## ABSTRACT

Characteristics of the wind shear for 25 meter layers were prepared from a series of 175 detailed wind ascents to 18 km taken with a Jimsphere balloon followed by FPS-16 radar from November 1964 to June 1965. To determine how well the shears for small layers could be estimated from rawinsonde data, two new sets of ascents were created from the original Jimsphere data. One set consisted of wind data at 23 levels corresponding only to standard pressure levels, and the other set at the 46 "minute" levels at which winds are reported on observational forms. The differences in results were thus due only to the differing vertical resolution in the three series.

The results showed that the magnitudes of the mean pressure and minute shears for 25 meters are smoothed to about  $1/3$  and  $1/2$  respectively of the Jimsphere shears. Graphs of corrections for pressure and minute data needed to approximate the Jimsphere shear are presented both in terms of thickness of layer, and, for 25 m as a function of height.

The regressions proposed by Essenwanger between the mean, or the standard deviation, of the shear and the mean thickness of the layer, and also between the standard deviation and the mean of the shear are confirmed in principle using Jimsphere data.

Tabulations of bivariate frequency distributions (direction change vs magnitude), means and standard deviations of five parameters relating Jimsphere shears and winds to those of pressure and minute data, by 2 km layers, are included, both for the total data sample and for the time

changes in a sub-set consisting of 59 pairs of observations taken from 1-4 hours apart.

The mean Jimsphere shear for a 25 meter layer increases from 0.3 m/sec at the lowest levels to 0.5 at 11 km and to 0.8 at 17 km, with a standard deviation of about 70% of the mean.

## I. Introduction

It is necessary, for certain applications, to know the value of the vertical shear of the horizontal wind at very fine altitude increments. As this information is not normally available, it must be estimated from usual rawinsonde or radio wind observations.

Using a special series of high resolution wind observations from FPS-16 radar tracking of a Jimsphere balloon, this study attempts to estimate the wind shear for 25 meter layers from usual rawinsonde data and compares results with those of other papers. As a second part of this paper, statistics of the shears for 25 meter layers are presented.

## II. Data

The best available data for this research is the series of special wind observations taken at Cape Kennedy using a specially designed aluminized balloon with roughened surface, called a "Jimsphere" and tracked at 0.1 second intervals by FPS-16 radar. The data consists of 175 ascents from November 1964 to June 1965, each reporting about 700 levels between about 300 m and 18 km near which altitude the Jimsphere floats. The winds are smoothed by a least squares fit over a 50 meter layer and presented at each 25 meters. One hundred twelve of the 175 ascents have been published (Scoggins and Susko, 1965). All data used were made available by NASA, Huntsville.

A theoretical study (Scoggins, 1963) of accuracy of measurement indicated an RMS error in wind data of about 1 m/sec, but depended

upon unknown errors in radar tracking. An evaluation based upon simultaneous observation by two radars yielded RMS errors in wind speed generally less than 0.5 m/sec, although occasional large errors can appear (Scoggins and Susko, 1965).

To compare this fine-scale data with rawinsonde observations, the latter were simulated by extracting Jimsphere data only at height corresponding to (1) standard pressure surfaces, and to (2) those heights reported in maximum available detail on the original computation forms (WBAN-20). The relative information content of these three sources in the lowest 18 km is shown in Table I and the equivalent levels used are shown in Table II.

By confining the data to that of a single source and simulating the other sources by degrading the vertical resolution of the Jimsphere data, we can attribute differences in resulting shears to the effect of resolution alone. Had actual rawin data for the same station and day been used, there would have been additional differences which could be caused by the observations being taken at different time and location and by using different observational methods. While it would be desirable also to isolate the effect of the differing amount of smoothing in the two forms of observation which arise from the single reading once a minute and the average instantaneous readings while the balloon ascends a 50 meter layer, this can not be done with the available data.

The Jimsphere data were used to prepare three separate sets of ascents:

Table I: Relative Detail of Three Types of Available Data up to 18 km

<u>Source</u>	<u>Vertical Resolution</u>	<u>No. of levels</u>
Jimsphere	Overlapping 50 meter means, given each 25 meters	720
Rawin (WBAN-20 original record)	1 min. to 7 km (approx. 300 m) 2 min. above 7 km (500-1000m)	46
Rawin (Standard pressure levels)	50 mb to 12 km (500m) 20 mb to 18 km (1000m)	23

1. The original 25 meter Jimsphere data for some 700 levels. (J)
2. Jimsphere data for some 23 fixed heights corresponding to the annual mean height of the 23 standard pressure surfaces from the surface to 80 mb (17,900 m) at Cape Kennedy. (P)
3. Jimsphere data for 46 levels corresponding to those represented by one or two minute data on WBAN-20 for Cape Kennedy. (M)

As constant pressure or regular minute data are the only data normally available from which to estimate shears, it was desired to see how well they could do so, using simplest methods. From the latter two sets of data, winds were estimated at each 25 meter level using only linear interpolation. The differences of the estimated shears using the crude pressure-level or minute data, from the actual Jimsphere shears, provide the relative error or "correction factors" to obtain the average shears for shallow layers from generally available data. For this first attempt only linear interpolation was used; the use of higher order fitting methods might have reduced the differences at the expense of more complicated computations. In any event, the derived shears will always be smaller than those from the original detailed data and the differences will depend upon the interpolation method used.

At those levels for which pressure (or minute) data are available, and for which no interpolation is needed, a zero error exists between 25 meter data and original Jimsphere data. In all statistics, these non-interpolated levels are therefore excluded in computations of error.

For convenience, the following notation will be used:

- J = Original detailed Jimsphere wind
- P = Equivalent Constant Pressure wind
- M = Equivalent Minute wind
- JS, PS, MS = Jimsphere, Pressure, Minute vector shear
- Subscript s = Magnitude of wind or shear vector
- Subscript d = Difference in the directions of wind or  
of shear vectors
- F.D. = Frequency distribution
- $\sigma$  or S.D. = Standard Deviation
- $\Delta$  = time change

Bivariate frequency distributions, means and standard deviations of the five basic parameters below were computed for 2 km layers for the consolidated 175 ascents. These tabulations are reproduced in Appendix A. The means and deviations were also plotted by computer for each 25 meter level.

1.  $(JS)_s$
2.  $(J - P)_s$
3.  $(J - M)_s$
4.  $(JS - PS)_s$
5.  $(JS - MS)_s$

To evaluate short-period time changes, some 59 pairs of observations taken from one to four hours apart, were also processed in the same manner. The summaries are given as Appendix B.

Direction change statistics were first separated into clockwise and counter-clockwise to see if persistent patterns of wind interpolation

error, or if shear existed. As no significant differences were found by level, all direction changes were treated without regard to sign.

To keep the size of this report within practical limits, most parameters are tabulated in the Appendix summarized for 2 km layers. Other detailed tabulations are available but are only shown graphically here. For simplicity, the symbolic form of each parameter will be used in the discussion.

### III. Results

#### A. Estimating fine-scale shear from rawinsonde data

The differences in the shear indicated by the estimated data, from Jimsphere original data are shown in Figs. 1-14. Fig. 1 shows the variation with height of  $(JS)_s - (PS)_s$  for each 25 meter increment. There is a general increase with height of the error from 0.3 m/sec/25m at 1 km to about 1 m/sec at 17 km. The corresponding standard deviations in Fig. 2 show the same increase with height with values about 60% of the means. The numerous peaks in the deviation profile are caused by occasional, extreme shears although no physical reason is known for these occasional, large values. Separate frequency distributions were made at each 25 m level, for all basic parameters, and each peak in the deviation profile curves (Figs. 2, 4, 22) could always be traced to the occurrence of a single shear generally in the classes 4-6 or 6-8 m/sec/25m. Those as large as 5 m/sec are discussed separately below. One large occurrence, compared to the 140 to 170 instances in the classes

less than 2 m/sec is sufficient to cause these noticeable peaks. Figs. 3 and 4 are almost identical to Figs. 1 and 2, and, as will be seen, Figs. 1 and 3 are almost the same as Fig. 21, the Jimsphere shear itself. It might thus appear that both  $\overline{(PS)}_s$  and  $\overline{(MS)}_s$  are relatively very small compared to  $\overline{(JS)}_s$ . However, in Figs. 5 and 6, the values of  $\overline{(PS)}_s$  and  $\overline{(MS)}_s$  are seen to be larger than one would expect from the differences of Figs. 1 and 3 from Fig. 21. This is because the mean of the difference in magnitude of pairs of vectors includes the unknown contributions of the varying direction changes of corresponding pairs as well as magnitude changes. The mean of  $(PS)_s$  or  $(MS)_s$  is therefore not derivable indirectly from other parameters and must be computed from the original observations.

The mean errors and deviations in interpolating winds from the P and M data are shown in Figs. 7-10. At levels for which P and M data exist there is of course no error and hence the curve has a serrated appearance. The errors normally increase with height but an exception to this occurs near 13 km where the vertical resolution of the P, and especially of the M, data is increased, which causes a reduction in interpolation error. The maximum errors from the M winds are about one-half those of the P winds due to the doubled density of M data with height. Another property of the PS and MS data is the discontinuous changes of layers with constant shear with height, shown in Figs. 5 and 6, caused by linear interpolation between given data levels.

One of the principal aims of this study is to approximate the JS from PS or MS. To consolidate the results of Figs. 1-10, the data in

Figs. 11-14 show the variation with height of the relative error, defined as:

$$\frac{(JS)_s - (PS)_s}{(PS)_s} \quad \text{and} \quad \frac{(JS)_s - (MS)_s}{(MS)_s}$$

This can be applied to usual pressure data to estimate the finer scale shear.

The values of relative error indicate the percentage to be added to the  $(PS)_s$  or  $(MS)_s$  values. Hence if Fig. 11 indicates a relative error of, say, 3, then the  $(JS)_s$  is 4 times the  $(PS)_s$ . Thus Figs. 11 and 13 show that  $(JS)_s$  varies from 3 to 5 times the  $(PS)_s$  and from 2.5 to 3.5 times the  $(MS)_s$  data. The standard deviations of  $(JS)_s$  range from 2.5 to 3.5 times  $(PS)_s$  and from 2.25 to 3 times  $(MS)_s$  data. The minimum error near 13 km shows up in the mean relative error of  $(MS)_s$  graph also.

As  $\overline{(PS)_s}$  and  $\overline{(MS)_s}$  are sometimes very small, the relative error computations occasionally yielded exceedingly large ratios when individual values of  $(PS)_s$  or  $(MS)_s$  approached zero. To avoid these extreme values, the results in Figs. 11-14 were smoothed by eliminating values of PS or MS less than 0.05 m/sec/25m. Approximately 10-15% of the observations were eliminated in this way. Thus, when  $(PS)_s$  or  $(MS)_s$  is near zero, correction factors can not be applied. However, it is probably reasonable to assume that in most instances, when  $(PS)_s$  or  $(MS)_s$  is near zero:  $(JS)_s$  is also.

Naturally these results are applicable only to Cape Kennedy. However, as no other comparative data exists for other stations (except Point Mugu

and Wallops Island), it may be necessary to use these estimates elsewhere as a first approximation.

B. Relationship of shear to layer thickness

In his study of this problem, for application to missile response, Essenwanger (1963) has found that the magnitude of the mean shear can be related simply to the thickness of the layer through which it is measured:

$$\bar{S} = A_0 + a_0 (\Delta z)^{a_1}$$

where  $\bar{S}$  is mean shear,  $\Delta z$  is layer thickness,  $A_0$ ,  $a_0$ ,  $a_1$  are constants which depend on atmospheric conditions which change with season. This result appears valid only if the data are averages of all non-overlapping layers of an arbitrary thickness throughout each ascent, and for many ascents. For example, each ascent to 30 km would provide 30-1 km layers, 20-1.5 km layers, 60-500 meter layers, etc. The relationship appears to be independent of how the wind increases or decreases with height. Essenwanger's results for Cape Kennedy derived from rocket response measurements have been confirmed by Armendariz and Rider (1966) using independent photo-theodolite observations of a pibal balloon at White Sands. The coefficients in the relationship vary with place and month as would be expected from inherent differences in the wind profiles and the type of smoothing used in processing the raw observations.

Using the consolidated 175 Jimsphere ascents, over a seven month period, the regression curve (3) in Fig. 15 was obtained with  $a_0 = 0.058$  and  $a_1 = 0.68$  which agrees reasonably well with those of Essenwanger's data for February and July (Essenwanger and Billions (1965)).

As specially observed, fine-scale, data are not normally available, an attempt was also made to see how well such a regression curve could be established using only rawinsonde constant pressure data. To obtain a wide range of thickness, the linearly interpolated data for 25 meter levels were used in the averaging as pressure surfaces are at least 500 meters apart and could not provide points at the shorter thickness half of the scale. Also, had only the levels equivalent to all the reporting pressure levels in an ascent been used, the thickness between them would almost always be different and thus the consolidated time means would only represent a time average of a certain layer at a particular height. Although regressions could be based on such data, the method used was chosen to make results comparable with Essenwanger's.

The resulting curves are shown in Fig. 16 which demonstrates how much  $(\overline{PS})_s$  and  $(\overline{MS})_s$  underestimate  $(\overline{JS})_s$ . For 25 meter layers, the  $(\overline{JS})_s$  is about twice that of  $(\overline{MS})_s$  and three times that of  $(\overline{PS})_s$ . The errors naturally decrease as the layer thickness increases towards values approaching the thicknesses between the observed standard pressure and 1 or 2 minute levels. However, it seems possible that once the relationship is established from temporary Jimsphere ascents,  $(\overline{PS})_s$  or  $(\overline{MS})_s$  data can be used to estimate finer-scale mean shears. It is interesting to note that the exponents of the power function tend to increase with the increase of smoothing.

In the theoretical development by Essenwanger (1963) the standard deviation plus a constant  $A_0$  is also related to a power function of the thickness. The constant is determined from the intercept in the regression between the standard deviation and the mean (for example, as in Fig.

24). However, Armendariz and Rider (1966 ) show a linear relation without a constant. In our data it appears from a comparison of regressions similar to those in Fig. 24 for  $(PS)_s$  and  $(MS)_s$ , that the constant is very close to zero and thus is not needed in this particular instance. Fig. 17 shows  $\sigma(JS)_s$  with a constant for comparison with Essenwanger's regressions, and Fig. 17A shows  $\sigma(JS)_s$  without the constant for comparison with Armendariz's regressions. The coefficient changes slightly if the constant is not used. Fig. 18 compares  $\sigma(JS)_s$  with  $\sigma(PS)_s$  and  $\sigma(MS)_s$  not employing a constant.

As the regressions have been drawn by eye here, a closer fit by numerical methods would change the coefficients also. Further, it seems possible from some of our data that a polynomial might provide a better fit than a straight line which was used for the sake of uniform comparison with the literature. This can only be decided by large samples of independent data from various sources.

The agreement of these various regressions is evidently dependent on location, season and probably altitude range, as well as the degree of smoothing employed in data reduction. Only analysis of additional data using a single type of observation, taken frequently at different locations and seasons, will help identify the contribution of these factors.

### C. Direction change with height

To help evaluate the magnitudes of the shear differences discussed already, that portion of the shear which is due to the rotation

of the wind is shown in Fig. 19 as a frequency distribution of  $(JS - PS)_d$  for 2 km layers. Fig. 20 does the same for  $(JS - MS)_d$ . In both instances the direction differences are smallest near 10 km and largest both near the surface layer and at the highest layer.

#### D. Properties of 25 meter shears from Jimsphere data

Fig. 21 shows that  $\overline{(JS)}_s$  is about 0.3 m/sec/25m from 0-9 km, and then increases to about 0.8 m/sec/25m at 17 km. Fig. 22, of the standard deviation, shows a similar pattern but reveals numerous sharp peaks, especially about 8 km. Many of these are due to single occurrences of extreme shears which hardly affect the mean at the level but are large enough to be outstanding in terms of standard deviation. A frequency distribution of  $\overline{(JS)}_s$  by 2 km layers in Fig. 23 shows how the larger shear classes increase with height. The frequency curves for layers below 10 km show similar shapes with peak values in the minimum class (0-0.25 m/sec/25m). This peak frequency shifts to 0.50-0.75 m/sec/25m at 16-18 km.

A linear relation of  $\overline{(JS)}_s$  to its standard deviation was also pointed out by Essenwanger (1963). In Fig. 24, the slope of the Jimsphere regression is .65 which is less than the .78 of his rocket data. The rocket data are for unspecified months and period of record which may help account for the appreciable discrepancy at higher values of shear.

#### E. Extreme shears

Table III shows the source of all observations of shears greater than 5.0 m/sec/25m. Examination of the original 50 meter average wind

Table III: Extreme Jimsphere Shears ( $\geq 5.0$  m/sec/25m)

data showed several instances of abrupt change of direction and/or speed for one or two layers, then a return to previous values.

It is not possible to state categorically that such observations could not exist, even if they appear unusual and may have been caused by instrumental characteristics such as radar searching for its target. On the recommendation of J. Scoggins, NASA, Huntsville, all data were retained as each value is smoothed over about 80 points in each 50 meter layer.

F. Comparison of shear magnitude with direction change

In Appendix A a frequency distribution will be found, giving by 2 km layers, a bivariate distribution of magnitude against direction change for each of the five parameters treated in this report. Means, deviations, absolute and relative frequency are also included. The unequal class intervals should be noted when interpreting distributions. This was done to provide greater resolution of the most frequent categories. Fig. 25 presents the frequency distribution of  $(JS)_d$  for each 2 km layer from this tabulation. It shows essentially the same features as already discussed above for Figs. 19 and 20. For extreme direction changes, ( $\geq 10^\circ/25m$ ), maximum frequency (2.8%) occurs at the surface layer. This frequency decreases to 0 at the tropopause and then increases upward.

G. Short period time variations

Among the 175 ascents, there were 59 pairs of observations which were taken within four hours of each other. The average time interval is

about one hour but varies from 15 minutes to 4 hours. All five parameters were computed as was done for the entire data set and the results are tabulated in Appendix B. Time-height sections of the ascents were even made for each parameter to see if persistent patterns could be found. All changes used in the tabulations were taken without regard to sign. In addition, the time variations of the original Jimsphere winds and of their vertical shears were graphed.

The dominant feature of the wind profiles about 10 km altitude is high persistence in time. For example, on February 10, 1965, at 12-16 km altitude, a small scale perturbation existed which could be followed throughout the series of profiles. Meanwhile, large wind shears of 1 m/sec/25m layer occurred at 15-16 km, and persisted for more than 6 hours. This feature of persistence can be important in prediction of wind shears.

Fig. 26 shows the frequency distribution of the wind speed change for consolidated levels. The peak value occurs at the 1.5-2.0 m/sec interval, and wind speed changes of less than 4 m/sec occur 80% of the time. These seem to indicate that in general the wind speeds are rather persistent up to 4 hours.

As may be seen in Figs. 27 and 28, the profiles of mean and standard deviation of wind speed change  $\Delta J_s$  depend on altitude. In the friction layer, the mean curve tends to decrease with altitude. The minimum mean values occur in the mid-troposphere between 2 to 6 km. The largest values occur at 10 to 13 km at the subtropical jet stream level, and above 13 km in the lower stratosphere the speed change decreases. The standard deviation shows similar features.

The frequency distribution of the magnitude of wind shear change  $\Delta (J_S)_s$  in Fig. 29, also shows the same shape as the wind speed changes  $\Delta J_s$ . Its peak frequency occurs at .250 to .375 m/sec/25m. Large shear changes of greater than 1.0 m/sec/25m are infrequent, occurring in less than 15 percent of the observations. Such large shear changes are usually found above 10 km altitude. The mean values of wind shear change are shown in Fig. 30. Those above 10 km altitudes are much larger than at lower altitudes. The standard deviation of the wind shear change represented in Fig. 31 shows similar features.

#### Acknowledgement

The authors wish to thank the Aero-Astroynamics Laboratory for the use of the Jimsphere data and J. P. Scoggins for helpful discussions of data reliability.

13. ABSTRACT			
<p>Characteristics of the wind shear for 25 meter layers were prepared from a series of 175 detailed wind ascents to 18 km taken with a Jimsphere balloon followed by FPS-16 radar from November 1964 to June 1965. To determine how well the shears for small layers could be estimated from rawinsonde data, two new sets of ascents were created from the original Jimsphere data. One set consisted of wind data at 23 levels corresponding only to standard pressure levels, and the other set at the 46 "minute" levels at which winds are reported on observational forms. The differences in results were thus due only to the differing vertical resolution in the three series.</p> <p>The results showed that the magnitudes of the mean pressure and minute shears for 25 meters are smoothed to about 1/3 and 1/2 respectively of the Jimsphere shears. Graphs of corrections for pressure and minute data needed to approximate the Jimsphere shear are presented both in terms of thickness of layer, and, for 25 m as a function of height.</p> <p>The regressions proposed by Essenwanger between the mean, or the standard deviation, of the shear and the mean thickness of the layer, and also between the standard deviation and the mean of the shear are confirmed in principle using Jimsphere data. Tabulations of bivariate frequency distributions (direction change vs magnitude), means and standard deviations of five parameters relating Jimsphere shears and winds to those of pressure and minute data, by 2 km layers, are included, both for the total data sample and for the time changes in a sub-set consisting of 59 pairs of observations taken from 1-4 hours apart.</p> <p>The mean Jimsphere shear for a 25 meter layer increases from 0.3 m/sec at the lowest level to 0.5 at 11 km and to 0.8 at 17 km, with a standard deviation of about</p>

INSTRUCTIONS

1. **ORIGINATING ACTIVITY:** Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (*corporate author*) issuing the report.
- 2a. **REPORT SECURITY CLASSIFICATION:** Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.
- 2b. **GROUP:** Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.
3. **REPORT TITLE:** Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.
4. **DESCRIPTIVE NOTES:** If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.
5. **AUTHOR(S):** Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.
6. **REPORT DATE:** Enter the date of the report as day, month, year, or month, year. If more than one date appears on the report, use date of publication.
- 7a. **TOTAL NUMBER OF PAGES:** The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.
- 7b. **NUMBER OF REFERENCES:** Enter the total number of references cited in the report.
- 8a. **CONTRACT OR GRANT NUMBER:** If appropriate, enter the applicable number of the contract or grant under which the report was written.
- 8b, 8c, & 8d. **PROJECT NUMBER:** Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.
- 9a. **ORIGINATOR'S REPORT NUMBER(S):** Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.
- 9b. **OTHER REPORT NUMBER(S):** If the report has been assigned any other report numbers (*either by the originator or by the sponsor*), also enter this number(s).
10. **AVAILABILITY/LIMITATION NOTICES:** Enter any limitations on further dissemination of the report, other than those

imposed by security classification, using standard statements such as:

- (1) "Qualified requesters may obtain copies of this report from DDC."
- (2) "Foreign announcement and dissemination of this report by DDC is not authorized."
- (3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through \_\_\_\_\_."
- (4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through \_\_\_\_\_."
- (5) "All distribution of this report is controlled. Qualified DDC users shall request through \_\_\_\_\_."

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

11. **SUPPLEMENTARY NOTES:** Use for additional explanatory notes.
12. **SPONSORING MILITARY ACTIVITY:** Enter the name of the departmental project office or laboratory sponsoring (*paying for*) the research and development. Include address.
13. **ABSTRACT:** Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C), or (U).

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. **KEY WORDS:** Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, roles, and weights is optional.
