ABSTRACT

In the Haystack Pointing system, errors caused by atmospheric refraction, gravitational deformation of the antenna, skewed axes and resolver error are compensated for by a correction program in the computer which adds the necessary biases to the geometric values of azimuth and elevation to produce an effectively correct aiming of the antenna.

Accepted for the Air Force

HAYSTACK POINTING SYSTEM: RADAR COORDINATE CORRECTION

I. INTRODUCTION

The Radar Coordinate Correction program of the Haystack Pointing system accepts as input a pair of angles (θ , ϕ) which are the azimuth and elevation coordinates of a point at which the antenna is to be pointed. The program modifies these angles by adding corrections derived from tables using the method of table look-up and interpolation and produces as output a pair of antenna pointing angles (θ_c , ϕ_c) which are corrected for gravitational deformation of the antenna, atmospheric refraction, resolver error, and skew of axes.

II. PROGRAM OPERATION*

The program is composed of two parts, the initializing package and the worker package. Entrance to each package from a calling routine is made with an RJP instruction.

The initializing package sets up standard correction tables during system initialization. If the correction program is called via the attention symbol route for reinitialization, the initializing package asks the operator to enter values for the various parameters used in computing the correction tables. See Fig. 1 for typical sequence of questions and answers. A vacuous answer (the carriage return alone) results in use of a prestored "standard" value for that particular parameter. The operator also has the option of omitting from use any or all correction tables. After all parameters have been entered, the package computes the correction values and stores them in the various tables. Control is returned to the calling routine from the initializing package with an EXIT instruction.

If temperature or pressure should vary significantly during an experiment, these values can be re-entered and a new refraction correction table computed without interrupting the experiment. The time necessary to recompute the refraction table after the parameters have been entered via the console is approximately 4 milliseconds.

There are three tables involved in the correction of the pointing angles (see Appendix B). The table REFRACTBL corrects for atmospheric refraction and is a

function of elevation only. The argument varies from 0° to 90° and is more densely packed for angles below 25° . The parameters associated with this table are temperature in degrees centigrade and atmospheric (i.e., total) and partial pressures in millibars.

The equations used in computing atmospheric refraction corrections are based on the results of a paper published by W. R. Illiff and J. M. Holt.¹ They verified by experiment that the total atmospheric refraction correction angle τ could be accurately estimated by an equation of the form

$$\tau = b_{\phi} \cdot N_s - a_{\phi} ,$$

where N_s is the surface refractivity, a_{ϕ} , b_{ϕ} are functions of the elevation angle

1. W. R. Illiff, and J. M. Holt, "Use of Surface Refractivity in the Empirical Prediction of Total Atmospheric Refraction," J. Research NBS 67D (Radio Prop.) No. 1 (January-February, 1963).

ϕ . The value of the surface refractivity is computed using the Smith and Weintraub equation²

$$N_s = \frac{77.6}{T + 273.15} \left[p + \frac{4810e}{T + 273.15} \right] ,$$

where e is the partial pressure of water vapor in millibars, p is the total pressure in millibars, and T is the temperature in degrees centigrade. The values of a_ϕ and b_ϕ will be precomputed and stored as constants in two tables called ATBL and BTBL for values of ϕ ranging from 0° to 90° . See Appendix A for calculation of a_ϕ and b_ϕ .

The tables AZTBL and ELTBL are each functions of azimuth and elevation. They correct for antenna sag, resolver error, and skew of axes, with AZTBL containing the corrections for azimuth and ELTBL the corrections for elevation. Each table has associated with it a pair of vectors containing the arguments of azimuth and elevation. They range from 0° to 90° in elevation and 0° to 360° in azimuth. The arguments can be irregularly spaced. See Appendix B for the table format.

The worker package uses the angle ϕ in a table look-up in REFRACTBL to produce a correction δ_1 for elevation due to refraction. This correction is added to ϕ to produce the angle $\bar{\phi}$. The angles $(\theta, \bar{\phi})$ are used as arguments in separate table look-ups of AZTBL and ELTBL to produce correction values δ_2 and δ_3 for azimuth and elevation, respectively. These values are added to $(\theta, \bar{\phi})$ to produce final corrected angles (θ_c, ϕ_c) . While the values of (θ, ϕ) are in revolutions (with a binary point at B27) the table look-up and interpolation are done in degrees with the correction values converted to revolutions (B27) just prior to being added to (θ, ϕ) . Control is returned to the calling routine from the correction package with an EXIT instruction. The time required for one pass through the worker package is of the order of 2 milliseconds.

III. TABLE LOOK UP AND INTERPOLATION

The correction value for each table is computed according to the following equations:

2. E. K. Smith and S. Weintraub, "The Constants in the Equation for Atmospheric Refractive Index at Radio Frequencies," Proc. IRE 41, No. 8, 1035-1037 (1953).

A. δ_1

The values stored in the refraction table REFRACTBLE are τ_i .

The values stored in the elevation argument table REFRACARG are s_i .

$$\delta_1 = \tau_i + \frac{\phi - s_i}{s_{i+1} - s_i} (\tau_{i+1} - \tau_i) ,$$

where $s_i \leq \phi < s_{i+1}$.

B. δ_2

The values stored in the azimuth correction table AZTBL are $\delta_{i,j}$.

The values stored in the azimuth argument table AZTBLAZARG are u_j .

The values stored in the elevation argument table AZTBLELARG are v_i .

$$D_{i,j} = \delta_{i,j} + \frac{\theta - u_j}{u_{j+1} - u_j} (\delta_{i,j+1} - \delta_{i,j}) .$$

$$\delta_2 = D_{i,j} + \frac{\phi - v_i}{v_{i+1} - v_i} (D_{i+1,j} - D_{i,j}) ,$$

where $u_j \leq \theta < u_{j+1}$,

$v_i \leq \phi < v_{i+1}$.

C. δ_3

The values stored in the elevation correction table ELTBL are $\epsilon_{i,j}$.

The values stored in the azimuth argument table ELTBLAZARG are x_j .

The values stored in the elevation argument table ELTBLELARG are

y_i .

$$E_{i,j} = \epsilon_{i,j} + \frac{\theta - x_j}{x_{j+1} - x_j} (\epsilon_{j,j+1} - \epsilon_i) \quad .$$

$$\delta_3 = E_{i,j} + \frac{\phi - y_i}{y_{i+1} - y_i} (E_{i+1,j} - E_{i,j}) \quad ,$$

where $x_j \leq \theta < x_{j+1} \quad ,$

$y_i \leq \phi < y_{i+1} \quad .$

For an elevation angle ϕ greater than 90° , the correction value δ_k is computed using the angle $180^\circ - \phi$. The correction value δ_k so obtained is subtracted from the angle ϕ . For a negative angle ϕ , δ_k is computed by means of extrapolation and is added to the elevation angle ϕ .

Interpolation is linear in both elevation and azimuth with an accuracy compatible with the accuracy of the input angles. All operations are carried out in single precision, fixed point arithmetic.

APPENDIX A

The following equations were used in precomputing the values of a_ϕ and b_ϕ which are stored as constants in the correction program. All equations and parameter values were taken from the paper cited in Reference 1.

The refraction correction angle τ , measured in revolutions, is given by

$$\tau = b_\phi \cdot N_s - a_\phi ,$$

where N_s is the surface refractivity. The values of a_ϕ and b_ϕ are given by

$$a_\phi = \frac{A}{(\alpha + B)^C}$$

$$b_\phi = \frac{180}{\pi \cdot 10^6} \left[\cot \alpha - \frac{D}{(\alpha + E)^F} \right] ,$$

where α is the elevation angle measured in degrees. The functions a_ϕ and b_ϕ have the dimensions of degrees and degrees per surface refractivity unit, respectively. As α becomes large, a_ϕ approaches zero and b_ϕ approaches the product of a constant times the cotangent of the elevation angle. The parameters A, B, C, D, E, F are positive constants and were determined empirically.

Their values are as follows:

$$A = 40.0$$

$$D = 42.5$$

$$B = 2.7$$

$$E = 0.4$$

$$C = 4.0$$

$$F = 2.64$$

APPENDIX B

The following discusses the contents and formats of the tables used in the correction program. In all tables, the subscripts (i, j) vary with elevation and azimuth, respectively.

REFRACARG

REFRACTBL

| |
|----------|
| τ_o |
| |
| τ_i |
| |

The elevation argument s_i is stored as degrees with the binary point at B20. The values of a_i and b_i will be precomputed and stored in these tables as constants, with a binary point at B20. They are functions of elevation angle and are used in computing the refraction correction table REFRACTBL. The refraction correction value τ_i is computed as a function of temperature, atmospheric pressure, vapor pressure, a_i and b_i . The value τ_i is expressed in degrees with the binary point at B20.

| $\epsilon_{o,o}$ | | $\epsilon_{o,j}$ | |
| | | | |
| $\epsilon_{i,o}$ | | $\epsilon_{i,j}$ | |
| | | | |

The arguments u_j, v_i, x_j, y_i are stored as degrees with the binary point at B20. The correction values $\delta_{i,j}$ and $\epsilon_{i,j}$ will be precomputed and stored in these tables as constants, where $\delta_{i,j}$ is the correction value for azimuth and $\epsilon_{i,j}$ is the correction value for elevation. They represent the corrections necessary to account for errors other than the refraction error. Both $\delta_{i,j}$ and $\epsilon_{i,j}$ are expressed in degrees with the binary point at B20.
