THE MOORE SCHOOL INFORMATION
SYSTEMS LABORATORY

The Information Systems Laboratory of The Moore School of Electrical Engineering, Unive 'ity of Pennsylvania, was established in 1962 to develop a design for a mec lized information system in the information processing field, with special attencion to the implementation criteria entering into on-line retrieval through man-machine dialogue from a remote console. The program is currently concentrating upon four major tasks at the system level; specifications for capturing search strategies; specifications for machine storage of indexer aids, including lists of index items, synonymic equivalences, classification tables, and other semantic tools; organization of disk file storage to accommodate system routines for the load and quest modes; and study of uses of graphic display. The search mode has been implemented in minimal form and informal tests have been run. The long-range goal is to provide for machine-directed search, with computer-aided instruction on how to conduct a search, and with the search conducted in a problem-solving mode.

Out of the early reflections on the problems of indexing documents, Moore School conviction grew that information system problems stem primarily from the limitations and complexities of natural language as a means for communication. These convictions have been reinforced as the research advanced. The many attempts made by other researchers to mechanize the indexing process underscore these difficulties and suggest that they result partly from the multitude of synonymic alternatives and homographic ambiguities that pervade natural language, and partly from the omission of presumed common knowledge where the author presupposes that the reader will supply the broad framework of underlying material.

It follows that conventional schemes for cataloging and indexing are inherently limited in their ability to assist the search process. The newer procedures employ "deep indexing" techniques, whereby a substantial number of index terms, often as many as 100, are assigned to each document to supplement conventional bibliographic elements such as author, title, date, publisher, etc. As used here, an index term means a single word, number, or symbol or a brief phrase, which gives a clue to a substantial topic or item discussed in a document or denotes a subject area relevant to the document's contents.

The procedure which currently enjoys the greatest popularity makes use of an "authority list" or "thesaurus" of index terms. The thesaurus is prescribed by a group of experts in the subject specialty. These experts select a set of (relatively) independent index terms to span the topics that they believe should be included in the document file. The

primary limitation of a thesaurus is that it presupposes an arbitrary and fixed characterization of subject matter; indexing is thus restricted to these preconceived notions, and new ideas are withheld from the searcher. From the vantage point of information theory, a thesaurus restricts the apparent growth of the file to an accumulation of more and more documents on the same subject matter through extension of ideas beyond the boundaries existing at thesaurus-making time.

The Moore School research team has therefore concentrated upon the preparation of a functional and procedural plan for a mechanized information system which recognizes the limitations of index terms, whether taken freely from natural language or limited to a prescribed thesaurus. The system calls for computer aid not only in searching the document file but also in providing instructions on how the file has been organized, what index term meanings were assumed by the indexers at indexing time, which homographic meanings of index terms are allowed by the system; which synonyms are recognized, etc. In short, a "librarian" is built into the system and the user can obtain the librarian-like assistance, in real time, directly through his on-line console.

More specifically, the system is planned with the following features:

(1) the user has direct access to the system via on-line console;

(2) in addition to catalog and index data, the system will store a complete description of itself;

(3) the user will be permitted an unrestricted search vocabulary. It will be the responsibility of the system to interpret search terms, request clarification where ambiguity arises, and provide meanings of terms upon request;

(4) the user will gain access to the document file through any one or more of a large number of entry ports, such as author, data, color of document, language, etc.;

(5) the user will be able to search from an initial category through related categories, with assistance provided by the system in designating and locating related categories, terms, and other entries.

The mechanized information system has been implemented in its first form. The system has been designed with a modular structure in order that commands may be added with ease and general-purpose routines may be shared by commands. The mass store is an IBM 1301 disk storage unit accessed from an IBM 7040 computer. The jobs of editing, printing, and accepting messages from local or remote users are performed by a DEC PDP-8. Direct on-line console access is through a 33-ASR Teletypewriter; remote stations utilize the same model Teletype units with Dataphones for telephone-line connection.

Summary of Progress to Date

The procedural specifications of an information system encompass the information flow through the system from the moment that a document is retrieved through the intervals when the document is indexed, ingested, and periodically retrieved and eventually to the time that the document is purged from the system because of its obsolescence. The procedural specifications reflect the actions of individuals and groups in processing the documents and their characterization by index terms (including conventional bibliographic elements, etc.) but the responsibilities of individuals and groups are generally spelled out in the functional specifications.
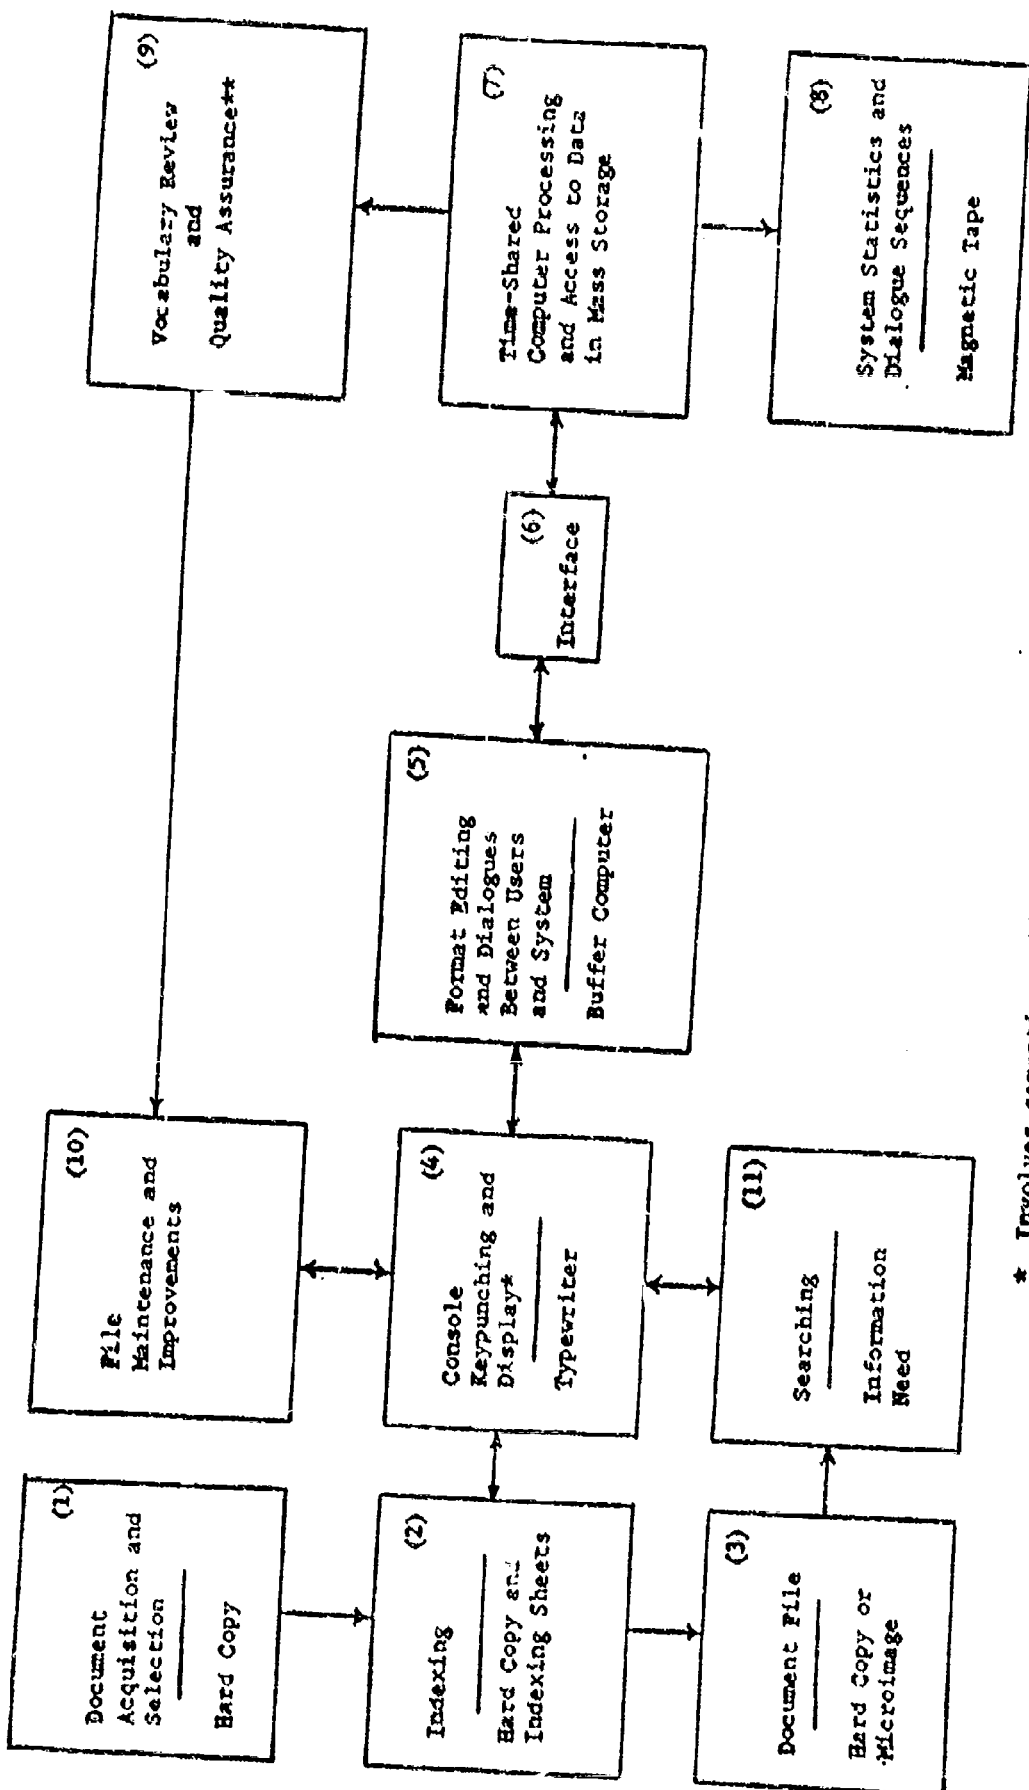

Figure 1 illustrates the information flow through the system. Each box indicates the function performed at that point and the equipment and/or form of information record. The first box depicts the arrival of new documents in hard copy form, their evaluation on the basis of prescribed criteria and their acceptance/rejection as file documents. The second box denotes the indexing of accepted documents by human indexers. The original document is then transferred to the document file (box 3) in its hard copy and/or microimage form.

The indexing sheets are forwarded to the console operator for loading into the mechanized file (box 4). Only authorized users are allowed to load new information into the files; such users are assigned special codes to identify themselves to the system and to gain access to the subroutines of the loading program.

Console keying is forwarded by Dataphone communication line (box 4) from the Moore School to the Computer Laboratory elsewhere on campus; since commercial telephone system lines are being used, any compatible teletypewriter can gain access to the system equally well. Indexing sheets and other file updating information are loaded periodically on a batch basis; this has significant influence on the file organization and the loading programs, particularly on disk file rearrangement procedures.

Messages enter the computer system through a buffer computer (box 5), where they are assembled and edited. Commands for message editing are illustrated briefly below, where one may also note the manner in which dialogue is promoted in natural English between man and machine through typewritten responses from the buffer. When the loading message and the indexing terms have been fully assembled in the buffers, a "message termination symbol" is keyed at the console which initiates transfer through a hardware interface into the computer/disk file system (box 7).

The new document index is then automatically loaded onto the disk and stored on magnetic tape. Deviations from the standards, such as index terms that do not appear in the descriptor lexicon, are summarized and forwarded to the vocabulary review board (box 9) where instructions are generated for file maintenance and improvements (box 10). The latter include expansion of the lexicon of transients, promotion of transients to free terms and free terms to descriptors, adjustment of spelling errors,

4.

etc. The review board instructions are then implemented through the console, also in the privileged load mode.

Certain system statistics are summarized periodically. These include frequency of descriptor usage, extremely high or low document activity, difficulties in man-machine dialogue, etc. The summarized statistics are reviewed by the quality assurance board which writes instructions for system modification including descriptor demotion, document purging, and adjustments to console commands and the retrieval language. These instructions are also entered via the console in the load mode.

The user gains access to the system when the teletypewriter console is free for user search (box 11). The user is only permitted to use the search mode to access the system. Suggested system improvements can be inserted into his search sequen but these are simply stored on magnetic tape (box 8) for later review by the quality assurance board.

About 2000 documents have been manually indexed. All have been key-punched onto Hollerith cards and are loaded onto disk for search experiments. The programs have been written for deriving inverted lists of accession numbers, which facilitate rapid retrieval through logical combinations of index terms. An executive control system has been written which interprets search commands, corrects minor spelling errors in the search message, and provides a number of similar user services.

Operation of the system may be better understood, at least in part, by reference to the results of an actual search displayed in Figure 2. The print-out begins with a succession of lines of STANDBY; these were typed by the buffer computer at one-minute intervals to assure the searcher that his console was still connected but that the IBM 7040 had not yet been turned over to the system by the Computer Center personnel. Possession is finally indicated by the buffer notification, I AM :- .

The searcher gave his code number (indicating character erasure with a left arrow) and the buffer requested mode designation. SEARCH was recognized as an existing mode, and the searcher was permitted to proceed.

The searcher requested a combinational search (keyword: COMBINE) on four terms, three of which were descriptors ($B) and one a date ($A2). After message printout, a correction was made by the searcher who added another term to the request. Finally after another message printout, retrieval was implemented and the searcher informed of the results. The buffer automatically asked if catalog data on these documents were desired, with "DO YOU WANT TO SEE ANY?"

Affirmative response was followed by a sequence of queries to determine which of the documents and which catalog data were desired. Note that the machine directed the searcher at this point. In fact, the searcher was interested in accession numbers only, and all 37 he requested were printed out.

In the next man-machine dialogue (Figure 2c), the RETRIEVE command

CONNECTION TERMINATED.

was employed, allowing for any logical combination of request terms. The union of documents by two authors was requested, and again, the searcher was directed to specify catalog data desired. Note that the searcher misspelled RETRIEVE and was corrected. As soon as format was determined the machine printed out two documents. More could have been obtained i y answering YES to the machine query MORE?.

In the last dialogue (figure 2d), the DISPLAY command was used in order to have certain catalog data of specific documents printed out. The rest of the dialogue should be self-explanatory. The message END terminated the connection.

Easy English

The commands RETRIEVE and COMBINE illustrate the operation and behavior of Symbolic Command Language (SCL) as a means for man/machine communication through a typewriter console. SCL proved satisfactory for users of the information system who participated in the study or who happened to wander in during demonstrations. It was therefore decided to perform an experiment with a more universal set of subjects who were less skilled with mathematics and computer languages than the study participants and casual visitors. The new subjects consisted of secretaries and under-graduate students, and their poor results deflated the confidence in SCL that had been building up.

A far-reaching action was then taken, to leapfrog ahead, rejecting all artificial languages and turning instead to a somewhat restricted but nevertheless real version of English. Fortunately, as mentioned above, SCL was designed in modular form and it has been found possible to set the new command language, "Easy English", directly over the top of SCL which it then uses for the actual search. The following is a summary description of the new command language, which has been fully operational since February 1967.

Easy English is a plain command language designed to simplify dialogues between man and machine through a remote typewriter console. It is made up of readily recognized sentences of the English language, sentences which any layman might be expected to use in everyday requests for services or articles from a familiar source. Easy English has been developed as a command language for retrieval of documents from a computerized data base, specifically from the Moore School Information Systems Laboratory (MSISL) files. It is intended for all information retrieval systems using remote typewriter consoles in a conversational mode.

Easy English is imbedded in the MSISL retrieval program which provides computer-directed search, computer-aided editing, and other forms of computer assistance. The attached typewriter printout presents a typical man-machine conversation which illustrates Easy English along with a number of features of the Laboratory retrieval system. Note that the latter currently provides the option of translation of the Easy English request into Symbolic Command

Language while searching the files; this is a convenience for those who might like to learn Symbolic Command Language on their own and use its shorter but more formal statements in place of Easy English.

Because Easy English is in fact real English, the only thing that the searcher needs to learn is that requests for information from the system should be formulated in the following syntactical form:

Introductory Clause   Document Clause   Data Clause   .

The following sentences present five forms in which the same retrieval request can be phrased in Easy English.

(1) PLEASE LOCATE EVERYTHING WRITTEN BY ROBERT PERKINS ABOUT EASIAC OR PSEUDO-COMPUTERS BETWEEN 1955 AND 1959 < >

(2) COULD YOU FIND FOR ME SOMETHING CONTAINED IN THE REPOSITORY CONCERNING EASIAC OR PSEUDO-COMPUTERS THAT WAS AUTHORIZED BY ROBERT PERKINS AFTER 1954 AND BEFORE 1960 < >

(3) I NEED ALL THE AVAILABLE DOCUMENTS PUBLISHED DURING THE PERIOD 1955 TO 1959 BY ROBERT PERKINS ON THE SUBJECTS OF EASIAC OR PSEUDO-COMPUTERS < >

(4) WE'RE INTERESTED IN HAVING REFERENCES AND MATERIAL ON EITHER PSEUDO-COMPUTERS OR EASIAC AUTHORED BY ROBERT PERKINS FROM 1955 TO 1959 < >

(5) I WOULD LIKE YOU TO HELP ME OBTAIN INFORMATION FROM YOUR LIBRARY RELATED TO EASIAC OR PSEUDO-COMPUTERS AND WRITTEN BY ROBERT PERKINS IN THE YEARS 1955 THROUGH 1959 < >

Notice that despite the differences in vocabulary, all of these statements follow the same basic pattern; for example,

COULD YOU FIND FOR ME   SOMETHING CONTAINED IN

THE REPOSITORY   CONCERNING ...

Typical examples of phrases acceptable in the three clause categories are:

Introductory clause

(1) I would like ...
(2) Please find for me ...
(3) I have need of ...
(4) I desire ...

Document clause

(1) ... documents in the system ...
(2) ... information ...
(3) ... any available book or article in the repository ...
(4) ... references from the files ...
(5) ... all the stuff ...

Data clause

(1) ... written by Carr between 1958 and 1965.
(2) ... published in 1960 on information retrieval
     and word association but not programming.
(3) ... dated September 1966 by J.H. Smith, Joe Doe
     but not K.L. Jones about analog computers.

In the event that a word appearing in either the introductory or the document clause is not recognized, the computer initiates a man-machine dialogue in order to determine whether the word is essential and, if so, to seek out a synonym in its vocabulary. Examples of such dialogues appear on the attached typewriter printout.

Current Tasks

With the system operational in its first form, attention has been directed to accommodation of the many other features implied by the procedural flow chart in Figure 1. A number of tasks have been defined and are described below. Documentation of the mechanization to date has been initiated on three levels: detailed microflowcharts, programs, and related descriptive text; macroflowcharts and related text describing the gross features of the system and showing the interrelationships among the detailed programs; and brief summaries of the main features of the system, cross-referenced to the macroflowcharts.

As mentioned above, the Moore School information system plan calls for computer-aided search. The basic tactic for computer aid is a sophisticated use of man-machine dialogue in a problem-solving mode. The system incorporates computer-aided instruction as a means for assisting the searcher to find not only information about the document file but also information on how to go about the search, i.e., computer-aided instruction on computer-aided search. At the same time, the Moore School recognizes the services provided by conventional bibliographic tools, and particularly those which expedite search through condensed display of bibliographic coupling. The tasks reflect this broad range of information system support.

The tasks may be delineated in the following order, proceeding from the simplest aids to the most advanced:

. Syntactic Tools

- Semantic Tools

- Indexer Aids

- Graphic Display

- Adaptive Interface

- Intersystem Switching

A few comments will be made on each item.

Syntactic tools are those which make use of word associations or author-designated couplings. Specific examples are permuted title indexes (KWIC) and citation indexes. The program to derive a KWIC index of the collection has been prepared, and citation index preparation has been initiated. Both will be printed for visual use in the Moore School library; KWIC is automatically available in the mechanized system and the citation index will be added.

KWIC does not pretend to be a sophisticated cataloging system, but its use in association with a document library has the following advantages:

1. It is an inexpensive way to produce a printed catalog of the library, since it can be automatically produced by the system in a format ready for photo reduction and offset printing.

2. It is easy to keep up to date, as the documents are already indexed and stored in the mechanized system.

3. It can be widely distributed in simple loose-leaf or book form.

4. It provides a printed record of the documents stored in the system at any time in its development.

It is conjectured that a citation network, connecting every document in a library to every other one which cites it or is cited by it, might be a useful tool. Various studies will be made of experimental citation networks, with the goal of adding this tool to the system. The citation network might be made directly available to the user, so that he may start at any document and follow a trail of citations either forward or backward in his document search. More important, manipulations of a citation network may be applicable to adaptive interface techniques for unsolicited machine assistance to the searcher.

Research has been initiated to investigate the uses and effectiveness of word associations to a greater depth than previously attempted by other experimenters. An important shortcoming in earlier attempts was their failure to distinguish among various types of intellectual coupling that contributed in equal amount to the derived association factor. For example,

if index terms (A, E) are strongly associated, and (B, E) are strongly
associated, but (A, B) are weakly associated, there are at least two inter-
pretations which have opposite implications for information retrieval. The
first interpretation is that A and B are synonyms and authors have subjective
preferences for one or the other. The second interpretation is that E is a
homograph with two different meanings, A and B, and that the latter have no
intellectual ties whatsoever. The first task will be therefore to seek out
the various intellectual relationships that may be associated with different
patterns of word associations.

It is important to note that word associations could serve information
systems in a number of ways. In establishing a system, word associations
readily lend themselves to vocabulary synthesis, to document indexing, and
to determination of relevance of a document to the scope of the file. In
system search, word association lends itself to extension of search scope
by searching on unsolicited but strongly associated words.

Semantic tools include a number of devices, such as sets of synonymic
equivalents, classification tables based on a variety of word relationships,
and semantic expansions. These tools are applicable both to index terms and
to system commands. Synonyms are used even on conventional thesauri, but it
is intended to expand their use and provide automatic substitution where use
of a preferred synonym leads to system efficiencies. Classification tables
(Figures 3a-3f) provide tools for browsing through the indexing structure,
discovering relationships among words, branching between unrelated topics
through homographic coupling, etc. And semantic expansions provide explana-
tions and illustrations at several levels of detail which serve to instruct
the searcher on the meanings of words and their mode of employment in the
system. For example, consider the following semantic expansion of the des-
criptor INTERPRETIVE PROGRAM, supposing that a searcher has asked that this
term be explained for him and that he requests further explanation after
each of the first three system responses. (Underlining indicates that
explanation of the underlined term is also available from the system.)

A. First-level response:

   "An INTERPRETIVE PROGRAM is a computer program that combines
   translation and execution."

B. Second-level response:

   "An INTERPRETIVE PROGRAM is a computer program which receives
   a sequence of commands in a source language, examines each
   command, determines a translation to replace it in the object
   language, and executes it if possible. The major character-
   istic of an INTERPRETIVE PROGRAM is that the translation of
   an instruction is performed each time the instruction is to be
   obeyed."

C. Third-level response:

   "An INTERPRETIVE PROGRAM carries out the instructions of a
   program written in one language by translating each instruction

of that source language into a sequence of computer instructions
in the language of the computer being used, and by allowing these
computer instructions to be obeyed before translating the next
instruction. This step-by-step translation and execution becomes
significant when the execution of one instruction causes a change
in the meaning of that instruction or another one. A new trans-
lation of the changed instruction will be necessary then before
it can be correctly executed."

D. Fourth-level response:

"Consider the following sequence of instructions:

Position	Instruction
1	FETCH 5
2	ADD 6
3	STORE 5
4	GO TO 1
5	. . .
6	. . .

An INTERPRETIVE PROGRAM might first translate FETCH 5 into
24005 ("bring into the accumulator the contents of memory position
5") and execute the instruction. Then it might translate ADD 6
into 28006 ("add to the accumulator the contents of memory position
6") and execute that instruction. Then it might translate STORE 5
into 02005 ("store the contents of the accumulator in memory
position 5") and execute that instruction. Finally, it might
translate GO TO 1 into 32001 ("go to the instruction located in
memory position 1 and execute it"). The instruction located at
memory position 1 is FETCH 5. Because the INTERPRETIVE PROGRAM
has carried out all instructions immediately after translating
them, memory position 5 now contains a new value which will be
incorporated into all further instructions involving it. If
translation of all instructions had been completed before any of
them had been executed, such a change would have been ignored.
This demonstrates the major characteristic of an INTERPRETIVE
PROGRAM -- that translation of an instruction is performed each
time the instruction is to be obeyed."

While such semantic tools as classification tables and semantic
expansions were originally conceived and developed by the Moore School as
searcher aids, it appears that they are also necessary in the areas of
vocabulary control and document indexing. As mentioned earlier, much of

the search process is dependent upon the quality of indexing, and indexing quality is likewise dependent upon the quality of the thesaurus from which items are chosen. The Laboratory has concluded that research and implementation of semantic tools are necessary to the development of better mechanized information systems. Figure 4 illustrates the role that semantic tools play in the interactions that exist among those who devise and control the vocabulary and those who use it for indexing and searching.
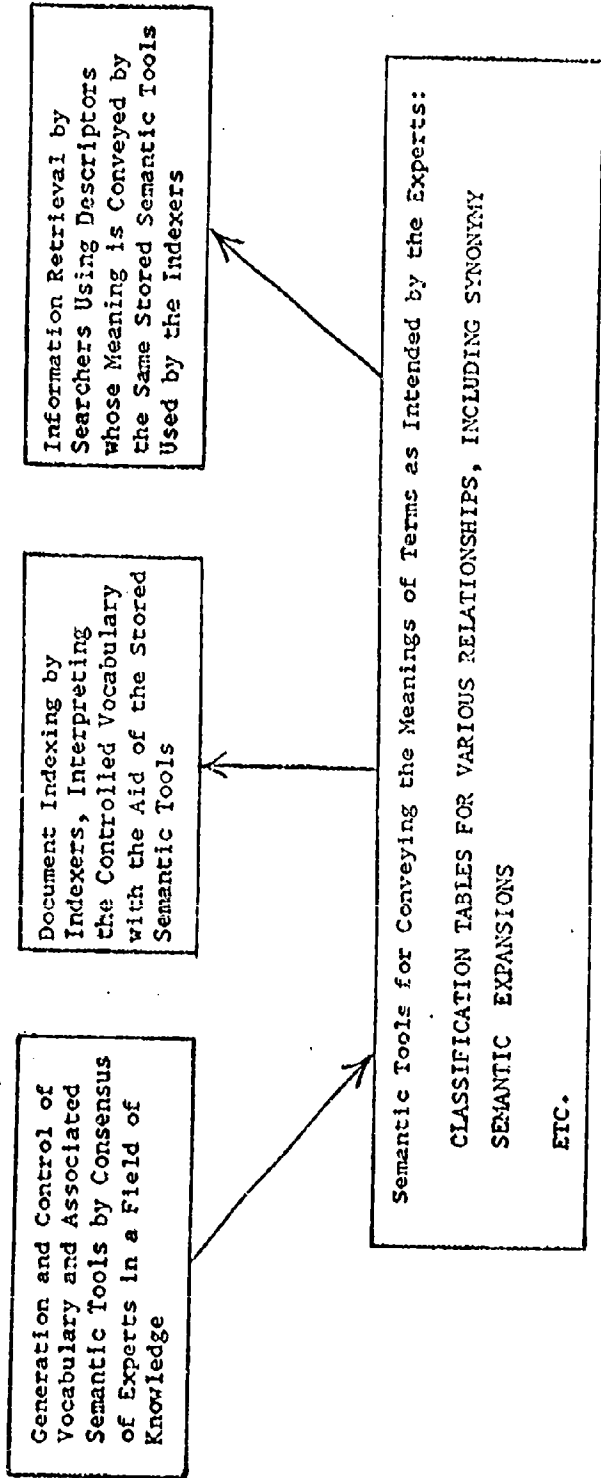

It should be recalled that the system aims to provide a broad cross-section of users with access to the file of documents. This requires a system which is self-explanatory to a user who has no experience with a mechanized library, and is only superficially familiar with usual library techniques, including the availability of a librarian's guidance. The capability of "carrying on a conversation" with the user will explain, instruct, volunteer suggestions, and guide. These semantic tools, and especially semantic expansion, will incorporate ideas from the field of programmed instruction (teaching machines), specifically techniques of what is known as "intrinsic programming". At a superficial level this means that any user may request instruction in the use of any or all phases of the system. If simple information does not satisfy him, he may request more detailed information, first about the general organization of the system, and then about the actual structure and inner workings of any or all of its substructures. "Semantic expansion" techniques will afford the user any degree of detail he may desire (see Figures 5a and 5b for a semantic expansion of the system command RETRIEVE). This feature of the mechanized system corresponds to a librarian's ability to explain how a library is organized or structured, either superficially, or in great detail.

At present, all document indexing is done manually. This introduces the difficulty of searching for indexing terms that may have been used previously and would serve again. A second difficulty stems from the delays and errors introduced in the multi-step process of writing down the index terms, sending the indexing sheets to be keypunched, listing the results on a high-speed printer, and then comparing against the original. Both difficulties can be alleviated by providing the indexer with an on-line direct-access console.

Initially, the mechanized system will be provided with the capability of accepting new document information directly from the indexer. It will request the desired information item by item, and it will accept this information only in a standard format, rejecting ambiguous entries. Eventually, by means of the semantic tools mentioned earlier, the system will assist the indexer with his choice of subject index and secondary index terms, assuring greater standardization of index terminology and omission of extraneous material.

Graphic display consoles offer many advantages over teletypewriters as terminal units. Currently in use at the Moore School are two Bunker-Ramo Teleregister consoles which allow character display only. More sophisticated devices, permitting diagram display and light pen operation are currently being developed. Such devices have great potential in the information laboratory, as they free the system design from many constraints imposed by

Figure 4

Semantic Expansion of the Command RETRIEVE

[N.B. Underlining indicates that further explanation is available from the
system by specifying the underlined word or word phrase.]

A. First-level response:

"RETRIEVE is a command used to obtain information about documents in
the data base, according to the specifications of a user of the system."

B. Second-level response:

"The RETRIEVE command provides information about documents in response
to given index term specifications. You may specify the required
document(s) by bibliographic data (category $A with sector codes
$A1 - $A9) , descriptors (category $B), or added information
(category $C). Your request will be formulated by the following
logical combinations of your specifications:

a)   documents characterized by all of the terms (and, &)

b)   documents characterized by at least one term (or, +)

c)   documents characterized by all of some terms but not by one or
more other terms (and not, †).

When you have given a RETRIEVE command, you will be informed how many
documents have been retrieved and will be asked to specify the types
of information (accession numbers, $A, $B, $C) you would like to have.
The requested information for each retrieved documents will then be
printed out."

C. Third-level response:

"Consider the RETRIEVE command

RETRIEVE ($A1 CARR, J W III + $B PROGRAMMING LANGUAGES) † IBM MANUALS < >

The machine will respond to this instruction by finding the accession
numbers of all documents having J. W. Carr, III, as an author ($A1)
and "Programming Languages" but not "IBM Manuals" as descriptors ($B).
The machine will type out the number of documents satisfying these
conditions, offer to PRINT SOME?:* , and, if your answer is YES, ask
which categories of the documents' full description (accession numbers,
$A, $B, $C) you would like to see. The machine will then type out the
appropriate information stopping periodically to ask MORE?:*. When you
answer NO < > at any time during this sequence or when all the requested
information has been printed out, the machine will indicate readiness to
receive a new instruction with YOU MAY PROCEED:*.

D. Fourth-level response:

See Flowchart and Table for RETRIEVE Command.

Figure 5a

Results following from actions (on left) under the indicated conditions:

15. System prints accession numbers for all documents found.	12				

* Condition applies only to action 8   ** Result follows only if "NO" is only condition

Table (Fourth-level Response in Semantic Expansion of RETRIEVE Command)

the ten-character-per-second teletype. On many occasions in man-machine
dialogue, the searcher is offered a choice among a number of alternatives,
eac. alternative leading to another sequence of choices. A video con ole
allows simultaneous display of all alternatives and the wherewithall for a
better decision. Furthermore, text and catalog data can be instantly dis-
played. The light-pen feature invites rapid reply by the searcher.
Similarly, on-line indexing is facilitated by display of portions of micro-
thesauri and classification tables. Flowcharts like that in Figure 6
replace the harder-to-read tables (Figure 5b) in semantic expansions. These
and other advantages of graphic display will be considered in the current
design and implementation.

"Adaptive interface" refers to the system capability of unsolicited
suggestion and assistance to the user. This capability will probably be
comprised of a large variety of techniques and will be employed in many
modes of operation of the system. It may be compared to the unsolicited
assistance offered by a librarian who has come to understand the problem
of a library user through his questions. The librarian might say: "You
are asking the wrong kind of questions, so let me suggest ...". Much of
the adaptive interface technique will probably be based on results of the
study of search strategies of various users. Pragmatic experiments will
be set up. Choice of subjects will take account of their background,
motivation, and adaptability with respect to the mechanized system. Use
will be made of the large amount of literature in the field of "artificial
intelligence", including work in machine problem-solving and self-organizing
systems. The work being done in word association and citation networks will
also come into play.

A flowchart delineating the organization and sequence of tasks is
shown in Figure 7. Implementation tasks are supported by Army Research
Office (Durham); system studies are supported by the Air Force Office of
Scientific Research.

(1) User types RETRIEVE command such as RETRIEVE $A1 RUBINOFF & $B AUTOMATA < > using logical combinations (&, +, !) of the specifications (author, title, index terms, etc.) of the documents he needs, with the specifications prefixed by their appropriate category symbols ($A1-$A9, $B, $C).

(4) System types YOU MAY PROCEED

(2) System finds documents about AUTOMATA written by RUBINOFF.

NO

(3) System informs user that NO DOCUMENTS HAVE BEEN RETRIEVED

YES

(5) System informs user how many documents have been retrieved; asks PRINT SOME?

(6) User answers system's question in (5).

NO → (4)

YES

(7) System asks user to specify desired information categories by answering questions about each and asks user to answer YES, NO, ALL, or FORGET to each question.

(8) User answers system's question in (7).

FORGET → (4)

YES or ALL to any question

NO to all questions

(9) System prints out the desired information, stopping periodically to ask MORE?

(13) System prints out accession numbers for all documents found, stopping periodically to ask MORE?

(14) User answers system's question in (13).

NO → (4)

(10) User answers system's question in (9).

NO → (4)

YES

YES

(15) System prints accession numbers for all documents found.

(11) System prints all desired information for all documents found.

13. ABSTRACT

The report briefly describes the goals of the Moore School Information Laboratory which are primarily in the following tasks at the system level: specifications for machine storage of indexer aids, including lists of index items, synonymic equivalences, classification tables, and other semantic tools; organization of disk file storage; study of uses of graphic display. The report also summates the progress made by the Laboratory in these tasks.
