ABSTRACT

Neutron cross-section sets have been prepared for N, O, Al, Si, Fe, D, and Be for neutron energies from 0.037 eV to 18 MeV. The cross sections tabulated include the total, elastic, inelastic, (n,2n), and cross sections for charged particle emission. Information is also given on the angular distribution of elastically scattered neutrons and on the energy distribution of neutrons and γ-rays following nonelastic reactions.

INTRODUCTION

Complete sets of neutron cross-section data are presented for N, O, Al, Si, Fe, D, and Be in the energy range from 0.037 eV to 18 MeV. The cross sections of N, O, Al, Si, and Fe have been recompiled and present major revisions of our earlier reports on these elements. The cross sections of D and Be are essentially those which we reported earlier.

Data are given on the total cross section, σ_{nT}, on the elastic cross section, $\sigma_{n,n}$, on the capture cross section, $\sigma_{n,\gamma}$, and on cross sections for charged particle emission. The inelastic cross section is broken into two parts. The part that corresponds to discrete level excitation is labeled $\sigma_{n,n'}$ levels. The remaining part corresponds to the emission of a continuous neutron spectrum; this part is added to the cross section for all other neutron-producing reactions, giving a cross section which is labeled $\sigma_{n,n'}$ continuum. Values of $\sigma_{n,2n}$ are also given.

Level excitation cross sections are presented in a normalized form: the excitation of level ν is

$$\sigma_{n,n'\nu}(E) = \sigma_{n,n'}(\text{levels})(E)a_{\nu}(E)$$

with

$$\sum_{\nu=1}^{\nu_{max}} a_{\nu}(E) = 1.$$

Tables of a_ν are given.

The continuous part of the inelastic spectrum is described, when applicable, by a statistical model (B. Eisenman and F. R. Nakache, UNC-5093, p. 14ff).

The angular distribution of elastically scattered neutrons is presented in the form of an expansion in Legendre polynomials (center-of-mass system):

$$\sigma_{n,n}(E,\theta) = \frac{\sigma_{n,n}(E)}{4\pi} \sum_{\ell=0}^{L} (2\ell+1)\, f_\ell(E)\, P_\ell(\cos\,\theta),$$

where $f_0 = 1$, and L is large enough (≤ 14). Tables of f_ℓ are given.

Information is also given on γ-ray spectra following absorption and following inelastic reactions. The neutron energy range is broken into groups. The energy E_n given in the tables is the upper energy of the group; the spectrum quoted is considered as constant in that group. The γ-ray energy range is also broken into groups. The spectra have been integrated over these groups. The groups are labeled by a single energy, E_γ, which is either the energy of a predominant line in that group or the mean energy of that group.

TABLE OF CONTENTS

TABLES

FIGURES

1. NITROGEN

1.1 NEUTRON CROSS SECTIONS

1.1.1 The Total Cross Section

Over the entire range of incident neutron energies from 0.037 eV to 18 MeV the total cross section is the same as that given in our previous compilation, UNC-5002[1] (see Table 1 and Fig. 1).

Mention should be made here of very detailed measurements made at Hanford even though they are too recent to have been included in this compilation.[2] From 2 to 8 MeV these measurements are considered to be the best available at present; above 8 MeV they are suspected of being too high, and below 2 MeV the shape, but not the normalization of the data, was fixed at the time of communication (late August 1965).

1.1.2 The Elastic-Scattering Cross Section

Throughout the entire range the elastic-scattering cross section is the difference between the total cross section and the sum of the cross sections for all other reactions (see Table 1).

1.1.3 The Radiative-Capture Cross Section

The cross section for the radiative capture (n,γ) reaction is the same as in UNC-5002[1] (see Table 1). It is taken to follow the 1/v law from 0.18 barn at 0.0253 eV

to 0.08 millibarn at 0.0253 MeV. At higher energies the cross section is taken to be zero.

1.1.4 The (n,α) Cross Section

For energies below about 8 MeV the measurements of Gabbard, Bichsel, and Bonner[3] were used. At higher energies, the only measurement is the old one of Randolph.[4] We used our usual French curve art work to bring the curve through Randolph's point to 18 MeV (see Table 1).

1.1.5 The (n,d) Cross Section

Differential cross sections for the angular distribution of the deuterons from the (n,d) reaction in nitrogen are given by Chase et al.[5] The Legendre analysis code was used to integrate these to give total (n,d) cross sections at the appropriate energies. As in the case of the (n,α) reaction, the only cross section measurement is that of Randolph.[4] French curves were again used to extend the cross-section curve through Randolph's point and on to 18 MeV (see Table 1).

1.1.6 The (n,2α) Cross Section

Randolph[4] quotes a value of 15 mb for the (n, 2α) reaction in nitrogen at an incident neutron energy of 14 MeV. A curve was drawn through this point passing through zero at 11.5 MeV (see Table 1).

1.1.7 The (n,p) Cross Section

For incident neutron energies below about 1.25 MeV the values from UNC-5002 were used.[1] Between 1.25 and about 8 MeV we took the measurements of Gabbard, Bichsel, and Bonner.[3] There are no measurements of this cross section at higher energies. After some agonizing, we finally made the assumption that the (n,p) cross section should roughly parallel the (n,α) cross section and extrapolated accordingly (see Table 1).

1.1.8 The (n,t) Cross Section

Gabbard, Bichsel, and Bonner[3] have measured the cross section for neutron-initiated triton emission for neutron energies below about 8 MeV. There are no measurements at higher energies. Here we assumed that the cross section should rise similarly to the (n,d) cross section but should maintain a slowly varying sum when added to the (n,p) cross section, since competition with that reaction might be expected (see Table 1).

1.1.9 The Absorption Cross Section

The absorption cross section is equal to $\sigma_{n,\gamma} + \sigma_{n,\alpha} + \sigma_{n,d} + \sigma_{n,2\alpha} + \sigma_{n,p} + \sigma_{n,t}$. A curve is given in Fig. 2.

1.1.10 The (n,2n) Cross Section

Ashby and Catron[6] give -10.55 MeV as the Q value for the (n,2n) reaction in N^{14} and -10.84 MeV as the value in N^{15}. The latest supplement to BNL-325[7] has a graph showing measurements by nine authors of the (n,2n) cross section in N^{14} but gives no data on the reaction in N^{15}. Because of the low relative abundance of N^{15} and because of the similarity of the Q values in the two isotopes, we have used the N^{14} data to describe the (n,2n) cross section in the natural element (see Table 1).

1.1.11 The Nonelastic Cross Section

At six energies from 5 MeV to 11.6 MeV Chase et al.[5] have calculated the nonelastic cross section as the difference between their measured values of the total cross section and integrated values of their differential elastic-scattering cross section measurements. Bauer et al.[8] have similarly found a value at 14 MeV. Flerov and Talyzin[9] and Phillips, Davis, and Graves[10] have obtained nonelastic cross sections by sphere transmission measurements at neutron energies between 14 and 15 MeV. For neutron energies below about 5.5 MeV we have taken the nonelastic cross section to be the sum of the cross sections for all reactions except

elastic scattering. For higher energies we have drawn a curve guided by the measurements given above.

1.1.12 The Inelastic-Scattering Cross Section

For energies below about 5.5 MeV we have used values from UNC-5002.[1] For higher energies we have used the difference between the nonelastic cross section and the sum of all other nonelastic reactions. The sum of inelastic and (n,2n) cross sections is given in Fig. 3.

1.2 ANGULAR DISTRIBUTION OF ELASTICALLY SCATTERED NEUTRONS

For neutron energies above about 3 MeV the situation is, as usual, quite complicated. Bostrom et al.[11] have measured differential cross sections at 10 energies between 3 and 16 MeV, but with a large gap from 7 to 15 MeV. Chase et al.[5] have made measurements at seven energies between 5 and 11.6 MeV. Legendre coefficients have been derived from both sets of measurements, and the agreement between the two sets of coefficients is, to say the least, poor. Phillips[12] has measured the angular distribution at 7 MeV, and, on analysis, his data yield the same Legendre coefficients as those of Chase at the same energy. Analysis of the measurements of Bauer[8] and those of Strizlak et al.[13] gives coefficients which agree well for low values of ℓ, but the agreement deteriorates as the order of the expansion increases.

In drawing curves of f_ℓ vs energy we have used the results of Fowler and Johnson[14] for energies below 2.5 MeV, and, for higher energies, we have favored the results of Chase and of Bauer. We have also, at high energies particularly, had to avoid the Scylla and Charybdis[15] of finding, on resynthesis, either negative differential cross sections (resulting from excessively high coefficients) or violation of the Wick limit (which often results from excessively low coefficients). The Legendre coefficients are listed in Table 2.

1.3 ENERGY DISTRIBUTION OF INELASTICALLY SCATTERED NEUTRONS

Nitrogen-14 has isolated energy levels at 2.31 MeV, 3.95 MeV, and a multitude of closely spaced levels above 4.9 MeV. R. B. Day[16] investigated the neutron energy range from 2.56 to 4.2 MeV for the presence of a 2.3-MeV gamma ray and succeeded in detecting one only above 3.95 MeV. He quotes a cross section of 6 mb, a value which does not disagree with the low energy data of Hall and Bonner[17] who measured the cross section for production of the 2.31-MeV gamma ray by neutrons with energy between 4.73 and 8 MeV. The observation of no gamma rays produced by neutrons with energy below 3.95 MeV disagrees with the data of Bostrom et al.[18]; the disagreement became even worse after Bostrom corrected his data.[19] In fact, Bostrom's data also disagree with the low energy data of Hall and Bonner. Therefore, we have decided to follow Day in assuming that inelastic scattering is negligible for neutrons below 3.95 MeV, and, furthermore, to assume that excitation of the 2.31-MeV level is negligible for incident neutrons of any energy. An experimental check of this assumption is available only for 14-MeV neutrons for which Bauer[8] estimated that the cross section for exciting the 2.31-MeV level is of the order of 4 mb; this datum is, however, in disagreement with an estimate of about 15 mb given earlier by Bobyr et al.[20]

For incident neutron energies less than 4.91 MeV, the inelastic scattering cross section was assumed to be equal to the excitation of the 3.91-MeV level. For higher energies, the inelastic scattering cross section is for the excitation of a continuum of levels. The energy distribution of emergent neutrons is here governed by statistical theory with parameters:

$E_t = 10.8$ MeV
$a^{(1)} = 0.63$ MeV^{-1}
$a^{(2)} = 0.63$ MeV^{-1}
$E_0^{(1)} = 8.5$ MeV

$E_0^{(2)} = 16.$ MeV
$E_1^{(1)} = 4.02$ MeV
$E_1^{(2)} = 0.01$ MeV

1.4 ENERGY DISTRIBUTION OF GAMMA RAYS FOLLOWING NONELASTIC REACTIONS

1.4.1 Gamma Rays Following Absorption

Motz et al.[21] give the relative intensities of the gamma rays following thermal neutron capture. We assume that the capture spectrum does not change as a function of energy. We also assume that the (n,p) reaction causes no secondary gamma emission. Therefore, we obtain the number of γ-rays per absorption by multiplying the radiative capture spectrum by the factor:

$$\frac{\sigma_{n,\gamma}}{(\sigma_{n,\gamma}+\sigma_{n,p})}$$

Luckily both the (n,p) and (n,γ) cross sections follow the 1/v relation over the entire range of energies for which the (n,γ) reaction is of interest so that the intensity factor is constant. At 0.0253 eV we have used 1.80 barn for $\sigma_{n,p}$ and 0.08 barn for $\sigma_{n,\gamma}$. The absorption spectrum is given in Table 3.

1.4.2 Gamma Rays Following Inelastic Scattering

The spectrum of gamma rays following inelastic scattering of neutrons by nitrogen was calculated by statistical theory for neutron energies above 5.7 MeV. In considering the spectrum of inelastically scattered neutrons we assumed that the excitation of the 2.31-MeV level could be safely neglected. In considering gamma-ray emission we cannot make that assumption; several higher energy levels decay by cascades which include the 2.31-MeV level. This level was included in the gamma-ray spectrum calculations as one for which excitation by decay of higher levels was allowed, but for which excitation by incident neutrons was not allowed.

For neutron energies below 5.7 MeV the gamma-ray spectrum was governed by the decay scheme shown above. Excitation functions for the various levels were based on the work of Hall and Bonner.[17] The γ-ray spectra are given in Table 4.

2. OXYGEN

2.1 NEUTRON CROSS SECTIONS

2.1.1 The Total Cross Section

For incident neutron energies below about 3.5 MeV the data of UNC-5038[1] have withstood the onslaught of the years. For higher energies we have used the data of Fossan et al.[2] quoted in the latest supplement to BNL-325[3] (see Table 5 and Fig. 4).

2.1.2 The Elastic-Scattering Cross Section

For energies above about 3.5 MeV the elastic-scattering cross section was calculated from

$$\sigma_{n,n} = \sigma_{nT} - \sigma_{nX}$$

For lower energies the total and elastic-scattering cross sections were assumed to be identical.

2.1.3 The Nonelastic Cross Section

In the energy range below 10 MeV the cross section for nonelastic reactions is given by

$$\sigma_{nX} = \sigma_{n,n'} + \sigma_{n,\alpha}$$

Above 10 MeV a smooth curve was drawn, guided by the data of Flerov and Talyzin[4] and of Bauer et al.[5] Confirmation was given by the data of Chase et al.[6]

2.1.4 The (n,α) Cross Section

The cross section for the (n,α) reaction in oxygen has been measured by E.A. Davis et al.[7] at a great many incident neutron energies between 5 and 8.8 MeV. For energies below 5 MeV the values in UNC-5038 were retained.

Until recently, the only measurement of the (n,α) cross section in oxygen at higher energies was that of Randolph[8] at 14 MeV. In 1963, however, Bormann and coworkers[9] published a set of values for neutron energies between 12 and 20 MeV. We have used these and have bridged the gap between these and Davis's data by a smooth curve.

2.1.5 The (n,d) Cross Section

The (n,d) cross section has been measured at 14 MeV by Randolph.[8] The angular distribution of neutrons from the (d,n) reaction in N^{15} has been measured by Weil and Jones[10] for several deuteron energies. We have analyzed and integrated these distributions, and, from the resulting cross sections for the inverse reaction, cross sections for the direct reaction have been calculated.

2.1.6 The (n,p) Cross Section

The data of DeJuren, Stooksberry, and Wallis were used.[11]

2.1.7 The Absorption Cross Section

The absorption cross section is equal to $\sigma_{n,\alpha} + \sigma_{n,p} + \sigma_{n,d}$. A curve is given in Fig. 5.

2.1.8 The Inelastic-Scattering Cross Section

For energies below about 10 MeV we have still used the data for excitation of individual levels measured by the Rice group and quoted in BNL-325,[12] but otherwise unpublished except in compilations.[1,13-16] At higher energies the only measurement found in the literature is the cloud chamber work of J. P. Conner[17] in 1953. Consequently we have taken

$$\sigma_{n,n'} = \sigma_{nX} - \sigma_{n,\alpha} - \sigma_{n,p} - \sigma_{n,d}$$

to describe the inelastic-scattering cross section for neutron energies above 10 MeV (see Table 5 and Fig. 6).

2.2 ANGULAR DISTRIBUTION OF ELASTICALLY SCATTERED NEUTRONS

Detailed measurements of the angular distribution of neutrons elastically scattered from oxygen have recently been made by Lane[18] in the energy range below about 1.7 MeV and by Sayres[19] between about 3 and 4.75 MeV. Otherwise one cannot say that the situation is much better than it was two years ago. The old gaps and conflicting experimental results still exist. Above 5 MeV the only new measurement is that of Bauer[5] at 14 MeV.

The work of Fowler and Cohn[20] confirms Lane's data, and that of Phillips[21] and of Johnson and Fowler[22] confirms Sayres' data. We have generally ignored the data of Hunzinger and Huber[23] since their data conflict with those of other workers perhaps because of their lack of measurements at small scattering angles. In the range just below 3 MeV we have been guided by the calculated Legendre coefficients of Lustig,[13] since his work predicted the main features of Lane's experimental results.

We have analyzed angular distributions from many sources, plotted the resulting Legendre coefficients, and drawn curves through the data. Where there are serious gaps or conflicts in the data it is obvious that more than one curve will be

possible. In such cases, the judgments cannot alw e rational; a species of aesthetics is also necessary. Point values are then read from the curves at the energies used in the tables. Where the values change rapidly with energy, average values are prepared corresponding to these tabular energies. These point values are then used to resynthesize angular distributions to make sure that no negative cross sections are being generated.

It is also necessary to examine the forward peak of the resynthesized angular distribution at each energy. G. C. Wick[24] has shown that the differential cross section at 0° ($\cos\theta = 1.0$) is limited by

$$\sigma_{n,n}(E,0) \geq \left(\frac{k\sigma_{nT}(E)}{4\pi}\right)^2$$

where $k = 1/\lambda$, the reciprocal of the reduced neutron wavelength. It is patently impossible to make measurements at zero deflection in the undeflected neutron beam, as that experimental verification of the Wick limit is not available; further, the measurements at other angles (e.g., $\cos\theta = 0.7$ to 0.95) may be such that a least-squares routine, like our LEGEND code, will predict $\sigma_{n,n}(E,0)$ values below the Wick limit. In such cases, the Wick limit may be entered as a data point at $\theta = 0$, or the normalization may be raised by increasing $\sigma_{n,n}$ relative to σ_{nT}, or the limit may be lowered by decreasing σ_{nT}. One must be careful, however, since these measures to insure strict observance of the Wick limit generate some distortion of either the angular distribution or the cross sections themselves. The Legendre coefficients are listed in Table 6.

2.3 ENERGY DISTRIBUTION OF INELASTICALLY SCATTERED NEUTRONS

As shown in the Nuclear Data Sheets,[25] the first excited level in oxygen at 6.06 MeV has the same spin and parity as the ground state, and pair emission is given as the probable mode of decay. Lustig, Goldstein, and Kalos[13] cite

T. W. Bonner as having concluded, after a search for these pairs, that excitation of this level by inelastic scattering is rare compared with that of other levels. We have followed their example and ignored the contribution of the 6.06-MeV level to inelastic scattering.

Because of the relatively large gap (1.76 MeV) between the fourth and fifth levels, we have decided to treat the fifth and higher levels as forming a continuum and to treat the lower levels as individually excited.

At 18 MeV it seems most likely that the spectrum of secondary neutrons will be given adequately by statistical theory since the influence of the very large number of high energy levels will probably overwhelm that of the lowest levels. We have used French curves to bridge the gap between 10 and 18 MeV, bringing the level excitation curves to zero at 18 MeV.

The discrete part of the neutron spectrum is given in Table 7. The continuous part has been calculated using the parameters:

$$a_1 = 18\ \text{MeV}^{-1}$$

$$E_{01} = 17\ \text{MeV}$$

$$E_{11} = 9\ \text{MeV}.$$

2.4 ENERGY DISTRIBUTION OF GAMMA RAYS FOLLOWING NONELASTIC REACTIONS

2.4.1 Gamma Rays Following Absorption

We have taken the radiative-capture cross section to be zero. The only source of absorption γ-rays which we take into account is that due from the reaction $O^{16}(n,\alpha)C^{13*}$. The data given in Table 8 are based on the work of Davis et al.[7]

2.4.2 Gamma Rays Following Inelastic Scattering

The spectrum of gamma rays following inelastic neutron scattering, shown in Table 9, was calculated from the excitation curves for the three discrete levels along with the continuum theory parameters. The level density was assumed to be 4 per MeV up to 17 MeV.

3. ALUMINUM

3.1 NEUTRON CROSS SECTIONS

3.1.1 The Total Cross Section

For incident neutron energies above 2.4 MeV we have used the composite curve from the second supplement to BNL-325[1] to represent the total cross section, and from 0.4 to 2.4 MeV the composite curve from the second edition of BNL-325.[2] From about 5.5 to 400 keV we have used the results of Garg, Rainwater, and Havens[3] as reported in the BNL-325 Supplement.[1] Since the Columbia results[3] tend to indicate distinctly lower values of the total cross section at low energies, and since they reported no measurements below 4 keV, we have used the results of Hibdon[4] below the 5.9-keV resonance which lead into the composite curve in the second edition of BNL-325.[2] We used this curve, which rises very slowly with decreasing energy, for all energies below 4 keV (see Table 10 and Fig. 7).

3.1.2 The Elastic-Scattering Cross Section

Over the entire energy range we took the elastic-scattering cross section to be the difference between the total and nonelastic cross sections.

3.1.3 The Radiative Capture Cross Section

From about 20 keV to 5 MeV we used the results of many experimentalists[5-11] quoted in the BNL-325 supplement. The most detailed and extensive measure-

ments were those of Henkel and Barschall,[5] Henkel,[6] and of Calvi et al.[7] Where a choice between two measurements was necessary we used the more recent measurement. In ranges where measured points were sparse (from about 45 to 120 keV and from about 20 to about 30 keV) we used the "eye guide" curve from the BNL-325 supplement. The lower portion of this eye guide curve was brought smoothly into the 1/v line drawn through the BNL-325 "recommended" value of 0.235 barn at 0.0253 eV. The 5.9-keV resonance was assumed to make no appreciable contribution to the (n,γ) cross section. It is, after all, a p-wave resonance and consequently very narrow. Above 5 MeV the (n,γ) cross-section curve was brought upward through the 14-MeV data points of Csikai[12] and Perkin.[13] We attribute the rather sharp rise in the cross section to the onset of a direct interaction type of capture reaction.

3.1.4 The (n,α) Cross Section

For the (n,α) cross section we have used the measurements of Butler and Santry[14] and Ferguson.[15] The measurements of Ferguson cover only the range from about 12.7 to about 14.3 MeV and are given in "arbitrary units." We normalized them to the data of Butler and Santry.

3.1.5 The (n,p) Cross Section

The BNL-325 Supplement[1] shows composite curves of the (n,p) cross section covering the energy ranges from about 12 to about 21 MeV and from 2.7 to 5.1 MeV. The contributors in the upper energy range were Gabbard and Kern,[16] Mani, McCallum, and Ferguson,[17] and Hudson and Morgan.[18] For the lower range, the measurements of Calvi et al.[7] were normalized to those of Henkel.[19] BNL-325[2] gives a curve running from about 2.6 to about 8 MeV attributed to "Los Alamos, unpublished;" presumably these are the work of Henkel.[19] We have followed the composite curve of the BNL-325 supplement up to 5.1 MeV, the curve from BNL-325 from 5.1 to 8 MeV, and the BNL-325 supplement's composite from

12 to 18 MeV. We bridged the gap from 8 to 12 MeV with a smooth curve rising to a peak at about 10 MeV and then descending.

3.1.6 The Absorption Cross Section

We have taken the absorption cross section as equal to $\sigma_{n,\gamma} + \sigma_{n,\alpha} + \sigma_{n,p}$. A curve is given in Fig. 8. The Q-values given by Ashby and Catron[20] show three additional neutron-absorbing reactions to be energetically possible. These are the (n,t), (n,He^3), and (n,d) reactions. The values shown for the (n,t) and (n,He^3) cross sections in the BNL-325 Supplement[1] for 14 to 15-MeV neutrons are upper bounds only, and, even so, are very small compared with the (n,p) and (n,α) cross sections. We have ignored them.

Several measurements are quoted in the BNL-325 Supplement[1] for the (n,np) reaction at incident neutron energies between 14 and 15 MeV. Since the (n,np) reaction comes about because of the break-up of the deuteron from the (n,d) reaction, and since the (n,np) reaction produces a secondary neutron, we have taken the (n,d) cross section to be negligible and counted the (n,np) reaction as part of the (n,n′) reaction.

3.1.7 The (n,2n) Cross Section

Mani et al.[17] have measured the cross section for the (n,2n) reaction leading to the 229-keV isomeric state, 6.5 sec Al^{26m}. There are no other measurements of this reaction save those of Csikai et al.,[12] which are an upper bound. We have assumed that half of the (n,2n) events will lead to the ground state of Al^{26} and have drawn one curve through a set of points resulting from doubling Mani's measured values.

3.1.8 The Nonelastic Cross Section

The BNL-325 Supplement[1] shows a curve of the nonelastic cross section for neutron energies from somewhat below 2 to well over 100 MeV. The lower energy

portion of this curve was drawn through the data points of Beyster, Walt, and Salmi.[21] We have drawn a similarly shaped smooth curve through the inelastic scattering cross-section measurements of Towle and Gilboy[22] at 2, 3, and 4 MeV. Our curve lies somewhat higher than the BNL-325 eye-guide, although it is within the experimental error of the Beyster measurements at 2.5, 3.25, and 4 MeV. Cross sections derived from the inelastic gamma-ray measurements of Kiehn and Goodman[23] fall about a factor of two above our curves. In the energy range from 1 to 4 MeV, the cross sections for the (n,γ), (n,p), and (n,α) reactions are entirely negligible, and the nonelastic cross section can be regarded as the inelastic-scattering cross section.

Above 4 MeV we drew our curve smoothly through the usual cluster of points at 14 MeV[1] and between the two points of Degtyarev and Nadtochii[24] at about 16 MeV. Our curve crosses the BNL-325 eye-guide between 9 and 10 MeV where it passes through one of the data points of Ball, MacGregor, and Booth[25] at 9.5 MeV.

3.1.9 The Inelastic-Scattering Cross Section

We have calculated the inelastic-scattering cross section from the formula

$$\sigma_{n,n'} = \sigma_{nX} - \sigma_{n,\gamma} - \sigma_{n,p} - \sigma_{n,\alpha} - \sigma_{n,2n}$$

At 7 MeV our calculated value is within the experimental error of a measurement of this cross section by Thomson.[26] Values of $\sigma_{n,n'}$ are given in Table 10 and Fig. 9.

3.2 ANGULAR DISTRIBUTION OF ELASTICALLY SCATTERED NEUTRONS

Aluminum is no exception to the rule which has held for most elements for which we have compiled angular distribution data. In some energy ranges there are detailed measurements: those of Langsdorf, Lane, and Monahan[27] and of Ji-Peng Chien[28] below 1.5 MeV as well as isolated measurements by Lovchikova[29] and

Bostrom and Morgan.[30] At one energy, 14 MeV, there is a superabundance of data.[31-33] There is a range in which conflicting measurements abound: between 2 and 5 MeV there are 18 different measurements by eight different workers.[21,22,34-38] Finally, there is a large range in which there are no measurements at all. In this case it runs from 7 to 14 MeV. There are rarely any trustworthy measurements above 14 MeV, and for aluminum there are none. We are fortunate in having a set of optical model calculations, by Bühler and Emendörfer[40] which span the unmeasured energies and agree well with experiments at both ends.

In preparing our Legendre coefficients we have analyzed the 14-MeV data[31-33] as a composite angular distribution with 45 points. For each of the 14 coefficients we drew our curve midway between the point resulting from the analysis of the 14-MeV composite and the point given by Bühler and Emendörfer's calculations[40] at that energy. Between 6 and 12 MeV we used the Bühler and Emendörfer results. Between 1.55 and 5 MeV we were guided by the trend of the data, although our curve did not often pass through points resulting from analysis of the measured distributions. From 0.3 to 1.5 MeV we used Chien's data,[28] and below 0.3 MeV we used Langsdorf's data.[27] For the extrapolation to 18 MeV we followed the trend of the data below 14 MeV consistent with the necessity of avoiding Wick limit violations on the one hand and avoiding generation of negative cross sections on the other. The Legendre coefficients for aluminum are shown in Table 11.

3.3 ENERGY DISTRIBUTION OF INELASTICALLY SCATTERED NEUTRONS

For incident neutron energies below 4.02 MeV we have assumed the excitation of five discrete levels (0.842, 1.013, 2.206, 2.73, and 2.977 MeV). The level at 2.206 MeV is that given in the Landolt-Börnstein tables[41] with the excitation energy of 2.21 MeV lowered slightly to bring it below the lowest of our mesh points for which there will be a cross section for excitation of this level. Similarly,

our 2.977-MeV level is a combination of those given in the Landolt-Börnstein tables at 2.98 and 3.0 MeV with excitation energy slightly lowered as for the 2.21-MeV level (see Table 12).

For energies above 4.02 MeV we have calculated the distribution of scattered neutrons according to statistical theory using the following parameters:

E_t = 14. MeV $a^{(1)} = a^{(2)}$ = 3. MeV^{-1} $E_l^{(1)}$ = 0.842 MeV

$E_0^{(1)} = E_0^{(2)}$ = 6.5 MeV $E_l^{(2)}$ = 0.01 MeV

3.4 ENERGY DISTRIBUTION OF GAMMA RAYS FOLLOWING NONELASTIC REACTIONS

3.4.1 Gamma Rays Following Neutron Capture

Troubetzkoy and Goldstein[42] and Draper and Bostrom[43] have given the spectrum of gamma rays following thermal neutron capture. We have assumed that the spectrum is the same for all neutron energies of interest (see Table 13).

3.4.2 Gamma Rays Following Inelastic Scattering

For neutron energies below 4.02 MeV the spectrum of gamma rays emitted in inelastic neutron scattering was derived from the level excitation information described above. Between 4.02 and 8. MeV there are the experimental data of Perkin,[44] and at 14 MeV those of several experimenters.[45-48] Statistical model calculations, as given by Troubetzkoy,[49] were performed to interpolate between the two sets of data (see Table 14).

4. SILICON

4.1 NEUTRON CROSS SECTIONS

4.1.1 The Total Cross Section

For neutron energies above 0.5 MeV the data presented in the latest supplement of BNL-325[1] have been used. Between 2.6 MeV and 5.4 MeV the data of Calvi et al.[2] have been used exclusively since it is the most recent and complete set of measurements in this energy interval. Below 0.5 MeV the data were obtained from BNL-325, 2nd Ed.[3] Measurements performed since then, such as Rayburn and Wollan[4] and the earlier tabulation of Howerton,[5] are consistent with these data (see Table 15 and Fig. 10).

4.1.2 The Elastic-Scattering Cross Section

For the entire energy range of interest the elastic-scattering cross section was calculated by

$$\sigma_{n,n} = \sigma_{nT} - \sigma_{nX}$$

4.1.3 The Nonelastic Cross Section

In the energy range below 4.5 MeV the cross section for nonelastic reaction is given by

$$\sigma_{nX} = \sigma_{n,n'} + \sigma_{n,p} + \sigma_{n,\alpha} + \sigma_{n,\gamma}$$

Above 4.5 MeV, the only measurement available is at 14.0 MeV, BNL-325.[1] This point was used along with the data presented for aluminum to give a reasonable representation of the cross section above 4.5 MeV.

4.1.4 The (n,α) Cross Section

Below 8.5 MeV the cross sections for the (n,α) reaction were taken from measurements of Mainsbridge et al.[6] These data are also shown in BNL-325.[1] Above 8.5 MeV the data reported by Colli et al.[7] have been used.

4.1.5 The (n,p) Cross Section

The cross sections for the (n,p) reactions have been obtained from measurements reported in the latest supplement of BNL-325. As for the (n,α) compilation, the data below 8.5 MeV were obtained from Mainsbridge et al. Above 8.5 MeV a smooth curve similar to the one shown in BNL-325 has been used to represent the abundant data available.

4.1.6 The (n,γ) Cross Section

Since the last revision of silicon cross sections reported in UNC-5002,[8] some additional data of Macklin et al.,[9] at 65 keV, have become available. These are consistent with the last compilation which also makes use of some of Macklin's earlier work.

4.1.7 The Absorption Cross Section

The absorption cross section is here taken to be

$$\sigma_{n,\gamma} + \sigma_{n,\alpha} + \sigma_{n,p}$$

A curve is given in Fig. 11.

4.1.8 The Inelastic-Scattering Cross Section

Below 4.5 MeV the cross section for the inelastic-scattering reaction has been obtained from the discrete level excitation data of Lind and Day,[10] and the Rice group.[11] There were also data available from Engesser et al.[12] at 14 MeV. At other energies the data obtained for aluminum were used as guides to draw a reasonable curve for silicon (see Fig. 12).

4.2 ANGULAR DISTRIBUTION OF ELASTICALLY SCATTERED NEUTRONS

Between 0.9 and 4.8 MeV, the data for angular distribution were obtained from BNL-400.[13] Below 0.9 MeV, the data of Lane et al.[14] were used. There was also the work of Martin et al.[15] at 14 MeV. These data compared well with the angular distribution of 14-MeV neutrons from aluminum shown in BNL-400. On this basis the Legendre polynomials calculated for aluminum were also used for silicon above 4.8 MeV. The Legendre coefficients are shown in Table 16.

4.3 SPECTRUM OF INELASTICALLY SCATTERED NEUTRONS

The neutron distribution of inelastically scattered neutrons with incident energies less than 4.5 MeV was governed by the excitation of five levels (1.28, 1.78, 2.02, 2.20, and 2.41 MeV). Cross-section data for these levels were obtained from the work of Lind and Day[10] and the Rice group[11] (see Table 17). For energies greater than 4.5 MeV a continuum of levels was assumed, with parameters:

$a = 2.8\ \text{MeV}^{-1}$

$E_1 = 2\ \text{MeV}$

$E_0 = 10\ \text{MeV}.$

4.4 ENERGY DISTRIBUTION OF GAMMA RAYS FOLLOWING NONELASTIC REACTIONS

4.4.1 Gamma Rays Following Neutron Capture

The spectrum of gamma rays following thermal neutron capture was obtained from a compilation by Troubetzkoy and Goldstein.[16] We assume the same spectrum holds for all incident neutron energies (see Table 18).

4.4.2 Gamma Rays Following Inelastic Scattering

The data for the spectrum of gamma rays following inelastic scattering were obtained from Perkin[17] at energies from 3.5 to 8.5 MeV. Below 3.5 MeV it was calculated from data on discrete levels.[10,11] Above 8.5 MeV the data of Engesser et al. at 14 MeV were used and enabled an extrapolation of the data at lower energies to be made (see Table 19).

5. IRON

5.1 NEUTRON CROSS SECTIONS

5.1.1 The Total Cross Section

For incident neutron energies above about 0.23 MeV we have used the supplement to the second edition of BNL-325.[1] The measurements of Nereson and Darden,[2] and those of Mazari and Alba[3] which lie below the "eye-guide" curve in the range from about 4 to about 15 MeV are balanced by those of Weil and Jones,[4] which lie above it from 4 to 8 MeV, and those of Bratenahl, Peterson, and Stoering,[5] and of Armitage et al.[6] which lie above the "eye-guide" from 9 to 14 MeV.

From 4 keV to 0.23 MeV we used the data of Garg, Rainwater, and Havens[7] and followed the curve of the second edition of BNL-325[8] for lower energies. An exception to this was the range from 1.1 to 1.2 keV where we summed the BNL-325 values and the capture cross-section measurements from Harwell[9] to delineate the 1150 eV resonance (see Table 20 and Fig. 13).

5.1.2 The Elastic-Scattering Cross Section

Over the whole energy range we calculated the elastic-scattering cross section as the difference between the total and nonelastic cross sections. That is:

$$\sigma_{n,n} = \sigma_{nT} - \sigma_{nX}$$

5.1.3 The Radiative-Capture Cross Section

In the low energy part of the resonance region, from 1 to about 30 keV, we are fortunate in having the detailed measurements made by Moxon at Harwell and reported by Rae et al. at Geneva.[9] The measurements of Mitzel and Plendl[10] in this range were not used since they show the 1150 keV resonance as much lower and broader then do those of Moxon. Those of Macklin et al.[11] were not used since, in the range around 20 keV, they show resonance peaks as lower and broader than Moxon's work. From about 35 keV to about 2 MeV we have drawn a composite curve through the measurements of many workers,[12-15] and have continued the curve to 18 MeV mitigating the steep descent slightly at the higher energies. Below the Harwell data, from 10 to 1000 eV, we have taken the data of Isakov[16] and joined a 1/v curve which passes through the value measured by Isakov[17] (2.57 barns at 0.0253 eV).

5.1.4 The (n,p) Cross Section

The cross section for the (n,p) reaction in Fe^{56} has been measured in great detail by Santry and Butler,[18] and their results agree well with those of Bormann et al.[19] and of Terrell and Holm.[20] Since Fe^{56} accounts for about 92% of the naturally occurring isotopic mixture, we have taken this cross section to represent that of the natural element.

5.1.5 The (n,α) Cross Section

No measurements of the cross section for the (n,α) reaction in either natural iron or Fe^{56} are available. The calculations of Bullock and Moore,[21] however, indicate that the (n,α) cross section should be roughly the same size as the (n,p) cross section but should reach its peak at about 16 MeV instead of between 13 and 14 MeV. Calculations and measurements in other iron isotopes[22-24] lead one to expect the (n,α) cross section to be somewhat smaller than the (n,p) cross section. Accordingly, we have used our (n,p) curve for the (n,α) cross section, dis-

placing it so that the peak value is about 10% higher in energy and about 10% lower in magnitude.

5.1.6 The Absorption Cross Section

The work of Heinrich and Tanner[25] gives the (n,t) cross section in iron as very small and with a threshold above 15 MeV. We have therefore ignored this reaction and counted the absorption cross section as $\sigma_{n,\gamma} + \sigma_{n,p} + \sigma_{n,\alpha}$ (see Fig. 14).

5.1.7 The Nonelastic Cross Section

Data on the nonelastic cross section from seven workers are given in the supplement to BNL-325.[1] We have used these along with several more recent measurements[26-29] to draw a composite curve of σ_{nX} above about 3.5 MeV. For lower energies the inelastic-scattering cross section and the radiative-capture cross section are the only contributors to σ_{nX}, and the values of the inelastic-scattering cross section are in good agreement with the nonelastic cross section between about 0.85 to 3.5 MeV. For most of this range the capture cross section is, of course, negligible compared with the other cross sections.

5.1.8 The Inelastic-Scattering Cross Section

Measurements of the inelastic-scattering cross section are available from Gilboy and Towle,[29] Sukhanov and Rukavishnikov,[30] and Thomson.[31] We have derived the lower energy portion of this cross section, below about 3.5 MeV, from the inelastic gamma-ray production cross-section measurements of Montague and Paul.[32] At higher energies we have taken the inelastic-scattering cross section (including $\sigma_{n,2n}$) as the difference between the nonelastic and the absorption cross sections, i.e.,

$$\sigma_{n,n'} + \sigma_{n,2n} = \sigma_{nX} - \sigma_{n,p} - \sigma_{n,\alpha} - \sigma_{n,\gamma}$$

Our calculated values agree well with the measured values (see Fig. 15).

5.1.9 The (n,2n) Cross Section

Ashby and Catron[33] give -11.2 MeV as the Q value for the (n,2n) reaction in Fe^{56}, -13.3 MeV in Fe^{54}, -7.63 MeV in Fe^{57}, and -10.0 MeV in Fe^{58}. We have taken the threshold to be 10.9 MeV and drawn our curve rising from there and passing through the 14-MeV measurement of Ashby et al.[34] Lebedev et al.[35] state that the difference between the (n,2n) and capture cross sections is 0.26 ± 0.1 barn at 14 MeV. A value of the (n,2n) cross section derived from our values of $\sigma_{n,p}$ and $\sigma_{n,\alpha}$ with this formula is in good agreement with Ashby's measurement. This agreement may also be taken as confirmation of our choice of $\sigma_{n,\alpha}$.

5.2 ANGULAR DISTRIBUTION OF ELASTICALLY SCATTERED NEUTRONS

At 14 MeV we analyzed the composite distribution, given in the second edition of BNL-400,[36] which is made up from the work of Elliot,[37] Yuasa,[38] Coon et al.,[27] and Anderson et al.[39] We did not, however, use the work of Khaletskii[40] since his values do not agree well with those of the other workers. Between 14 and 7 MeV no angular distribution measurements were found. Between about 1.5 and 7 MeV there are 20 measurements by 15 groups of workers.[29,41-54] The calculated coefficients of Bühler and Emendörfer,[55] which were so helpful in bridging the 7- to 14-MeV gap in the aluminum angular distributions, were not used. The authors mentioned that their results could be compared with experiments at 7 and 14 MeV but make no statement about how good the agreement is. They do say that their curves agree "essentially" with the calculated results of Bjorklund and Fernbach.[56]

Below 1.5 MeV we have used the recent measurements of Smith[57] which supersede the earlier detailed work of Langsdorf, Lane, and Monahan.[58] Isolated measurements by several workers[53,59-64] are in good agreement with Smith's data.

The Legendre coefficients are given in Table 21.

5.3 ENERGY DISTRIBUTION OF INELASTICALLY SCATTERED NEUTRONS

For incident neutron energies we have taken the energy distribution of inelastically scattered neutrons to be governed by the excitation of six levels with energies of 0.845, 1.41, 2.1, 2.658, 3.0, and 3.4 MeV (see Table 22). The level excitation cross sections were derived from the work of Montague and Paul.[32] For higher energies we have assumed a continuum of levels with secondary neutron distribution parameters:

$$E_t = 11.0 \text{ MeV}$$
$$a^{(1)} = 5.7 \text{ MeV}^{-1}$$
$$a^{(2)} = 5.7 \text{ MeV}^{-1}$$
$$E_0^{(1)} = 3.73 \text{ MeV}$$
$$E_0^{(2)} = 3.73 \text{ MeV}$$
$$E_1^{(1)} = 0.845 \text{ MeV}$$
$$E_1^{(2)} = 0.01 \text{ MeV}.$$

5.4 ENERGY DISTRIBUTION OF GAMMA RAYS FOLLOWING NONELASTIC REACTIONS

5.4.1 Gamma Rays Following Neutron Capture

We have assumed that the spectrum of gamma rays given by Troubetzkoy and Goldstein[65] is valid for incident neutron energies below about 4.5 MeV. Above this energy the radiative capture cross section is negligible compared with the (n,p) and (n,α) cross sections. The charged particle reactions are assumed to produce no gamma rays (see Table 23).

5.4.2 Gamma Rays Following Inelastic Scattering

For neutron energies below about 3.5 MeV we have used the gamma-ray production cross sections of Montague and Paul,[32] from 3.5 to 8.5 MeV we have used the data of Perkin,[66] and at 14 MeV we have used the data of Caldwell et al.[67] We have used graphical methods to bridge the gap between 8.5 and 14 MeV and extrapolate the data to 18 MeV (see Table 24).

6. DEUTERIUM AND BERYLLIUM

The cross sections of deuterium were taken from the report UNC-5038,[1] those of beryllium, from UNC-5014, Vol. B.[2] They are listed in Tables 25 through 30 with out any essential modifications.

13 ABSTRACT

Neutron cross-section sets have been prepared for N, O, Al, Si, Fe, D, and Be for neutron energies from 0.037 eV to 18 MeV. The cross sections tabulated include the total, elastic, inelastic, (n,2n), and cross sections for charged particle emission. Information is also given on the angular distribution of elastically scattered neutrons and on the energy distribution of neutrons and γ—rays following nonelastic reactions.

INSTRUCTIONS

1. **ORIGINATING ACTIVITY:** Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization *(corporate author)* issuing the report.

2a. **REPORT SECURITY CLASSIFICATION:** Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.

2b. **GROUP:** Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.

3. **REPORT TITLE:** Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.

4. **DESCRIPTIVE NOTES:** If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.

5. **AUTHOR(S):** Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.

6. **REPORT DATE:** Enter the date of the report as day, month, year; or month, year. If more than one date appears on the report, use date of publication.

7a. **TOTAL NUMBER OF PAGES:** The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.

7b. **NUMBER OF REFERENCES:** Enter the total number of references cited in the report.

8a. **CONTRACT OR GRANT NUMBER:** If appropriate, enter the applicable number of the contract or grant under which the report was written.

8b, 8c, & 8d. **PROJECT NUMBER:** Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.

9a. **ORIGINATOR'S REPORT NUMBER(S):** Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.

9b. **OTHER REPORT NUMBER(S):** If the report has been assigned any other report numbers *(either by the originator or by the sponsor)*, also enter this number(s).

10. **AVAILABILITY/LIMITATION NOTICES:** Enter any limitations on further dissemination of the report, other than those imposed by security classification, using standard statements such as:

(1) "Qualified requesters may obtain copies of this report from DDC."

(2) "Foreign announcement and dissemination of this report by DDC is not authorized."

(3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through _____."

(4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through _____."

(5) "All distribution of this report is controlled. Qualified DDC users shall request through _____."

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

11. **SUPPLEMENTARY NOTES:** Use for additional explanatory notes.

12. **SPONSORING MILITARY ACTIVITY:** Enter the name of the departmental project office or laboratory sponsoring *(paying for)* the research and development. Include address.

13. **ABSTRACT:** Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as *(TS), (S), (C), or (U)*.

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. **KEY WORDS:** Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Idenfiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, rules, and weights is optional.
