. *Brit. J. Psychol.*, 1956, 47 (4), 271-282. (University of Durham).

9783
Errors in tracking a moving pointer on a circular scale were measured for different quadrants of the circle and for direct and reverse linkage between display and control. The results of similar tracking tasks on a linear scale are discussed together with the nature of the errors to which a circular scale gives rise.

Frerker, P. RELATIONSHIP BETWEEN VESTIBULAR REACTIONS AND VEGETATIVE REFLEXES, STUDIED IN MAN BY MEANS OF A REVOLVING CHAIR OF A NEW DESIGN. *Acta Oto-laryngologica*, 1956, 46(3), 207-229. (Stockholm, Sweden).

9786

A revolving chair of new design is described together with associated apparatus for recording myogram, skin resistance, blood pressure and electrocardiogram. The results of an experiment on the effect of rotation on skin resistance in about 100 subjects is reported.

9786

Palva, Jarmo. ABSOLUTE THRESHOLDS FOR COXTENSIONS AND EXTENDED PURE TONES. *Acta Oto-laryngologica*, 1956, 46(2), 127-136. (Oto-laryngological Clinic, University of Turku, Finland).

9786

The absolute threshold for pure tones in the frequency range 125-4000 cps was measured with a continuous tone and with tone pulses interrupted at rates varying from 1 to 12 times per second. Audiograms were obtained on 15 ears by the binaural technique. The effect of the interruption rate on the absolute threshold is discussed.

9787

Christiansen, E. AUDITORY PATIENCE AND WHITE NOISE. *Acta Oto-laryngologica*, 1956, 46(2), 99-106.

9787

An attempt is made to develop a test that will identify individuals who are susceptible to hearing loss induced by exposure to industrial noise. The shift and recovery time of the threshold for a 4000 cps tone was measured in 41 normal ears after exposure to a white noise at 105 db SPL for 3 minutes. The research which is required to make such measurements into useful predictors of deafness is discussed.

9788

Sandstrom, G.V. SEX DIFFERENCES IN TACTILE KINESTHETIC AND VISUAL PERCEPTION OF VERTICALITY. *Quart. J. exp. Psychol.*, 1956, 8(1), 1-7. (Psychological Lab., University of Stockholm).

9788

To determine the nature of perceptual errors in setting a rod into the vertical position in a dark room by visual and by purely tactual kinesthetic cues, a large number of subjects (at least 30 of each sex) performed this task under a variety of conditions. Each combination of the following conditions was used: head upright, head tilted 30° left, head tilted 30° right; adjustment made with right hand, the left and both hands; and the initial position of the rod 60° left and 60° right. The results are analyzed in terms of the effects of the sex of the subject and the experimental conditions upon the error made in the setting of the rod.

9789

Gheesman, G.H., & Townsend, N.J. FURTHER EXPERIMENTS ON THE OLFACTORY THRESHOLDS OF PURE CHEMICAL SUBSTANCES USING THE "SNIFF-BOTTLE METHOD." *Quart. J. exp. Psychol.*, 1956, 8(1), 9-14. (Reading University).

9789

The degree to which exposure to the odor of four chemicals—iso-propanol, cyclopentane, cyclopentanol, and dioxan—influences the threshold for the odor of each of the others was determined by the "sniff-bottle method." The extent to which mutual adaptation occurs is treated as a measure of the "community of odor property" of these substances. Some of the technical problems of utilizing the "sniff-bottle method" are also discussed.

9790

Davis, E. THE LIMITS OF THE PSYCHOLOGICAL REFRACTORY PERIOD. *Quart. J. exp. Psychol.*, 1956, 8(1), 24-41. (Institute of Experimental Psychology, University of Oxford).

9790

The effects of reacting to a prior signal upon the reaction to a subsequent signal were measured as functions of the length of the time interval between them. The subjects responded whenever a spot was exposed in a slit. In one experimental condition the response to each signal was made with the same finger of different hands and in the other experimental condition the two responses were made with different fingers of the same hand. The effects of the interval between spots and the method of making the response upon reaction time are discussed in terms of a "psychological refractory period."

9791

Brillatort, P.J. LES REACTIONS VESTIBULAIRES AUX EXERCICES ROTATOIRES SYNCHRONES. (VESTIBULAR REACTIONS TO SYNCHRONAL ROTATION TESTS). *Acta-Oto-laryngologica*, 1956, 46(3), 221-226.

9791

The threshold for circumferential rotation in alternating directions was measured in terms of the least detectable acceleration. The range of angular accelerations used was from 0.3 to 100 degrees/second². Myogenic eye movements were employed indirectly to define the threshold. The subject viewed a stereoscopic image that moved with him, and indicated the lateral direction in which it appeared to move. The least angular acceleration at which the reports of the subject were in phase with the actual motion was taken as the threshold. The implications of the results for an understanding of the mechanism of vestibular adaptation are discussed.

9792

Kantried, A. REPERES PSYCHOTOMIQUES: NOUVELLE METHODE D'ADJONCTION CONJECTIVE. (PSYCHOLOGICAL REFLEX: A NEW METHOD OF CONJECTIVE ADJUNCTION). *Acta-Oto-laryngologica*, 1956, 46(3), 231-243.

9792

A technique is described for using the psychodynamic skin response as a means of determining the threshold of hearing. The design of a differential bridge for measuring skin resistance and the interpretation of the resulting records are discussed. The use of the psychodynamic skin response with supraliminal stimuli is also described, and some results obtained with partially deaf children are given.

Peterson, J.E., Silverstein, Eva, & Subrahmanyam,
D.L. INTELLIGIBILITY OF DIPHASIC SPEECH.
J. acoust. Soc. Amer., 1956, 28 (3), 404-411.
(Speech Research Laboratory, University of
Michigan).

9796
The effects of switching abrupt reversals of phase
in and out of speech upon its intelligibility are in-
vestigated. Three speakers, an adult male, an adult female,
and a female child, read lists of 50 phonetically balanced
words which were recorded and played to 4 adult male lis-
teners through a switching and phase inverting channel at
a gain level set by each listener. The results are ex-
pressed in terms of the percent words understood as a
function of the switching rate (0.24 to 10600 cps), the
diphasic ratio (the relative durations of the in phase
and out of phase conditions which varied from 1:1 to 1:3)
and the rise-fall time of switching (from as short as pos-
sible to a maximum of 10 microseconds at frequencies
below 50 cps). T. C. R 4

9797

AUDITORY DETECTION OF THE PRESENCE AND ABSENCE
OF SIGNALS IN NOISE. *J. acoust. Soc. Amer.*,
1956, 28 (4), 614-616. (Speech Research
Laboratory and Control Systems Laboratory,
University of Illinois).

9797
This study is an investigation of the effects of
the set induced in a psychophysical subject by in-
structing him to report the absence of a signal as op-
posed to the usual instruction to report the presence of
a signal. A 1500 cps tone pulse one second long was
presented or omitted during a three second burst of
white noise at 60 db sensation and at a level near
threshold level. The subjects were 36 young men with
normal hearing. Half of the subjects were instructed to
report the presence of the signal and half to report its
absence. The two groups are compared with respect to the
proportion of correct signal detections, correct null
detections, signal misses and false alarms as a function
of small differences in the level of the test tone.

Hughes, G.W., & Halle, H. SPECTRAL PROPERTIES
OF FRICATIVE CONSONANTS. *J. acoust. Soc.
Amer.*, 1956, 28 (2), 303-310. (Research Lab-
oratory of Electronics, MIT).

9798
To determine the distinctive acoustic features of 6
English fricative consonants, they were recorded as
spoken by a number of talkers reading isolated words
designed so that the fricatives were located before or
after a major vowel. The fricatives were isolated by
an electronic gate and their energy density spectra
determined with a band-pass filter 150 cps wide. Dif-
ferences between speakers and between classes of fri-
catives, labial, dental, and palatal, are analyzed and
a set of objective criteria for differentiating fri-
catives are developed. The analysis was verified by having
listeners attempt to identify the now isolated fricative
sounds.

Bryant, G.L. THE AUTOMASTS: AN AUTOMATICALLY
RECORDING TEST OF ELECTRONICS TROUBLE SHOOTING.
1954, Dept. of Psychology, University of
California.

9799
This report describes the design and use of a
device for simulating a variety of electronic trouble-
shooting problems. The testing of data flow and com-
ponent characteristics can be simulated by the subject
by operating hand controls. Information on the result
of each test is presented to the subject on a printed
card which is exposed when a crank is pulled. Each
test made by the subject is automatically recorded on
a perforated tape. Some experience (but no actual data)
in the use of a trial form of 12 problems on four dif-
ferent simulated equipment is discussed.

Bowen, J.H., & Chernikoff, R. THE RELATIONSHIPS BETWEEN MAGNIFICATION AND COURSE-FREQUENCY IN
COMPENSATORY AIDED TRACKING. *NAL Rep. 4913*, April 1957, 6pp. *Applications Research Div.,
USN Research Lab., Washington, D.C.*

6 naval enlisted men received 20 testing cycles on each of the 12 combinations of magnifi-
cations and courses. The effects of the various magnifications on tracking performance with
the 3 course levels were examined at both the early (cycles 2-4) and late (cycles 18-20)
learning stages. The following results were found: a) Early in learning, increasing the
magnification produced a decrease in error for the low-frequency course, but produced no
systematic changes at the other course levels. b) After learning had stabilized, all magnifi-
cation levels showed equal improvement over the 1X condition for the low- and inter-mediate
frequency course, there were no differences between any pair of conditions. c) The nonlinear
magnification condition did not differ significantly from the 5X or 10X linear conditions
with any of the courses. When taken with the results of previous work comparing pursuit and
compensatory displays, the present study shows that the beneficial effects of magnification
occur at low and intermediate course frequencies, while the use of a pursuit display effec-
tively lowers error at intermediate- and high-frequency levels.

Coedry, F.E., Peacock, L.J., & Cramer, R.L. NYSTAGMIC EYE MOVEMENTS DURING INTERACTING VESTIBULAR STIMULI. Proj. 6 95 20 001, Rep. 275, March 1957, 8pp. USA Medical Research Lab., Fort Knox, Ky.

This is a study of the ocular nystagmic reaction to angular acceleration followed immediately by angular deceleration. During the deceleration period, nystagmus from the acceleration terminates and shortly thereafter nystagmus in the opposite direction commences. Time from the onset of deceleration to a point midway between nystagmus of opposite directions was measured. Electronic amplification of corneo-retinal potential was the method of recording eye-movement. The results obtained on vestibular nystagmus were essentially the same as those previously obtained where subjective reports were recorded. Both sets of results show close correspondence to theoretical curves but there is a small consistent difference between obtained and theoretical results.

Helfer, P.M. THE EFFECTS OF NOISE ON WORK OUTPUT AND PHYSIOLOGICAL ACTIVATION. Proj. 6 95 20 001, Rep. 270, March 1957, 25pp. USA Medical Research Lab., Fort Knox, Ky.

3 physiological variables (skin conductance, pulse interval, and muscle tension) were recorded during performance of a mental task, during exposure to 110 db noise, and during the noise and task combined. Noise by itself was found to be relatively non-stressful. However, it appeared that noise added slightly to the physiological cost of mental work, even though noise did not affect task performance. No correlation was found between physiological reactions to noise and the effects of noise on performance.

Cooning, L.J. ELEMENTS IN AIRCRAFT MAINTENANCE SCHEDULING. Research Rep., 1948. Purdue University.

9806

The literature on the application of factory production scheduling methods to aircraft maintenance is reviewed in the form of a narrative discussion. The topics covered are the influence of the nature of the flying operation, the nature of the maintenance operation, the saturation limit of teamwork, the system of assigning, recording and forecasting work requirements, and the system of evaluating the effectiveness of the scheduling methods in use.

Brown, J.L., Hill, J.E., & Burke, R.E. THE EFFECT OF HYPOXIA ON THE HUMAN ELECTRORETINOGRAM. Baled & Surg Proj. SM 001 110 300, Rep. 2, MADC-XA-5615, Nov. 1956, 23pp. Aviation Medical Acceleration Lab., MADC, Johnsville, Penn.

9807

To study the effect of hypoxia on the human electroretinogram (ERG), measurements were made of two subjects. Hypoxia was induced by breathing, at atmospheric pressure, oxygen-nitrogen mixtures that contain lower percentages of oxygen than that found in normal air (nine degrees and fifteen degrees). The ERG response to stimulation with a red, blue, or white test light was recorded before, during, and after 15-minute periods of breathing the oxygen-poor gas mixture. Amplitudes of both negative (A-wave) and positive (X-wave for red light, B-wave for blue light) deflections were studied for differential effects of hypoxia. Implications of the results are discussed in relation to current interpretations of the electroretinogram.

Madden, H.L., & Friedman, G. A FACTOR ANALYSIS OF THE STENQUIST MECHANICAL APTITUDE AND THE COOPERATIVE SCIENCES TEST IN 1949 NORMATIVE SURVEY BATTERY. 1952. HRRC, Air Training Command, Lackland Air Force Base, Texas.

9805

This report describes the development of a written test to evaluate the technical competence of aviation mechanics with respect to the B-50 aircraft. Items composed by subject matter specialists were selected on the basis of item reliability and validity. The criterion was supervisory ratings. The items were grouped into test areas--e.g., hydraulic system--and analyzed separately as well as collectively. Reliabilities and validities are reported for the test areas and the whole test.

T. R 7

9808

This study was undertaken to determine the factorial structure of the Stenquist Mechanical Aptitude and the Cooperative Sciences tests and their relation to the Airman Classification Battery ACIA. The tests were administered to 645 airman as a part of a larger survey. A factor analysis of the test scores was made by the centroid method. Nine factors are extracted and six identified in psychological terms.

Klass, P.J. BOMBING SYSTEM KEVED TO NEW HIDI-CATCH. Aviation Week, July 1957, 67(3), 62-69.

9809

This article presents a detailed description of the Navy's A-7B-3 low-altitude bombing system (LBS). Emphasis is placed on a novel feature of the system, an all-altitude indicator which combines the information previously presented by three instruments into a single instrument display system. Functionally adequate in both the loft and over-the-shoulder bombing systems, the all-altitude indicator is said to have received enthusiastic support from pilots who have employed it. The technical aspects of its construction are outlined and discussed.

Dix, M.R. LOUDNESS RECRUITMENT. Brit. med. Bull., 1956, 12(2), 119-124. (Medical Research Council, London, England).

The loudness recruitment phenomenon was first described by Fowler. Its occurrence in Ss suffering from certain varieties of nerve deafness has since been abundantly confirmed. Such Ss, although unable to understand speech at ordinary levels of intensity, complain of excessive loudness if these levels are exceeded. The investigation of loudness recruitment is best undertaken in cases of nocural deafness by means of the binocular balancing technique first described by Fowler. A brief description of the test follows, along with the anatomical basis of loudness recruitment, its relation to adaptation, its relation to speech intelligibility, technique of loudness recruitment tests with special reference to the measurement of the intensity difference limen and pure tone audiometry, and the clinical value of the loudness recruitment test.

9819

Merton, P.A. PROBLEMS OF MUSCULAR FATIGUE. Brit. med. Bull., 1956, 12(3), 219-221. (Medical Research Council, London, England).

This paper describes the problems of muscular fatigue through a discussion of 3 related topics: site of muscular fatigue, nature of fatigue, fatigue of skilled movements. Some of the points made are as follows: a) There are strong indications that fatigue is peripheral and is due to failure of the muscle to contract when motor impulses reach it and this failure is not due to blockage of impulses at the neuromuscular junction; b) To date, there is no evidence that fatigue is due to failure of the action potential-contraction coupling; c) muscular fatigue makes little difference to the performance of skilled movements until the muscles are almost too weak to make the necessary movements; d) experimental results indicate that the limit of muscular endurance may be nearer than is imagined even in light skilled tasks; e) Muscular fatigue is likely to be of importance in causing a sudden breakdown of performance when working near the limits of reserve, and it probably will not be significant at other times owing, perhaps, to the excellence of the muscle's proprioceptive servo-control which compensates automatically for fatigue. (HEIAS)

9820

Bannister, R.G. MUSCULAR EFFORT. Brit. med. Bull., 1956, 12(3), 222-225. (Hammersmith Hospital, London, England).

This paper deals with various aspects of muscular effort involved in sprint running, middle distance running, and long distance running. The rise in ventilation during exercise and oxygen transfer in the lungs are also discussed along with the increase in cardiac output which accompanies exercise. Factors, such as the role of the autonomic system in the smooth integration of exercise and that of the sympathetico-adrenal system, are also mentioned. It is concluded that the muscular effort of running is limited to 2 factors: a) the maximal contractile activity of muscle, which limits speed in sprinting, and b) the rate of supply of oxygen and metabolites to muscles along with the removal of the products of muscular contraction. (HEIAS)

Beranek, L.L. CRITERIA FOR OFFICE QUIETING BASED ON QUESTIONNAIRE RATING STUDIES. *J. acoust. Soc. Amer.*, 1956, 28 (5), 833-832. (Bolt Beranek and Newman Inc., Cambridge, Mass.).

9829

In order to determine criteria for the maximum acceptable noise levels in offices, 17 locations in buildings at an Air Force Base were studied. Ratings of the intensity and the ambient noise and of such adverse effects as interference with direct and telephone communication were made on 15 different scales by 190 office workers. Time samples of the noise were made at each location and octave band analyzed. The median noise ratings given at different locations are related to the speech interference level (the average of the sound pressure levels in the three octave bands between 500 and 4500 cps) and the loudness level (computed by Stevens' method). An attempt is also made to equate the effects of intermittent and continuous noises. A set of criteria are suggested for executive and general offices in terms of the speech interference and loudness levels. T. G. R 11

Blodgett, H.C., Wilbanks, W.A., & Jeffress, L.A. EFFECT OF LARGE INTERAURAL TIME DIFFERENCES UPON THE JUDGMENT OF SILENCE. *J. acoust. Soc. Amer.*, 1956, 28 (4), 639-643. (University of Texas).

9830

The maximum interaural time difference that could be introduced into the dichotic presentation of bands of noise was determined as a function of the frequency of the band. Noise bands of 105-212, 100-4800, 2400-4800 cps, and a narrow band centering around 425 cps were used. The listeners were nine experienced adult males. In one experiment the maximum time difference was determined by the method of adjustment, and in another the minimum time difference sufficient to offset a level difference of 3 db was determined by the method of constant stimuli. Individual differences among listeners are described, as well as the average trend of the results. T. G. R 1

Cherry, C.E., & Sayers, B. McA. "HUMAN 'CROSS-CORRELATOR'" -- A TECHNIQUE FOR MEASURING CERTAIN PARAMETERS OF SPEECH PERCEPTION. *J. acoust. Soc. Amer.*, 1956, 28 (5), 889-895. (Imperial College, University of London).

9832

A method is described for using the human listener as a cross-correlator to extract the perceptually critical invariant properties of auditory signals such as normal or compressed speech. One signal is fed directly to one ear, and another, having undergone the transformation under investigation, is fed to the other ear through a variable delay line. The listener reports whether the resulting sound image is located to the right or to the left. The results are expressed in the form of a 'psychocorrelogram' analogous to the autocorrelation function. Examples are given of the results of applying this method to some signals such as peak clipped speech and speech mixed with correlated and uncorrelated noise. G. R 15

9833

Flanagan, J.L., & House, A.S. DEVELOPMENT AND TESTING OF A FORMANT-CODING SPEECH COMPRESSION SYSTEM. *J. acoust. Soc. Amer.*, 1956, 28 (6), 1099-1106. (AFSC & Acoustics Laboratory, MIT).

9833

A system is described for transmitting intelligible speech over a reduced bandwidth by coding the formant characteristics. Seven parameters are extracted from the speech--the frequencies of the first, second, and third formants, the fundamental voice frequency, the amplitude of voicing and friction, and the frequency of the spectral maximum of fricative excitation. The intelligibility of speech transmitted over this system was evaluated on the basis of monosyllables read to six listeners by three speakers. The results are analyzed in terms of the errors attributable to vowels and to consonants. T. G. R 14

Kirk, R.E. LEARNING, A MAJOR FACTOR INFLUENCING PREFERENCES FOR HIGH-FIDELITY REPRODUCING SYSTEMS. *J. acoust. Soc. Amer.*, 1956, 28 (6), 1113-1115. (Ohio State University).

9837
The preferences of 119 male and 91 female college students for electroacoustic reproductions of restricted and unrestricted frequency ranges were determined with four kinds of material--string quartet, symphony orchestra, organ, and popular music, and a male voice. The following bandwidths--130-3000, 120-5000, 90-9000, 30-15,000 cps--were compared by the method of paired comparisons. One experimental group then listened to wide range reproductions of similar materials for about nine hours over a period of six weeks. Another experimental group listened to the same reproductions over the 150-3000 cps bandwidth. A control group was given no special listening experience. The preferences expressed are analyzed by the kind of material, the musical training of the individual and the experimental exposure. T. G. R 4

Olson, H.P., & Belar, H. PHONETIC TYPEWRITER. *J. acoust. Soc. Amer.*, 1956, 28 (6), 1072-1081. (RCA Laboratories, Princeton, N.J.).

9840
This paper describes the construction and function of a device for automatically converting spoken English into an intelligible and more or less conventional typewritten text. It consists of a microphone, volume controlled amplifier, compressor, array of eight band pass filters, scanning switch, spectral memory, spectral to syllable recoder, syllable memory, syllable to letter recoder, letter matrix and electric typewriter. The device operates by making a time-frequency-amplitude analysis of the speech wave and comparing it to a set of 40 stored speech sounds, which are in turn compared to the syllable memory and transmitted through the recoder to the letter matrix and typewriter. Results obtained with an actual model with storage capacity for only ten syllables are described. T. G. R 3

Schubert, E.D. SOME PRELIMINARY EXPERIMENTS ON BINAURAL TIME DELAY AND INTELLIGIBILITY. *J. acoust. Soc. Amer.*, 1956, 28 (5), 895-901. (Cleveland Hearing and Speech Center).

9842
The effects of interaural differences in arrival time upon the intelligibility of speech in noise were investigated under three conditions: speech in phase, speech delayed in one ear by 0.2 to 7.0 milliseconds, and speech or noise out of phase. The intelligibility of simple prose was measured on 14 subjects at signal-to-noise ratios of -2 to -14 db. The effects of the antiphasic condition are compared to the effects of simultaneous arrival and to the effects of different lengths of interaural time delay as a function of the signal-to-noise ratio. T. C. R 19

9843
Stevens, S.S. CALCULATION OF THE LOUDNESS OF COMPLEX NOISE. *J. acoust. Soc. Amer.*, 1956, 28 (5), 807-832. (Psycho-Acoustics Laboratory, Harvard University).

9843
A method is described for calculating the loudness of a complex noise from a knowledge of its spectrum, a scale relating scores to phons, equal loudness contours for octave bands of noise, and a formula relating the total loudness of a noise to the individual loudnesses of the bands. A variety of experiments on loudness matching were performed to obtain the subjective relations required for this computation. The method is based upon a model of mutual inhibition, according to which each band of noise contributes less to the total loudness than it would alone, by an amount which depends primarily on the proximity of the bands and secondarily upon their level. Supplementary experiments are reported on the effects of intermittent noise, the continuity of the spectrum, and the width of the bands. T. G. R 15

9844

Tanner, W.P. Jr. THEORY OF RECOGNITION. *J. acoust. Soc. Amer.*, 1956, **28** (5), 882-888. (University of Michigan).

9845

A theory of recognition is developed to account for the situation in which an observer must decide, in the presence of noise, which of two possible signals has been received. In an experiment intended to test the adequacy of the model, two observers made forced choices, according to the method of constant stimuli, between tones of two frequencies separated by 25, 50, 100, 300, 400, 500, and 600 cps and of four durations—0.05, 0.1, 0.5 and 1.0 sec. The results are expressed in terms of a parameter in the theory reflecting the degree of independence of the probability of recognizing one signal from the probability of recognizing the other.

Webster, J.C., Thompson, P.O., & Beitscher, H.R. NOISE BANDS VERSUS PURE TONES AS STIMULI IN MEASURING THE ACOUSTIC ATTENUATION OF EAR PROTECTIVE DEVICES. *J. acoust. Soc. Amer.*, 1956, **28** (4), 631-638. (U.S. Navy Electronics Laboratory, San Diego).

9845

The acoustic attenuation afforded by several kinds of ear defenders (RAF 43490; and Graydon Stadler OOL ear-phone sockets; T-512 and Flents earplugs; Airphone inserts; Mindel and David Clark earmuffs; and the Sound Absorb helmet) was determined by the threshold shift technique using both pure tone and noise band audiometry. Ear-occluded and non-occluded thresholds were obtained on 10 inexperienced listeners for each ear defender. The advantages and disadvantages of noise band audiometry are discussed in some detail, and a system is outlined for equating the results obtained in attenuation tests with noise bands to those obtained with pure tones. The efficacy of the ear-defenders studied is described and the reasons for the differences discussed.

David, E.E., & McDonald, H.S. NOTE ON PITCH-SYNCHRONOUS PROCESSING OF SPEECH. *J. acoust. Soc. Amer.*, 1956, **28** (6), 1261-1266. (Bell Telephone Laboratories, Murray Hill, N.J.).

9853

A system for reducing the bandwidth necessary to transmit the voiced portions of speech is described. Since the waveform of voiced speech is highly repetitive over intervals of 20-70 msec., some of the redundant information can be removed by eliminating N-1 of every N pitch periods. A set of delay lines codes the reduced information for transmission as a running signal, which is decoded at the receiver. A voice simulator replaces the missing pitch periods from the one sample transmitted or from an interpolation between adjacent samples. The theoretical performance of such a system is derived as a function of the value of N selected and the method used for approximating the missing periods.

Neely, K.K. EFFECT OF VISUAL FACTORS ON THE INTELLIGIBILITY OF SPEECH. *J. acoust. Soc. Amer.*, 1956, 28 (6), 1275-1277. (Defence Research Medical Laboratory, Toronto, Canada).

9855

The purpose of this study was to estimate the contribution of visual cues, "lip reading," to the intelligibility of speech in face to face communication in a noisy environment. One trained speaker read words from a multiple choice intelligibility test to 35 listeners with normal hearing. The speech was transmitted over a microphone-carphone system at an average level of 80 db sound pressure level in a noise field at 100 db sound pressure level. Each listener sat in turn in one of 11 test positions which varied in distance from the speaker and the angle of regard to his face. The proportion of words heard correctly is analyzed as a function of the availability of visual cues to the subject.

Tarnoczy, T.H. DETERMINATION OF THE SPEECH SPECTRUM THROUGH MEASUREMENTS OF SUPERPOSED SAMPLES. *J. acoust. Soc. Amer.*, 1956, 28 (6), 1270-1275. (Post Research Institute, Budapest, Hungary).

9856

In order to measure the average spectrum of speech without regard to its short term modulation, recordings were made of several voices talking simultaneously. The resulting mixture is aperiodic and has a more stable spectrum level than the voice of a single speaker. Seven simultaneous recordings were made of Hungarian speech under standardized conditions--two of ten men, two of ten women, one of six men, one of six women, and one of five men and five women together. The spectra generated by this combination was octave band analyzed with one-half octave overlap. Male and female voices are contrasted and compared to the results of similar estimates of the speech spectra generated by English talkers.

Friedlander, Y.J. CHARACTERISTICS OF POSTURAL TREMOR IN NORMAL AND IN VARIOUS ABNORMAL STATES. *Neurology*, 1956, 6 (10), 716-724. (V.A. Hospital, San Francisco, Calif.).

9860

To investigate the phenomenon of tremor in normal and abnormal states, 1200 tracings were obtained on approximately 700 patients. In this group medical history and physical examination records were available. 39 of the 403 were categorized as normal whereas the remainder were classified in one of the following diagnostic categories: anxiety; chronic alcoholism; parkinsonism; and unilateral central nervous system pathology. The characteristics of postural tremor in normals are compared to those found in pathological disorders. Truography as a diagnostic technique is critically evaluated.

Promley, D.B. SOME EXPERIMENTAL TESTS OF THE EFFECT OF AGE ON CREATIVE INTELLECTUAL OUTPUT. *J. Geront.*, 1956, 11 (1), 74-82. (University of Liverpool).

9861

This article presents several investigations of the effects of age on creative intellectual output. Utilizing the Shaw Test, a test of creative thinking, 256 subjects composing four age-level groups (ranging from 17 to 82 years) were evaluated. The results are presented and discussed in terms of the comparability of the age distribution of scores with previously published data (Lehman's "Age and Achievement"). Conclusions are drawn concerning the loss of intellectual efficiency (quantity and quality) with age.

Clay, H.M. A STUDY OF PERFORMANCE IN RELATION TO AGE AT TWO PRINTING WORKS. *J. Geront.*, 1956, 11 (4), 417-424. (Nuffield Research Unit into Problems of Ageing, Psychological Laboratory, Cambridge, England).

9862

This article presents an investigation of the relation between age and performance as manifested in the operations of two printing works. The performance records were obtained of subjects ranging in age from 20 to 65 years and performing the following tasks: machine-compositors, hand compositors, and readers. The effect of an incentive scheme and the general trend of productivity are analyzed in terms of the age distribution.

Heglin, H.J. PROBLEM SOLVING SET IN DIFFERENT AGE GROUPS. *J. Geront.*, 1956, 11 (3), 310-317. (Interscutor Pilot Research Laboratory, Tyndall AFB, Fla.).

9864

In order to determine the relation of age to: (1) susceptibility to problem solving set, (2) ability to overcome set, and (3) training in avoiding set, 100 male and female subjects in each of three age groups (14-19, 20-29, and 50-55) were tested on the Luchins Water Jars and Coven's Alphabet Maze Tests (a variation of the Water Jars Test). Following the first test the effects of set were demonstrated and the subject cautioned to avoid them on the second test. An analysis of variance of the data was conducted to evaluate the role of age difference in reaction to set. The results are discussed in terms of the potential age factors operant in problem solving activity.

Thaler, Margaret. RELATIONSHIPS AMONG WECHSLER, WEIGL, RORSCHACH, EEG FINDINGS, AND ABSTRACT-CONCRETE BEHAVIOR IN A GROUP OF NORMAL AGED SUBJECTS. *J. Geront.*, 1956, 11 (4), 404-409. (Walter Reed Army Institute of Research, Washington, D.C.).

9867

This is a study of the abstract-concrete behavior of a group of normal aged subjects and the interrelationships among data on these subjects obtained with the following measures: Wechsler-Bellevue Intelligence Scale, the Weigl test, the Rorschach, and EEG findings. One hundred sixteen normal subjects over age 60 were tested on each of the measures. The results are presented and discussed in terms of the relations between the scores on the various tests. Conclusions are drawn concerning the concepts of abstract and concrete as applied to aged persons and the notion of "capacity" is offered as a potentially more pertinent concept.

Beecher, H.K. EVIDENCE FOR INCREASED EFFECTIVENESS OF PLACEBOS WITH INCREASED STRESS. *Am. J. Physiol.*, 1956, 137, (1), 163-169. (Anesthesia Laboratory, Harvard Medical School).

9868

To evaluate the effectiveness of placebos with varied intensities of stress, patients who had received four doses of placebo were compared to those who had received four doses of morphine in terms of percent of patients reporting relief of pain with each dose. Increasing stress was defined by degree of anxiety (i.e., response to saline) and the effectiveness of the placebo was ascertained for severe vs. mild anxiety. The implications for the utilization of drugs as well as placebos with increasing stress are discussed.

Bernstein, L.M., Johnston, L.C., Ryan, R., Inouye, T., & Hick, P.K. BODY COMPOSITION AS RELATED TO HEAT REGULATION IN WOMEN. *J. appl. Physiol.*, 1956, 9 (2), 241-256. (University of Illinois College of Medicine).

9876

This is an investigation of the relationship between body composition and heat regulation in women. Utilizing a total population of 76 young and aged normal, obese, and hyperthyroid women, lean body mass, cell mass, and fat mass were determined. Each of the subjects was then required to spend one hour in a hot environment, one hour in a comfortable environment, and three hours in comfortable and cooling environments. Appropriate indices were applied to ascertain heat regulation. The results are treated in terms of the relative rates of oxygen consumption, skin temperature, heat loss, etc., as functions of body composition. In addition, comparisons of body compositions for the various types of subjects are presented and discussed.

Colville, P., Stagg, C., & Ferris, B.G. Jr. EFFECTS OF BODY TILTING ON RESPIRATORY MECHANICS. *J. appl. Physiol.*, 1956, 9 (1), 15-24. (Harvard School of Public Health).

9878

To conduct a quantitative evaluation of the effects of body tilting on respiratory mechanics, 12 subjects with severe respiratory muscle paralysis (poliomyelitis) and three normal subjects were protected for functional residual capacity (with a helium dilution technique) in the supine and horizontal position. Measures were then taken with the tilt bed facilities head-down and foot-down (limits of tilt: 30° head-down, 40° foot-down). Volume changes, angle, and airway pressure were recorded simultaneously. The results are presented and discussed in terms of volume-angle-airway relations as a function of trunk angle and compliance of the respiratory mechanisms (lung, diaphragm, rib cage, etc.).

Goff, L.G., Frassetto, R., & Specht, E. OXYGEN REQUIREMENTS IN UNDERWATER SWIMMING. *J. appl. Physiol.*, 1956, 9 (2), 219-221. (National Institute of Arthritis and Metabolic Diseases, National Institute of Health, Bethesda, Md.).

9882
To determine the average speeds and oxygen requirements during free open water swimming and to investigate the validity of laboratory data application to field problems, a total of 27 subjects were observed over a total of 200 open water swims of varying distances. Oxygen consumption was measured by the pressure-drop method and average swimming rates determined by the amount of time required to swim a known distance. The results are presented in terms of average swimming rate as a function of distance and the range of oxygen consumption as a function of various swimming rates. These findings are related to previous ones.

Le Blanc, J. EVIDENCE AND MEANING OF ACCLIMATIZATION TO COLD IN MAN. *J. appl. Physiol.*, 1956, 9 (3), 355-358. (Defence Research Northern Laboratory, Fort Churchill, Manitoba, Canada).

9883
In this study of acclimatization to cold, observations were made of ten soldiers exposed for 4 months to Arctic climate. During the day they performed a 10 mile walk and in the evening simulated watchkeeping conditions by standing motionless for 2-3 hours. Skin and body temperature, and oxygen consumption (Barbier Metabolator) measures were taken and compared with a non-acclimatized group. The results are presented and discussed in terms of differences in physiological measures (between the groups) as indicative of the occurrence and character of acclimatization.

Marshall, R., Lamphier, E.H., & DeBois, A.B. RESISTANCE TO BREATHING IN NORMAL SUBJECTS DURING SIMULATED DIVES. *J. appl. Physiol.*, 1956, 9 (1), 5-10. (Graduate School of Medicine, University of Pennsylvania).

9885
This is an investigation of difficulty in breathing as a function of the ambient pressures resulting from dives to depths of 100 or more feet of water. Utilizing an occluding balloon technique, intrapulmonary pressures were made on three normal male subjects during simulated dives varying from 66 and 99 feet for two of the subjects and 132 feet for the third. Maximal expiratory and inspiratory flow were recorded electrically with an (Osterlind) low resistance spirometer (with rapid kymograph). The data are presented and discussed in terms of resistance to breathing at various depths as indicated by inspiratory and expiratory flows and as a function of quiet vs. forced breathing.

Burton, A.C., Snyder, B.A., & Leach, W.G. COLD VS. DRY COLD. SPECIFIC EFFECTS OF EXHAUSTION ON HEAT EXCHANGE OF UNACCLIMED MAN. *J. appl. Physiol.*, 1955, 2 (3), 269-273. (University of Western Ontario Faculty of Medicine, London, Canada).

9890

This article presents a series of quantitative and qualitative studies on the effects of humidity on unclothed subjects conducted on the basis of predictions from physical theory concerning the nonradiative heat loss of a warm body. Nine subjects were placed in an air-conditioned room for 2-2 1/2 hours in each experiment under temperatures of 50° and 60° F. Relative humidity was varied and air movement was measured along with skin temperature, oxygen consumption, and so forth. The data were analyzed in terms of skin and rectal temperatures, mean tissue temperature and heat debt, piloerector response, etc. The relative effect of humidity at various temperature levels is discussed. T. G. R 14

9891

Larey, C.R., Schaefer, E.E., & Alvis, H.J. EFFECT OF SKIN DIVING ON LUNG VOLUMES. *J. appl. Physiol.*, 1956, 8 (5), 519-523. (U.S. N. Medical Research Laboratory, Naval Submarine Base, New London, Conn.).

9891

To evaluate the effect of skin diving on lung volumes, vital capacity (Collins Vitalometer), inspiratory-expiratory reserve and tidal volume (Collins Respirometer), and residual volume (modification of Lundsgaard-Yan Slyke method) measures were taken with three groups of subjects: (1) 16 Escape Training Tank instructors who had served in this capacity for an average of 1 1/2 years; (2) 16 male subjects; and (3) 20 additional tank instructors. The initial study involved a simple comparison between groups one and two while a second study attempted a longitudinal analysis, i.e., tested two months and again after one year of duty. The results are presented and discussed in terms of relative difference in lung capacity measures between tank instructors and other personnel as indicative of skin diving effects on lung capacity. Hall, J.P., Jr., & Polte, J.W. EFFECT OF WATER CONTENT AND COMPRESSION ON CLOTHING INSULATION. *J. appl. Physiol.*, 1956, 8 (5), 533-545. (Aero Medical Laboratory, AFSC, Wright-Patterson AFB, Ohio).

9894

This is a study of: (1) the effects of water compression and clothing water content on thermal insulation; (2) the relative heat loss of a clothed manikin in air and water under conditions of dry versus wet clothing; and (3) the effect of wetting small as compared to large areas of the body. Utilizing a copper manikin dressed in various combinations of clothing both wet and dry, thermal insulation measures were taken in the air and under water. The results are presented and discussed in terms of the relative thermal insulation values of particular clothing assemblies, the relative heat loss of the clothed manikin, and so forth. T. G. R 10

9895

Hellon, R.P., & Lind, A.R. OBSERVATIONS ON THE ACTIVITY OF SWEAT GLANDS WITH SPECIAL REFERENCE TO THE INFLUENCE OF AGEING. *J. Physiol.*, 1956, 133 (1), 132-144. (University of Oxford).

9895

To evaluate the effect of age on activity of palmar sweat glands, a total of twenty-four subjects, reflecting two age groups (18 to 23 and 45 to 57 years), were exposed to cool and hot environments and records taken of sweat gland activity (Thomson and Jutarman technique). The results are presented and discussed in terms of the differences between the groups and the general nature of palmar gland activity under conditions of heat and cold as reflected by the measures on all of the subjects. T. G. R 25

9896

Hellon, R.P., Lind, A.R., & Weiner, J.S. THE PHYSIOLOGICAL REACTIONS OF MEN OF TWO AGE GROUPS TO A HOT ENVIRONMENT. *J. Physiol.*, 1956, 133 (1), 118-131. (Medical Research Council Unit for Research on Climate and Working Efficiency, University of Oxford).

9896

To investigate the potential relationship between age and heat regulatory and circulatory responses, 36 subjects, divided into two groups with the following age range: 19-31 and 39-45 years, were exposed to controlled heat conditions of 37.8° C dry-bulb and 29.4° C wet-bulb temperatures for a period entailing a four hour work routine. The work, consisting of stepping on and off a stool, was interspersed with rest periods (sitting on stool). Sweat losses, oxygen consumption, blood flow, etc., were measured at intervals. The results are presented and discussed in terms of the relative differences in the physiological measures between the two groups as indicative of the influence of age. T. G. R 22

Roffman, B.P., Seckling, E.E., Brooks, C.M., Penick, E.E., Coleman, E.S., & Treisman, H.J. QUANTITATIVE ESTIMATION OF SLEEP. *J. appl. Physiol.*, 1956, 8 (4), 361-368. (State University of New York College of Medicine).

9898

This study attempts to determine the measures best suited to quantitative evaluation of depth of unconsciousness and degree of muscular relaxation during normal uninterrupted sleep and to evaluate the interrelations among the functions of various organ systems during sleep. Three conscious subjects and six sleeping subjects were studied for changes in heart rate, metabolic rate, skin and rectal temperatures, etc. In addition, electroencephalogram and electrocardiogram records were taken on sleeping subjects. The results compare and contrast the effectiveness of the various measures of depth of consciousness and relaxation. The relation of heart rate to over-all metabolism is discussed. T. G. I. R 12

9899

Seifert, B.P., Streeley, W.P., Myers, J.R., & Chinn, R.I. EFFECT OF HEAD IMMOBILIZATION ON INCIDENCE OF AIRSICKNESS. *J. appl. Physiol.*, 1956, 8 (4), 369-370. (Infantry School, Fort Benning, Ga.).

9899

To evaluate the effects of head immobilization and drugs on incidence of airsickness, 112 paratroopers received either a placebo or 0.45 mg. of hyosine hydrobromide prior to embarking upon a two hour flight in which alternate subjects were strapped to head restraints. The flight employed tactics designed to increase severity of exposure. The subjects flew and jumped in three flights. The results are presented in terms of incidence of airsickness as a function of medication, head rest, and the combination of the two. The previously affirmed prophylactic effects of head immobilization are questioned. T. B 5

Lurt, U.C., & Noell, W.K. MANIFESTATIONS OF BRIEF INSTANTANEOUS ANOXIA IN MAN. *J. appl. Physiol.*, 1956, 8 (4), 444-454. (Lovelace Foundation, Albuquerque, N.M.).

9899

In this study of cerebral and neurological manifestations of brief instantaneous anoxia in man, oscillographic, electroencephalographic, and photographic records were made on two subjects during and after exposure to a barometric pressure of 68-70 mm Hg by rapid decompression. The results are analyzed in terms of changes in blood oxygen saturation, changes in posture and movement, the occurrence of anoxia, electroencephalographic effects, and so forth. Photographic illustrations of the subjects' reactions are presented. T. G. I. R 21

Moncrieff, R.W. OLFACTORY ADAPTATION AND ODOUR LIKENESS. *J. Physiol.*, 1956, 133 (2), 301-316. (Consulting Laboratory, 93 St., Pancras, Chichester, England).

9900

A series of experiments were conducted in this investigation of the effect of likeness of pairs of smells on their mutual adaptation effects. With the odorants consisting of acetone, isopropanol, n-butanol, diacetone alcohol, cellosolve, methanol, and odorants of similar smells, e.g., n-butanol and sec-butanol, cellosolve and benzylamine, etc., three subjects were tested to determine the following thresholds: 1) having first smelt water, the threshold of the components of each pair; 2) threshold concentration of each component after self-adaptation; and 3) having first smelt the other, the threshold of each component of the pair. The results compare and discuss self-adaptation vs. heterogeneous adaptation, the effect of similarity of smells on consequent adaptation, the effect of entities with almost indistinguishable smells on adaptation, etc. T. R 12

9901

Miller, A.T., & Blyth, C.S. INFLUENCE OF BODY TYPE AND BODY FAT CONTENT ON THE METABOLIC COST OF WORK. *J. appl. Physiol.*, 1956, 8 (2), 135-141. (School of Medicine, University of North Carolina).

9901

This is an investigation of the influence of body type and body fat content upon the metabolic cost of work. Thirty subjects reflecting a wide range of body type and of fat content and varying in age from 19 to 25 years were measured for rate of oxygen consumption (by the open circuit method) during the last five minutes of a 15 minute exercise period (treadmill walking). The data are treated in terms of multiple correlations among the various factors, e.g., exercise vs. height, weight, etc., height vs. weight, etc. On the basis of three correlations, the most accurate predictor of metabolic cost of work is specified and discussed. T. R 7

9902

Boddie, R.A. EFFECT OF ARM POSITION ON CIRCULATION THROUGH THE FINGERS. *J. appl. Physiol.*, 1956, 8 (1), 67-72. (The Queen's University, Belfast, Northern Ireland).

9902

In this investigation of the effect of arm position on circulation through the fingers, observations were made on 19 healthy subjects of the heat elimination from fingers of both hands to water (29°-32° C) with a calorimeter. The finger tips were supported at various levels above or below the horizontal plane. The results are presented and discussed in terms of rate of heat elimination as a function of level of arm position. G. B 23

9903

Schaefer, L.E. OXYGEN TOXICITY STUDIES IN UNDERWATER SWIMMING. *J. appl. Physiol.*, 1956, 8 (5), 524-531. (U.S.E. Medical Research Laboratory, Naval Submarine Base, New London, Conn.).

9903

To investigate oxygen toxicity in underwater swimming, twelve trained subjects swam in a 100-foot lock at depths of surface, 20, 30, and 40 feet while breathing oxygen for 93 minutes with rest periods after each 15 minutes. Pulse rate and respiratory rate (oxygen consumption) were recorded. The results are presented and discussed in terms of the relative changes in pulse and respiratory rates at each submergence level as a function of the amount of continuing exercise. T. G. R 21

9904

Schilling, J.A., Harvey, R.B., Becker, C.L., Velasquez, T., Wells, G., & Baake, B. WORK PERFORMANCE AT ALTITUDE AFTER ADAPTATION IN MAN AND DOG. *J. appl. Physiol.*, 1956, 8 (4), 381-387. (University of Rochester School of Medicine and Dentistry).

9904

In this study of work capacity before, during, and after adaptation to varied altitudes (14,900 feet, 760 feet, and 19,000 feet) three human subjects and four dogs were employed. Work capacity, defined by performance on a treadmill test, was measured along with other physiological indices (pulse rate, oxygen consumption, etc.). The results are presented and discussed in terms of the relation of work capacity to characteristic physiological changes found at each altitude level. G. R 13

Schneider, A., & Wolf, S. OLFACTORY PERCEPTION THRESHOLDS FOR CITRAL UTILIZING A NEW TYPE OLFACTORY. *J. appl. Physiol.*, 1956, 5 (3), 337-342. (University of Oklahoma, School of Medicine).

9906

This article presents a description of a new type of wall-in olfactory and its utilization in the determination of odor perception thresholds for citral (an aromatic organic compound). Thresholds were made on 150 occasions in 53 healthy Ss under varied conditions of humidity and temperature and by means of three methods: 1) proceeding up from smallest amount of odor, 2) starting well above threshold and working down, and 3) random amounts of odor. The results are discussed in terms of mean threshold for citral and threshold fluctuation as a function of menstrual flow, stress, and pressure of nasal obstruction.

Strydom, J.B., Morrison, J.F., Scoones, J., & Peter, J. COMPARISON OF ORAL AND RECTAL TEMPERATURES DURING WORK IN HEAT. *J. appl. Physiol.*, 1956, 8 (4), 406-408. (Applied Physiology Laboratory, Transvaal and Orange Free State Chamber of Mines, Johannesburg, South Africa).

9906

This study attempts to determine the accuracy with which oral temperature reflects rectal temperature during work in the heat, the latter having been found a reliable safeguard against heat illnesses but impossible for practical reasons. Simultaneous oral and rectal temperature measurements were taken on 229 underground laborers at ten mines under environmental conditions of 20° to 93° F and following a 2-3 hour work period. The data are treated in terms of the relative differences and variation of differences between oral and rectal temperatures. An oral temperature equivalent to 103° F rectal is selected and discussed.

White, R.P., Rinaldi, P., & Himwich, H.E. CENTRAL AND PERIPHERAL NERVOUS EFFECTS OF ATROPINE SULFATE AND MEPERPERPHENIDOL BROMIDE (DARSTINE) ON HUMAN SUBJECTS. *J. appl. Physiol.*, 1956, 8 (6), 635-642. (Hindichum Psychiatric Research Laboratory, Galesburg State Research Hospital, Galesburg, Ill.).

9907

To evaluate the central and peripheral effects of atropine sulfate and meperperphenidol bromide (darstine) on humans, 27 subjects were administered either one or the other or a combination of the drugs. Electroencephalograph, electrocardiograph, blood pressure, oral dryness, and other physiological and psychophysiological phenomena were recorded prior to and compared with the same measures following administration of the drugs. The results are presented and discussed in terms of the relative effect of each of the drugs and their combination upon central and peripheral nervous system functioning.

Joseph, J., & Nightingale, A. ELECTROMYOGRAPHY OF MUSCLES OF POSTURE: LEG AND THIGH MUSCLES IN WOMEN, INCLUDING THE EFFECTS OF HIGH HEELS. *J. Physiol.*, 1956, 132 (3), 465-468. (Guy's Hospital Medical School, London, England).

9908

This investigation of the electromyography of leg and thigh muscles (of posture) in women includes an assessment of the effects of high heels. Electromyographic records of 21 women age 18-28 years wearing both low and high heels were obtained while each subject maintained a standard posture. The results are discussed in terms of defining the muscular areas of continuous activity and the effect on this activity of the wearing of high heels.

Balliday, A.N., & Redfearn, J.W.P. AN ANALYSIS OF THE FREQUENCIES OF FINGER TREMOR IN HEALTHY SUBJECTS. *J. Physiol.*, 1956, 134 (3), 600-611. (Medical Research Council Neurological Research Unit, National Hospital, Queens Sq., London, England).

9909

To investigate the phenomenon of finger tremor, a method utilizing a system free from inertia was employed to record finger tremor in 46 healthy subjects (male and female). An analysis of the frequencies of tremor was conducted and the results are presented in terms of the mean spectra of tremor frequencies with loaded vs. unloaded finger, for male vs. female, and for subjects clinically defined as having active vs. those having not very active reflexes. A discussion is presented concerning the possible causes of the rhythm of finger tremor as demonstrated here.

Stanger, Priscilla H. PITCH-INTENSITY DEPENDENCE AND ITS RELATION TO THE THRESHOLD OF HEARING FOR HIGH FREQUENCIES. *J. Physiol.*, 1956, 134 (3), 741-746. (Institute of Ophthalmology, Judd St., London, England).

9911

This is an investigation of pitch intensity dependence and its relation to the threshold of hearing for high frequencies. Utilizing subjects with a slight perceptive deafness (i.e., hearing loss at highest frequencies of the audiogram), and subjects with good hearing at frequencies up to 12,000 c/s, a series of pitch tests were conducted and consisted of forced-choice comparisons of pairs of pure tones. With the first tone constant, the intensity of the second was varied. The results are presented and discussed in terms of the relative effect of intensity upon pitch as perceived by subjects with normal and partially defective hearing at high frequencies.

AUTOMOBILE DRIVERS. US Armed Forces Med. J.
1956, 7 (12), 1741-1749. (U.S. Naval Hospital,
Philadelphia, Penn.).

9913
This study of highway safety employed two groups of
67 subjects each, whose accident history had been screened
so as to define one group as accident- and violation-free
and the other as having had at least one accident and
violation (of traffic regulations). Both groups were
tested on a series of personality tests and the results
analyzed in terms of the significant personality differ-
ences between the groups. A list of personality
characteristics reflecting the safe-driver is presented
and discussed.

McGuire, P.L. AN OUTLINE FOR A NEW APPROACH
TO THE PROBLEM OF HIGHWAY ACCIDENTS. US
Armed Forces Med. J., 1956, 7 (8), 1157-1166.
(U.S. Naval Hospital, Philadelphia, Penn.).

9914
The author assesses the highway safety program (in
the military) and advocates a new approach based on the
definition of different personality groups. Six types
of groups (e.g., well-adjusted; emotional problems, but
socially responsible and controlled; etc.) are defined
in terms of their personality makeup, expected driving
record, and program of treatment most adequate for
achieving safe driving (with the particular group). In
addition to the personal approach, a program of mass con-
sultation is described and discussed.

McGuire, P.L. THE SAFE-DRIVER INVENTORY: A
TEST FOR SELECTING THE SAFE AUTOMOBILE DRIVER.
US Armed Forces Med. J., 1956, 7 (9), 1249-
1264. (U.S. Naval Hospital, Philadelphia,
Penn.).

9915
This article presents a description of the Safe-
Driver Inventory, a paper and pencil test designed to
select the safe automobile driver. Four hundred forty-
six subjects were screened on attitude, intelligence, and
personality tests in the process of selecting test items.
The validity and reliability of two forms of the Inven-
tory were assessed with two matched groups of subjects
with known accident and violation histories. The inter-
pretation of the Inventory is discussed in terms of the
theory underlying its construction. Both forms of the
Inventory are presented in the appendix.

Mayer, Jean, Purnima, R., & Kamakhya, P.M.
RELATION BETWEEN CALORIC INTAKE, BODY WEIGHT,
AND PHYSICAL WORK: STUDIES IN AN INDUSTRIAL
MALE POPULATION IN WEST BENGAL. Amer. J. Clin.
Nutrition, 4 (2), 169-175. (Harvard School
of Public Health).

9916
To investigate the relation between caloric intake,
body weight, and physical work, 213 mill workers (in
West Bengal) varying in physical activity from sedentary
to very hard work were studied. Food intakes were deter-
mined by dietary interviews, additional information was
obtained concerning height, weight, etc., and five
classes of work ranging from sedentary to very heavy
work were defined. An analysis of the data was conducted
in terms of the intercorrelations among caloric intake,
physical activity, and body weight. The results are
discussed with specific regard to the implications of
sedentary life for the mechanism of regulation of food
intake.

House, E.P., Davis, E., Glorig, A. Jr., Hoople,
G.D., & Fox, H.S. A REPORT FROM THE SUBCOM-
MITTEE ON NOISE IN INDUSTRY. Trans. Amer.
Acad. Ophthalmol. & Otolaryngol., 1956, 50 (6),
821-931. (Los Angeles, Calif.).

9917
This report presents several articles concerning the
problem of noise in industry. Two articles outline con-
temporary research problems (e.g., temporary threshold
shift, permanent effects of exposure to noise, etc.) and
briefly review results of research on such aspects of the
problem as prophylaxis, ear protection, etc. In another
section the principles for evaluating hearing loss are
critically reviewed and in the final section the role of
the otologist in the industrial noise problem is dis-
cussed.

Hill, S.R., Goetz, F.C., Fox, H.M., Murawski,
B.J., et al. STUDIES ON ADRENOCORTICAL AND
PSYCHOLOGICAL RESPONSE TO STRESS IN MAN. Ann
Arch. Internal Med., 1956, 97 (3), 269-298.
(Departments of Medicine and Psychiatry,
Harvard Medical School).

9918
This is a report of an extensive series of studies on
adrenocortical and psychological responses to stress.
Utilizing metabolic, statistical, and physiological tech-
niques of evaluation, the effect of stress was investi-
gated as manifested in the physical and psychological
responses of two crews of college cadets prior to and
following actual (and practice) races. An analysis of
the data was conducted in terms of a comparison between
"winning" and "losing" crews and the general effects of
stress for all subjects with regard to changes in psycho-
logical and metabolic tests.

Chin, N.B., & Horn, R.F. INFRARED SKIASCOPE
MEASUREMENTS OF REFRACTIVE CHANGES IN DIM
ILLUMINATION AND DARKNESS. J. opt. Soc. Amer.,
1956, 46 (1), 60-66. (Aero Medical Labora-
tory, WADC, Wright-Patterson AFB, Ohio).

9919
Measurements of the refractive state of one eye were
made on nine subjects with an infrared skiascope. This
apparatus permits the experimenter to view the image of
the retina which is formed in the pupil without stimulat-
ing the subject with visible light. The subjects viewed
a Landolt ring at luminance levels of from 10.6 ft.L. to
complete darkness while skiascopic measurements were made
on the other eye. The implications of the results for
the interpretation of night and empty field myopia are
discussed.

Johannsen, Dorothea E., McBride, P.I., & Wul-
fbeck, J.W. STUDIES ON DARK ADAPTATION: I.
THE PRE-EXPOSURE TOLERANCE OF THE DARK-ADAPTED
FOVEA. J. opt. Soc. Amer., 1956, 46 (1),
67-71. (Institute for Applied Experimental
Psychology, Tufts University).

9920
The effect of brief pre-exposure to low intensity
light on foveal dark-adaptation was measured on two adult
subjects with a modified Crozier-Holway discriminometer.
After ten minutes of dark-adaptation one eye was exposed
for 1.0, 10, or 100 seconds to a 27° patch of light at
0.1, 1.0, 10, or 100 ft.L. The course of re-adaptation
was followed by the method limits (ascending only) with
a 1° test patch until the threshold stabilized. The re-
sults are compared with those predicted from the ItC
relation for the pre-exposure stimulus.

9921

Polinsky, D.M., & Young, P.A. EFFECT OF HUE DURATION ON ADAPTATION TO DARKNESS. *J. opt. Soc. Amer.*, 1956, 46 (2), 118-121. (State College of Washington).

9921

Dark-adaptation curves were determined on 10 young men with a Bost adapter following exposure to red, green or blue pre-exposure lights. The subject was exposed for a white light of 150 m. for 10 minutes. He then wore goggles with written #25, #2, #56, or C5 #47 filters for 2, 3, 5, 5, or 10 minutes before the light was extinguished. The filters each admitted a luminance of 16 m. in the selected band of wavelengths. The test light was a 3° spot from a #47 filter. It was located to the nasal side of the field and flashed for 0.2 sec. every sec. The measure of adaptation was the time required before the test spot was seen at each of 15 pre-selected levels which grew progressively lower. The differential effects of hue and duration of pre-exposure are described by a trend analysis of the adaptation curves. T. G. R 22

9922

Teichner, W.H., Kobrick, J.L., & Dasek, E.R. EFFECTS OF TARGET SEPARATION AND DISTANCE ON COMMONPLACE BINOCULAR DEPTH DISCRIMINATION. *J. opt. Soc. Amer.*, 1956, 46 (2), 122-125. (Quartermaster Research and Development Center, Natick, Mass.).

9922

The effect of the separation between the targets on the acuity of depth discrimination in commonplace binocular viewing was investigated as a function of the viewing distance. The separation between targets was varied so as to give constant angular or constant linear lateral displacement between them. The range of viewing distance was 10 to 100 ft. The subjects were two sophisticated and three unsophisticated observers. The size of the angle of binocular disparity corresponding to the depth threshold is described as a function of the viewing distance, and the significance of target separation for vernier and stereoscopic acuity is discussed in relation to the importance of the other cues to depth present in commonplace binocular viewing. T. G. R 16

9923

Westheimer, G.L., & Tanzman, I.J. QUALITATIVE DEPTH LOCALIZATION WITH DIPLOPIC IMAGES. *J. opt. Soc. Amer.*, 1956, 46 (2), 116-117. (School of Optometry, Ohio State University).

9923

The effects of unnaturally large binocular disparities on the qualitative perception of depth was measured on six subjects. Two spots of oppositely polarized white light were flashed tachistoscopically on a screen which the subject viewed through oppositely polarized lenses. The subject judged the diplopic image in front or behind an unpolarized spot of light presented continuously on the same screen. Crossed and uncrossed disparities were presented ranging from 1° to 10°. The upper limit of disparity for the induction of the stereoscopic illusion is described as a function of the direction of the disparity and experience of the observer. G. R 4

9924

Harker, G.S., & Weaver, L.A. RELATIVE PRECISION OF RANGE INFORMATION OBTAINABLE WITH FIXED BALLISTIC AND WANDERMARK STEREOSCOPIC RETICLES. *J. opt. Soc. Amer.*, 1956, 46 (3), 195-200. (AMRL, Fort Knox, Ky.).

9924

The accuracy of stereoscopic range finding for three natural targets was measured with two different types of range finder reticles. The Army "V" wandermark reticle was compared to an experimental reticle incorporating a series of markings in the form of a shell trajectory. The subjects were five experienced observers and 25 naive soldiers. Each subject took 20 readings on each target with each instrument. The order of the targets and the initial dial settings on the instruments were randomized. The accuracy obtained with each of the reticles is compared separately for the experienced and naive subjects. T. G. R 4

9925

Leibowitz, H., & Walker, L. EFFECT OF FIELD SIZE AND LUMINANCE ON THE BINOCULAR SUMMATION OF SUPRATHRESHOLD STIMULI. *J. opt. Soc. Amer.*, 1956, 46 (3), 171-172. (University of Wisconsin).

9925

The extent of binocular brightness summation at suprathreshold levels was determined as function of the size and luminance of the stimulus fields. Two subjects adjusted one of a pair of targets, viewed diplopically, to equal brightness, and then repeated the adjustment while one eye was exposed to both stimuli. Two standard luminance levels, 300 and .03 m., and three sizes, 15, 30 and 60 min., were used. Disagreements found among previous experiments on binocular summation are discussed in the light of the relation between summation and the stimulus area. G. P 5

9926

Fendoff, R. COLORS OF NATURAL OBJECTS. *J. opt. Soc. Amer.*, 1956, 46 (3), 180-182. (Geophysics Research Directorate, AFRC, Bedford, Mass.).

9926

The colors of various natural objects are calculated (for vegetation, forests, soil, water, etc.) as seen from different distances and altitudes under the illumination of a clear day at noon. The data are taken from the large number of spectrograms obtained by Krinov and the colors calculated from the C.I.E. standard in the usual way. The application of these results to the problem of aerial recognition is discussed briefly. T. G. R 6

9927

Kulowski, J. INTRODUCTION TO SUPPLEMENTARY SAFETY: THE CRASH-IMPACT ENGINEERING POINT OF VIEW. *Clinical Orthopaedics*, 1956, (3), 261-264. (Saint Joseph, Mo.).

9927

This is an introductory article to a symposium on highway safety. The author discusses the role of human engineering in automotive safety engineering and design and defines the concept of crash-impact engineering. The investigation of the interrelations among human, mechanical, and environmental variables is emphasized as an effective approach to resolving problems of motorway safety.

9928

Jessup, F.A., & Paul, E.C. HISTORY OF AUTO CRASH INJURY RESEARCH: POLICE POINT OF VIEW. *Clinical Orthopaedics*, 1956, (8), 265-267. (Indiana State Police).

9928

This article presents a brief historical description of the contribution of comprehensive police observation to effective crash-impact engineering. The results of a pilot study are reported in terms of the evidence they lend to the hypothesis that crash injuries to automobile passengers are of a repetitive nature. The data reporting form used in this study is described as consisting of a vehicle report, a medical report, and on-the-scene photographs.

9929

Hasbrook, A.H. THE HISTORICAL DEVELOPMENT OF THE CRASH-IMPACT ENGINEERING POINT OF VIEW. *Clinical Orthopaedics*, 1956, (8), 268-274. (Cornell University Aviation Crash Injury Research).

9929

The author describes the historical development of the crash-impact engineering point of view with emphasis upon the types of research conducted on aircraft and automotive safety. The various safety devices and their development are discussed along with techniques of recording accident data. A special injury scale is presented as an illustration of an effective means of recording and coding accident and injury data.

9930

Severy, D.L., & Mathewson, J.H. AUTOMOBILE-BARRIER IMPACTS, SERIES II. Clinical Orthopaedics, 1956, (3), 275-300. (University of California, Los Angeles).

9930

This article describes the experimental procedures and results of studies utilizing the barrier impact as a technique of evaluating crash phenomena under controlled automobile velocities. Utilizing high-speed photography, electrical accelerometers, safety-belt tensionometers, and dummy damage diagnosis, the effects upon the human body of a collision were determined under five conditions of restraint and varied conditions of deceleration. The results are presented and discussed in terms of the relative safety provided by the types of restraint (e.g., lap belt, chest belt, etc.). Autonomic analysis provides a basis for discussing implications for safety design in automobiles.

9932

Lissner, H.R., & Evans, P.G. ENGINEERING ASPECTS OF FRACTURES. Clinical Orthopaedics, 1956, (8), 310-322. (Wayne University).

9932

This article presents an extensive survey of the experimental results of studies concerned with the relation between various types of accidents and the resultant types of bone fractures. The effects of velocity, energy input, structure of the bone, etc., are discussed in terms of their effects upon fractures of the skull, femur and pelvis. Illustrations of tensile strain patterns are presented along with a description of the Stresscoat technique (i.e., a means of investigating fractures which employs a brittle lacquer designed to crack in response to tensile strain).
I. R 15

9933

Kulowski, J. SUMMARY AND CONCLUSIONS. Clinical Orthopaedics, 1956, (8), 323-326. (Saint Joseph, Mo.).

9933

This is a summary article of a symposium on motorist safety and injury reduction. In addition to summarizing the results of the various researches, the author draws specific conclusions with regard to the status of crash-impact engineering and the implications for accident prevention and reduction of injury potential.
R 3

9934

Kulowski, J. GENERAL INTRODUCTION: ACCIDENT PREVENTION, REDUCTION OF INJURIES AND AIDS TO RECOVERY. Clinical Orthopaedics, 1956, (7), 243-245. (Saint Joseph, Mo.).

9934

This is an introductory article to a series of papers which are concerned with several aspects of motor vehicle safety. The author discusses briefly the etiological factors in accidents, the role of crash-impact engineering in reduction of motorist injuries and safety design, and the clinical aspects of motorist injuries.
R 21

9935

Kulowski, J. ETIOLOGY OF MOTORIST INJURIES. Clinical Orthopaedics, 1956, (7), 245-252. (Saint Joseph, Mo.).

9936

The etiology of motorist injuries is discussed in terms of factors stemming from the external automotive environment (i.e., pertaining to the vehicle) and those stemming from the internal automotive environment (i.e., pertaining to the occupant). In addition to the explicit implications for medical diagnosis and treatment, this article offers considerable data (e.g., effects of acceleration and deceleration) pertinent to the human engineering aspect of motorist safety.
G. I. R 40

9937

Kulowski, J. PATHOLOGY OF MOTORIST INJURIES. Clinical Orthopaedics, 1956, (7), 253-260. (Saint Joseph, Mo.).

9937

Among the data analyzed in this discussion of motorist injuries is included a comparison of internal injuries occurring in aircraft and in ground vehicle accidents. In addition to specifying the primary injuries in automotive accidents, the author discusses direct and indirect complications. Many implications for accident and injury prevention may be found in this treatment of motorist injuries.
T. O. R 16

9938

Kulowski, J. IMPLICATIONS OF TIME INTERVALS BETWEEN INJURY AND DEATH (MORTALITY DIFFERENTIALS). Clinical Orthopaedics, 1956, (7), 261-266. (Saint Joseph, Mo.).

9938

The time intervals between accidental injury and death for 29 motorist casualties are analyzed in terms of the implications for automotive design, first aid, emergency care, and definitive diagnosis and treatment. An illustration of the effects of faulty automotive safety design is presented and discussed with regard to the relative pressure areas offered by various projecting structures on the dash-board and the resultant injuries.
G. I. R 4

9939

Kulowski, J. PILOT STUDY: THE GENERAL MORBIDITY. Clinical Orthopaedics, 1956, (7), 267-271. (Saint Joseph, Mo.).

9939

In order to evaluate the types of injuries resulting from motor vehicle accidents, 661 motorist casualties whose injuries were severe enough to require inpatient hospital treatment were analyzed with regard to pattern and type of injury. Since the casualty group reflected an age span of three months to 82 years, both males and females, drivers and non-drivers, the analysis includes implications concerning areas of bodily involvement, relation of type of injury to seating position (i.e., front back, driver, etc.) and so forth, and on a more general level, implications for the role of automotive design in degree of morbidity.
T. I. R 11

9940

Kulowski, J. HEAD INJURIES: JANUSLIKE PROBLEM. Clinical Orthopaedics, 1956, (7), 272-278. (Saint Joseph, Mo.).

9940

An analysis of 532 motorist survivors was conducted to determine the relation of type of head injury to seating, the nature of head injuries as related to the type of impact, the relative distribution of injuries to the head, etc. The results are discussed in terms of the injury potentials of dashboard design and seating (including position and lack of safety restraints), and the need for protective head equipment, changes in spatial relationships between occupants and impact areas, etc.
T. O. I. R 16

9941
Kulowski, J. INJURIES OF CHEST AND ABDOMEN. Clinical Orthopaedics, 1956, (7), 279-285. (Saint Joseph, Mo.).

9941
A total of 216 motorist-casualty survivors were investigated to determine the extent and type of injury to the chest and abdomen. Type of injury is related to seating and type of impact. The results are then discussed in terms of the need for safety restraint devices and the general implications for automotive safety design.
T. G. I. R 13

9942
Kulowski, J. EXTREMITY INJURIES: THE COMMON DENOMINATOR. Clinical Orthopaedics, 1956, (7), 235-294. (Saint Joseph, Mo.).

9942
The records of 378 motorist-casualty survivors were consulted in this analysis of extremity injuries. The buffer action of soft (body) tissues is discussed along with the role of age, sex, seating, type of impact, etc. The data contain many implications for automotive safety design.
T. G. I. R 5

9943
Kulowski, J. EXTREMITY INJURIES: SPECIAL CONSIDERATIONS. Clinical Orthopaedics, 1956, (7), 295-301. (Saint Joseph, Mo.).

9943
In this discussion of extremity injuries resulting from motor vehicle accidents the author describes several preventive measures, e.g., elbow contained within vehicle rather than on car-window ledge, change in truck width, etc., which are specifically oriented towards elimination of elbow injuries. Case studies are presented as illustrative examples of the results of maintaining the elbow on the window ledge during accidents.
I. R 6

9944
Kulowski, J. ACUTE MOTORIST INJURIES OF THE SPINE. Clinical Orthopaedics, 1956, (7), 307-312. (Saint Joseph, Mo.).

9944
Injuries to the neck, back and pelvis as a result of motor vehicle accidents were studied with 189 motorist casualty survivors. The data are treated in terms of the relation of type of injury to seating, type of impact, and distribution of soft tissue (at site of injury). Implications for automotive safety design are noted.
T. G. R 3

9945
Kulowski, J. ACUTE INJURIES OF THE LUMBAR SPINE AND THE PELVIS. Clinical Orthopaedics, 1956, (7), 313-317. (Saint Joseph, Mo.).

9945
In this article the author discusses the role of seating, type of impact, etc., in acute injuries of the lumbar spine and pelvis. Techniques of safety design are mentioned and include the following: seat retention devices and adequate seat, seat back, and gear installations.
T. G. R 8

9946
Kulowski, J. INJURIES OF YOUNG AND OLD. Clinical Orthopaedics, 1956, (7), 316-323. (Saint Joseph, Mo.).

9946
To investigate the potential relation of age to incidence and type of motor vehicle accident injury, 661 motorist casualty survivors were divided into four major age groups (0-15, 15-20, 20-60, and 60-85 years). The particular body areas involved, distribution of young and old casualties according to seating incidence of injuries as a function of age, and the types of injuries and accidents are analyzed and discussed in terms of the implications for accident prevention.
T. G. R 6

9947
Kulowski, J. RESIDUAL DISABILITIES: GENERAL SKELETAL. Clinical Orthopaedics, 1956, (7), 324-328. (Saint Joseph, Mo.).

9947
Two hundred fifteen motorist casualty survivors were used in this study of general skeletal disabilities resulting from motor vehicle accidents. Age distribution, type of impact, and type of vehicle are examined in terms of incidence and type of residual injury to the musculoskeletal system. Implications for motor safety design are noted.
T.

9948
Kulowski, J. RESIDUAL DISABILITIES: NECK AND BACK. Clinical Orthopaedics, 1956, (7), 329-332. (Saint Joseph, Mo.).

9948
Incidence and type of residual disability injury to the neck and back of motorist casualty survivors are examined in terms of their relation to seating, posture, etc. The implications for seating design are noted and discussed.

9949
Brandeleone, H., & Friedman, G.J. PHYSICAL STANDARDS FOR VEHICLE OPERATORS: AN AID TO ACCIDENT PREVENTION. Industr. Med. & Surg., 1956, 25 (1), 17-22. (Third Avenue Transit System, N.Y.).

9949
This article presents a Profile Classification of medical standards to be used specifically with bus drivers but which may be adapted to truck and private vehicle operators. Its utilization is described as an aid to accident prevention. The system includes physical, mental, motorability, psychophysical and psychological examinations.

9950
Fox, H.S. OCCUPATIONAL HEARING LOSS: WISCONSIN'S APPROACH TO THE PROBLEM. Industr. Med. & Surg., 1956, 25 (7), 310-316. (Milwaukee, Wisconsin).

9950
The author describes the work of the Wisconsin Industrial Commission in its attempt to define medical and legal criteria of occupational hearing loss (resulting primarily from noise exposure) and to develop a hearing conservation program. Equipment and audiometric techniques used in such a program are described and discussed along with the general problem of noise reduction in industry.

9951
Goodman, V.H. IMPROVED SAFETY THROUGH EFFECTIVE COMMUNICATION. Bell Telephone Magazine, 1956, 35 (2), 106-115. (Northwestern Bell Telephone Co.).

9951
The author discusses the importance of effective communication as a means of improving safety and presents charts to demonstrate the effect of the Bell System's attempts to communicate safety knowledge and practices. These charts present data concerning the following aspects of safety development: (1) frequency of lost time due to work injuries over an 11 year period (2) a comparison of on-the-job vs. off-the-job injuries in terms of frequency; (3) number of fatalities occurring on-the-job vs. off-the-job; and (4) an analysis of causal factors in a series of work injuries. The factors involved in establishing an adequate safety program are discussed in a general manner.

Hoven, A.L. HOW TO MAKE A LIGHTING SURVEY;
A VISION SURVEY. PART II. VISION. Industr. Med. & Surg., 1956, 25 (4), 159-163. (US
Public Health Service, Washington, D.C.).

9952
This discussion of techniques of assessing visual functional ability is presented in terms of two major aspects: (1) assessment of the individual's visual capacity, and (2) assessment of the visual requirements of the task. Included are the following topics: proper job placement (employing such visual tests as the Telebinocular, the Ortho-Rater, and the Sight-Screener), job analysis (for visual requirements), emergency eye care, and eye safety. Included is a form (Industrial Vision Survey) used to assess visual functional ability.

9953
Schulzinger, H.S. THE PRE-ACCIDENT PATIENT -
DIAGNOSIS AND TREATMENT. Industr. Med. & Surg., 1956, 25 (10), 451-458. (Cincinnati, Ohio).

9953
In this discussion of the pre-accident patient the author offers information concerning the diagnosis and treatment of accident proneness and also data concerning personality and environmental factors which seem to effect the incidence of accidents. Included are the following: effects of temperature, humidity, season, basic attitudes of the individual toward society, traffic rules, etc., psychological impairments, etc. Specific recommendations are offered concerning treatment of accident prone patients and prevention of occupational and motor vehicle accidents.

9955
American Aviation. AF DEVELOPS LOW-LEVEL EJECTION SEAT.
Amer. Aviat., 1956, 19(20), p.41.

9955
This article presents a brief description and illustrations of a low-level ejection seat escape system developed by the Air Force Wright Air Development Center. A brief summary of experimental tests with this escape system is presented along with test data concerning aircraft speed and height of ejected dummy.

9956
Steier, H.P. CAA IDEAS ON HOW TO AVOID COLLISIONS.
Amer. Aviat., 1956, 20(12), 34-37.

9956
This article presents the recommendations offered by CAA's Technical Development Center with regard to the problem of aircraft collision prevention. Three basic needs are specified: "sensing and alerting devices; increased conspicuity of aircraft; and increased angles of vision for the pilot from his cockpit position". Results of studies on each of these aspects are presented and discussed. These include conspicuity aids, devices to provide greater contrast, and angles of vision as functions of cockpit and windshield configurations.

The Aeroplane. DEVELOPING THE MARTIN-BAKER EJECTION SEAT. The Aeroplane, 1956, 40(2325), 168-171.

9957
This article presents illustrations and a detailed description of the Martin-Baker automatic ejection seat. Actual experiences with this as well as with other types of seats are recounted and discussed in terms of the relative efficacy of specific seats in meeting problems of high and low speed ejection, oxygen supply, etc. Current developments in this area of research are discussed. The specific seats mentioned in this article are the following: Martin-Baker Mk.1, Mk.2, Mk.3, Swifts Mk.2, Hunters Mk.2H, Javelins Mk.2J, and others.

9958
The Aeroplane. DISCUSSING APPROACH AND RUNWAY LIGHTING.
AIR TRANSPORT. The Aeroplane, 1956, 40(2339), 624-625.

9958
This article presents a summary of a report on aerodrome approach and runway lighting problems. By utilizing a simulator, known as the cyclogram, four types of lighting patterns were evaluated: Newark/Jalaviid (A.L.P.A.) approach lights with narrow-gauge runway pattern, Type J (Jenks); Calvert approach lights with narrow-gauge runway pattern (but lights 300 ft. apart), Type E; London Calvert approach lights with narrow-gauge pattern, Type G (Gater); and Schiphol approach lights with broad-gauge runway lights and ILS reference point lighting. The results are discussed in terms of the particular characteristics of each of these systems and their contribution to the problem of providing adequate visibility conditions for pilots.

9960
The Aeroplane. SURVIVAL AND MILITARY EQUIPMENT.
FARNBOROUGH FINAL. The Aeroplane, 1956, 41(2350), 431-432.

9960
This article presents a survey of contemporary British aviation equipment. It describes partial and full-pressure suits, pressure helmets, the Martin-Baker Mk.4 ejection seat, the Folland Aircraft Type 3 ejection seat, and other equipment of this sort. The emphasis is upon the principle improvements reflected in these new equipments and their application to problems of survival at high altitudes and hypersonic speeds.

9961
Davis, R.C. AIRCRAFT ACCIDENT INVESTIGATION.
Aeronautical engng. Rev., 1956, 15 (2), 37-38, 47. (Royal Canadian AP).

9961
This article presents a discussion of aircraft accidents in terms of four specific precepts concerning safety design and including factors of maintenance, operating procedures, uncontrollable human errors, permanence of design structures, and the failure of parts or components of an aircraft. Each of the precepts is illustrated by an example of an aircraft accident in which the situation, the results of investigation, the hazard, and the fix (i.e., remedial measure) are specified. Conclusions are drawn concerning the use of accident data in safety design.

9962
Kirchner, O.E. AIR SAFETY. Aeronautical engng. Rev., 1956, 15 (2), 48-53.

9962
In this report on the Six Annual Air Safety Seminar (held in Taxco, Mexico, Nov. 17-20, 1955) brief descriptions of papers on the following topics are presented: turbulence, vortex wakes, Strategic Air Command experience with jets, pilot stress in accidents, the crash location beacon, crash-resistant fuel tanks, traffic density, collision lights, crash rescue, survival in the tropics, backward facing seats, and others.

[illegible]

Integrated flight equipment systems are discussed with emphasis upon the design of instrumentation and controls from the point of view of integration with human pilot characteristics. A brief theoretical exposition of controls and cockpit environment is presented along with specific methods for the design of the optimum system. Such features as the following are considered: definition of mission objectives, the function of sections in the system, the need for excess redundancy with instruments, etc. Several specific systems are illustrated and discussed, e.g., Sperry Integrated Instrument System, 1, 2, 3, 4.

Brinkley, J. J., Jr. THE H-FLIGHT COLLISION
PHENOMENON. Aeronautical Engng. Ser., 1966,
15 (7), 45-53. (Cornell Aeronautical Labo-
ratory, Inc.).

The author discusses the problem of in-flight air-
craft collision in terms of the various solutions which
have been proposed, e.g., cooperative collision warning,
air-borne radar system, etc. Following a definition of
the problem the basic function and basic classification
of various collision warning systems are elaborated.
The cooperative system is contrasted to the air-
borne radar or self-sufficient system, and the advan-
tages and disadvantages of each are specified within the
context of collision prevention under conditions of
heavy air traffic.

Beth, G.L. PILOT, INSTRUMENTS, CONTROLS.
Aeronautical Engng. Rev., 1956, 15 (9),
66-71. (General, Division of General Dynamics
Corporation).

This article presents an historical description of the development of flight control systems and visual aids for the pilot. The components of the contemporary flight system along with partial or additional systems are described and discussed in terms of their coordinated operation. Implications for the future development of systems and their modification of the pilot's function are briefly discussed.

Baron, P. PROPAGATION DU SON DANS L'ATMOSPHERE ET L'AUDIBILITE DES SIGNAUX AVERTISSEURS DANS UN ENVIRONNEMENT AGITANT. (PROPAGATION OF SOUND IN THE ATMOSPHERE AND AUDIBILITY OF ALARM SIGNALS IN SURROUNDING NOISE). Le Groupeement des Acousticiens de Langue Francaise, No. 56, 1954, 259-274. Oct. 1956, 19pp. Langley Aeronautical Laboratory, NACA. (Commission for Study and Research of Electricity in France).

To determine the optimal method of locating public alarm sirens, measurements of sound propagation were made under a variety of meteorological conditions in the Yonne valley, and in Paris France. Tests were made with a sound source (15 hp siren) at ground level and on a tower at heights of 5, 15, or 37 meters. Temperature, humidity, wind velocity and direction were measured at the same tower. Sound pressure levels were measured and averaged over a period of 1 min. Two listening stations were maintained, one at a fixed position, and the other, at various positions from the tower. Records of sound pressure level are analyzed for the effects of the topography of the area, the wind velocity, and direction. Threshold of hearing for a sound from the same source was determined on 6 observers as a function of ambient level of street noise in Paris. T. G. I. R 4 11

TOLSON, J. EDWARD, JR., 1956, 1957, 1958, 1959, 1960, 1961, 1962, 1963, 1964, 1965, 1966, 1967, 1968, 1969, 1970, 1971, 1972, 1973, 1974, 1975, 1976, 1977, 1978, 1979, 1980, 1981, 1982, 1983, 1984, 1985, 1986, 1987, 1988, 1989, 1990, 1991, 1992, 1993, 1994, 1995, 1996, 1997, 1998, 1999, 2000, 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010, 2011, 2012, 2013, 2014, 2015, 2016, 2017, 2018, 2019, 2020, 2021, 2022, 2023, 2024, 2025, 2026, 2027, 2028, 2029, 2030, 2031, 2032, 2033, 2034, 2035, 2036, 2037, 2038, 2039, 2040, 2041, 2042, 2043, 2044, 2045, 2046, 2047, 2048, 2049, 2050, 2051, 2052, 2053, 2054, 2055, 2056, 2057, 2058, 2059, 2060, 2061, 2062, 2063, 2064, 2065, 2066, 2067, 2068, 2069, 2070, 2071, 2072, 2073, 2074, 2075, 2076, 2077, 2078, 2079, 2080, 2081, 2082, 2083, 2084, 2085, 2086, 2087, 2088, 2089, 2090, 2091, 2092, 2093, 2094, 2095, 2096, 2097, 2098, 2099, 2100, 2101, 2102, 2103, 2104, 2105, 2106, 2107, 2108, 2109, 2110, 2111, 2112, 2113, 2114, 2115, 2116, 2117, 2118, 2119, 2120, 2121, 2122, 2123, 2124, 2125, 2126, 2127, 2128, 2129, 2130, 2131, 2132, 2133, 2134, 2135, 2136, 2137, 2138, 2139, 2140, 2141, 2142, 2143, 2144, 2145, 2146, 2147, 2148, 2149, 2150, 2151, 2152, 2153, 2154, 2155, 2156, 2157, 2158, 2159, 2160, 2161, 2162, 2163, 2164, 2165, 2166, 2167, 2168, 2169, 2170, 2171, 2172, 2173, 2174, 2175, 2176, 2177, 2178, 2179, 2180, 2181, 2182, 2183, 2184, 2185, 2186, 2187, 2188, 2189, 2190, 2191, 2192, 2193, 2194, 2195, 2196, 2197, 2198, 2199, 2200, 2201, 2202, 2203, 2204, 2205, 2206, 2207, 2208, 2209, 2210, 2211, 2212, 2213, 2214, 2215, 2216, 2217, 2218, 2219, 2220, 2221, 2222, 2223, 2224, 2225, 2226, 2227, 2228, 2229, 2230, 2231, 2232, 2233, 2234, 2235, 2236, 2237, 2238, 2239, 2240, 2241, 2242, 2243, 2244, 2245, 2246, 2247, 2248, 2249, 2250, 2251, 2252, 2253, 2254, 2255, 2256, 2257, 2258, 2259, 2260, 2261, 2262, 2263, 2264, 2265, 2266, 2267, 2268, 2269, 2270, 2271, 2272, 2273, 2274, 2275, 2276, 2277, 2278, 2279, 2280, 2281, 2282, 2283, 2284, 2285, 2286, 2287, 2288, 2289, 2290, 2291, 2292, 2293, 2294, 2295, 2296, 2297, 2298, 2299, 2300, 2301, 2302, 2303, 2304, 2305, 2306, 2307, 2308, 2309, 2310, 2311, 2312, 2313, 2314, 2315, 2316, 2317, 2318, 2319, 2320, 2321, 2322, 2323, 2324, 2325, 2326, 2327, 2328, 2329, 2330, 2331, 2332, 2333, 2334, 2335, 2336, 2337, 2338, 2339, 2340, 2341, 2342, 2343, 2344, 2345, 2346, 2347, 2348, 2349, 2350, 2351, 2352, 2353, 2354, 2355, 2356, 2357, 2358, 2359, 2360, 2361, 2362, 2363, 2364, 2365, 2366, 2367, 2368, 2369, 2370, 2371, 2372, 2373, 2374, 2375, 2376, 2377, 2378, 2379, 2380, 2381, 2382, 2383, 2384, 2385, 2386, 2387, 2388, 2389, 2390, 2391, 2392, 2393, 2394, 2395, 2396, 2397, 2398, 2399, 2400, 2401, 2402, 2403, 2404, 2405, 2406, 2407, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417, 2418, 2419, 2420, 2421, 2422, 2423, 2424, 2425, 2426, 2427, 2428, 2429, 2430, 2431, 2432, 2433, 2434, 2435, 2436, 2437, 2438, 2439, 2440, 2441, 2442, 2443, 2444, 2445, 2446, 2447, 2448, 2449, 2450, 2451, 2452, 2453, 2454, 2455, 2456, 2457, 2458, 2459, 2460, 2461, 2462, 2463, 2464, 2465, 2466, 2467, 2468, 2469, 2470, 2471, 2472, 2473, 2474, 2475, 2476, 2477, 2478, 2479, 2480, 2481, 2482, 2483, 2484, 2485, 2486, 2487, 2488, 2489, 2490, 2491, 2492, 2493, 2494, 2495, 2496, 2497, 2498, 2499, 2500, 2501, 2502, 2503, 2504, 2505, 2506, 2507, 2508, 2509, 2510, 2511, 2512, 2513, 2514, 2515, 2516, 2517, 2518, 2519, 2520, 2521, 2522, 2523, 2524, 2525, 2526, 2527, 2528, 2529, 2530, 2531, 2532, 2533, 2534, 2535, 2536, 2537, 2538, 2539, 2540, 2541, 2542, 2543, 2544, 2545, 2546, 2547, 2548, 2549, 2550, 2551, 2552, 2553, 2554, 2555, 2556, 2557, 2558, 2559, 2560, 2561, 2562, 2563, 2564, 2565, 2566, 2567, 2568, 2569, 2570, 2571, 2572, 2573, 2574, 2575, 2576, 2577, 2578, 2579, 2580, 2581, 2582, 2583, 2584, 2585, 2586, 2587, 2588, 2589, 2590, 2591, 2592, 2593, 2594, 2595, 2596, 2597, 2598, 2599, 2600, 2601, 2602, 2603, 2604, 2605, 2606, 2607, 2608, 2609, 2610, 2611, 2612, 2613, 2614, 2615, 2616, 2617, 2618, 2619, 2620, 2621, 2622, 2623, 2624, 2625, 2626, 2627, 2628, 2629, 2630, 2631, 2632, 2633, 2634, 2635,

The implications of high-speed aircraft for the pilot's control function are investigated in this study of the effects of human dynamics upon control of an aircraft in pitch. Another aspect of the study involves determining criteria to predict pilot transfer function during pitching flight. Specific transfer functions involving reaction time, muscular lag, etc., are expected by formulas which consider the aerodynamic, inertial, and other parameters of various aircraft. Conclusions are drawn concerning the effects upon pilot control of reducing aircraft size and shortening the aircraft period.

Schwartz, L.S. PRINCIPLES OF WIRELESS COMMUNICATION
BY COMMUNICATION CHANNELS. Trans. Amer. Inst.
Electrical Eng., Part 1: Communication and
Electronics, 1956, 75, 44-50. (New York Uni-
versity).

The author discusses the principles of noise reduction in communication channels in terms of communication objectives, filtering principles in error minimization, improving signal-to-noise ratio as a means of maintaining the probability of error and applications of linear filtering techniques. Conclusions are drawn concerning optimal techniques for reducing signal-to-noise ratio.

Trans. Inst. electrical Eng., Part 1: Communication and Electronics, 1956, 75, 75-79. (Station WGB, Fort Worth, Tex.).

Following a description of the lighting facilities on hand, the author elaborates upon the conversion from black and white to color television operation. Illustrations are presented along with a description of changes in lighting layout, switchboard design, etc.

Bice, S.O. A FIRST LOOK AT RANDOM NOISE.
Trans. Amer. Inst. electrical Engr., Part I:
Communication and Electronics, 1956, 75,
129-131. (Bell Telephone Laboratories, Inc.,
New York, N.Y.).

The author presents a discussion of the elementary aspects of "random" or "Gaussian" noise. A representation of random noise is presented and the power spectrum is discussed and related to the autocorrelation function. Two probability distributions of noise are discussed.

Johannsen, Dorothea E., McBride, Patricia I., & Wulfeck, J.W. STUDIES ON DARK ADAPTATION: II. THE PRE-EXPOSURE TOLERANCE OF THE HUMAN POPEYE ADAPTED TO DIFFERENT BRIGHTNESS LEVELS. J. opt. Soc. Amer., 1956, 46 (4), 266-269. (Institute for Applied Experimental Psychology, Dart. University).

The course of dark adaptation in the human fovea was traced following adaptation to luminance levels of 0.1, 1.0 or 100 fL, and a pre-exposure period of 0, 1, 10 or 100 sec at 1.0, 10, or 100 fL. The adaptation and pre-exposure fields subtended 27°. The test patch was centrally located and subtended 1°. Successive thresholds were determined during dark adaptation by the method of limits, employing only ascending series. The criteria used to evaluate the effects of pre-exposure were the initial threshold, the shape of the curve, and the time required for the curve to level off.

Gale, E.S. STEREOSCOPIC ACTIVITY AND THE ROLE OF OVERTURNING. *J. opt. Soc. Amer.*, 1956, 46 (4), 274-277. (New York State College of Optometry, Rochester, N.Y.).

9976

To determine whether stereoscopic cues of convergence contribute to stereoscopic acuity, stereoscopy was measured while a reference object (a vertical needle) was fixated continuously, and also while the fixation was alternated between the reference and the comparison object (also a vertical needle). The angle of separation between the reference and comparison needles was varied from 2-24 degrees. Each of three subjects made 20 adjustments at each separation of the needles to match the apparent depth of the comparison needle to that of the reference needle. The stereo threshold was taken as one standard deviation of the matched position. The amount of improvement in stereoscopy found during alternating fixation is compared to the improvement to be expected theoretically on the basis of the change in the extent of the binocular disparity.

Hahn, E.T., & Averback, E. SPATIAL EFFECTS IN PURSUIT DISCRIMINATION. *J. opt. Soc. Amer.*, 1956, 46 (4), 274-277. (Johns Hopkins University).

9978

Sensitivity to luminance differences between two separated homogeneous visual fields was measured as a function of the angle of separation and the luminance pattern in the intervening space. Four separations, 1, 10, 15 and 25 min. were used. The intervening space was either dark, or consisted of a linear gradient of luminance increasing from that of the darker field to that of the brighter. In a third experimental condition the intervening space was occupied by an extension of either the brighter or the darker field. The observers were two male undergraduates, who made 10 judgments of relative brightness at each value of the variable field under each experimental condition during 45 sessions. The results are presented in terms of the relative difference limit $\Delta I/I$. T. G. R 14

9979

Heathcote, G. EFFECT OF BINOCULAR MAGNIFICATION DEVICES ON STEREOSCOPIC DEPTH RESOLUTION. *J. opt. Soc. Amer.*, 1956, 46 (4), 278-280. (Ohio State University).

9978

The effect of optical magnification on stereoscopic acuity is deduced theoretically, and the prediction tested by an experiment comparing six diopter magnification with unaided viewing. The stimuli were two parallel vertical lines, 0.5 mm wide, 8 mm long and 2 mm apart, scribed on a glass plate viewed from a distance of 25 cm. The glass plate could be rotated to bring one line nearer than the other with sufficient precision to control the binocular disparity within 0.1 sec. Stereo thresholds were obtained on two normal emmetropic observers by the method of constant stimuli, using 30 presentations of each of seven different disparities. The differences between the thresholds obtained with and without optical magnification is compared to that predicted from the theoretical analysis. T. G. R 3

Dianick, P.L. SPECIFICATIONS AND CALIBRATION OF THE 1953 EDITION OF THE INTER-SOCIETY COLOR COUNCIL COLOR APTITUDE TEST. *J. opt. Soc. Amer.*, 1956, 46 (6), 349-393. (U.S.N. Medical Research Laboratory, Naval Submarine Base, New London, Conn.).

9979

The specification and calibration of the 1953 edition of the Inter-Society Color Council Color Aptitude Test are described. The test consists of matching separate color chips to a saturation series in four colors. The specification of the color chips and the method of testing are outlined briefly. A system of scoring was developed on the basis of an item analysis of the performance of a group of 200 subjects. Test-retest reliability was established by retesting the same 200 subjects. The distribution of the scores obtained by the standardization population of 698 subjects is compared to the normal distribution. T. G. R 3

9980

Baker, C.A., Lebons, A., & Roberts, D.P. DARK ADAPTATION AS A FUNCTION OF THE INTENSITY AND DISTRIBUTION OF LIGHT ACROSS THE RETINOTOPIC FIELD. *J. opt. Soc. Amer.*, 1956, 46 (6), 491-504. (Arco Medical Laboratory, Waco, Wright-Patterson AFB, Ohio).

9980

The effects of the distribution of light across the visual field during the preadaptation period on the course of subsequent dark adaptation were determined at total preadapting luminances of 2500, 500, 100, 20, 4 and 0.8 cd. The preadapting field and test flash were produced by a modified Beck-Dolner adapter. The preadapting field subtended 30° and was broken up by a perforated screen which confined the illumination to 100, 20, 4, or 0.8% of the total area. The test flash was a patch subtending 4° located 70° temporally and lasting for 0.2 sec. Three subjects were adapted for five min to 2500 cd., for 30-50 min to darkness, and for 10 min to the experimental preadaptation field, just before the course of dark adaptation was traced by the method of limits. T. G. R 2

9981

Kasdan, D.L. CHROMATIC ADAPTATION. *J. opt. Soc. Amer.*, 1956, 46 (7), 500-513. (Research Laboratories, Eastman Kodak Co., Rochester, N.Y.).

9982

The effects of chromatic adaptation on the apparent color of light seen after an adaptation period were determined with a wide field colorimeter. The observer ($N = 2$) fixated a line dividing a binocular field into two halves. Different adapting colors were presented in either half of the field for a period of nine seconds, followed by a period of one second during which two different test colors were presented, one of which could be varied by the observer to match the other. The cycle of adapting and test periods was repeated until the observer reported that he had succeeded in matching the test colors. The adapting colors were tungsten light and daylight, green and pink, red and daylight. The chromatic coordinates are given for colors equivalent in the normal and adapted states. T. I. G. R 19

9982

Barlow, H.B. RETINAL NOISE AND ABSOLUTE THRESHOLD. *J. opt. Soc. Amer.*, 1956, 46 (8), 634-639. (Physiological Laboratory, Cambridge, England).

9982

The absolute threshold of visibility was determined on a single subject with a narrow band of light centering around 495 mμ, subtending 7.5 min, located 20° nasal of the fixation point, and lasting for 2.4 sec. The subject triggered the stimulus shutter to present himself with 100 flashes at each 5 randomly ordered intensity levels interspersed with 300 blanks. He responded, yes, possible or no. The resulting psychometric functions are analyzed in relation to other available evidence to show that the factor limiting the visual threshold is noise in the nervous system at a level higher than the first order neuron. T. G. R 27

9983

Walls, G.L., & Heath, G.G. NEUTRAL POINTS IN 138 PROTANOPES AND DEUTERANOPES. *J. opt. Soc. Amer.*, 1956, 46 (8), 640-649. (School of Optometry, University of California; Division of Optometry, Indiana University).

9983

The neutral points of 71 protanopes and 77 deuteranopes were determined by means of a rotary mixer and Munsell papers. The illuminant used was the CIE standard C for 58 protanopes and 52 deuteranopes, and D for 13 protanopes and 15 deuteranopes. The subjects were diagnosed on the basis of clinical tests prior to the experiment. Some of the subjects who were close relatives provided data on genetic relations. The mean and standard deviation of the neutral points are given for each type of dichromat. The use of the neutral points alone to differentiate protanopia from deuteranopia is evaluated. The effects of ocular pigmentation on the validity of neutral points obtained by this and other methods and the choice of illuminant C or D as the true "physiologic white" is discussed. T. R 12

9934

Hopkinson, R.G. GLARE DISCOMFORT AND PUPIL DIAMETER. *J. Opt. Soc. Amer.*, 1956, 46 (6), 549-556. (Department for Scientific and Industrial Research, Building Research Station, Garston, Watford, England).

9984

The relation between pupillary diameter and glare discomfort was measured on two subjects. The subject sat in a white-painted room at a diffuse luminance level of 0.16 to 200 fcd. In front of a glare source which projected a beam of up to 20,000 fcd. in a beam 9 x 10° steradians. The intensity level of this source at which the glare was just noticeable, just acceptable, just uncomfortable, just tolerable, and definitely intolerable was determined as a function of the surround luminance. At each threshold level a photograph was made of the eye from which accurate measurements of the diameter of the pupil could be made. The significance of pupillary diameter as an indicator of subjective discomfort is evaluated.

Baldwin, M.W., & Nielsen, G. SUBJECTIVE SHARPNESS OF SIMULATED COLOR TELEVISION PICTURES. *J. Opt. Soc. Amer.*, 1956, 46 (9), 581-585. (Bell Telephone Laboratories, Murray Hill, N.J.).

9985

The subjective sharpness of a simulated color television image was measured on ten observers as a function of the total bandwidth, bandwidth apportionment, and viewing distance. The image was produced by three optical projectors that could be focused independently without altering their mutual register. The apparent sharpness of any focus combination was equated by the subject to the sharpness of the image produced when all three projectors were out of focus by the same amount. To equate bandwidth to focus, the subjects matched the sharpness of an image transmitted over a telephoto circuit of known bandwidth to that of the same picture optically defocused. The principal result is expressed as a statistically fitted surface relating bandwidth apportionment to equivalent total bandwidth.

Leistner, K. EXPERIMENTS CONCERNING THE INTERRELATIONSHIP OF RESOLVING POWER AND RECOGNITION. *J. Opt. Soc. Amer.*, 1956, 46 (9), 686-690. (Signal Corps Engineering Laboratories, Fort Monmouth, N.J.).

9986

Several camera lenses of equal focal length and aperture, but of different design, were evaluated in terms of both resolution and image recognition. The heads of eight soldiers were photographed standing in each of five different arrangements from each of five distances. At each distance 15 to 18 negatives were made at focus settings 0.03 mm apart. The reduction of the image varied from 1830 to 2400. Nine observers identified the faces of the soldiers by comparing positives, mounted on microscope slides and viewed through a 50 power microscope, with numbered enlargements of the faces. The results of the recognition test are compared to a measure of line resolution obtained from the same subjects.

MacDonald, D.E., & Watson, J.T. DETECTION AND RECOGNITION OF PHOTOGRAPHIC DETAIL: I. EMPIRICAL DATA APPLICABLE TO THE PREDICTION OF PERFORMANCE OF DIFFRACTION LIMITED SYSTEMS. *J. Opt. Soc. Amer.*, 1956, 46 (9), 715-720. (Physical Research Laboratory, Boston University).

9987

This experiment was undertaken to provide an empirical basis for predicting the performance of diffraction limited optical systems in terms of the detection and recognition of visual objects. A matrix of 16 squares, circles or blanks at one of three levels of contrast (relative log luminances of 0.07, 0.14 and 0.26) was photographed. The scale of the image varied from 1:1250 to 1:20,000 and the aperture ratio from 1/25 to 1/450. Four experienced observers viewed the images under a magnification that they could vary at will from 7 to 45. Each image was presented at least twice to each observer; the total number of observations made was of the order of 105. The results are described in terms of the probabilities of detection and of recognition as a function of target resolution and contrast.

Higgins, G.C., Wolfe, R.E., & Lamberts, R.L. RELATIONSHIP BETWEEN DEFINITION AND RESOLVING POWER WITH TEST OBJECTS DIFFERING IN CONTRAST. *J. Opt. Soc. Amer.*, 1956, 46 (9), 752-754. (Research Laboratories, Eastman Kodak Co., Rochester, N.Y.).

9988

To determine the relation between definition and resolution in photographic images, a series of pictures were made of a uniform grating. The lengthwidth of the bars was 3:1 and the spaces were as wide as the bars. The luminance ratio was 0.2. Exposures were made at nine focal positions covering a range of 0.5 inches. Relative definition thresholds were obtained from the standard deviation of the arrangements of nine positive transparencies made in order of apparent definition by 20 subjects. A just-noticeable-difference scale is given as a function of resolution at low contrast and also from a previous experiment at high contrast.

Soynton, R.W., & Bush, W.R. RECOGNITION OF FORMS AGAINST A COMPLEX BACKGROUND. *J. Opt. Soc. Amer.*, 1956, 46(9), 758-764. (Department of Psychology, University of Rochester, Rochester, N.Y.).

9989

The purpose of this investigation was to determine some of the factors that influence the recognition of a target figure against a background of many figures. The targets were six rectilinear forms, and the background figures were curvilinear patches without sharp corners. Targets were present in 50% of the presentations. They subtended 5-13° and the whole array 2-6°. The subjects were nine undergraduates, who were rewarded randomly for 35% of the correct responses. Each subject viewed 36 targets once during each of 18 experimental sessions. The proportion of trials resulting in correct recognition is reported as a function of the total number of figures in the array (16, 32 or 64), the exposure time (3, 6, 12 or 24 seconds) and the viewing distance (798, 1116, 1431, 1749, or 2065 cm).

Campbell, C.J., McEachern, L.J. & Marg, E. AIRCRAFT FLIGHT BY AN OPTICAL PERISCOPE. *J. Opt. Soc. Amer.*, 1956, 46(11), 944-949. (Institute of Ophthalmology, Columbia-Presbyterian Medical Center, New York, N.Y.; USAF: School of Optometry, University of California, Berkeley, Calif.).

9990

To determine the feasibility of flying an aircraft by viewing through a periscope, 20 Air Force pilots carried out routine flight operations with an experimental periscope mounted in a B-17. The magnification factor was one or three and the field of view 70°, augmented by hand controlled azimuth and declination prisms which scanned 180°. A reticle indicated the position of the aircraft relative to the field of view. The flight instruments were introduced into the bottom of the same field of view. The pilot operated the aircraft from the prone position by means of a specially designed one-hand control. The results are expressed qualitatively in terms of the pilots' and observers' judgments.

Cornsweet, T.N. DETERMINATION OF THE STIMULI FOR INVOLUNTARY DRIFTS AND SACCADIC EYE MOVEMENT. *J. Opt. Soc. Amer.*, 1956, 46 (11), 987-993. (Department of Psychology, Yale University, New Haven, Conn.).

9991

The purpose of this study was to determine the adequate stimuli for saccadic and drifting motions of the eye. The eye movements of two subjects were recorded photographically by a black annulus bisected by a fine black line. The target was viewed under normal conditions and also with the contact lens mirror in the optical path so as to stop the image at one point on the retina. The fine black line was flickered on and off at 0.8 to 4.4 cps, and the disappearance time of its image recorded under normal and stopped viewing. Eye movements were also measured in darkness with and without a fixation point. The probability, direction and magnitude of saccades are reported as a function of the position of the image on the retina under both normal and stopped viewing.

9992 Vos, J.J., Lazet, A., & Bouman, M.A. VISUAL CONTRAST THRESHOLDS IN PRACTICAL PROBLEMS. Opt. Soc. Amer., 1956, 46 (12), 1065-1068. (Research Institute for Perception, National Defence Research Council, TNO, Kampweg 3, Soesterberg, The Netherlands).

The purpose of this investigation was to determine thresholds for visual contrast and to estimate the variability of thresholds between different observers. Four trained observers judged the position of the break in a Landolt ring projected on a screen a distance of four meters. Both positive and negative contrast was used. The luminance of the brighter portion of the image was varied from 10^{-6} to 0.6 cd/m^2 . Contrast was varied by projecting light from another source onto the same area at luminances of 10^{-5} to 10^3 cd/m^2 . In a similar experiment contrast thresholds for dots in positive contrast were determined on 11 untrained observers. The dots were the same size and in the same positions as the breaks in the Landolt rings. The results are reported in terms of the average, minimum and maximum threshold contrast as a function of the background luminance.

9993 Mertens, J.J. INFLUENCE OF KNOWLEDGE OF TARGET LOCATION UPON THE PROBABILITY OF OBSERVATION OF PERIPHERALLY OBSERVABLE TEST FLASHES. J. opt. Soc. Amer., 1956, 46 (12), 1069-1070. (Research Department of N.V. KEMA Laboratories, Arnhem, The Netherlands).

9993 This investigation was undertaken to determine the influence of knowledge of target location upon the threshold for a peripheral flash of light. Four target locations were arranged symmetrically around a fixation point. In one experiment test flashes came from only one point, and in another from all four points in random order. The size of the test flash was $12'$ or $26'$, the separation from the fixation point 7° or 15° , and the duration 0.2, 2.5, or 5.0 sec. Measurements were made on two experienced and three inexperienced observers in the dark adapted state. Not all observers served under all experimental conditions. The threshold intensities with fixed and variable target locations are compared, and the difference tested for statistical significance.

FOR PROTECTION AGAINST MOTION SICKNESS ABOARD TRANSPORT
SHIPS. J. Amer. Med. Ass., March 1956, 160(9), 755-760.
(USAF School of Aviation Medicine, Brooks AFB, Tex.).

10,003
This is a report of a study conducted by the Army,
Navy, Air Force Motion Sickness Team and designed to
evaluate the effectiveness of certain drugs in affording
protection against motion sickness. Approximately 17,000
servicemen were used to compare the effectiveness of 26
drug compounds with that of a placebo in preventing sea-
sickness. The results are presented and discussed in
terms of the most effective drugs, incidence of side-
effects, the role of age, and the effect of past history
of motion sickness.

Beecher, H.K. RELATIONSHIP OF SIGNIFICANCE
OF WOUND TO PAIN EXPERIENCE. J. Amer. Med.
Ass., 1956, 161 (17), 1609-1613. (Harvard
Medical School).

10,005
To investigate the relationship between experienced
significance of a wound and the degree of pain experi-
enced, data were collected on the frequency of pain of
sufficient severity to require a narcotic in 150 male
civilian patients. These data were then contrasted to
similar data collected in a previous study with wartime
casualties. The results are presented and discussed in
terms of the relative influence of situationally induced
anxiety, attitude of patient, and reaction to wound on
the severity of pain experienced.

Basowitz, H., Korchin, S.J., Oken, D., Gold-
stein, M.D., & Gussack, H. ANXIETY AND PER-
FORMANCE CHANGES WITH A MINIMAL DOSE OF EPIN-
EPHRINE. AMA Arch. Neurology & Psychiatry,
1956, 76 (1), 98-105. (Michael Reese Hospi-
tal).

10,006
This study was designed to investigate the effects
of epinephrine at a low dose level on anxiety patterns,
cardiovascular activity, and psychological and motor
performance. Twelve subjects were interviewed to de-
termine past history of stress and then given epine-
phrine and saline injections. Half the subjects re-
ceived the placebo first while the others were given the
epinephrine first. A series of tests was administered
following each of the two injections. The results are
presented and discussed in terms of the relative degree
to which epinephrine produces anxiety symptoms con-
sistent with the subjects characteristic reaction to
stress.

Hamburg, D.J., Sabshin, M., et. al. A THE-
ORETICAL AND EXPERIMENTAL APPROACH TO PRO-
BLEMS OF ANXIETY. AMA Arch. Neurology &
Psychiatry, 1956, 76 (4), 420-431. (Michael
Reese Hospital).

10,007
The authors present an extensive discussion of anxi-
ety based on experimental research and including such
aspects as the following: types of anxiety (e.g., shame,
guilt); the function of anxiety in the general psycho-
biological organization; the disparity in time between
stimulus and duration of total anxiety response; the
relation of subsystems to the central process of anxiety;
and other aspects. A general overall picture is pre-
sented of the design of the research being conducted.
Some of the variables under investigation are perception,
decision, physiological measures, hormonal measures,
and affective variables.

PSYCHOLOGIC STRESS RESPONSE EVALUATION BY
FOCUSED INTERVIEWING. A.M.A. Arch. Neurology
& Psychiatry, 1956, 76 (5), 670-674. (Aero
Medical Laboratory, WADC, Wright-Patterson
AFB, Ohio).

10,008
To investigate the technique of focused interviewing
as a means of assessing physiologic stress response, 6
subjects were interviewed following completion of a
series of trials in a human centrifuge. Prior to the
initial run they were chastized by the experimenter.
This was then used for the focal point of the interview.
On the basis of the affective constellations expressed
in the interview an estimate was made of g tolerance and
compared to the actual level of g tolerance. The re-
sults are discussed in terms of the relative value of
this method in predicting reaction to physiologic stress.

Morant, G.M. & Smith, H.F.R. CRITICAL DIMENSIONS OF A STANDARD HELICOPTER COCKPIT. FPRC 1002, March 1957, 10pp. Flying Personnel Research Committee, London, England. (Institute of Aviation Medicine, RAF, Farnborough, England).

This report deals with an enquiry carried out to determine all the dimensions of significance to pilots which could best be chosen for a "standard" helicopter cockpit developed by the Ministry of Supply for the RAF. 20 Ss, 7 of whom were pilots (none having been trained to fly helicopters) were chosen. 4 were service personnel and the remaining 9 were civilians. The group was chosen for its wide range of body sizes. Body measurements were taken and critical dimensions of the cockpit determined. Factors taken into consideration were: a) vision; b) leg reach and movement; c) arm reach and movement; d) clearances; e) the distance of the pivoting point on the floor from the seat; f) eye heights of the pilots; and g) comparisons with other standard cockpits. 4 drawings appended give all the critical dimensions recommended for adoption in the helicopter cockpit. Aviation Week. USAF PILOTS FAVOR CENTERLINE LIGHTING.
Aviation Week, Sept. 1957, 67(10), 117-119.

10,044
This article presents the results of Air Force and Navy evaluations of a centerline approach lighting system utilizing flush-mounted threshold lights. The tests were conducted at Marsh Air Force Base and utilized United States Air Force lighting equipment with the exception of Sylvania Stroboscopic Condenser Discharge Lights and Elfaka Flush Lighting units. Pilot preferences following 395 approaches are reported along with the particular technical and performance advantages offered by a centerline system. The flush lights are evaluated with regard to their role in aiding depth perception.

Aviation Week. TWO GROUND EJECTION SEATS TESTED IN
LIVE, DUMMY RUNS. Aviation Week, Sept. 1957, 67(11),
69-89.

10,045
The performance of two ground ejection seats is described in a series of photographs. The British Martin-Baker Mark V ground level ejection seat was tested with a live subject while the North American seat employed an anthropomorphic dummy. The presentation permits a general comparison of the characteristics of each seat though specific technical details are not defined for either of them.

Sweeney, R. PILOT'S PICTURE TUBE DISPLAY
TEST FLOWN. Aviation Week, Oct. 21, 1957,
67(16), p.34, 37.

10,050
This article briefly describes some of the basic contact flying analog units utilized in the Army-Navy Instrument Program (ANIP) for integrated cockpit development. Included are the following: (1) a flat cathode ray tube designed to present a symbolic display of altitude and speed, (2) a lightweight airborne digital computer designed to record information from sensors and relay computed data concerning altitude and speed, and (3) a display generator designed to translate computer and cathode ray tube information into electronic signals to be read by the pilot.

Butz, J.S. Jr. NACA STUDIES WAYS TO SOFTEN
JET NOISE. Aviation Week, Nov. 4, 1957, 67(18),
73-77.

10,051
This report describes the research efforts of the National Advisory Committee for Aeronautics directed towards resolving the problem of reducing turbojet noise to piston-engine levels. The relative efficiency of each of the following approaches to noise reduction is discussed: (1) the utilization of mechanical suppressors (e.g., nozzle-ejectors, and so forth); (2) change in turbojet design; and (3) variation of the aircraft flight technique. The effect of potential combination of all three aspects is briefly considered.

Aviation Week. OPTICAL TRACKING DATA SPEEDED BY HUMAN-ENGINEERED THEODOLITE. Aviation Week, July 1957, 66(26), 71-72, 75-76.

10,054

This article describes the specifications and human engineering features of a prototype optical tracking theodolite designed to present near on-time digital read-out and thus obviate data reduction difficulties. The device, designated as the RADOTT (Recording Angular Data Optical Tracking Theodolite), utilizes second order aided tracking, open loop programming, a pencil type control stick rather than steering wheels, and other novel features. The limiting aspects of the theodolite are discussed along with the probable efficiency of this device.

Christian, G.L. CRASH PROGRAM SEEKS EJECTOR FOR HIGH MACH ESCAPE. Aviation Week, May 1957, 66(18), 94-116.

10,056

This article presents an extensive description of three supersonic aircraft escape systems: (1) the Bobbed or B-seat upward ejection system; (2) the D-seat downward ejection system; and (3) the A-seat upward ejection system. The new design features of the various seats and systems are described and illustrated. Included among these features are the following: a skip flow generator to divert trapezoidal air flow, foot retention devices, seat-frame design to eliminate tip off, etc. Human safety requirements of supersonic ejection are elaborated and applied to each system. Also emphasized are the relative differences between upward and downward ejection systems.

Sweeney, R. STUDIES PROBE MAN'S FUNCTION IN SPACE. Aviation Week, Dec. 1957, 67(26), 45-47, 49.

10,060

This article outlines the studies being conducted at several installations on the problems of man's existence and function in space flight. The organizations mentioned include North American Aviation, Convair, and Douglas Aircraft. Research sponsored by the Office of Naval Research is included among the various studies mentioned. The general areas of endeavor characterized in this article are the following: display and navigational aids design, human tolerance to environmental stress, programming of research, weightlessness, job assessment, and others.

10,061

Aviation Week. IMPROVING PERFORMANCE, SAFETY OF MAN IS ARDC GROUP'S GOAL. Aviation Week, Dec. 1957, 67(26), p.49.

10,061

This article briefly describes the three primary directions of research being conducted by the Human Factors Directorate of Air Research Development Command. These research goals are characterized as (1) the development of adequate means to protect the human operator in the weapon system and accordingly, the assessment of real and potential hazards; (2) to human engineer the weapon system so as to provide optimum performance efficiency; and (3) to facilitate communication between and coordinate the endeavors of system engineers and human factors groups.

10,067
Projector, T.H. EFFECTIVE INTENSITY OF FLASHING LIGHTS. *Illum. Engng.*, Dec. 1957, 52(12), 630-640. (National Bureau of Standards, Washington, D.C.)

10,067
This article reviews the attempts to assess the effective intensity of flashing lights with specific emphasis on the work of Blondel and Rey and the Blondel-Rey equation. The latter is discussed in terms of its applicability to a variety of conditions under which it is desirable to assess effective intensity. Two aspects receive particular attention: (1) the validity of the equation with extremely short flashes, and (2) the effect of above threshold illuminance on the equation. Conclusions are drawn concerning the general validity of the equation.
F. G. R 16

10,068
Douglas, C.A. COMPUTATION OF THE EFFECTIVE INTENSITY OF FLASHING LIGHTS. *Illum. Engng.*, Dec. 1957, 52(12), 641-646. (National Bureau of Standards, Washington, D.C.)

10,068
The author presents a method for the computation of the effective intensity of flashing lights. The fundamental theorems of the effective intensity formula are presented along with guides for the computation of effective intensity, conformance of a flashing light (to specifications), and visual range. Also discussed are the formula's application to complex intensity-time curves, and to groups of short flashes. Numerical examples of such applications are presented.

10,072
Tobias, P.E. (Chm.). LIGHTING FOR THE COLOR APPRAISAL OF REFLECTION-TYPE MATERIALS IN GRAPHIC ART. *Illum. Engng.*, Sept. 1957, 52(9), 492-500. (Color Appraisal Task Committee, Illuminating Engineering Society, New York, N.Y.).

10,072
This report offers an extensive outline of recommended requirements for appraising certain color properties of reflective-type materials used in graphic arts. Following an introductory statement on the role of visual response, light source, and color of basic materials in color appraisal, a series of requirements are presented for the appraisal of color quality and color uniformity. The report also presents requirements for color matching of basic materials and an outline of methodological test procedures. The use of fluorescent materials, the effect of the illuminator on a color transparency, the use of contrast to inspect individual colors, and some applications of the Primary Standard Light Source are discussed in an appendix.
T. G. I. R 15

10,073
Semple, W.N. PRECISION SEEING TASKS AND HOW TO LIGHT THEM. *Illum. Engng.*, Aug. 1957, 52(8), 410-411.

10,073
In this brief article the author emphasizes the importance of providing and maintaining adequate illumination for tasks which require precise manipulation of visually minute objects. A specific system of luminaires is described and the various effects of its components upon the marker defined and exemplified. Illustrations are included.

Hopkinson, R.G. EVALUATION OF GLARE. Illum. Engng., June 1957, LII(6), 305-316. (Dept. of Scientific & Industrial Research, Building Research Station, Watford, England).

10,075
The author reviews a basic formula utilized in the assessment of glare discomfort with specific emphasis upon its limitations. Following an explicit definition of each of the exponents in the glare formula, its relative value is described to be a function of the precision required and such aspects as observed variance, method of experimentation, etc. Also discussed is the additivity of glare with specific relation to the saturation characteristics of the adaptation mechanism. Finally, the primary research needs in the evaluation of glare discomfort are defined.

Hauptschheim, A., & Schwartz, L.S. SEMANTIC CONSTRAINTS IN THE ANALYSIS OF COMMUNICATION SYSTEMS. Proc. of I.R.E., Sept. 1957, 45(9), 1284-1285. (New York University).

10,076
A problem highlighted in the Shannon theory of communications, namely, the implication that the speaker of a language possesses an unusually extensive knowledge of the statistics of that language, received preliminary investigation. Phrasing the problem as the ability of the speaker to fill in missing or incorrect letters in proofreading, subjects were required to reconstruct variously coded, corrupted messages. Two systems of transmission were constructed to reflect natural and artificial restraints in one group and natural restraints alone in the other. Systems of coding and transmission are evaluated and conclusions drawn covering the effect of speaker's knowledge of the language upon reduction of uncertainty implicit in a message utilizing that language.

10,078
Kilgariff, T.G. ESCAPE FROM HIGH-PERFORMANCE AIRCRAFT. Aeronaut. Engng. Rev., July 1957, 16(7), 59-64. (Douglas Aircraft Co., Santa Monica, Calif.).

10,078
The author examines the historical trends in aircraft performance and compares these with the trends in successful escape from aircraft. Contemporary limitations on successful escape imposed by high speed, high altitude aircraft are examined and ten criteria elaborated in the definition of the successful escape sequence. An escape factor is defined as a function of the relation between area of escape envelope and area of level flight envelope. This relation is compared graphically. Conclusions are drawn concerning escape system and flight equipment design and evaluation, the role of basic research on the aerodynamic coefficients of the human body in escape-system research, and the types of investigation necessary to contribute further knowledge about the topics discussed in this article. T. G. R 19

10,079
Price, E., & Westerwick, R. ANALYSIS OF AN ELECTRICAL FLIGHT-CONTROL SYSTEM FOR INTERCEPTOR-TYPE AIRCRAFT. Aeronaut. Engng. Rev., Aug. 1957, 16(8), 63-67, 77. (Convair, San Diego, Calif.).

10,079
The authors describe the efforts on behalf of Convair to develop an electrical primary control system for advanced aircraft. The program of research is discussed under four major developmental endeavors: (1) system dynamic analysis, i.e., the selection of the most adequate type of system, e.g., closed-loop, electrical equivalent of typical mechanical system, etc., (2) evaluation of systems, i.e., the techniques of assessing the selected system, (3) stick configurations, i.e., selection of the most adequate type of stick for electrical control system, and (4) reliability summary, i.e., assessment of the reliability of the electrical as compared to the mechanical control system.

Stellar, H.P. HUMAN FACTORS: KEY TO EQUIPMENT RELIABILITY. Amer. Aviat., Aug. 1957, 21(7), 43-44.

10,081
This article presents a summary of a report by Aeronautical Radio Inc.'s Reliability Research Department on the major factors involved in producing unreliability in military electronic equipment. The "human environment" is specified as one major factor and its specific manifestations are elaborated. These include disregard for user satisfaction in equipment design, inappropriate and/or inadequate field tests of equipment, insufficient consideration of many human engineering aspects of equipment design and maintenance, inadequate assessment of the role of human handling of equipment in the breakdown of such equipment, etc. Specific examples of such oversights and their effects are cited.

Billinski, C.R. AN EVALUATIVE SURVEY OF MAINTENANCE TRAINING AT THE FLEET SONAR SCHOOL, SAN DIEGO. PRPASD Rep. No. 64, Jan. 1955, 155pp. USN Personnel Research Field Activity, San Diego, Calif.

10,087
This report presents the results of an investigation of the extent of involvement and utility of the different ratings involved in A/S sonar maintenance. Appropriate rating scales were constructed and presented to pertinent personnel on 45 destroyer type ships. In addition, sonar men engaged in technical maintenance and sonar specialist field engineers were interviewed and completed a card sort in which 295 sonar training topics were rated with regard to their utility, difficulty, importance, and so forth. On the basis of the survey, conclusions are drawn concerning (1) the allocation of ratings in preventive and technical sonar maintenance, (2) the effect of contemporary sonar maintenance training, and (3) the types of changes necessary to increase the efficiency of such training programs. T. R 4

10,088
Roemmich, H. A SURVEY OF SHIPBOARD TRAINING IN SONAR OPERATION AND MAINTENANCE. PRPASD Rep. No. 79, May 1955, 90pp. USN Personnel Research Field Activity, San Diego, Calif.

10,088
In order to obtain descriptive information with regard to sonar maintenance and operation tasks as performed by various sonar rates aboard ship and to determine the status of shipboard sonar training, a survey was conducted among 39 A/S officers and 272 sonar men on 48 destroyer-type ships. Survey forms were constructed and survey teams were organized and appropriately trained. The results of the survey are presented and conclusions are drawn concerning delay in utilization of skills and knowledge imparted by the basic training course, the means of acquisition of additional skills, the relevancy of available training aids and references, techniques to assess training proficiency and progress, and the general efficiency of training aboard ship vs. shoreboard training. T. R 4

10,089
Asher, J.W., Hanley, T.D., & Steer, M.D. A FACTOR ANALYSIS OF TWELVE PHYSICAL MEASURES OF VOICE. Contract N6ori-104, Proj. 20-F-8, Tech. Rep. 104-2-48, Feb. 1957, 11pp. USN Training Device Center, Port Washington, L.I., N.Y.

10,089
In order to assess more accurately the effects of a variety of voice variables upon speech intelligibility, the data on twelve such variables obtained in a previous study were subjected to factor analysis. The four factors which emerged as significant are discussed in terms of their implications for the design of communications training programs. Each of the twelve variables treated is described in the appendix and include the following: median pitch, pitch variability, functional pitch range, downward pitch inflection, etc. T. R 6

Bowman, D.W., & Lang, A.T. EFFECT OF POLARIZATION ON THE COLOR APPEARANCE OF VARIOUS SURFACES AND SUBSTANCES VIEWED BY INFRA-RED, VISIBLE AND ULTRA VIOLET LIGHT. DA Proj. 5 B 9901004, Rep. 3723, Oct. 1956, 13pp. Applied Physics Lab., Detroit Arsenal, Center Line, Mich.

10,090
This study was designed to assess the effect of polarized light upon the color and surface appearance of vegetation, certain metallic and non-metallic surfaces, and several colors of paint kodachrome transparencies were made of trees, grass, metal doors, painted cinder block walls, red, green, blue, and yellow paper panels and similarly colored wood and enameled steel panels. The pictures were exposed under natural and artificial lighting systems, with and without polarizing filters. Transmittance curves and dominant wave lengths were computed. Conclusions are drawn concerning the degree and nature of the color difference attributable to polarization. T. G. I.

10,091
Moseley, H.G. AEROMEDICAL INVESTIGATION OF AIRCRAFT ACCIDENTS. Aeronaut. Engng. Rev., Aug. 1957, 16(8), 74-75.

10,091
The author discusses the importance and types of aeromedical investigation utilized in determining the cause of aircraft accidents. The problems to be considered in assessing types and cause of injury are elaborated and related to the provision of safety measures. Emphasis is placed on determining the role of human factors as causative agents in accidents. Factors such as the following are isolated: hypoxia, disorientation, discipline delinquencies, inexperience, complications and distractions, temporary illness, and others. Conclusions are drawn concerning the dependence of effective corrective action upon thorough assessment of the human errors in aircraft accidents.

10,092
Illuminating Engineering. LIGHTING TRAFFIC TUNNELS AND UNDERPASSES. Illum. Engng., June 1957, 52(6), 325-335.

10,092
This article presents a series of recommendations formulated by the Subcommittee on Tunnel and Underpass Lighting of the Street and Highway Committee of the Illuminating Engineering Society and offered as an aid to engineers and agencies concerned with the illumination of traffic tunnels and underpasses. The outlined recommendations are presented under the following general headings: basic objectives in tunnel and underpass illumination, atmospheric requirements for lighting equipment, brightness, reflectance, daytime tunnel entrance lighting, etc. The article includes many illustrations of the effects of various lighting systems. Robinson, W. MANAGEMENT, LIGHTING AND ENGINEERS. *Engng.*, Nov. 1957, 184(4783), 578-580.

10,097

This is the first of a series of three articles (see 10,097, 10,099) on industrial lighting. In this article the author reviews the general developments in industrial lighting, defines the role of management in industrial lighting practice, and discusses some of the primary problems in the attempt to achieve optimal lighting systems. The contemporary channels of lighting information and education are enumerated and the relation between research and application is assessed in terms of the acceptance of lighting engineering as a profession.

I.

10,098

Robinson, W. MANAGEMENT, LIGHTING AND ENGINEERS. *Engng.*, Nov. 1957, 184(4784), 626-630.

10,096

In this, the second of three articles on industrial lighting (see 10,097, 10,099), the author is concerned with current design and practice. Among the topics discussed are the following: brightness control, new methods of lighting design, lamps and the cost of lighting, lighting fittings, lighting maintenance, lamp replacement, and so forth. Appropriate data and illustrations are presented.

G. I.

10,099

Robinson, W. MANAGEMENT, LIGHTING AND ENGINEERS. *Engng.*, Nov. 1957, 184(4785), 656-661.

10,099

This is the third and concluding article of a series of three articles on industrial lighting (see 10,097, 10,098). In this article the author is concerned with factory layout and productivity. Lighting is related to several aspects of the factory installation, including heating, but primary emphasis is upon its relation to the total integrated structure. The results of tests of the effect of lighting on productivity are presented along with a brief discussion of the broader aspects of lighting design and assessment.

Murrell, E.P.H. DATA ON HUMAN PERFORMANCE FOR ENGINEERING DESIGNERS. *Engng.*, Aug. 1957, 184(4772), 194-198. (Dept. of Psychology, University of Bristol).

10,100

This is the first in a series of five articles (see 10,100, 10,102, 10,103, 10,104) which present data on human performance collected in a variety of areas and offered for use by engineering designers. This article discusses the general problems in designing equipment for human use and presents specific data in body structure and movement and body measurements as applied to the design of optimal seating. Specifications are offered for seat height, length, width, and shape, backrests, padding and seating under conditions of restricted leg room.

T. I. R 17

10,101

Murrell, E.P.H. DATA ON HUMAN PERFORMANCE FOR ENGINEERING DESIGNERS. *Engng.*, Aug. 1957, 184(4772), 247-249. (Dept. of Psychology, University of Bristol).

10,101

This article, the second of a series presenting data on human performance for engineering designers (see 10,100, 10,102, 10,103, 10,104) is concerned with the design of dials and indicators in visual displays. Data and recommendations are presented concerning: (a) the choice of displays for various uses (e.g., warning, check controlling, setting, etc.); (b) methods of increasing the readability of such displays (including such factors as color, reading distance, numeral design, etc.); and (c) techniques for the optimal utilization of indicators. Auditory and tactual displays are briefly discussed.

Murrell, E.P.H. DATA ON HUMAN PERFORMANCE FOR ENGINEERING DESIGNERS. *Engng.*, Sept. 1957, 184(4774), 302-310. (Dept. of Psychology, University of Bristol).

10,102

The control-display relationship is the general topic of this article, the third in a series of five articles presenting data on human performance for engineering designers (see 10,100, 10,101, 10,103, 10,104). Following a general discussion of the principles of control-display relationships, data and recommendations are offered concerning: (1) the choice of controls (considering such factors as multiple switching slow movement, and so forth), and (2) the design of controls (including each of the following types: cranks, handwheels, knobs, levers, joysticks, pedals, and push buttons).

T. I. R 2

10,103

Marrell, K.P.H. DATA ON HUMAN PERFORMANCE FOR ENGINEERING DESIGNERS. *Engng.*, Sept. 1957, 184(4775), 344-347. (Dept. of Psychology, University of Bristol).

10,103

Industrial heat and noise are the topics discussed in this article, the fourth of a series of five articles presenting data on human performance for use by engineering designers (see 10,100, 10,101, 10,102, 10,104). Methods of measuring industrial heat are presented along with a discussion of its effects on human performance, the use of personal protective devices, and techniques to deflect and/or reduce heat at its source. Noise is discussed in terms of its function of hearing impairment, methods of noise protection, its role in communication, and its effect on efficiency. Some illustrations and pertinent references are included.
F. G. I. R 11

10,104

Marrell, K.P.H. DATA ON HUMAN PERFORMANCE FOR ENGINEERING DESIGNERS. *Engng.*, Oct. 1957, 184(4778), 438-440. (Dept. of Psychology, University of Bristol).

10,104

This is the concluding article of a series of five articles presenting data on human performance for engineering designers (see 10,100, 10,101, 10,102, 10,103). This article is concerned with the effects of lighting and color on visual efficiency and comfort. Data are presented to define three primary factors in efficient visual performance of a task: (1) the amount of light on the task; (2) the time allowed for seeing; and (3) the effect of glare. Recommendations for optimal design are offered throughout the discussion of the various factors which influence visual performance.
G. R 6

10,105

King, A.J. VIBRATION AND NOISE OF MECHANISMS AND MACHINES. *Engng.*, June 7, 1957, 183(4761), 716-719.

10,105

Vibration and noise are defined in terms of units of measurement, subjective response, and methods of measurement. The common causes of noise and vibration are described and various techniques of reduction discussed. Particular emphasis is placed upon machine installation effects, the effect of the foundation block on noise and vibration, avoidance of transmission effects, and the use of a special kind of enclosure, the gearbox. Some general conclusions are drawn concerning the problems of noise and vibration and their solution.

10,109

Sorens, C., Girard, L.J., Ponda, G., & Sells, S.R. EFFECTS OF TACHISTOSCOPIC TRAINING ON VISUAL FUNCTIONS IN MYOPIC PATIENTS. *Amer. J. Ophthalmol.*, 1957, 44(4), Part II, 25-49. (USAF School of Aviation Medicine, Randolph AFB, Tex.).

10,109

To test the effects of tachistoscopic training on visual functions in myopic patients, two groups of myopic subjects were used. Eighty highly motivated subjects constituted the experimental group, while the control group was composed of 60 poorly motivated individuals. The experimental group received three training sessions per week for 10 weeks. At the completion of the course, both groups received ophthalmological examinations identical to those given before training. The effects of training were determined in terms of the differences between initial and final measurements for the two groups.

Sells, S.B., & Fixott, R.S. EVALUATION OF RESEARCH ON EFFECTS OF VISUAL TRAINING ON VISUAL FUNCTIONS. *Amer. J. Ophthalmol.*, 1957, 44(2), 230-236. (USAF School of Aviation Medicine, Randolph AFB, Tex.).

10,110

This report presents an evaluation of research on visual training with reference to a number of visual functions. One phase of visual performance, the perceptual phase, is selected for particular emphasis. The nature of perception, the reciprocal relation between perception and learning, and the conditions of learning conducive to learning, retention, and transfer are all discussed briefly.

10,111

Carbajal, U.K. PLOTTING THE BLINDSPOT. *Amer. J. Ophthalmol.*, 1957, 44(3), 379-384.

10,111

The author describes current methods of mapping the blindspot, gives average measurements, and enumerates the factors affecting the size of the blindspot for the benefit of the clinician concerned with the diagnosis of certain visual anomalies.
I. R 23

10,112

Taylor, E.A. THE SPANS: PERCEPTION, APPREHENSION, AND RECOGNITION, AS RELATED TO READING AND SPEED READING. *Amer. J. Ophthalmol.*, 1957, 44(4), Part I, 501-507.

10,112

Some of the history of research on eye movements is reviewed, but the major emphasis in this article is on defining concepts which the author considers to be important considerations in reading instruction: span of perception (the visual field as measured by perimetry), span of apprehension (the amount of material seen during a tachistoscopic exposure), and span of recognition (amount of print perceived and organized during a single eye stop).
R 27

10,113

Danielson, R.W. THE RELATIONSHIP OF FIELDS OF VISION TO SAFETY IN DRIVING. *Amer. J. Ophthalm.*, 1957, 44(5), Part I, 657-680. (University of Colorado).

10,113

This paper discusses the various facets of the problem of the relationship of fields of vision to safety in driving. Factors affecting fields of vision, such as diseases of the media, fundi, visual tracts and blindspot, loss of an eye, effect of drugs, errors of refraction, and fatigue are discussed in some detail. From a study of the literature and cases, certain conclusions are suggested as to the importance of defects in fields of vision as a cause of accidents. T. G. I. R 52

Kobrak, H.G. OBJECTIVE AUDIOMETRY: UTILIZATION OF AN UNCONDITIONED MUSCLE REFLEX FOR THE DETERMINATION OF SOUND PERCEPTION. *Arch. Otolaryng.*, 1957, 65(1), 26-31. (Wayne State University).

10,114

For this paper, the contractions of the two intratympanic muscles are analyzed as to their usefulness as objective indicators of cochlear function. Animal experiments demonstrating the quantitative relation between sound stimuli and muscular response are quoted. A limited number of observations made on patients through a perforation of the eardrum are also given. Representative values which were found under acoustic stimulation are given and the results evaluated. G. I. R 5

Epstein, A., & Schubert, E.D. REVERSIBLE AUDITORY FATIGUE RESULTING FROM EXPOSURE TO A PURE TONE. PART I. *Arch. Otolaryng.*, 1957, 65(2), 174-182. (University of Pittsburgh).

10,115

This paper is a report of an attempt to determine the critical fatiguing intensity for a 4000 cycles per second pure tone of three-minute duration as measured by post-stimulatory auditory fatigue. The measures used are (1) amount of threshold shift, (2) length of recovery time, (3) intensity of exposure tone at the half-octave shift of the frequency of maximal fatigue, and (4) the amount of recruitment present after stimulation. Results are presented for twenty-three adult subjects. G. I. R 20.

Spuehler, H.E., & Hanley, T.D. AN AUDITORY LOUDNESS RECRUITMENT TEST BATTERY: ANALYSIS AND COMPARISON OF SUBTESTS. *Arch. Otolaryng.*, 1957, 65(2), 183-190. (Purdue University).

10,116

The purpose of the investigation was to establish, by rigorous statistical analysis, the capability of a series of tests to distinguish between normal hearing and that characterized by recruitment in the loudness function. The results for five normal subjects and four with known auditory loss are given for the following tests: (1) range of comfortable loudness (RCL) test, (2) difference limen (DL) test, and (3) speech sound discrimination (SSD) test. T. G. R 11

10,117

Winchester, R.A., & Gibbons, E.W. RELATIVE EFFECTIVENESS OF THREE MODES OF DELAYED SIDETONE PRESENTATION. *Arch. Otolaryng.*, 1957, 65, 275-279.

10,117

Adults (160) with normal hearing were tested under three different methods of delayed sidetone presentation and one condition of unimpeded reading in an effort to investigate the relative effectiveness of these different modes of presentation in relation to speech distortion. Results are presented for: 1) binaural presentation, 2) uniaural presentation without contralateral masking, and 3) uniaural presentation with contralateral masking. T. R 6

Shimizu, H., Sugano, T., Segawa, Y., & Nakamura, P. A STUDY IN PSYCHOGALVANIC SKIN RESISTANCE AUDIOMETRY. *Arch. Otolaryng.*, 1957, 65, 499-508. (Kyoto Prefectural Medical University, Japan).

10,118

This paper explores the usefulness of psychogalvanic skin resistance (PSCR) audiometry for confirming deaf-mutism and for judging the level of residual hearing throughout the frequency range. Various measuring methods and confidence limits were studied and results are given for a number of child patients. G. I. R 10

10,119

Palva, T. SELF-RECORDING THRESHOLD AUDIOMETRY AND RECRUITMENT. *Arch. Otolaryng.*, 1957, 65, 591-602. (University of Turku, Finland).

10,119

This paper gives a short review of papers dealing with self-recording audiometry and reports results of such testing on 17 normal subjects and 56 perceptively deaf persons for 101 frequencies. The experimental procedure is described in some detail, along with an analysis of threshold variability as a function of time, and the differential results for normal and deaf subjects. T. G. R 15

10,120

Mahoney, J.L., Harlan, W.L., & Bickford, R.G. VISUAL AND OTHER FACTORS INFLUENCING CALORIC NYSTAGMUS IN NORMAL SUBJECTS. *Arch. Otolaryng.*, 1957, 66(1), 46-53. (The Mayo Foundation, Rochester, Minn.).

10,120

This paper reports observations made to determine the effect of fixation, eye closure, and alerting activity on caloric nystagmus. The caloric responses of eighteen normal subjects were recorded electrographically. The average amplitude, frequency, and duration of response under the various conditions is analyzed and discussed in relation to certain cerebral concomitants. G. I. R 12

10,121

Gibbons, E.W., & Winchester, R.A. A DELAYED SIDETONE TEST FOR DETECTING UNIAURAL FUNCTIONAL DEAFNESS. *Arch. Otolaryng.*, 1957, 66(1), 76-78.

10,121

Seventy cases of uniaural organic deafness were studied in order to validate a new delayed sidetone test designed to detect uniaural functional deafness. A tape recorder provided the delayed sidetone. Testing involved obtaining two oral reading times for each subject, one obtained during the provision of masking noise to the better ear and one when the poorer ear receives masking noise. The time differences between the two test conditions were examined to establish a minimal standard below which a functional involvement must be suspected. T. R 13

10,122

Pell, S. THE RELATION OF OCCUPATIONAL NOISE EXPOSURE TO LOSS OF HEARING ACUITY. *Arch. Otolaryng.*, 1957, 66(1), 79-92. (University of Pittsburgh).

10,122

The audiograms of 1049 male employees of a manufacturing plant were utilized to study the relation of occupational noise exposure to five-year audiometric changes, taking into account the variables of age and hearing acuity at the onset of the five-year study period. Each employee was placed in one of three over-all noise level categories. Statistical analysis of the difference between auditory acuity of the worst ear at the beginning and end of the study is used as the basis for certain conclusions. T. G. R 18

10,123
Palva, T. RECRUITMENT TESTING. Arch. Otolaryng., 1957, 66(1), 93-98. (University of Turku, Finland).

10,123
This paper reviews and evaluates various indirect recruitment tests, e.g., tests for intensity and frequency difference lines, masking, auditory fatigue and adaptation, self-recording threshold audiometry, and speech intelligibility. These tests are compared for reliability with direct tests and certain conclusions are reached.

Eisenberg, Rita B. STUDY OF THE REPEATABILITY OF ONE DECIBEL STEP PULSED-TONE THRESHOLDS IN NORMAL HEARING PERSONS. Arch. Otolaryng., 1957, 66(3), 278-280. (San Francisco Hearing and Speech Center, Calif.).

10,129
This paper gives the results of repeated threshold measurements for a 250 millisecond pulsed tone repeated once per second on 15 subjects with normal hearing. The results are analyzed to determine the repeatability of such thresholds measured in one decibel steps.
I. R 9

10,130
Bergman, M. BINAURAL HEARING. Arch. Otolaryng., 1957, 66(5), 572-576. (Hunter College).

10,130
This paper reviews the advantages of binaural hearing with respect to localization, selectivity, speech discrimination, identification of common sounds, and ease of listening and suggests a new battery of tests to quantify these advantages.
G. R 9

10,131
Corso, J.F., & Wilson, J.F. ADDITIONAL VARIABLES ON THE BEKESY-TYPE AUDIOMETER. Arch. Otolaryng., 1957, 66(6), 719-728. (Aero Medical Lab., WADC, ARDC, Wright-Patterson AFB, Ohio).

10,131
This study was conducted to determine the effects of four operating conditions on a Bekesy-type audiometer on the absolute threshold of hearing: (1) attenuation rate, (2) testing time, (3) direction of frequency sweep, and (4) type of stimulus noise. Right ears of ten subjects were tested by an analysis of variance design. The results are analyzed so that ideal operating conditions with this type of audiometer can be stated.

10,133
Shock, N.W. AGE CHANGES IN SOME PHYSIOLOGIC PROCESSES. Geriatrics, 1957, 12(1), 40-48. (Baltimore City Hospital, Baltimore, Md.).

10,133
As part of a symposium on physiological aspects of aging, clinical evidence is presented on such topics as (1) physiological functions which are affected by age as opposed to those which are not, (2) individual differences in the effects of age, and (3) age and diminishing protoplasm.
G. R 20

10,134
Masserman, J.H. THE PSYCHODYNAMICS OF AGING. Geriatrics, 1957, 12(2), 115-122. (Northwestern University).

10,134
This paper constitutes a part of a symposium on the psychiatric aspects of aging. The author discusses the concept of senility, the problems inherent in adapting to advanced age, and the place of psychotherapy and institutional care in this sphere.

10,135
Craig, F.M., & Cain, S.M. BREATH HOLDING AFTER EXERCISE. *J. appl. Physiol.*, 1957, 10(1), 19-25. (Chemical Warfare Labs., Army Chemical Center, Md.).

10,135
Twelve enlisted men served as subjects in this experiment to determine the influence of certain factors on the length of time the breath can be held. Breath holding time was measured after exercise of the five following types: standing, walking at 3 miles per hour (mph) on the level and 3.5 mph up a 6 per cent grade (for 1.5 minutes), and running at 6 mph (for 2 minutes) and 9 mph (for 1.5 minutes) on the level. The stimulus was evaluated in terms of a rate of accumulation of a chemical stimulating condition proportional to the previous respiratory minute volume, multiplied by the length of the hold and divided by the estimated volume of the lungs during the hold.

10,141
Brozek, J., Grande, P., Taylor, H.L., Anderson, J.T., et al. CHANGES IN BODY WEIGHT AND BODY DIMENSIONS IN MEN PERFORMING WORK ON A LOW CALORIC CARBOHYDRATE DIET. *J. appl. Physiol.*, 1957, 10(3), 412-420. (Physiological Hygiene Lab., University of Minnesota).

10,141
This is a study of the effect of maintenance on low caloric carbohydrate diet on body dimensions and weight. Twenty-five soldiers served as subjects, half as controls on a diet of C rations, half on 580 calories per day for 12 days or 1010 calories for 24 days. Physical work (treadmill and outside walking) was the same for all conditions. Weight, basal metabolism, oxygen consumption, and body measurements were traced throughout the period of the experiment and constitute the data of the study.

10,142
Taylor, H.L., Buskirk, E.R., Brozek, J., et al. PERFORMANCE CAPACITY AND EFFECTS OF CALORIC RESTRICTION WITH HARD PHYSICAL WORK ON YOUNG MEN. *J. appl. Physiol.*, 1957, 10(3), 421-429. (Physiological Hygiene Lab., University of Minnesota).

10,142
The effects of caloric restriction while maintaining a rigorous schedule of physical activity (running and walking) were measured by pulse rate, oxygen consumption, and blood sugar determinations. The conditions specifically investigated were: (1) 3100 calories per day (Cal/day) for the entire experiment (control group of 6 men) (2) 580 Cal/day for 12 days (6 men), and (3) 1010 Cal/day for 24 days (13 men). Performance and symptoms are discussed in detail.
T. G. R 18

10,143
Rasch, P.J., & Morehouse, L.E. EFFECT OF STATIC AND DYNAMIC EXERCISES ON MUSCULAR STRENGTH AND HYPERTROPHY. *J. appl. Physiol.*, July 1957, 11(1), 29-34. (Los Angeles County Osteopathic Hospital, Los Angeles, Calif.).

10,143
To assess the differential effects of isometric and isometric exercises on muscular strength and hypertrophy, two groups of subjects (approximately 25 in each) matched for height and weight performed either isometric or isometric exercises for a period of six weeks. Anthropometric and strength measures were made prior to, during, and following the exercise period. The results are presented and discussed in terms of the differential changes demonstrated in strength and hypertrophy on tests of elbow flexion, arm elevator, unpracticed elbow, and the modified Martin test. The physiological and psychological desirability of the particular type of exercise is discussed.

Lind, A.R., & Mellon, R.F. ASSESSMENT OF PHYSIOLOGICAL SEVERITY OF HOT CLIMATES. *J. appl. Physiol.*, July 1957, *II*(1), 35-40. (Medical Research Council Unit for Research on Climate and Working Efficiency, Oxford, England).

10,144

This study was designed to assess the differential accuracy of the Effective Temperature scale and the MSR scale in assessing the physiological severity of hot climates. Ten healthy subjects, ranging in age from 20 to 28 years, were exposed, following a period of appropriate acclimatization, to eight different climates with temperatures chosen to correspond to an increasing order of severity on the Effective Temperature scale. Measures of rectal and skin temperature, pulse rate, weight loss, and blood flow were taken prior to and during exposure to the climates. The results were plotted against the MSR scale. The predicted severity of each scale is evaluated against the experimentally demonstrated severity. Conclusions are drawn concerning the accuracy of each scale. T. G. R 18

Spurr, G.B., Hutt, B.K., & Horvath, S.M. SHIVERING, OXYGEN CONSUMPTION AND BODY TEMPERATURES IN ACUTE EXPOSURE OF MEN TO TWO DIFFERENT COLD ENVIRONMENTS. *J. appl. Physiol.*, July 1957, *II*(1), 58-64. (State University of Iowa College of Medicine).

10,145

In order to determine the initial metabolic and body temperature changes occurring upon exposure of the human to a 10°C environment (and their relation to shivering) 9 nude male adults were placed in such an environment in a series of 11 experiments. Skin and rectal temperature, oxygen consumption, respiratory minute volume and quotient, carbon dioxide production, metabolic rate, and shivering were recorded during and after exposure. Control observations were made on nude subjects in a 26°C environment. The results are compared statistically with an earlier study employing a -3°C environment in terms of the significant differences in metabolic and body temperature changes and the relative effectiveness of shivering (as a protective measure) under each environment. Bartlett, R.G. Jr., & Specht, H. MAXIMUM BREATHING CAPACITY WITH VARIOUS EXPIRATORY AND INSPIRATORY RESISTANCES (SINGLE AND COMBINED) AT VARIOUS BREATHING RATES. *J. appl. Physiol.*, July 1957, *II*(1), 79-83. (National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, Bethesda, Md.).

10,146

This study was designed to assess the effect of breathing rate on maximum breathing capacity (MBC) and the effect of added inspiratory or expiratory resistances on the MBC. Utilizing a 50-liter Douglas bag, the MBC was determined for three subjects under conditions of varied breathing rates and varied expiratory and inspiratory resistances. The results are presented and discussed in terms of the differential effects of each of the variables upon MBC. A discussion of the results centers upon their implications for previous conceptions of MBC and the testing equipment necessary to assess the MBC for normal subjects. T. G. R 3

Cain, S.M. BREAKING POINT OF TWO BREATH HOLDS SEPARATED BY A SINGLE INSPIRATION. *J. appl. Physiol.*, July 1957, *II*(1), 87-90. (Chemical Warfare Labs., Army Chemical Center, Md.).

10,147

To determine the factors affecting the breaking point of breath holding, three male subjects pursued six trials characterized by breathing for five minutes from a recording 13-liter spirometer with a final maximal inspiration; the same procedure but with the subject holding his breath on the maximal inspiration; and the same procedure again but following the maximal inspiration a second maximum breath hold was made. Appropriate measures were applied and the resultant data are analyzed in terms of duration of initial versus secondary breath holding times, the volume of inspiration, and so forth. The potential influences of non-chemical stimuli upon this phenomenon is emphasized. T. G. R 10

Wyndham, C.H., & Jacobs, G.E. LOSS OF ACCLIMATIZATION AFTER SIX DAYS OF WORK IN COOL CONDITIONS ON THE SURFACE OF A MINE. *J. appl. Physiol.*, Sept. 1957, *II*(2), 197-198. (Applied Physiology Lab., Transvaal and Orange Free State Chamber of Mines, Johannesburg, South Africa).

10,148

To investigate the duration of acclimatization, 73 men having been acclimatized for a period of 12 days to a temperature of 91 degrees Fahrenheit were placed in a cool environment for six days and then returned to the original environment. Mouth temperatures were measured at each stage and plotted. Significant differences in the temperatures are discussed as indicative of the relative lack of stability of acclimatization under the specific conditions employed in this study. G. R 2

Rennie, D.W. & Adams, T. COMPARATIVE THERMOREGULATORY RESPONSES OF NEGROES AND WHITE PERSONS TO ACUTE COLD STRESS. *J. appl. Physiol.*, Sept. 1957, *II*(2), 201-204. (Arctic Aeromedical Lab., Seattle, Wash.).

10,149

To investigate the hypothesis that Negroes are more susceptible on a physiologic basis to cold injury, eight Negro and eight white combat infantrymen stationed near Fairbanks, Alaska, were given an acute cold test during both the summer and winter seasons. Each subject, lying supine on a cot, was exposed to an air temperature of -120°C for 90 minutes while fully clothed except for hands and fingers. Body temperatures and metabolism were assessed continuously. The results are presented in terms of a statistical analysis of the differences in the general thermal state, mean finger temperatures, cold vasodilation, and metabolism between the two groups. The observed differences in thermoregulatory response are discussed with regard to predisposition to cold injury. G. R 10

Teichner, W.H. MANUAL DEXTERITY IN THE COLD. *J. appl. Physiol.*, Nov. 1957, *II*(3), 333-338. (USA Quartermaster Research and Engineering Center, Natick, Mass.).

10,150

In this study of the effects of cold on manual dexterity, 560 subjects were placed in a climatic chamber under varied temperatures, wind speed, windchill, and clothing conditions (arctic, nude, and fatigues). The first 25 minutes consisted of acclimatization followed by 15 trials on the Minnesota Rate of Manipulation Test, assessment of visual reaction times, three minutes of mild exercise, and, finally, five additional trials on the manual dexterity test. The data are presented and analyzed in terms of performance time and body temperatures as functions of each of the experimental conditions and their combination. A brief discussion of the findings focuses upon the potential role of psychological factors in influencing a decrement in manual dexterity under conditions of exposure to cold. G. R 9

Kreider, M.B., & Buskirk, E.R. SUPPLEMENTAL FEEDING AND THERMAL COMFORT DURING SLEEP IN THE COLD. *J. appl. Physiol.*, Nov. 1957, *II*(3), 339-343. (USA Quartermaster Research and Development Center, Natick, Mass.).

10,151

This study was designed to investigate the effect of feeding practice upon thermal comfort during sleep in the cold. Six subjects were presented dietary supplements of 0, 600, or 1200 calories (in addition to usual three meals per day) at ten minutes prior to sleeping in arctic sleeping bags at -34.5 degrees Centigrade. Rectal, toe and mean skin temperatures and measures of oxygen consumption were taken at predetermined intervals throughout the sleeping period. The results are presented and discussed in terms of the differential effects of each group of supplements upon the thermal comfort assessment scores. Wakefulness and certain subjective factors as a function of dietary supplement are also discussed. T. G. R 6

LeBlanc, J.A., & Rosenberg, P.J. LOCAL AND SYSTEMIC ADAPTATION TO TOPICAL COLD EXPOSURE. *J. appl. Physiol.*, Nov. 1957, II(3), 344-348. (Chemical Warfare Labs., Army Chemical Center, Md.).

10,152

In this study of local and systemic adaptation to topical cold exposure, a total of 12 subjects were utilized in a series of three experiments in which the hand was immersed in a cold water bath (30°C). The conditions experimentally varied included occlusion of circulation to immersed hand, duration of immersion, number of cold immersion tests, and others. Blood pressure and finger-tip temperatures were recorded during and following the immersion at regular intervals. The results are presented and discussed in terms of the relative changes in these measures under the varied experimental conditions as being indicative of the underlying determinants of local and systemic adaptation to cold. T. G. R 14

Rubin, L.S., & Goldberg, M.N. EFFECT OF SARIN ON DARK ADAPTATION IN MAN: THRESHOLD CHANGES. *J. appl. Physiol.*, Nov. 1957, II(3), 439-444. (Directorate of Medical Research, Army Chemical Center, Md.).

10,154

In order to assess the effects of sarin on the course and absolute threshold of dark adaptation, two subjects were exposed to sarin, with a third acting as a control, and then assessed for dark adaptation under appropriate experimental conditions. Erythrocyte (RBC) cholinesterase levels were determined prior to and following exposure to sarin. In addition, extent of miosis was similarly determined. The results are treated in terms of significance of difference in absolute and relative threshold values pre- and post-exposure. The implications for the photochemical theory of brightness vision are discussed. T. G. R 10

10,155

Rubin, L.S., Krop, S., & Goldberg, M.N. EFFECT OF SARIN ON DARK ADAPTATION IN MAN: MECHANISM OF ACTION. *J. appl. Physiol.*, Nov. 1957, II(3), 445-449. (Chemical Warfare Labs., Army Chemical Center, Md.).

10,155

In order to clarify the site of action (i.e., intra versus extracellular) of sarin, three subjects were tested with the Hecht-Shlaer adaptometer for dark adaptation thresholds following exposure to sarin. Method of exposure was varied with each subject in order to assess the drug's effect as being direct, systemic, or extracellular (e.g., an action on central neural factors). The effect of the drug on each of the subjects is analyzed in terms of the changes in pre- and post-exposure thresholds. Conclusions are drawn as to the probable site of its action. T. G. R 7

Houtz, S.J., Lebow, M.J., & Beyer, P.R. EFFECT OF POSTURE ON STRENGTH OF THE KNEE FLEXOR AND EXTENSOR MUSCLES. *J. appl. Physiol.*, Nov. 1957, II(3), 475-480. (Detroit Orthopaedic Clinic, Detroit, Mich.).

10,156

This study was designed to introduce a specially developed strain gauge and by its application to assess the effects of the prone, seated, and supine postures on two muscles, the knee antagonist and extensor. Eight females, ranging in age from 23 to 50 years and in weight from 102 to 160 pounds, were required to manifest maximum contractions of knee flexion and extension through various angles while assuming each of the three postures. The specially designed muscle dynamometer was employed in a total of 150 experiments. The results are analyzed in terms of the significance of difference between mean strength of the muscles at various angles in the different postures. Discussion concerns itself with the effectiveness of the dynamometer and the effect of posture on knee strength. T. G. I. R 7

VEOLAR AIR ON MOUNT EVEREST: WITH REMARKS ON
THE RELATION OF BAROMETRIC PRESSURE TO ALTI-
TITUDE IN MOUNTAINS. J. Physiol., 1957, 135,
590-610. (National Institute for Medical Re-
search, Hampstead, London, England).

10,168
To study physiological changes associated with accli-
matization to altitudes above 15,000 feet, alveolar air
samples were obtained from mountain climbers at altitudes
ranging from 15,000 to 24,000 feet and resting ventila-
tion was followed in a single subject up to 21,000 feet.
Data on the effect of breathing supplementary oxygen on
the alveolar gases in resting subjects are also presented
to check for evidence of loss of acclimatization in per-
sons using oxygen over prolonged periods. The relation
of barometric pressure to altitude is also discussed in
relation to simulation.

Dickson, J.A. THE EFFECT OF LIMB POSITION ON
THE VASODILATOR RESPONSE TO COLD IN THE FINGER.
J. Physiol., 1957, 135, 93-97. (Dept. of
Physiology, Queen's University of Belfast).

10,169
The purpose of this experiment was to determine how
a reduction of perfusion pressure (by elevating the arm
to various heights) affects the vasodilator response to
cold in the finger. The heat elimination from the finger
tips of nine subjects to water in the zero to four degree
Centigrade range was measured calorimetrically at various
limb positions. The results are discussed in relation
to perfusion pressure.

 Doyle, H.N. EMERGING INDUSTRIAL HEALTH PROBLEMS. *Indust. Med. Surg.*, Jan. 1957, 26(1), 1-5. (U.S. Dept. of Health, Education, and Welfare, Washington, D.C.).

10,173
 The author notes the contemporary and potential developments in industry as these will affect problems of industrial health. Specific emphasis is placed on human engineering and the type of problems it presents to the physician in industry and to health programs. Specific discussion of the following emerging health problems is presented: (1) dangers of radiation; (2) industrial toxicology; (3) the determination of occupational factors in chronic disease; (4) the maintenance of health; and (5) the role of the private physician in industrial health programs.

10,174
 Brandaleone, H., Blaney, L., Irwin, G.H., Kuhn, H.S., Miller, S.E., Penalter, R., Soth, R.E., Sim, R., & Friedman, G.J. RECOMMENDATIONS FOR MEDICAL STANDARDS FOR MOTOR VEHICLE DRIVERS. *Indust. Med. Surg.*, Jan. 1957, 26(1), 25-32.

10,174
 Following a brief discussion of the role of the human factor in motor vehicle accidents, the authors note the positive relation between accident prevention and the comprehensive medical program (and subsequently improved driver selection). Recommendations are offered concerning frequency of examination and type of examination in the form of four charts entitled: (1) "Private or Civilian Drivers Health History", (2) "Commercial or Industrial Drivers Health History", (3) "Physical Examination Motor Vehicle Drivers", and (4) "A Reference List of Conditions Which May be Non-Acceptable for Driving."

Griggs, W., Summerfield, Anne & Glorig, A. HEARING LOSS IN RELATION TO INDUSTRIAL NOISE EXPOSURE. Indust. Med. Surg., Oct. 1957, 26(10), 451-458. (Research Center, Subcommittee on Noise in Industry, Los Angeles, Calif.).

10,180
This report presents a definition and discussion of a number of major issues in the problem of noise-induced hearing loss. To exemplify these issues a study of the audiometric records of 5,816 aircraft employees was conducted. Analysis of the data demonstrates three primary aspects: 1) evidence of hearing loss attributable to noise exposure; 2) the differential occurrence of hearing loss as a function of type of occupation; and 3) definition of sources of error which occur in making such audiometric comparisons. Conclusions are drawn concerning the validity of such studies and recommendations offered for the optimal collection and utilization of data of this sort.

Smith, S.W., & Dimmick, F.L. MEASUREMENT OF THE LIGHT ADAPTATION OF THE RODS. J. opt. Soc. Amer., May 1957, 47(5), 391-395. (USN Medical Research Lab., New London, Conn.).

10,182
In order to assess the length of time required to attain stable light adaptation, dark adaptation curves were obtained for three subjects through: an initial period of 30 minutes, 21 minutes, and a test period in which a white stimulus was presented in an adaptometer at an intensity somewhat below threshold. The latter stimulus occurred at three second intervals for 0.20 seconds until it was seen twice in succession. Brightness was then reduced. The results are presented and discussed in terms of the relative differences in scotopic sensitivity under each of the conditions of adaptation. The influences of light history on the course of adaptation are illustrated graphically.

Burnham, R.W., Clark, Joyce R. & Newhall, S.M. SPACE ERROR IN COLOR MATCHING. J. opt. Soc. Amer., Oct. 1957, 47(10), 959-966. (Eastman Kodak Co., Rochester, N.Y.).

10,183
This study was designed to assess the magnitude of the space-error in the typical color matching task and to evaluate the effect of stimulus position on precision and time of matching. Three observers were required to make a series of matches of 4 test colors in each of 4 positions under conditions designed to ensure the assessment of the potential space-error. CIE tristimulus values and chromaticities were computed and the results are discussed in terms of matching precision and time as a function of position. Having found no evidence for assuming a space-error in color matching, conclusions are drawn concerning the generalizability of this finding and its implications for results which indicate space-error.

Gerstewohl, S.J. CONSPICUITY OF FLASHING LIGHT SIGNALS: EFFECTS OF VARIATION AMONG FREQUENCY, DURATION, AND CONTRAST OF THE SIGNALS. J. opt. Soc. Amer., Jan. 1957, 47(1), 27-29. (USAF School of Aviation Medicine, Randolph AFB, Tex.).

10,184
This study was designed to assess the interaction between flash frequency, duration, and brightness contrast of flashing light signals and its effect upon the conspicuity of such signals. Three brightness contrasts, one of three frequencies, and one of two flash duration were utilized to compare the conspicuity of a total of 18 different flashing signals. Each of 18 observers seated six feet before a Multiple Complex Reaction Apparatus responded to a series of 120 signals by either operating a handle or pushing a button. The results are presented in terms of mean response time as a function of contrast, frequency, and duration. Relative conspicuity as a function of the variance factors and their interaction is discussed with an attempt to explain the findings of this and previous studies.

Buchmann-Olsen, B., & Rosenfalck, A.M. SPECTRAL ENERGY CALIBRATION OF A LIGHT FLASH SOURCE USED IN PHYSIOLOGICAL EXPERIMENTS. J. opt. Soc. Amer., Jan. 1957, 47(1), 30-34. (University of Copenhagen).

10,185
The authors describe a technique for utilizing the Sylvania glow modulator tube in the study of color vision. The results of its application in an experiment are presented and include the following information: (1) the relative spectral irradiance from three types of glow modulator tube, (2) the short- and long-term stability of the relative spectral distribution of the glow modulator tube over a 350-700 millimeter range, (3) the individual variation of seven tubes, (4) the variation in concentration of irradiance for two wavelengths (blue and yellow), and (5) the absolute energy of the light flashes from the tube.

Nowhall, S.M., Burnham, R.W., & Clark, Joyce R. COMPARISON OF SUCCESSIVE WITH SIMULTANEOUS COLOR MATCHING. J. opt. Soc. Amer., Jan. 1957, 47(1), 43-56. (Eastman Kodak Co., Rochester, N.Y.).

10,186
This study was designed to provide a basis for the prediction of color appearance with different adaptation illumination. Twelve comparison colors (a colorimetrically mixed comparison color to right eye and a variable colorimetric mixture to left eye) were presented to four color-normal subjects, under each of three illuminants, to be appearance matched. CIE tristimulus values were obtained for each of the matches (a total of 1260) and CIE chromaticities plotted for pairs of illuminants. Color shift is discussed along with a computational method for the prediction of color appearance and the theoretical implications of the findings.

Westheimer, G. ACCOMMODATION MEASUREMENTS IN EMPTY VISUAL FIELDS. *J. opt. Soc. Amer.*, Aug. 1957, 47(8), 714-718. (Ohio State University).

10,188
This paper reports the use of a subjective measuring technique for evaluating accommodative level in empty visual fields, both dark and light. The eye's accommodative response to the empty field is measured by flashing into the eye for .05 second every ten seconds a beam whose configuration indicates over-accommodation, correct versus under-accommodation for the measuring level. Harmonic analysis is performed on the data obtained from five subjects and the results are discussed in detail.

Brown, W.R.J. COLOR DISCRIMINATION OF TWELVE OBSERVERS. *J. opt. Soc. Amer.*, Feb. 1957, 47(2), 137-143. (Eastman Kodak Co., Rochester, N.Y.).
- 10,201
Twelve observers were used to study color discrimination by the method of color matches about a color center with the added refinement of using a binocular wide-field colorimeter with a broad surrounding field. The colorimeter provided a circular field, subtending 10 degrees at the observer's position, with white surround. Twenty-two color centers from various parts of the chromaticity diagram were used, the average luminance of the colors being 4.9 foot lamberts. The results were transformed to primaries allowing plotting on the chromaticity diagram.

Alvis, H.J. SUBMARINE MEDICINE - AN OCCUPATIONAL SPECIALTY. *New England J. Med.*, Jan. 1957, 256(1), 21-25. (Submarine Medicine Div., Bureau of Medicine and Surgery, Washington, D.C.).

10,231

This is a survey of the occupational problems existent in submarine medicine. In addition to the problems, the author includes the research findings pertinent to the following aspects of submarine service: visual and hearing requirements; psychological factors in crew selection training, and interpersonal relations; the psychological and physiological effects of the work environment; exposure to toxic substances (e.g., freon, oil vapors, and so forth), and others.

Lanphier, E.H. DIVING MEDICINE. *New England J. Med.*, Jan. 1957, 256(3), 120-131. (USN Experimental Diving Unit, Naval Gun Factory, Washington, D.C.).

10,232

The author presents an extensive description of recent developments and contemporary problems in diving medicine. The material is presented under the following five major aspects: (1) the physical condition of the diver (e.g., obesity, diabetes, otitis, and so forth); (2) environmental factors (e.g., effects of pressure, nitrogen narcosis, oxygen poison, decompression sickness and so forth); (3) miscellaneous accidents and conditions (drowning, anoxia, overexertion, cold, and so forth); (4) recognition and treatment of diving accidents (e.g., barotrauma, conditions requiring recompression, and so forth); and (5) preventive measures (e.g., "buddy system" in "scuba" diving, and so forth).

McFarland, R.A., & Moore, R.C. HUMAN FACTORS IN HIGHWAY SAFETY. *New England J. Med.*, April 1957, 256(17), 792-799. (Harvard School of Public Health).

10,233

This is the first of a series of three articles (see 10,234, 10,235) which present an extensive review and evaluation of research on the role of human factors in highway safety. In this article the discussion concerns data on the following: the accident repeater, characteristics of drivers as related to accidents, and the influence of fatigue, alcohol consumption, emotional stress, drugs and medications upon driving performance. A definition of the epidemiologic approach to accident prevention is also included.

T. G. I. R 27

10,234

McFarland, R.A. & Moore, R.C. HUMAN FACTORS IN HIGHWAY SAFETY. A REVIEW AND EVALUATION. *New England J. Med.*, May 1957, 256(18), 837-845. (Harvard School of Public Health, Boston, Mass.).

10,234

This is the second of a series of three articles (see 10,233, 10,235) on the role of human factors in highway safety. In this article the authors review and evaluate the research pertinent to the following: the development of driving ability criteria, the establishment of minimal physical standards for licensing, the role of physiological deficits in accidents, the role of driver training in accident reduction and the improvement of safety through the design of equipment with regard to human factors, i.e., human engineering. Within this latter category discussion centers on the design of controls, instruments, and visual displays and on the general anthropometric factors involved in the design of automotive equipment.

McFarland, R.A., & Moore, R.C. HUMAN FACTORS IN HIGHWAY SAFETY. A REVIEW AND EVALUATION. *New England J. Med.*, May 1957, 256(19), 890-897. (Harvard School of Public Health).

10,235

This is the concluding article of a series of three (see 10,234, 10,233) on the role of human factors in highway safety. The research data reviewed and evaluated in this article concerns the aspects of control of physical variables which influence the driver and the driver-environment interrelations in highway safety. Under the former category the following are included: temperature, humidity, ventilation, carbon monoxide, noise, vibration, and impact forces. The driver-environment relation is discussed in terms of environmental influence on visibility, the effects of weather, the role of the social environment, the design of highways, and traffic engineering with regard to human factors. A summary statement based on the series of articles is included.

10,237

Hill, R.V. THE HYPERBOLAS OF ACCOMMODATION AND CONVERGENCE. *A.M.A. Arch. Ophthalmol.*, Feb. 1957, 57(2), 259-265. (Dept. of Ophthalmology, University of Oregon Medical School).

10,237

The author presents a mathematical analysis of accommodation and convergence with regard to their normal functions and their interrelationships. Utilizing the prism diopter, the parametric variable and focal distance of each function are analyzed mathematically. Certain mathematical, physiologic, and clinical advantages are discussed.

G. R 3

10,238

Alpern, M. THE POSITION OF THE EYES DURING PRISM VERGENCE. *AMA Arch. Ophthalmol.*, March 1957, 57(3), 345-353. (University of Michigan).

10,238

Two experiments are reported in this study of the position of the eyes during prism vergence. In the first, horizontal movements were electrically recorded when base-in and base-out prisms were alternately presented and withdrawn before one eye. The second experiment was designed to assess the effects of presenting a prism and then occluding the eye upon the perception of Maxwell's spot. The results are presented and discussed in terms of their implications for the explanation of perceptual distortions occurring during prism vergence tests.

Breinin, G.M. QUANTITATION OF EXTRAOCULAR MUSCLE INNERVATION. *A.M.A. Arch. Ophthalmol.*, May 1957, 57(5), 644-650. (Dept. of Ophthalmology, New York University Post-graduate School of Medicine).

10,239

The author describes an instrument designed to integrate electromyographic potentials and thus provide a technique for quantitative evaluation of innervation in ocular motility. A full wave integrator and differentiator are combined in this instrument. The value is demonstrated by the presentation of the results obtained with its application to studies of kinesiology. Also included are results obtained in measuring lens-induced innervation and in the assessment of the effects of drugs on extraocular muscle innervation.

Gunkel, R.D., & Bornschein, H. AUTOMATIC INTENSITY CONTROL IN TESTING DARK ADAPTATION. *AMA Arch. Ophthalmol.*, May 1957, 57(5), 681-686. (National Institute of Neurological Diseases and Blindness, Bethesda, Md.).

10,240

The authors describe an automatic device designed to operate the intensity control of the Goldmann-Weekers adapter and thus provide better standardization of the test and a reduction of examination time. Following a definition of the primary technique which the method utilizes, a statistical comparison of results obtained with conventional and automatic methods is presented and discussed in terms of the relative advantages of the automatic method.

Hain, Y., & Graham, C.H. SPECTRAL LUMINOSITY CURVES FOR PROTANOPIC, DEUTERANOPIC, AND NORMAL SUBJECTS. *Proc. Nat. Acad. Sci. USA*, 1957, 43, 1011-1019. (Dept. of Psychology, Columbia University).

10,242

This study was designed to evaluate the cone sensitivity of deuteranopes as compared to normals and to define similar threshold luminosity data for protanopes. Utilizing the Ishihara and Stilling plates, the Hecht-Schlaer anomaloscope, and a modified Helmholtz color mixer, five protanopes, six deuteranopes, and seven normal subjects were defined. Spectral luminosity curves were plotted for each of the subjects. The results are presented in the form of log sensitivity curves as a function of wave length for each of the subjects and the average log sensitivity curves for each of the groups. Relative loss of luminosity in red and green by color blind subjects is discussed.

T. G. R 13

10,243

This study was designed to assess the effects of anxiety on perceptual functioning. Nineteen anxiety-prone patients were tested for accuracy and speed of size discrimination over a four-day period during which stress interviews were conducted. Eighteen normal subjects served as a control by taking the same perceptual test (the Area Judgment Test). Each of the experimental subjects was tested both prior to and following the stress interview. The resultant scores are compared with regard to those of the control subjects and in terms of pre- versus post-stress scores throughout the experiment. The relation between accuracy and decision time is discussed along with the general effects of anxiety on perceptual functioning.

Glorig, A. SOME MEDICAL IMPLICATIONS OF THE 1954 WISCONSIN STATE FAIR HEARING SURVEY. *Trans. Amer. Acad. Ophthalm. & Otolaryng.*, March-April 1957, 61(2), 160-171. (Research Center, Subcommittee on Noise in Industry, Los Angeles, Calif.).

10,244

To evaluate the significance of the relation between various items in the medical histories used to diagnose otologic disease and actual hearing loss reflected in measured auditory thresholds, data on 3500 persons participating in a hearing survey at the 1954 Wisconsin State Fair were statistically analyzed. The data consisted of a medical history and otologic examination, a personal history, a non-medical history, and auditory tests consisting of air conduction and speech reception threshold tests. Degree of hearing loss reflected in the auditory tests is evaluated statistically with regard to its relation to (1) subjective report of otologic disorder, (2) subjective report of familial hearing loss, and (3) evidence of disease of external ear. The validity of these three indices of hearing loss is discussed. T. G. R 2

Spaeth, E.B. ESTIMATION OF LOSS OF VISUAL EFFICIENCY. *Trans. Amer. Acad. Ophthalm. & Otolaryng.*, Sept.-Oct. 1957, 61(5), 592-597.

10,245

The author presents a discussion of the revisions of the American Medical Association's publication "Appraisal of Loss of Visual Efficiency" presented by a committee of the Council on Industrial Health. A brief history of the need for such revisions is followed by a discussion of the legal and methodological implications of the proposed methods of assessing loss of visual efficiency. Data are presented to illustrate some of the diagnostic interrelationships of the criteria offered in this revision.

10,246

McFarland, R.A. THE ROLE OF HUMAN FACTORS IN ACCIDENTAL TRAUMA. *Amer. J. Med. Sci.*, July 1957, 234(1), 1-27. (Harvard School of Public Health).

10,246

Three primary aspects are emphasized in this discussion of the role of human factors in accidental trauma: (1) the role of preventive medicine in accident prevention; (2) human factors as primary causal agents in accidents; and (3) the role of the medical officer in accident control and prevention. The epidemiological approach to accident investigation is defined and representative data generated by utilizing this approach are presented for industrial, air, and motor vehicular accidents. The interrelations of human and environmental factors are defined and their application by human engineering in the control and prevention of accidents is exemplified.

Benjamin, F.B. THE EFFECT OF PAIN ON PERFORMANCE. US Armed Forces Med. J., March 1957, 8(3), 332-345. (Aviation Medical Acceleration Lab., NADC, Johnsville, Penn.).

10,247

In this investigation of the effects of pain on performance, 25 subjects, each serving as his own control, were required to perform a series of mental, memory, time perception, muscular coordination, and reaction time tests under normal and pain conditions. Three methods of inducing pain were used: (1) a Styrofoam helmet in which water pressure was controlled to yield pain of approximately 1 dol, (2) a pressure cuff yielding 2-3 dols, and (3) ice water to produce 4 dols. Reflex activity, pulse rate, respiratory function, and work performance on an ergometer bicycle were determined. The results are presented and discussed in terms of change in rate and accuracy of performance as a function of degree of pain. T. R 21

10,248

Johnson, L.C. ATTITUDES AND MOTIVATIONS OF TEST PILOTS. US Armed Forces Med. J., May 1957, 8(5), 718-724. (Dept. of Psychiatry & Neurology, Washington University School of Medicine).

10,248

This explanatory study was designed to assess the attitudes and motivations of test pilots and thus afford more accurate selection and performance criteria. An unstructured open-ended interview was conducted with 12 randomly selected test pilots and an additional 21 pilots completed an attitude-motivation questionnaire. The results of both techniques are presented and discussed in terms of the predominant motivations found to exist among both groups of pilots and their functional values for individuals performing tasks of this nature. G. I. R 4

Lawton, W.H. PHYSIOLOGICAL INVESTIGATIONS IN THE FLYING SAFETY PROGRAM OF THE FLYING TRAINING AIR FORCE. US Armed Forces Med. J., July 1957, 8(7), 937-944. (Flying Training Air Force, Waco, Tex.).

10,249

The author discusses the physiological problems being investigated in a program of research designed to improve flying safety. The practice effects of three specific applications of the research findings (i.e., use of a Physiological Near Accident Report, education regarding hyperventilation, and a program to improve pilot eating habits) are noted. Problems yet to be solved are outlined. T. R 11

10,250

Wilber, C.G. WATER REQUIREMENTS OF MAN. US Armed Forces Med. J., Aug. 1957, 8(8), 1121-1130. (USA Chemical Center, Md.).

10,250

The author presents a summary, based on experimental findings, of the water requirements of man under various environmental conditions including the desert, the tropics and cold climates. Also discussed are the following general topics: the average water exchange in man, the role of water in temperature regulation, survival at sea, and others. T. R 35

10,251

Burke, E.L., Glenn, C.G., & Wales, J.F. RIFLE-SLING PALSY IN MARINE CORPS RECRUITS. US Armed Forces Med. J., Aug. 1957, 8(8), 1189-1194. (US Naval Hospital, San Diego, Calif.).

10,251

This article presents the results of a study of 15 Marine Corps recruits who were hospitalized with rifle-sling palsy. An additional screening of 1213 recruits completing the rifle-training course was conducted to assess degree of similar nerve deficit. Incidence, duration, and severity of disorders are discussed with regard to the implications for redesign of the "tourniquet" type rifle sling. T. I. R 2

10,252

Ogle, D.C. MAN IN A SPACE VEHICLE. US Armed Forces Med. J., Nov. 1957, 8(8), 1561-1570. (Surgeon General of the AF).

10,252

The author presents a general discussion of the problems of space flight from the points of view of aviation medicine and human engineering. Among the problems defined as facing man in a space vehicle, the following are included: acclimatization to space, thermal stress, psychological isolation and boredom, cosmic radiation, and so forth. Also discussed is the process of selection and adaptation of personnel for space flight. R 10

10,254

Kornetsky, C., Humphries, O., & Everts, E.V. COMPARISON OF PSYCHOLOGICAL EFFECTS OF CERTAIN CENTRALLY ACTING DRUGS IN MAN. AMA Arch. Neurol. & Psychiat., March 1957, 77(3), 318-325. (National Institute of Mental Health, Bethesda, Md.).

10,254

This study was designed to assess the effects of lysergic acid diethylamide (LSD), meprobamate, scopolamine, and chlorpromazine (all centrally acting drugs) on the performance of a variety of intellectual, motor, and perceptual tasks. Ten subjects, six male and four female, ranging in age between 18 and 23 years were required to perform the various tasks 75 minutes after injection of the particular drug. Analysis of variance of the resultant data was utilized to indicate the significant effects of the various drugs on the particular types of psychological behavior utilized in this study. Conclusions are drawn concerning the relative effects of each drug on psychological performance. T. G. R 24

10,255

Tindall, G.T., & Kunkle, E.C. PAIN-SPOT DENSITIES IN HUMAN SKIN. AMA Arch. Neurol. & Psychiat., June 1957, 77(6), 605-610. (Dept. of Medicine, Duke University School of Medicine).

10,255

This study was designed to systematically evaluate the phenomenon of pain-spot densities in human skin with emphasis upon the nature and degree of individual differences. Utilizing a two by two centimeter rubber stamp containing spaced squares and a calibrated needle algometer, 150 tests were made with a total of 21 subjects. While the principle area of testing was the dorsum of the hand, the forehead skin and dorsum of the foot were also tested in six of the subjects. The results are presented and discussed in terms of the interindividual variations in pain-spot densities as indicative of the range and variations in pain sensitivity. T. G. I. R 12

10,256

Kulowski, J. INTRODUCTION: PREVENTION OF ACCIDENTS. Clinical Orthopaedics, Spring, 1957, 9, 251-255.

10,256

This is the introductory article of a series of articles on motorist injuries and safety (see 10,257, 10,258, 10,259). The author directs his discussion toward the problems of accident prevention with emphasis upon the role of traffic law enforcement and traffic engineering. A bibliography and source list of agencies offering safety information is included. R 77

10,257

Vey, A.H. DRIVER PROFICIENCY. Clinical Orthopaedics, Spring 1957, 9, 256-259. (Simpson & Curtin, Transportation Engineers, Philadelphia, Penn.).

10,257

This is one of a series of articles (see 10,256, 10,258, 10,259) on motor vehicle safety. In this article driver proficiency as a problem in safety engineering is discussed in terms of both the environmental and motivational factors which must be considered in defining effective engineering design. The need for research on this problem is emphasized.

10,258
McFarland, R.A. HUMAN ENGINEERING AND AUTO-MOBILE SAFETY. Clinical Orthopaedics, Spring 1957, 9, 260-276. (Harvard School of Public Health).

10,259

This is one of a series of articles on motor vehicle safety (see 10,256, 10,257, 10,259). In this article, pertinent research data is presented to exemplify the role of human engineering in motor vehicle safety. Among the various aspects treated the following are included: the application of anthropometry to motor vehicle design, the design of controls and instruments as a function of human capabilities and limitations, the role and control of environmental factors (e.g., noise, temperature, vibration, etc.), and so forth. Conclusions are drawn concerning the type of research necessary for further progress in safety design.

10,259

White, A.J. THE ROLE OF SAFETY BELTS IN THE MOTORIST'S SAFETY. Clinical Orthopaedics, Spring 1957, 9, 317-330. (Motor Vehicle Research, Inc., So. Lee, N.H.).

10,259

This is one of a series of articles on motor vehicle safety (see 10,256, 10,257, 10,258). The role of the safety belt is examined in this article. The relative value of the belt as a safety device is discussed within the following frames of reference: design considerations kinematic behavior of passengers during a crash, and the contribution of the belt itself to various types of injuries. Wherever relevant the results of field investigations are brought to bear on the factors under consideration.

10,260

MacLeod, R.B. IMPACT OF DIET ON BEHAVIOR. Am. J. Clin. Nutrition, March-April 1957, 5(2), 107-108. (Cornell University).

10,260

This is a brief introductory article to a symposium on the relation between diet and behavior (see 10,261-10,267). The general problems to be discussed are outlined along with a brief historical statement of the general problem of the relation between diet and man's psychological and physiological state.

10,261

Brozek, J., & Guetzkow, H. PSYCHOLOGIC EFFECTS OF THIAMINE RESTRICTION AND DEPRIVATION IN NORMAL YOUNG MEN. Amer. J. Clin. Nutrition, March-April 1957, 5(2), 109-120. (University of Minnesota).

10,261

This is one of a series of articles (see 10,261 and 10,267) on the relation between diet and behavior. In this article an investigation of the psychological effects of thiamine restriction and deprivation upon the psychological and physiological state of the human organism is reported. Following a period of one month, during which dietary intake was controlled, ten subjects were required to perform exercise and physical fitness tasks through successive experimental periods of thiamine restriction, acute deprivation, and supplementation. Personality tests, intelligence scales, and tests of sensory function were administered at appropriate periods. Effects of the dietary stress are analyzed both in terms of the specific and gross changes in the subject's psychological and physiological functioning. T. G. R 24

10,262

Young, P.T. PSYCHOLOGIC FACTORS REGULATING THE FEEDING PROCESS. Am. J. Clin. Nutrition, March-April 1957, 5(2), 154-161. (University of Illinois).

10,262

This is one of a series of articles (see 10,261-10,267) presented at a symposium on the relation between diet and behavior. In this article the author presents a review and discussion of the literature pertinent to the psychological factors believed to exert a regulating effect on the feeding process. Included in this discussion are the following topics: the differentiation between taste and post-ingestion regulators of intake, the relation between bodily needs and feeding habits, palatability and appetite, food preference and body chemistry and others.

10,263

Siegel, P.S. THE REPETITIVE ELEMENT IN THE DIET. Am. J. Clin. Nutrition, March-April 1957, 5(2), 162-164. (University of Alabama).

10,263

This is one of a series of articles (see 10,261-10,267) presented at a symposium on the relation between diet and behavior. In this article the author presents a summary of the results of a series of studies on eating monotony. The basic study involved the presentation of two alternate daily menus to 79 subjects for a period of 22 days. The findings of this and similar studies are discussed with regard to the effects of repetitive diet on palatability, amount of food consumption, and so forth. The relation of the monotony effect to learning theory is discussed.

Pilgrim, F.J. THE COMPONENTS OF FOOD ACCEPTANCE AND THEIR MEASUREMENT. Amer. J. Clin. Nutrition, March-April 1957, 5(2), 171-175. (Quartermaster Food & Container Institute for the Armed Forces, Chicago, Ill.).

10,265

This is one of a series of articles (see 10,261-10,267) presented at a symposium on the relation between diet and behavior. This article is concerned with the problem of predicting the acceptance of foods. The author presents the relevant research data and a discussion of three primary aspects of the problem: (1) the establishment of criteria of food values, (2) the definition of the pertinent components of the human's behavior toward food, and (3) the formulation of adequate methods of assessing these components. Many of the problems encountered in studies attempting to assess and predict food behavior are outlined.

10,266

This is one of a series of articles (see 10,261-10,267) presented at a symposium on the relation between behavior and diet. This article reports three studies designed to assess the socio-psychological acceptability of a survival ration. Utilizing a total of 1152 subjects, an emergency ration, "Ration, Special Survival, RS-1" containing pemican, a meat food product of low acceptability rating, was presented under simulated survival situations to each of three experimental groups. Methods of pemican preparation were varied. The results are presented and discussed in terms of the relation of pemican acceptability to a variety of psychological and sociological factors, e.g., motivation, early experience, and so forth.

Booyens, J., & McCance, R.A. INDIVIDUAL VARIATIONS IN EXPENDITURE OF ENERGY. *The Lancet*, Feb. 1957, 1, 225-229. (University of Cambridge).

10,268

The research reported in this article was designed to assess the existence of individual variations in the expenditure of energy and to discover the causal factors underlying such variations. A trial investigation was conducted in which the metabolic rates of 36 male and female subjects were determined while they were in the basal state. Six subjects manifesting energy expenditures at the extremes of the normal range were selected and studied in detail for a period of from seven to 14 days. Caloric intake and energy expenditure were assessed while the subjects performed a variety of tasks. Results are discussed in terms of the validity of contemporary definition of normal basal rates and the potential causal factors in variations as a function of weight, type of activity, and so forth. McFarland, R.A. PSYCHOLOGICAL AND PSYCHIATRIC ASPECTS OF HIGHWAY SAFETY. *J. Amer. Med. Assoc.*, Jan. 1957, 163(4), 233-237. (Harvard School of Public Health).

10,274

The author presents a review and evaluation of studies concerned with the role of the human factors in accident causation. Data are presented and discussed in relation to the methodological approach to the problem, the attitudes and personal characteristics of accident repeaters, and the influence of age, fatigue, and automotive equipment design on highway safety. The role of the physician in accident prevention is defined.

Sutton, J. LET'S ELIMINATE A STATISTICAL STIGMA "PILOT ERROR". Flying, Feb. 1958, 62(2), 28-29, 80, 82. (Human Engineering Group, Convair-San Diego, Calif.).

10,278
The author discusses the concept of pilot error in terms of its definition application, and relative role as a causative factor in accidents. Techniques for minimizing pilot error are outlined and refer primarily to training and design of the aircraft and its controls. Certain design criteria are enumerated and discussed.

Geyer, B.H., & Johnson, C.W. MEMORY IN MAN AND MACHINES. General Electric Rev., 1957, 60(2), 29-33.

10,279
This article presents an extensive discussion of the memory function (the storage of information) in man and machines. Information is defined in terms of "bits" and then a comparison is made of the relative efficiency of the human brain versus electronic devices in the storage and integration of such information. Various storage devices are described and the future requirements of such devices discussed.

10,281
Snow, W.B. AUDITORY PERSPECTIVE. Audio, 1957, 41(8), 20-21, 45-46.

10,281
In this discussion of auditory perspective, the author presents a quantitative evaluation of two- and three-channel stereo systems. Included are evaluations of various microphones, loudspeakers, and their combinations. Angular and depth localization reverberation differences of loudness in the two ears, and similar topics are treated in the discussion.

Fletcher, H., & Munson, W.A. LOUDNESS, ITS DEFINITION, MEASUREMENT AND CALCULATION. PART I. Audio, 1957, 41(11), 53-54, 56, 58.

10,284
This is the first of a two part article on the definition, measurement and calculation of loudness. In this article the authors treat the following aspects of loudness: sound intensity, reference intensity, loudness level, intensity level, reference tone and the manner of listening to sound. A formulation of the empirical theory for calculating the loudness level of a steady complex tone is presented and discussed in detail.

Fletcher, H., & Munson, W.A. LOUDNESS, ITS DEFINITION, MEASUREMENT AND CALCULATION. PART II. Audio, 1957, 41(12), 40, 42, 44, 46, 48, 83.

10,285
This is the second of a two part article (see 10,284) on the definition, measurement and calculation of loudness. In this section the authors treat the field calibration of telephone receivers, the determination of loudness level contours, and the calculation of various aspects of loudness under varied conditions (e.g., masking, etc.). Tables are presented to illustrate among other aspects, the differential between calculated and observed fractional loudness.

Pierce, J.R., & Earlin, J.E. INFORMATION RATE OF A HUMAN CHANNEL. Proc. I.R.E., 1957, 45(3), p.368. (Bell Telephone Labs., Inc., Murray Hill, N.J.).

10,290

This is a brief article in which the authors present the results of research pertinent to the information rate of the human as a channel of communication. Reading rates expressed as bits per second, are presented in tabular form for the following varied conditions: number of syllables per word, form of the message (e.g., prose repetitive phrases, etc.), and reading while simultaneously tracking. Man's limitations as a communication channel are discussed briefly. G. R 5

10,291

Hardy, H.C. A GUIDE TO OFFICE ACOUSTICS. Architect. Record, 1957, 121(2), 235-240.

10,291

This article is concerned with the design of the environment to provide optimal acoustical conditions. Criteria are offered with regard to the definition of acoustical acceptance within the office environment; they pertain to the degree of noise which is acceptable, the extrinsic and intrinsic factors which contribute noise to this type of environment, the application of sound-proofing materials, the arrangement of office equipment, and the definition of adequate acoustics. Also offered, in tabular form, are data reflecting the differential loudness of various human environments. T. G. I.

Suckling, E.E., Koenig, E.H., Hoffman, B.F., & Brooks, C.M.C. THE PHYSIOLOGICAL EFFECTS OF SLEEPING ON HARD OR SOFT BEDS. Hum. Biol., 1957, 29(3), 274-288. (Psychology Dept., State University of New York).

10,292

To determine whether there is variation in certain physiological reactions recorded during sleep which can be related to type of supporting surface of the sleeper, four subjects were observed for a total of 90 sleep nights. The EEG (electro-encephalogram), heart rate, body movement, and skin temperature were recorded from each subject as he slept on a soft surface (feather bed) medium surface (innerspring mattress) or a hard surface (board covered by thin carpet). Sound stimuli were used at intervals during the EEG recording to evaluate depth of sleep. These data were analyzed for relationships between them and the supporting surfaces. Individual preferences were treated. T. G. R 6

10,293

Morrell, D.J. DOMINANCE OF EYE AND HAND. Hum. Biol., 1957, 29(4), 314-327. (University of Minnesota).

10,293

To investigate various aspects of eye and hand dominance, 123 subjects were tested for dominant eye and dominant hand (needle threading, throwing, striking match, writing, and yicking). These data were analyzed by correlational methods for relationships between dominant eye and hand. In addition, data on handedness was obtained, through correspondence, on 103 sets of parents and children and studied for hereditary inferences. The findings are compared with similar studies in the literature. T. R 34

10,294

McFarland, R.A. HUMAN LIMITATIONS AND VEHICLE DESIGN. Ergonomics, 1957, 1(1), 5-20. (Harvard School of Public Health).

10,294

This paper reviews an extensive research project on human variables in the design and operation of vehicular equipment, with particular reference to efficiency and safety. The various procedures used to collect and evaluate the necessary data are discussed and the following studies are described: size range of professional drivers, evaluation of trucks and buses, operational studies of driver activities (activities and work-load analysis, operating proficiency, eye-movements in relation to displays, and critical incidents analysis), and studies on visibility and design of windshields (man's area of vision, visibility through tinted windshields at low illumination). 10,295

Broadbent, D.E. EFFECTS OF NOISES OF HIGH AND LOW FREQUENCY ON BEHAVIOR. Ergonomics, 1957, 1(1), 21-29. (Applied Psychology Unit, Medical Research Council, Cambridge, England).

10,295

To investigate the effects of noise frequencies on performance: (1) Three groups of eight subjects worked for two 25-minute sessions in noise (intensities of 60, 90, and 100 decibels respectively) at a five-choice serial reaction task. During one session the noise was restricted to frequencies above 2000 cycles per second, and during the other frequencies below. Error data were analyzed for effects of frequencies and intensities. (2) Reaction times to these same noise frequencies at the lowest and highest intensity levels were measured on 26 subjects. The results from both experiments were analyzed in terms of the manner in which noise affects performance. Practical implications are discussed. T. R 15

10,296

Scholz, H. CHANGING PHYSICAL DEMANDS OF FOUNDRY WORKERS IN THE PRODUCTION OF MEDIUM WEIGHT CASTINGS. Ergonomics, 1957, 1(1), 30-38. (Max-Planck-Institut fur Arbeitsphysiologie, Dortmund, Germany).

10,296

This paper reviews extensive investigations in evaluating the degree of working stress in seven foundries producing medium weight castings. The methods used to gather and evaluate the data are listed: time studies, work intensity, extent of muscular fatigue, measurement of bodily performance capacity and measurements of noise and heat stress. Summaries of the results concerning physical demands in mechanized and non-mechanized foundries are discussed. Examples are given in which the findings are used as a basis for advice on methods of rationalization and mechanization for increased production at reasonable work loads for the worker. G. I. R 11

10,297

Collins, J.B., & Hopkinson, R.G. INTERMITTENT LIGHT STIMULATION AND FLICKER SENSATION. Ergonomics, 1957, 1(1), 61-76. (Dept. of Scientific and Industrial Research, Building Research Station, London, England).

10,297

To study the variability of frequency of intermittent light stimulus required for constant criteria of flicker discomfort, flicker judgments were obtained from 20 subjects. In one series of experiments the whole visual field was stimulated, in another a field of approximately 20 by 30 degrees. Four criteria of flicker sensation were used: just perceptible, just obvious, just uncomfortable, and just intolerable. Except in a series carried out to determine adaptation to flicker the method of decreasing frequency was used. The data were analyzed for effects of size of visual field, subject variability, adaptation and frequency. The use of the data to predict degree of complaint about lighting installations is discussed. T. G. I. R 18

Karlin, J.E. CONSIDERATION OF THE USER IN TELEPHONE RE-
SEARCH. *Ergonomics*, 1957, 1(1), 77-83. (Bell Tele-
phone Labs., Inc., Murray Hill, N.J.).

10,298
This paper discusses formal preference research among
telephone users that aims to guide technical research
and development. Some general problems of methods for
investigating preferences (polling, observation, and
simulation) are discussed and illustrated with examples
obtained in the course of telephone-user research.
Principles that are felt to be fundamental and well-
established are enumerated.

10,299
Schwab, R.S. FACTORS IN FATIGUE AND STRESS IN
THE OPERATION OF HIGH-SPEED DIESEL PASSENGER
RAILWAY CARS WITH ONLY ONE DRIVER PRESENT.
Ergonomics, 1957, 1(1), 84-90. (Harvard Med-
ical School).

10,299
This paper presents a case study of a railroad en-
gineer, age 74, who had on several occasions forgotten
to stop his train at certain stations and had had one or
two minor accidents. In addition to the medical examina-
tion, an observer accompanied the engineer on one of his
runs (a 200-mile trip) in a high-speed diesel car of
which he was the sole operator. Observations of factors
which increased both fatigue and stress are noted and
discussed. Recommendations for remedial action are
included.

Quinn, J.D. DEVELOPMENTS IN THE ANALYSIS OF
MAINTENANCE PROBLEMS. *Mech. Engng.*, 1957,
79(10), 931-933. (E.I. du Pont de Nemours &
Co., Wilmington, Del.).

10,300
This paper discusses available means for accumulating
adequate data on equipment component performance which
will permit systematic analysis of the maintenance prob-
lems. The use of equipment to facilitate correction of
these problems is also discussed. Accounting methods,
equipment-history cards, and adaptation of recording
equipment developed primarily for production control are
described in relation to data gathering. Types of data
analysis for proper diagnosis of difficulties as well as
for evaluation of improvements being considered and,
later, to establish effects of improvements are detailed.

10,301
Mechanical Engineering. MAN AND HIS THERMAL ENVIRONMENTS.
Mech. Engng., Nov. 1957, 79(11), 1029-1036.

10,301
This report presents condensed versions of six papers
contributed by the Heat Transfer Division and presented
at the Semi-Annual Meeting, San Francisco in June 1957
of the American Society of Mechanical Engineers. All the
papers relate to a new design factor confronting engi-
neers - human tolerance to heat or cold. Topics and
authors are: factors in heat stress (Alan E. Woodcock),
the body as a heat exchanger (L. P. Herrington), reaction
to extreme heat (Konrad Bueltner), reaction to extreme
cold (P. P. Meehan), exposure to infrared radiation (E.
Bendler), and histologic studies of burns (J. R. Hinshaw).

10,302
Gould, A.F. MATERIALS IN MOTION. *Mech.
Engng.*, 1957, 79(12), 1116-1118. (Lough
University).

10,302
This paper reviews new analytical methods that are
primarily associated with operations research but also
could prove to be useful for the materials-handling engi-
neer. These methods are: (1) work sampling, (2) waiting
line, or queueing theory, and (3) linear programming.
Applications to the solutions of shop problems, including
materials handling, are given to illustrate possible
uses.

Wilson, R.B. DESIGNING EQUIPMENT FOR RELIABILITY. *Mech.
Engng.*, 1957, 79(12), 1142-1144. (General Dynamics Corp.,
San Diego, Calif.).

10,303
Reliability concepts as applied to equipment design
are defined and discussed. Procedures for solving re-
liability problems are outlined beginning with systems re-
quirements, environmental factors to which the equipment
may be subjected, design stage, testing or "search for
critical weakness", and analyses of failures. A list of
design check-points and a form for reporting failures or
malfunctions are given.

10,304
Massey, B.H. & Chaudet, M.L. EFFECTS OF SYSTEMATIC,
HEAVY RESISTIVE EXERCISE ON RANGE OF JOINT MOVEMENTS IN
YOUNG MALE ADULTS. *Res. Quart.*, 1956, 27(1), 41-51.
(University of Maryland, College Park, Md.).

10,304
To investigate the effects of systematic, heavy resis-
tive exercise on the range of joint movements, two
matched groups of 13 young, male subjects were studied.
One group was trained in weight-lifting for six and one-
half months; the second group participated in general
physical education activity. Measurement of height,
weight, girths, joint movement (elbow, shoulder, knee,
and hip) and strength was conducted prior to, midway in,
and at the end of training. The data were analyzed for
differences due to weight-training program. The find-
ings are discussed in relation to "muscle-boundness"
believed to be induced by such activities as weight
training.

10,305
Vanderbie, J.H. METABOLIC COST OF SIMULATED
PULLING ON THE TREADMILL. *Res. Quart.*, 1956,
27(1), 111-116. (USA Quartermaster Research
and Development Center, Hattick, Mass.).

10,305
To investigate physiological changes in the body pro-
duced by sled-pulling, 12 men were studied on a simulat-
ed sled-pulling task before and after going a period of
work in Fort Churchill, Canada. Metabolic rates and
pulse responses to an exercise consisting of pulling
against a drag of 17.5 pounds while walking on a tread-
mill (2.5 and 3.5 miles per hour, with and without a
44-pound load) were measured. Metabolic rates, expressed
as Calories per square meter of body surface per hour
(Cal/M²/hr), and pulse rates were analyzed for effects of
the pull under the various speed and load conditions.
The possible applications of these experimental procedures
in designed experiments, clothing tests, and progressive
conditioning are discussed.

10,306
Clarke, H.H. RECENT ADVANCES IN MEASUREMENT AND UNDER-
STANDING OF VOLITIONAL STRENGTH. *Res. Quart.*, 1956, 27
(3), 263-275. (University of Oregon, Eugene, Ore.).

10,306
This report presents a critical discussion of some
strength measurement devices and reviews recent studies
on volitional muscular strength of the human organism.
The cable tensiometer, Newmen myometer, strain gauge de-
vices, and the Kelso Mellebrandt ergograph are described
briefly and their use indicated. Body position and
strength application, the relationship of strength to
endurance, training and various anthropometric measures,
and strength-decrement fatigue patterns are discussed.

10,307
Rasch, P. EFFECT OF POSITION OF FOREARM ON
STRENGTH OF ELBOW FLEXION. *Res. Quart.*, 1956,
27(3), 333-337. (Los Angeles County Osteo-
pathic Hospital, Los Angeles, Calif.).

10,307
To determine the effect of the position of the fore-
arm on the strength of elbow flexors with the subject
in the erect position normally assumed for manual labor
or operation of control panels, 24 adult male subjects
were tested. Strain gauge dynamometer measurements of
the amount of elbow flexor tension which could be exerted
with the forearm in the supine position, the midposition
and the prone position. The strength scores in pounds
were analyzed for differences due to forearm position.

Hunsicker, P., & Greay, G. STUDIES IN HUMAN STRENGTH. Res. Quart., 1957, 28(2), 109-122. (University of Michigan).

10,308
This paper reviews investigations in human strength and is primarily concerned with the area of strength testing. The results of such tests and relationships between strength and age, skeletal position, body build, and exercise are presented. Some theoretical considerations regarding strength are dealt with and gaps in present knowledge are indicated.
R 89

10,309
Slater-Hammel, A.T. MEASUREMENT OF KINESTHETIC PERCEPTION OF MUSCULAR FORCE WITH MUSCLE POTENTIAL CHANGES. Res. Quart., 1957, 28(2), 153-159. (Indiana University, Bloomington, Ind.).

10,309
To explore the usefulness of muscle potential measurements in the study of kinesthetic perception, forty subjects (twenty male and female with half of each group physical education majors) were given practice in contracting the triceps brachii at an intensity necessary to generate muscle potentials of approximately 150 microvolts. An electronic voltmeter was used to provide subject with information on his muscular force. Following practice, each subject attempted to reproduce the same muscular force without the voltmeter for a series of trials. Performance (error data) was analyzed for reliability of test methods and for differences due to sex and training in physical exercise.

10,310
Ulrich, Celeste & Burke, R. EFFECTS OF MOTIVATIONAL STRESS UPON PHYSICAL PERFORMANCE. Res. Quart., 1957, 28(4), 403-412. (Women's College, University of North Carolina, Chapel Hill, N.C. & Occidental College, Los Angeles, Calif.).

10,310
To investigate the effects of "encouraging" reports of success and "discouraging" reports of failure on work output, mechanical efficiency, and associated cardio-respiratory functions, 18 subjects (nine men and nine women) were studied. Three one-minute trials on a frictional bicycle ergometer were given: (1) base trial with knowledge of results given verbally, (2) buzzer, signalling poorer performance than on base trial, and (3) bell, signalling better performance. Half the subjects were assigned to bell-buzzer and half to buzzer-bell order. Pulse rate, respiratory rate, oxygen consumption, ergometer work (calories per hour), and gross mechanical efficiency (a derived measure) were analyzed for differences due to motivating conditions and sex.

Hunter, Gertrude S. SOUND REDUCTION PROGRAM FOR CONVAIR-LINER 340. Noise Control, 1956, 2(1), 27-32. (Engng. Dept., Convair Co., San Diego, Calif.).

10,312
A test model Convair-Liner 340 with sound modifications, designed to provide a quiet passenger cabin, is described. The design criteria based upon two groups of octave bands (S, or arithmetic average of noise levels in three bands covering range of frequencies important to speech communication and A, or arithmetic average of two bands at lower end of frequency spectrum) and initial sound level measurements are discussed. Three major phases of the program are presented: (1) analyses of existing noise levels and specification of noise reduction measures, (2) implementation, and (3) evaluation. Procedures and results obtained are described and presented graphically.

10,323

Berger, R.L. & Ackerman, E. THE PENN STATE ANECHOIC CHAMBER. Noise Control, Sept. 1956, 2(5), 16-21. (Pennsylvania State University, University Park, Penn.).

10,323

The design, construction, and calibration of an anechoic chamber are presented in detail. The noise levels in the chamber are such (per cycle level at least ten decibels below the MAF - minimum audible field - curve) that no masking of hearing due to noise should occur. Free-field studies on electro-acoustic equipment can also be made in the chamber. The overall sound level in the frequency band of 20 cycles per second to ten kilocycles of approximately 20 decibels is sufficiently low to be negligible for all acoustical experiments.
