NCAR Technical Notes

NATIONAL CENTER FOR ATMOSPHERIC RESEARCH
Boulder, Colorado

The National Center for Atmospheric Research (NCAR) is dedicated to the advancement of the atmospheric sciences for the benefit of mankind. It is operated by the University Corporation for Atmospheric Research (UCAR), a private, university-controlled, non-profit organization, and is sponsored and principally funded by the National Science Foundation.

NCAR shares with other atmospheric research groups four inter-related, long-range objectives that provide justification for major expenditures of public and private funds:

- To ascertain the feasibility of controlling weather and climate, to develop the techniques for control, and to bring about the beneficial application of this knowledge;
- To bring about improved description and prediction of astrophysical influences on the atmosphere and the space environment of our planet;
- To bring about improved description and prediction of atmospheric processes and the forecasting of weather and climate;
- To improve our understanding of the sources of air contamination and to bring about the application of better practices of air conservation.

The research and facilities operations of NCAR are conducted in four organizational entities:

The Laboratory of Atmospheric Sciences
The High Altitude Observatory
The Facilities Laboratory
The Advanced Study Program

All visiting scientist programs and joint-use facilities of NCAR are available to scientists from UCAR-member and non-member institutions (including private and government laboratories in the United States and abroad) on an equal basis. The member universities of UCAR are:

University of Alaska	Florida State University	University of Oklahoma
University of Arizona	University of Hawaii	Pennsylvania State University
University of California	The Johns Hopkins University	Saint Louis University
University of Chicago	University of Maryland	Texas A & M University
Colorado State University	Massachusetts Institute of Technology	University of Texas
University of Colorado	University of Michigan	University of Utah
Cornell University	University of Minnesota	University of Washington
University of Denver	New York University	University of Wisconsin

FOREWORD

The Line Islands Experiment was designed to provide comprehensive meteorological data in the oceanic part of the Equatorial Trough Zone for a variety of basic studies, to provide data with which to evaluate cloud photography performed by the ATS-1 synchronous satellite, and to serve as a pilot program for future experiments in tropical meteorology.

For the Experiment to achieve its objectives, interested scientists must have ready access to the data. This catalogue attempts to list comprehensively the kinds of data collected, dates and frequencies of observations, dates and times of satellite pictures, and any obvious limitations of the data. The format of the data is given, as well as the source of copies, which may be obtained on request. If not otherwise stated, the source of information or data is either of the co-editors.

Obviously, this catalogue will not perform its function until it is distributed. To reduce the preparation time as much as possible, most of the actual data are not included. The exception is surface data tabulations, which have been included because they are relatively compact and will enable the user to arrive at a rapid characterization of the meteorological situation on a given day at a given location and hence to determine which data to request.

It is important to note that this is the first, but not the last, data summarization of the Line Islands program. A series of data reports is planned which will include, tentatively, satellite data, rawinsonde data, aircraft data and sea temperature data -- probably in summary rather than complete form.

Finally, in the interest of rapid publication, which is a requirement for this catalogue, third only to accuracy and comprehensiveness, little attempt has been made to treat each form of data in exactly the same way. The reader is urged to seek additional information from the appropriate source if some point of interest has been covered inadequately.

ACKNOWLEDGMENTS

The detailed scientific plan for the Line Islands Experiment was formulated in August 1966. Planning of all phases of the program commenced at once, but a survey trip to the Line Islands did not take place until late November, and the operational, logistic and financial arrangements were not complete until January 1967. Despite the complexity of the operation and its very tight time schedule, the field program was carried out during February-April 1967, with a degree of success that equaled or exceeded our best hopes. The credit for this outcome goes to a large number of individuals in a large number of organizations, and the success of the program is a tribute to the hard work and dedication of all those who participated and assisted.

The National Science Foundation (especially Fred White, Randall Robertson, Gerald Greenwood and Leonard Gardner) made the Experiment possible by enthusiastic support in the face of complex and ever-changing problems.

Individuals within NCAR who made substantial personal contributions to the program include: William Lanterman, Experiment Field Manager and Field Observing Facility Manager; Jack Hinkelman, Research Aviation Facility Manager; William Jones, Assistant to the Director of the Laboratory of Atmospheric Sciences; Charles Palmer, Assistant to the Director of the Facilities Laboratory; Robert Greenwald, Procurement Officer; and Landis Parsons, Purchasing Agent. Robert James was manager of the Palmyra station during the program, and provided liaison between the scientific and operational groups from the earliest planning phase until the end of the program, while assuming some of the duties of both. Leo Crouch and Jack Tefft should be recognized for their untiring efforts in solving a great variety of practical problems. Henry van de Boogaard was of great assistance to the scientific effort, both in Honolulu and Palmyra. The NCAR Research Aviation Facility carried out 60 research

flights in 53 days in a hostile environment for a two-engined aircraft, an achievement that is due to the uncommon dedication of all concerned. The pilots were William Bullock, Loyd Newcomer, Robert Beabout, Lester Zinser and Clyde Hudson. Other Aviation Facility people who should share the credit are: Cleon Biter, Ed Brown, Melvin Busch, Frank Brunot, Gene Prantner, Al Dascher, and William Kleinlein, the last from Intermountain Aviation, Inc., Tuscon, Arizona. Ralph Coleman did an excellent cloud photography job on Fanning Island, and Frank Robitaille should be commended for a variety of observing jobs on Fanning Island. Robert Kubara took months away from his job in the Scientific Balloon Facility to coordinate the U.S. Air Force rawinsonde program and, in addition, did an outstanding job as station manager on Fanning Island. Brian Lewis established a communications network on the islands quickly and under primitive conditions. George Saum was vital in solving electronics and communications problems. Al Sorenson handled many technical problems and helped receive the APT pictures on Palmyra. Julian Pike served for a month as station manager on Christmas Island. Robert McBeth acted as impromptu cloud photographer and assisted at the APT station. Don Eklund was on the original survey trip and helped arrange for much of the surface observing systems. Ed Elsberry solved a great variety of practical difficulties in the field. The general photographic documentation of the program is largely due to Rodger Ewy.

The field program was assisted in several vital ways by the U.S. Air Force. The Sixth Weather Squadron (mobile), U.S. Air Force, supplied personnel and equipment for the three island rawinsonde stations, and subsequently supplied personnel for data reduction, and the 57th Weather Reconnaissance Squadron made 24 flights in support of the program. For their cooperation in making this support possible, Brig. Gen. Russell Pierce, Dr. Robert Fletcher, Col. William Barney, Col. Robert Kerr, Lt. Col. Glenn Patterson, Col. Lowell Stiles, and Col. Sievers, all of Headquarters, Air Weather Service, and Lt. Col. Lloyd Smith, Headquarters, U.S. Air Force, have our sincere gratitude.

In the Sixth Weather Squadron, the cooperation of Col. Elwyn Mosely, Commander, and CWO Wayne Sunderland throughout the program is appreciated. C. M. Sgt. John Shumaker deserves special thanks for supervising the rawinsonde program and assisting with many logistic problems of the operation that were above and beyond his own responsibilities. We are also indebted to the above gentlemen for making it possible for all unworked soundings to be worked up after the end of the formal program. T. Sgt. H. Coffin, A1C A. Miller, A1C A. Watson, A1C J. Yeager, A2C G. Mason and A2C B. Niewinski worked up these soundings. Although it is not customary to specially commend military men for doing their assigned tasks, we wish to recognize the rawinsonde observers on the islands for securing a valuable data sample under difficult conditions. By island, they were: Palmyra -- M. Sgt. N. Williams, S. Sgt. A. Bardouche, S. Sgt. H. Coffin, A1C W. King, A1C J. Kingston, A1C J. Lee, A2C W. Bucklin, A2C G. Mason, A2C B. Niewinski, and A2C A. Watson; Fanning -- T. Sgt. H. Brown, S. Sgt. D. Hassenbein, A1C H. Amaker, A1C T. Parker, A1C J. Washington, A2C R. Elliott, A2C K. Hermach, and A2C C. Thompson; Christmas -- S. Sgt. D. Coleman, S. Sgt. H. Fuller, S. Sgt. J. Kerwin, A1C H. Clifton, A1C R. McCurdy, A1C L. Rathburn, A2C B. Craft, and A2C A. Miller.

The cooperation of Col. Brenner, Capt. Windsor, and Capt. Bair, Ninth Weather Wing, who helped arrange the reconnaissance flights is appreciated. We are especially grateful to Col. John Horn, Commander, 57th Weather Reconnaissance Squadron, for his patient cooperation. Aircraft crews of the 57th WRS took a large quantity of well-documented cloud pictures in addition to their other duties. They include: Col. Evans, Col. Wolcott, Maj. Chapple, Maj. Collins, Maj. Hancock, Capt. Coan, Capt. Follmer, Capt. Hamilton, Capt. Payton, and Capt. Swanson.

The U.S. Army extended vital assistance to the Line Islands Experiment, most notably by supplying surface weather observers and equipment. The cooperation of Mrs. Frances Whedon, Chief, Research and Development Environmental Service Division, Dr. Kenneth Barnett and Dr. Marvin Lowenthal, Atmospheric Science Laboratory, USAEC, Ft. Monmouth, New Jersey,

is appreciated. We are most grateful to Lt. Col. Horace Linhares, USAECOM, Meteorological Support Activity, Ft. Huachuca, Arizona, for arranging for support to the program from his command and for his personal contributions. M. Sgt. Frank Harrison deserves special mention for supervising the work of all U.S. Army personnel in the field, and contributing greatly to the siting and maintenance of meteorological equipment sent to the islands by the U.S. Army and other groups. We wish to recognize the Army observers on the islands for their fine work under difficult field conditions. They are: Palmyra -- S. Sgt. F. Barreras, Sp4 D. Bell and Sp4 J. Reynolds; Fanning -- M. Sgt. J. Nichols, Sp4 R. Bethke and Pfc. R. Flint; Christmas -- S. Sgt. J. Turner, Sp5 W. Bordine, Sp5 A. Escobar, Sp4 D. Smith, Pvt. D. Sterling and Pfc. J. Lane.

The cooperation of the U.S. Navy and their support of the program is appreciated. Thanks are due to Adm. Roy Lee Johnson, Commander-in-Chief, U.S. Pacific Fleet, and Capt. USN Richard Sanborn, Weather Officer, U.S. Pacific Fleet, for assistance in arranging support. We are grateful to Cdr. John Gibbs, Commanding Officer, VW-1 Squadron, for cooperation in arranging reconnaissance flights. Three timely flights were made by the VR-21 Squadron to transport personnel and material out of the Line Islands at the end of the program. We are grateful for the interest and support of Capt. USN E. T. Harding, Director, Naval Weather Service, Mr. Max Edelstein and Capt. USN Thomas O'Neill, Office of Naval Weather Service.

Eleven flights made to and from the Line Islands by KC-97 aircraft of the Air National Guard provided essential logistic support. Our sincere gratitude is extended to Col. William Pendleton, Maj. J. Misterly and Maj. Arthur Streim, California Air National Guard, 146th Military Air Wing, and all who participated in the flights from the California, Arizona and Utah Air National Guard.

The cooperation of Adm. William J. Smith, Commandant, U.S. Coast Guard, is appreciated. The assistance of the Search and Rescue Squadron, Barbers Point, Hawaii, came at a critical time and enabled us to transport essential personnel to Palmyra at the beginning of the field program.

We are grateful to Rear Adm. Ben Engel, Commander, 14th Coast Guard District, Honolulu and particularly to Capt. Walter Kerwin, 14th Coast Guard District, for advice and assistance throughout the program.

For the contributions of the Environmental Science Services Administration to the Line Islands Experiment, listed in subsequent paragraphs, we thank Dr. Robert White, Administrator of ESSA. We appreciate the cooperation of the following in arranging participation of the U.S. Coast and Geodetic Survey Ship *Surveyor* in the program and in arranging for the radiosonde program on the *Surveyor*: Rear Adm. James Tyson, USC&GS; Mr. Wheatley Ward, Associate Director, Hydrography and Oceanography, USC&GS; Capt. Seaborg, Director, Seattle Marine Center, USC&GS; Capt. Whipp, Commander, Pacific Field Office, USC&GS; Cdr. Boyer, Operations Officer, Seattle Marine Center, USC&GS; Col. Edwin Cartwright and Dr. Richard Halgren, World Weather Watch Office, ESSA; Mr. Vaughn Rockney, Chief, Overseas Operations Division, U.S. Weather Bureau; Mr. Roger Nichols, Director, Pacific Marine Center, USWB; and Mr. Victor Davis, Director, Seattle Marine Center, USWB.

Special thanks go to Capt. Norman Taylor, Commanding Officer, *USC&GSS Surveyor*, and Cdr. Harley Nygren, Executive Officer, *USC&GSS Surveyor*, for their wholehearted cooperation before and during the program. In addition to their help during the observational phase, they cheerfully transported, on short notice, 30 people to the Line Islands when they were vitally needed there. Lt. Cdr. William Curtis supervised the surface weather observing program. James Perry, Florida State University, did a fine job as cloud photographer on the *Surveyor*. Mel Fields, J. Musumeci and E. Iverson, USWB, secured an outstanding series of radiosonde-pibal observations. Klaus Wyrтки, University of Hawaii, and his assistants were responsible for the oceanographic data secured during the two cruises.

We thank James Osmun, Director, Ray Belknap and Ed Carlstead, Pacific Regional Office, ESSA, for the varied assistance given the program by their office. Myron Kerner participated in the original survey

trip and helped to solve communications difficulties. Joseph Vederman, Meteorologist-in-Charge, and many others of the Honolulu Airport Office, USWB, also gave assistance. William Sapp, USWB, conducted the observing program on *Weather Ship II*.

We are grateful to David Johnson, Director, National Environmental Satellite Center, and C. Spohn, NESG, for their arrangements to supply us on a continuing basis with timely ESSA satellite pictures of the mid-Pacific Ocean.

The National Aeronautics and Space Administration assisted the program by scheduling the maximum possible coverage of the mid-Pacific by the ATS-1 synchronous satellite. For their interest and cooperation we wish to thank John Clark, Director, Goddard Space Flight Center, and Morris Tepper, Director of Meteorology, Office of Space Science and Applications. Gilbert Bullock, Robert Darcey, Richard Moore and Wendell Sunderland, ATS Project Office, Goddard Space Flight Center, gave much support to the Line Islands program in the face of great pressures. John Lindstrom, Manager, NIMBUS/ATS Data Utilization Center, GSFC, supplied NCAR and the research community with the large number of photographs needed to begin working on the data. Moe Schneebaum arranged for an APT receiver to be sent to Palmyra, and Charles Vermillion came to Palmyra to install the equipment, and to train others in its use and maintenance. John Masterson, NCAR, provided liaison with NASA throughout the program.

The Honolulu Area Office, Atomic Energy Commission, provided a staging area in Honolulu, office space, and much tangible assistance in solving logistic problems. Although we cannot name each individual involved, we are especially grateful to James Reeves, Manager, Nevada Operations Office; William Bonnet, Director, and Ben Finuff, Honolulu Area Office, AEC; and Joe Abreu, Bob Anderson, Al Carter and Pete Moon, Holmes and Narver, Inc., under contract to Honolulu Area Office, AEC.

F. Swatek, Director, and John Ing, Don Richmond, Bill Brown and George Reese, all of the Honolulu Regional Office, Federal Aviation Agency, helped secure clearance to operate navigational beacons in the

Line Islands, and advised and assisted on many problems which arose in planning and carrying out our aviation operations.

James Butler, Manager, Honolulu Office, General Services Administration, helped locate and obtain much-needed equipment and material.

Wally Joyce, Chief, Office of International Scientific and Technological Affairs, U.S. Department of State, and John Rouleau, Chief, Environmental Science Division, helped arrange for clearance into Christmas and Fanning Islands.

Dudley Cooke, District Commissioner, Line Islands District, Gilbert and Ellice Islands Colony, gave permission to use Christmas and Fanning Islands as bases for the program. The Resident Commissioner, Gilbert and Ellice Islands Colony, Tarawa, gave clearance into the Line Islands, and helped eliminate government red tape and granted tax relief. We are grateful to Dudley Cooke, in his capacity as Manager, Christmas Island Plantations, Inc., for the cooperation and assistance extended to our group on Christmas Island, as well as to our people passing through Christmas Island on their way to other islands.

We wish to thank Philip Palmer, Manager, Fanning Island Plantations, Ltd., Fanning Island, for the use of his facilities and services on Fanning Island, and for his wholehearted interest and cooperation with our group. He and John Fleetwood, his assistant, also helped in the PBV landing and takeoff operations and provided the services of some of the plantation's employees.

Colin Ramage, Chairman, Department of Geosciences, University of Hawaii, led the initial planning of the Line Islands Experiment, coordinated activities in the Pacific prior to the Experiment, and provided a useful and comfortable "rear base" for the many participants and visitors who came through Honolulu. We thank Frank Callendar, Director, Research Corporation, University of Hawaii and Martin Vitousek, Department of Geosciences, for their cooperation in allowing us the use of the Cable Station grounds on Fanning Island, leased by the University. Gerald Schaeffer, the University's representative on Fanning Island, gave much direct assistance to our group there.

Many university scientists and students participated in the Line Islands Experiment, but we can discuss the specific contributions of only a few. Verner Suomi, University of Wisconsin, who designed the cloud cameras on NASA's ATS-1 satellite, was an inspiration to the program from the initial planning phases, and when he visited the Line Islands during the Experiment. Don Frazee, Air Force Institute of Technology student at Texas A & M University, in addition to pursuing his own research, acted as station manager at Christmas Island for one month and carried out the cloud photography program there. Aylmer Thompson, Texas A & M University, assisted in many ways prior to the field program proper, and was responsible for much of the photographic coverage obtained from the Navy's VW-1 flights and from the Air National Guard flights. Heng-jen Hwang, St. Louis University, did an outstanding job in receiving APT satellite pictures and in the Palmyra cloud photography program. Also participating actively were: Clifford Murino and Albert Pallmann, St. Louis University; Stefan Hastenrath, Robert Ragotzkie, Kris Menon, James Maynard, Fritz Hasler, Stig Rossby and David Nelson, all of the University of Wisconsin; Peter Kuhn and Stephen Cox, ESSA - University of Wisconsin; William Marlatt and Don Hill, Colorado State University (with Andrew Bunker's group); and Tetsuya Fujita, Dorothy Bradbury and their group from the University of Chicago, who carried out photographic work on Maui. Andrew Bunker, Margaret Chaffee, and others participated on the C-540 research flights, Woods Hole Oceanographic Institution. Finally, although not field participants, the assistance rendered by William Gray, Colorado State University, and Charles Jordan, Florida State University, is appreciated.

The weather radar on Palmyra was provided by Atmospheric, Inc. Fred Clark did a splendid job in installing and operating the set, and substantially assisted the program in many ways beyond his own responsibility, as did Elmer Schnicke, M.D., University of Wisconsin, whose professional services were, fortunately, not frequently required. Holmes and Narver, Inc., contractors for construction and camp maintenance, not only performed their job in an outstanding manner, but assisted the program in many other ways; the contributions of Edwin Bowen, Charles

Kelley, Chick Leeds and Robert Berg deserve special mention. Rip Riddle and Wyatt Coley, Hawaiian Tug and Barge Co., Ltd., supervised transport of the project's heavy equipment and supplies to the Line Islands. Leslie Fullard-Leo and Joe Carvalho, Palmyra Island Estates, Inc., deserve thanks, particularly the latter for his personal assistance on Palmyra. Finally, we are indebted to Thomas Kendall and Robert Kendall, Carolina, Ltd., and their crew members for assistance, support and cooperation. Their PBV-5A, *Tiare Tahiti* (also known as the *Liki-Tiki*), flew the survey trip, transported personnel to Palmyra when it was accessible in no other way, and completely supported the group on Fanning Island.

Finally, thanks are due to those who helped prepare this catalogue. The cooperation and assistance of Colin Ramage, Jim Nicholson and James Sadler in providing space and student assistants for data reduction at the University of Hawaii are appreciated. Frank Robitaille and Marelynn Zipser helped with data reduction in Hawaii. At NCAR, Frank Robitaille helped draft the text and Ralph Coleman prepared the figures.

I. INTRODUCTION

Scientific Objectives of the Program 3
Limitations of the Program 3

I. INTRODUCTION

SCIENTIFIC OBJECTIVES OF THE PROGRAM

The goals of the Line Islands Experiment can be placed into three broad categories:

- To provide a data sample for basic observational studies of meteorological phenomena in the oceanic portion of the Equatorial Trough Zone. To be sure, the Trough Zone has not gone unobserved in the past; some oceanographic data exist, some surface and upper-air data exist, and some satellite observations exist. However, all these data have the crucial deficiency that they are uncorrelated, and/or that much of the atmospheric data comes from the vicinity of large islands or continents -- introducing complicating effects that, in the primitive state of our knowledge, are difficult to account for. The Line Islands program has provided the first comprehensive data sample in the oceanic Equatorial Trough Zone -- far from continents or significantly large islands -- that combines adequate satellite and meteorological data for a variety of basic studies.

- To provide a meteorological data sample with which to evaluate comprehensively cloud photography performed by the ATS-1 synchronous satellite.

- To serve as a pilot program for more extensive tropical meteorological experiments (i.e., TROMEX) in the future.

LIMITATIONS OF THE PROGRAM

The planning phase of the program began in earnest less than six months prior to the deployment of equipment and personnel in the field. The stimulus for this haste was the imminence of the ATS-1 launch (6 December 1966) and the desire to obtain comprehensive data within the useful lifetime of the cameras, which, of course, was not known at that time. Initial inquiries showed that vital observational and logistics

support would be available during early 1967 but might not have been available later. The February-April period was also the most logical scientifically, since the mean position of the Trough Zone then lies within the Line Islands, rather than north of the northernmost island, Palmyra, as it does during the second half of the year.

The choice of this observing period having solidified as February-April 1967, it was impossible to consider any instrumentation in the developmental or experimental stage; *the Line Islands Experiment was carried out with existing, off-the-shelf items, but with care taken to extract the maximum benefit from available technology.* In the evaluation of the data, another important goal of the program therefore emerges -- the evaluation of the adequacy of the available technology in tropical meteorological experiments. For example, the measurement of temperature in a standard instrument shelter is widely suspected to be inadequate for many purposes in the tropics. The *siting* of the shelter, however, was selected with great care, so that the effects of technique should be separable from the effects of site. In another example, the GMD-1B rawinsondes were carefully sited, evaluated with attention to detail, and operated at ten data points per minute in the boundary layer instead of the usual one per minute, in order to extract the maximum possible benefit from the system. The same general comments apply to all observing systems that were employed.

Finally, the program was limited in scope. The meteorological program was based on Palmyra, Fanning and Christmas Islands, and most of the ship- and aircraft-based observations were carried out within a 300 n mi radius of these islands. Therefore, the data obtained during the Line Islands Experiment can be exploited to its greatest potential in the study of meteorological processes on scales up to and including the small synoptic scale.

II. THE LINE ISLANDS

A. Christmas Island	9
B. Fanning Island	12
C. Palmyra	15

II. THE LINE ISLANDS

Straddling the equator between 6N and 11S, some 1,000 mi south of Hawaii, are eleven atolls, known collectively as the Line Islands (Fig. 1). The five northernmost islands -- Christmas, Fanning, Washington, Palmyra and Kingman Reef -- are usually identified as the Northern Line Islands, while the remaining six -- Jarvis, Malden, Starbuck, Caroline, Vostok and Flint -- are called the Southern Line Islands.

All these atolls lack significant orography; the tallest objects are generally the tops of the coconut palms some 60 to 80 ft above the land. Only four of the atolls -- Palmyra, Fanning, Christmas and Caroline -- have lagoons, while the rest have the familiar fringing reef. Washington, however, is unique, having a freshwater lake whose level is controlled by a lock opening seaward on the south side of the island. In addition, numerous canals have been constructed to facilitate the collection and transport of copra.

Some additional geographical data for the Northern Line Islands are presented in Table 1.

Possession of each of the atolls has, at one time or another, been disputed between the United States and Great Britain, although a quiet application of either squatters rights or the friendly visit of a naval ship has not infrequently settled rival claims. Christmas was contested as recently as 1957, and Washington was described as an American island as late as 1940. Fanning, on the other hand, has been an undisputed British possession for nearly a century. Today, all islands except Kingman Reef, Palmyra and Jarvis are recognized British possessions.

All the islands have been occupied at one time or another, although generally for short periods connected with either guano digging or copra production. Only Malden (1890-1926), Christmas (1937-present), Fanning (1902-present) and Washington (1925-present) have had sustained occupation. During the last twenty-five years the total population of the latter

Table 1

SOME GEOGRAPHICAL DATA OF THE LINE ISLANDS

Island	Position	Natural Acres	Lagoon Acres	Cultivated Acres	Total Acres	Population
Christmas	1°55'N 157°20'W	88,960	68,077	11,000	157,037	~200
Fanning	3°54'N 159°23'W	2,456 (land) 2,951 (salt flats)	28,800	3,122	33,207	~300
Washington	4°43'N 160°25'W	2,361	689 (lake) 444 (bog)	2,092	3,494	~350
Palmyra	5°53'N 162°05'W	1,470	5,690	None	7,160	Uninhabited

three has generally been just under 1,000 people, with the largest number consisting of contract Gilbertese labor working for the three copra plantations. In 1966 all three plantations produced 2,284 (long) tons of dried copra.

Administratively, all islands, save the latter three, are the ultimate responsibility of the High Commissioner for the Western Pacific Territories. The Northern Line Islands are administered through the Gilbert and Ellice Islands Colony with a District Commissioner resident on Christmas Island; the Southern Line Islands are directly under the High Commissioner resident in Honiara.

Christmas, Fanning and Washington are served about twice a year by northbound ships of the Bank Line enroute between Suva and the Panama Canal.

A. CHRISTMAS ISLAND

It is fitting to recall that the first published account of western contact with any of the Line Islands had, in part, a scientific objective: namely, to observe the eclipse of the sun on 30 December 1777. Six days before, the master of *HMS Resolution* noted in his log that:

"At half past seven this morning we discovered land to the northeast which proved to be a low sandy Island with many lagoons on it: about five o'clock in the afternoon we came to an anchor to leeward of it in lat. 1°58'N and long. 202°32'E."

On the morning of the 30th James Cook, King and Bayly:

"...went ashore, on the small island above-mentioned (i.e., Cook Island), to attend the observation. The sky was overcast, till past nine o'clock, when the clouds about the sun dispersed long enough to take its altitude, to rectify the time by the watch we made use of. After this it was again obscured till about thirty minutes past nine; and then we found, that the eclipse was begun. We now fixed the micrometers to the telescopes, and observed,

or measured, the uneclipsed part of the sun's disc. At these observations I continued about three-quarters of an hour before the end when I left off; being, in fact, unable to continue them longer, on account of the great heat of the sun, increased by the reflection from the land."

Captain Cook provided the first extensive description of the Island, including its name, since "...we kept our Christmas here, I called this discovery Christmas Island." He found little water but plenty of fish and large sea turtles, many of the latter weighing 100 lb or more.

Finally:

"During the time we lay here, the wind blew constantly, a fresh gale at East, or East by South, except one or two days. We had, always, a great swell from the Northward, which broke upon the reef, in a prodigious surf..."

Ten days after first sighting the Island, Captain Cook and his party set sail northward; eighteen days later (20 January 1778) he discovered the Hawaiian Islands.

Some 80 years following Cook's discovery, Christmas was known chiefly for the number of wrecks on its shores. The world's largest atoll possesses an unusual horn of land forming the southern side of the treacherous Bay of Wrecks. Both current and prevailing wind sweep into this Bay, forming an inevitable trap for sailing vessels unlucky enough to be caught on the windward side. These wrecks provided several involuntary residents of the Island, among them the officers and crew of the English whaler *Eriton*, wrecked on the eastern side of the Island in October 1836. Both Captain Benson (1838) and the ship's physician F. H. Tresilian (1838), published narratives of their eight-month residence, including a new map of the Island.

By the middle of the nineteenth century, guano was discovered on many equatorial atolls of the Central Pacific, which not only provided an opportunity for the first scientific examination of some of the islands, but also gave rise to what became a lengthy polemic over sovereignty. In

the case of Christmas, Maude (1957) has provided an informative discussion, including an obscure American claim -- under the Guano Act of 1856 -- of the U.S. Guano Company based upon John Stetson's "peaceable possession" of the Island in June 1858. Further, in 1872, the Island was visited by the *USS Narragansett* which "took formal possession for the United States," while in 1888 Sir William Wiseman took possession of Christmas on behalf of Great Britain as a possible relay station on the trans-Pacific cable route. As Maude points out, both American claims are of doubtful legality.

In 1882, the Island, still unoccupied, was taken possession of by a New Zealand firm which hoped to develop the commercial possibilities of both copra and pearl shell. Ten years later they relinquished their rights. Subsequently, the Island has been held under Occupation License by the Pacific Islands Company (1898-1902), Lever's Pacific Plantations (1902-1914), and the Central Pacific Coconut Plantations Ltd., the latter under the immediate supervision of Father Emmanuel Rougier. Father Rougier, with Louis Becke, wrote a notable book (1914) about the Island, which included numerous photographs taken before World War I. Rougier (1915, 1917, 1925) lived on the Island for many years with assets going to his heirs upon his death in 1936. The heirs sold their interests to the British Government soon after the end of World War II for 50,000 pounds sterling; the Government hoped to colonize the Island with migrants from the overcrowded Gilbert Islands.

Most of the companies and individuals who attempted to develop the Island's commercial prospects met with rather indifferent success, the difficulties of transportation and the vagaries of sustained drought playing no small part. Nevertheless, since 1946 the plantation has produced anywhere from 150 to 700 (long) tons of dried copra per year. A recent report of the Line Islands District Commissioner asserts that 11,000 acres are currently under cultivation, or about one-eighth of the total land area of the Island.

During World War II, the U.S. Government constructed an airstrip on the northern part of the Island, and garrisoned it with several thousand military personnel; upon the conclusion of the War all personnel were removed, though considerable quantities of rolling stock were left behind. One unconfirmed story asserts that the American military offered this equipment to the British authorities, but it was rejected. When the military then proposed to leave it, British authorities countered that they would have to pay duty, whereupon the Americans shoved the lot into the lagoon and left. Whether or not this account is entirely accurate, a dozen or so military trucks are today rotting in the lagoon near Bridges Point.

More recently (1956-1957), "Operation GRAPPLE," the British nuclear weapons tests, had its headquarters at Christmas with a detachment of RAF personnel remaining until June 1964. Finally, the U.S. nuclear weapons test of 1962 (April-July, September-November), "Operation DOMINIC," occupied the Island for about five months under the command of Joint Task Force Eight.

B. FANNING ISLAND

In June of 1798 the master and crew of the American whaler *Betsy* were bound northwest from the Marquesas. At 0300 on the morning of the 11th, the ship nearly foundered on the eastern shore of an atoll in latitude 3°54'N and longitude 159°20'W, but with consummate seamanship near-disaster was avoided. The ship's master and some of her crew went ashore on the west side of the atoll; while ashore Edmund Fanning (1833), the *Betsy's* master, found:

"On the south island, and near by a grove of coconut trees, whose fruit they lay strewed around, covering the ground from one to three feet deep, and seemed to have ripened and trees fallen for many years past..."

The atoll was indeed uninhabited, though Emory (1934, 1939) was later to infer a fifteenth century occupation of the Island, possibly by people from Tonga. Finally, a day later (12 June 1798), Fanning discovered and named Washington Island, 70 mi to the northwest.

Fanning Island was visited two or three times during the next thirty years, though still uninhabited. However, on 15 July 1848, Edward Lucatt (1851), "a merchant long resident in Tahiti," found "...a man of Crusoe habits had taken up his abode there with his family, and...had devoted himself to the rearing of pigs. His location is on the starboard side of the entrance to the lagoon..." A few months later, Lucatt established a "cocoa-nut oil business," but apparently, this was not sustained for very long. In 1852 Henry English acquired the title to the Island and employed about 200 Manihikians to manufacture coconut oil. To quiet his uneasiness at the appearance of American vessels, he was allowed to fly the British flag in 1857; four years later Keyte (1861) reported the visit of the steam sloop *Alert* on the occasion of the Island being taken under British protection. Subsequently, a Scotsman, William Greig, and an American, George Bicknell, joined the English and extended their copra operations to Washington Island, in 1860. Greig, his heirs and associates developed their commercial interests in both Washington and Fanning Islands during the next forty years.

After extensive litigation, Rougier finally bought both Washington and Fanning at public auction in Suva (30 November 1906); he paid \$125,000 and expected to export guano and copra. In December of 1906 he brought several sample bags of guano to Honolulu to be analyzed by Theo. H. Davies. Although the results of these tests are not known, it is unlikely that the guano was of high quality. With the exception of an unknown amount exported from Fanning between 1879 and 1885, none has been exported since. Significantly, in 1887 a boat load of lumber departed Honolulu to be used to construct drying sheds for copra; since then, copra has been the major economic asset of the Island, though not continuously.

Rougier's interests were finally purchased in 1935 by Fanning Island Plantations, Ltd., controlled by the Australian firm of Burns, Philp, Ltd. Since then the plantation has exported from 600 to 1,000 (long) tons of dried copra per year, the largest quantity being 1,119 tons in 1943.

The importance of Fanning Island in the public mind is undoubtedly associated with the Cable Station first established in 1902. It was the relay station between British Columbia and Suva until the new cable was completed in 1963. The Canadian-Fanning link was, at the time, the longest cable in the world (3,300 mi), and of great strategic importance.

The Germans acknowledged this importance in September 1914 by coming ashore (under a French flag!), cutting the cables, and destroying the batteries and other facilities at the Station. With the help of some heroic diving on the part of Greig, the Station was back in operation in two weeks.

In 1920 the British Admiralty sent no less a person than Lord Jellicoe to examine the Island and advise upon its suitability as a coaling station for British ships enroute to Australia from the Panama Canal. Although two naval engineers left Honolulu in May 1920 and spent several weeks on the Island, apparently no action was ever taken to convert Fanning to a fueling station.

Some twenty years later, at the commencement of World War II, Palmyra, Christmas and Fanning were all garrisoned with U.S. military personnel. Fanning probably had the smallest complement, stationed on the Island from April 1943 to June 1945. In addition, considerable quantities of munitions were placed there, including underwater mines. The thoughtless disposal of this equipment in late 1945 had serious implications several months later when S. G. Ross (1947) treated 95 cases of fish poisoning among a population of 224.

The military ordnance was disposed of by dumping it in the sea leeward of the Island, opposite both English Harbour and the Cable Station. It was Ross' judgment that "...the plankton and algae, as well as crustaceans and seaworms...on which fish feed, contain a poisonous principle emanating from deteriorating dumped war material." Fortunately, there were no fatalities.

Finally, in 1963 the Cable Station ceased operation and was offered for sale the following year for \$168,000. In 1966 the University of Hawaii leased the land and (15) buildings from the Gilbert and Ellice

Islands colony. The University intends to establish a scientific station for mid-Pacific investigations. The facilities will ultimately include a 2,000-ft airstrip near the Cable Station. Finally, a charge of \$25 per day for food and the use of all facilities, and \$200 for (one-way) air transportation is tentatively planned.

C. PALMYRA

Palmyra acquired the first of its two recorded names when an American vessel of the same name sought refuge there in November 1802; its second name, Samarang, was acquired during a similar incident in September 1840.

The first published account of the Island appears to be that of Lucatt (1851) who visited it in July 1848 in search of a reputed wrecked whaler (none was found); Lucatt was very impressed:

"It is without exception, the most singular formation I have seen. We landed on the east side, the vessel having suddenly shoaled her water when about two miles from the breakers observed upon the land... when we reached an islet, with its luxuriant foliage growing apparently from the very surface of the water; and we then discovered that Palmyra Island is more properly an archipelago of islets...The islets rise only a few feet above the level of the water...Sharks were numerous, and so voracious that they attacked both the boat and the steering oar as we were pulling ashore...Birds were innumerable... you could not move your foot without crushing eggs; and the cries of the birds...were deafening, and more peculiar than any combination of sounds I ever listened to...We made the island to be in latitude 5°51'N, longitude 162°10'W."

In October 1859, Gerrit P. Judd, agent for the American Guano Company, landed on Palmyra and laid claim to the Island on behalf of the Company. However, no claim was ever filed with the Department of State, and no guano was ever dug.

Three years later, February 1862, Zenas Bent and John Wilkinson were granted a petition by King Kamehameha IV enabling them to take possession of the Island under the Hawaiian flag. Captain Bent landed on the Island in April 1862, erected a flagpole, read the proclamation of annexation, buried it in a bottle at the foot of the pole, erected a building,

planted some vegetables, and left a white man and four Hawaiians on the Island. The Island became an official part of the Hawaiian kingdom in June 1862. In December of the same year, Bent sold his rights in Palmyra for \$500 to John Wilkinson, who in turn willed the Island to his wife Susan Kalama. Subsequently (in 1885) her rights were sold for \$550 to W. L. Wilcox, who in turn sold them to the Pacific Navigation Company.* The latter Company sent a man and his wife to Palmyra in 1885 to assert its claim. In December 1887, W. F. Allen took over the Island as trustee for the Company's creditors; a month later he sold it to William A. Kinney for \$750. Thus, in 26 years the Island's value had increased by 50 per cent!

In 1889 the *HMS Cormorant* annexed Palmyra to Great Britain in apparent ignorance of the Hawaiian annexation. Britain, however, never pressed this claim. Finally, in 1898 the 55th Congress specifically included Palmyra among the Hawaiian Islands.

In 1890 Kinney sold his title to the Island for \$500 to Judge Wundenberg, while Kalama's brother sold his divided interest to William Ringer for \$200. Judge Henry E. Cooper, of Honolulu, finally acquired Wundenberg's share for \$750 in 1911; a year later, after some litigation, Cooper received clear title to the Island.

The same year a British syndicate expressed renewed interest in the Island, and provided some stimulus to the American authorities in the form of dispatching the cruiser *West Virginia* (in February 1912) to Palmyra for the purpose of taking formal possession in the name of the United States. After this the British advanced no further claim to the Island.

Streets (1877) appears to have made the first scientific examination of the Island, although Rock's (1916) account was the most complete until modern times. Rock (1929) also published a popular account of the voyage, while Henry Cooper (1915), the owner, wrote another of the Island itself.

*According to Honolulu newspaper accounts, the selling price in this transaction was one dollar!

In 1920, the Palmyra Development Company was formed with an object of developing the commercial potential of the Island, particularly copra. The company sent William and Idelle Meng, and Edwin Benner, all of Honolulu, to the Island for a year's stay (1920-1921). Meng (1921) and his wife (1923) both published popular accounts of their residence on the Island. For various reasons, the commercial prospects for the Island were soon dropped by the Company, and the Island was finally sold for \$15,000 (19 August 1922) to Leslie and Ellen Fullard-Leo of Honolulu, the Island's present owners. The Fullard-Leo claim was contested by the Government -- on the basis that no private individual held legal title to the Island prior to the annexation of Hawaii to the United States -- but was finally sustained in behalf of the Fullard-Leo family by the Supreme Court in May 1947.

The U.S. Navy made a preliminary survey of the Island in 1938, with a larger party departing Honolulu on 14 November 1939; the Navy constructed a seaplane base, which was finally manned in January 1942. The Island was occupied by either military or civilian personnel until November 1949.

Like Christmas Island, Palmyra was occupied during Operation GRAPPLE, the British nuclear weapons test, in 1957 (April-June), and again during the DOMINIC nuclear tests in 1962 (April-July, September-November), the latter under Joint Task Force Eight.

Lastly, Palmyra was explicitly excluded from the Hawaii Statehood Act of 1960.

III. OBSERVING SITES AND INSTRUMENTATION

A. Observing Sites 21
B. Instrumentation 25

III. OBSERVING SITES AND INSTRUMENTATION

A. OBSERVING SITES

1. Palmyra

U.S. Army surface site (Figs. 2, 3, 4, and 5). This site was established close to the edge of the lagoon near the southwest corner of the runway. An area of 100 by 300 yd had to be cleared of brush, which was accomplished by 7 March. (Before that date, the instruments were about 100 yd farther inland.) Some palm trees were left along the lagoon edge, since preservation of the natural beauty of the Island was a consideration, but these formed no restriction to the airflow near the instruments. The orientation of the lagoon shoreline at this site is 85° to 265° . The site afforded unrestricted off-lagoon exposure for wind directions south of east, but flow was off the Island for northeast winds. The elevation of the site was 6 ft above MSL.*

Instrumentation: MRI, instrument shelter, and Dines and Jardi recording rain gauges. The barometer was in the observer's shack about 25 yd back from the lagoon.

Causeway site (Figs. 2, 3, 6, and 7). This site was established in the center of the causeway after road access and site clearing were accomplished on 14 March. The causeway is oriented almost north-south. Vegetation was cleared for a length of 378 ft, affording unrestricted off-lagoon exposure for all winds except due north or due south. The site is adjacent to the deep water portion of the east lagoon, with no upstream restrictions for about three-quarters of a mile. Elevation was 6 ft above MSL.

Instrumentation: MRI, GMQ-12 (on 40-ft tower), and water temperature sensor 400 ft east of site at 1 m depth over 30 m of water.

*The anemometer cups of the MRI sets were 6 to 6.5 ft above the site elevation in every case.

Barren Island site (Figs. 2 and 8). This site was established to approximate an open ocean exposure as closely as possible. Shrubbery is insignificant near the site and exposure is unrestricted except for north winds. Access was possible by a combination of skiff (at high tide) and wading. The elevation was 6 ft above MSL.

Instrumentation: MRI.

U.S. Air Force GMD (Figs. 3, 4, and 9). The GMD equipment was housed in a concrete blockhouse near the southwest corner of the runway a short distance west of the U.S. Army surface site. The balloon launches were made a short distance west of the blockhouse. This site is in the western portion of the large cleared area, but some palm trees are nearby to the south and southwest along the lagoon shore.

Radar (Figs. 3 and 10). There was no location on the Island where palm trees did not potentially restrict portions of the radar horizon below 5° or 6° . Consequently, a tower was built on top of a 20-ft blockhouse on the northwest portion of the Island. The electronics were housed in an air conditioned shack which was also built on top of the blockhouse, and the antenna was elevated 67 ft above the ground (73 ft above MSL) -- higher than any palm trees in that part of the Island.

Photography (Figs. 3 and 10). The routine still and time-lapse cine photography (Bolex B-1) was accomplished from the top of the radar tower just below the antenna, giving an almost unrestricted horizon view. A second time-lapse camera (Bolex B-1) was operated from the lagoon shore near the mess hall, looking southwest across the lagoon. The stereo photography was accomplished from one station on the radar tower and a second station at the southwest corner of the runway (baseline 3,100 ft).

Ground-based radlometers (Figs. 3, 11, and 12). These were located on a platform built out over the lagoon (water depth 20 to 30 ft) from a piling off the southwest tip of the runway.

2. Fanning Island

U.S. Army surface site (Figs. 13, 14, 15, and 16). This site was located at Huachuca Point, affording good exposure to all winds from north through east through south. There were palm trees and shrubbery downwind, but most of the foliage was cut down near the site. Elevation was 5 ft above MSL.

Instrumentation: MRI and instrument shelter. The barometer was in the observer's shack, a rehabilitated boathouse southwest of the site.

Robitaille's Beach (Figs. 13, 14, and 17). This site was located on the immediate beach ridge on the southeast extremity of Fanning Island, affording the closest possible approximation to oceanic exposure. The only exceptions (rare) are for winds north of northeast. Sea spray was severe, resulting in external corrosion of the MRI housing, but did not affect the wind recording to any observable degree. Access was by small boat. Elevation was about 9 ft above MSL.

Instrumentation: MRI.

U.S. Air Force GMD (Fig. 18). The GMD releases were made from a field of dark coral rock 200 ft north of the house used for work-up of the soundings. This field is about halfway between the lagoon and the ocean just north of the cable station, or about 1,500 ft northwest of the Army surface site. The field is free of palm trees but has scattered lower shrubbery. It is partially ringed with distant palm trees, extending to elevation angles up to 6°. This results in inhibited surface wind flow, and the coral field tends to be considerably hotter than the lagoon shore during the day.

Photography (Fig. 19). The routine still and time-lapse cine photography (Bolex B-3) was accomplished from the top of a 25-ft wooden tower which was constructed on the roof of the former administration building of the Cable Station. The cameras were elevated 65 ft above the ground, affording an unrestricted horizon view in all directions except north-northwest, where there is a grove of casuarina trees about 90 ft tall. Some of these trees were topped during the middle of the program.

3. Christmas Island

U.S. Army surface site (Figs. 20, 21, 22, 23, and 24). This site was at the eastern extremity of Northeast Point. The entire Northeast Point area is flat, open, and treeless, offering no exposure problems. The only vegetation is moderately sparse shrubbery from 3 to 5 ft high. The elevation was 6 ft above MSL. The salt spray was severe near the beach.

Instrumentation: MRI and instrument shelter located on the rim of the slope to the beach. The barometer was in the observer's shack, 500 ft inland from the beach.

London site (Figs. 20, 21, 25, and 26). The site chosen was on Bridges Point, just southeast of London Village. It afforded excellent exposure to all winds, and served as the off-lagoon site on Christmas Island. The elevation was about 3 ft above MSL.

Instrumentation: MRI.

New Camp (Figs. 20 and 27). This site is the only example of one in the interior of an atoll. It is just under 1 km from the northeast coastline. The site is in an open field just outside the entrance gate of New Camp. The field has scattered shrubbery to 6 ft, none within 50 ft of the instrument, but there are tall palms about 400 ft to the east. The elevation was approximately 6 ft above MSL.

Instrumentation: MRI (two weeks only).

Aeon Point (Figs. 20, 28, and 29). This site is near the southeastern extremity of the Island, and the 64-mi round trip was a handicap to frequent inspection. The exposure is similar to that at Northeast Point, just inland from the beach ridge. The elevation was about 7 ft above MSL.

Instrumentation: MRI.

U.S. Air Force GMD (Figs. 20, 21, 22, and 24). The GMD site was in the open area of Northeast Point, near the Army surface site. The recorder was in a building about 600 ft inland from the beach, and the releases were made from the antenna location, about 150 ft southeast of the building. Only sparse, 3-ft shrubbery occupied the area.

Double-theodolite pibal site (Figs. 20, 21, and 22). The balloons were released from a point about 100 ft north of the GMD releases. This was midway between the two theodolites, which formed a north-south baseline of 1 km.

Precision wind data (Figs. 20, 21, and 22). The first location of the totalizing anemometer was a short distance north of the GMQ-12 wind set; both instruments were mounted on 40-ft towers 500 ft inland from the beach ridge at Northeast Point, in the same generally open area. The second location of the totalizing anemometer was 20 ft inland from the beach ridge.

B. INSTRUMENTATION

1. Surface Instrumentation

All routine surface meteorological equipment, with the exceptions noted below, was provided by the Meteorological Support Activity, United States Army Electronics Command, Fort Huachuca, Arizona. A general discussion of the type of equipment used by the Army has been prepared by Jozy (1966). The specific equipment employed in the field during the Line Islands Experiment is listed in Table 2.

In addition to the equipment supplied by the U.S. Army, the University of Hawaii supplied seven instruments that, for the most part, were used only at Palmyra. These consisted of a Serdex microhygrograph, a thermograph, an Assmann psychrometer, a calibration mercury thermometer, a Dines tilting siphon rain gauge, a Jardi rate-of-rainfall recorder, and 24 plastic-wedge rain gauges; of the latter, half were exposed on Fanning and the rest on Palmyra.

The Serdex microhygrograph consists of an exposed animal membrane and provides a 24-hr record of the relative humidity; its full-scale response (0 to 100 per cent) covers 6 in. of chart paper and has an expected accuracy of ± 3 per cent over a range of 15 to 95 per cent relative humidity between 32° and 135°F. It was exposed at the Army site at Palmyra for 27 days (4 to 30 April), and was frequently checked with the Assmann psychrometer.

Table 2

A BRIEF INVENTORY OF SURFACE METEOROLOGICAL INSTRUMENTATION: LINE ISLANDS EXPERIMENT

Element	Instrument	Model	Serial No.	Scale Divisions	Recording Period	Remarks
CHRISTMAS ISLAND

The thermograph utilizes a bourdon sensing element with the full-scale response (5° to 150°F) covering 4.5 in. of chart paper; it was exposed at the Army site on Palmyra from 4 to 30 April.

The Assmann psychrometer (Casella) consists of two matched, sheathed thermometers in the familiar housing, with ventilation of 4 m/sec provided by a spring-driven fan; the instrument's accuracy is about ± 1 per cent relative humidity.

Both the Dines tilting siphon rain gauge and the Jardi rate-of-rainfall recorder are discussed by the Meteorological Office (1956); in both cases, the recording period was 24 hr and, again, both instruments were exposed at the Army surface site on Palmyra. Apparently, the clock spindle on the Dines rain gauge was bent in transit, resulting in an upward convex curvature to the ink trace when no rain had fallen; however, this defect is easily recognized and should not affect the siphoning mechanism, as can be seen from the discussion of instrument maintenance provided by the Meteorological Office (1963).

The mercury-in-glass calibration thermometer (Brooklyn Thermometer Co., Middleton, New York) was used as a field standard at Palmyra; it was used by Henry van de Boogaard to obtain field comparisons between the U.S. Army whirled psychrometer and the Assmann.

Additional surface instrumentation included eight MRI portable wind/rain gauge units. These units are purely mechanical and record wind direction, (hourly) run-of-the-wind, and rainfall (tipping bucket) on pressure sensitive paper. Three units were exposed on Palmyra and three on Christmas, while the remaining two were exposed on Fanning. (For exact location and site description see discussion in Section II.) All units except one (No. 236) were calibrated and checked at the factory and sent directly to the Line Islands; No. 236 was checked and tested at NCAR before being sent to Fanning. In addition to the MRI units, a GMQ-12 wind set was exposed on a 40-ft tower on the causeway site at Palmyra, and a second GMQ-12 on an identical tower at Northeast Point, Christmas Island. The GMQ-12 records instantaneous wind speed and direction; it was in operation for about 35 days on Palmyra and for

28 days on Christmas. A complete description of the instrument, including the relevant circuitry, is available from NCAR.

An Eppley pyrhelometer, a ventilated infrared radiometer, and an ATS Zenith pyrhelometer were operated at Palmyra by the University of Wisconsin. The instruments were exposed on a piling just offshore in the main lagoon. For additional details contact the Department of Meteorology, University of Wisconsin, Madison, Wisconsin 53706 (Attention: James Maynard).

2. Ship Instrumentation

During the Line Islands Experiment two ships assisted in making both surface and upper air observations: the *Surveyor* (Fig. 30) spent about 45 days (14 February to 30 March) directly attached to the field program, while *Weather Ship II* provided additional observations during its cruise between Hawaii, the Line Islands, and Samoa (13 March to 29 April).

Surface meteorological instrumentation aboard the *Surveyor* included a precision aneroid barometer, Aerovane wind sensors and recorder, an Assmann psychrometer, and three rain gauges. In addition, photographic equipment for still cloud pictures was included. Lastly, a bow-mounted thermistor was installed (in Seattle), although it was inoperative most of the time.

The precision aneroid (WB 478) was calibrated against the Pacific standard barometer on 10 October 1966 in Honolulu; at that time it had a zero correction. Upon the conclusion of the *Surveyor's* last cruise during the Line Islands Experiment (4 April 1967), the barometer was assigned a correction of +0.01 in. by the Port Supervisor, U.S. Weather Bureau, Honolulu.

The Assmann psychrometer (Casella No. 3579) consists of two matched, sheathed thermometers graduated in whole degrees Fahrenheit, and aspirated by a spring-driven fan; it is described in greater detail in Casella's Catalogue No. 877. With the conclusion of the field program, the two Assmann thermometers were calibrated in a water bath -- using an electrical thermometer with an accuracy of $\pm 0.01^{\circ}\text{C}$ -- over the range

23° to 29°C. Over this range both (matched) thermometers were 0.2°C too high; these corrections have not been applied to any of the Surveyor's observations listed in Appendix A4.

The rain gauges were the "remote visual type" and manufactured by the Belfort Instrument Corporation to U.S. Weather Bureau specification No. 450.2112. The gauge is 24 in. long and consists of the usual collector, measuring tube (10-in. capacity and graduated in tenths of an inch), and hydrophobic connecting tubing; rainfall is magnified by a 2:1 ratio. As noted above, remote visual reading was used only on the gauge mounted on the aftermast; the other two collectors were connected directly to the measuring tube and mounted on posts on both sides of the flying bridge about 15 ft apart.

The 24-hr rainfall amounts presented in Section V show a reasonable agreement, particularly between gauges 1 and 2 exposed on the flying bridge. On the other hand, amounts recorded by gauge 3, exposed on the aftermast, are consistently higher. There is some chance that the latter gauge may have collected additional water from parts of the mast or rigging, although this cannot presently be verified. Nevertheless, while the ship was on station (18-21 February and 14-25 March) gauges 1 and 2 recorded, respectively, 1.90 and 4.96, and 1.80 and 4.29 in.; gauge 3 recorded 2.20 and 5.70 in. Lastly, no consistent bias resulting from wind direction was apparent in a scatter diagram of amounts recorded by gauges 1 and 2 as a function of wind direction -- a notable and perhaps surprising result.

Surface instrumentation aboard *Weather Ship II* consisted of a precision aneroid barometer supplied by the Department of Geosciences, University of Hawaii. It is calibrated in whole millibars (10-1060) and is manufactured by Wallace and Tiernan (Belleville, New Jersey) from original specifications supplied by the U.S. Air Force. The instrument was tested in the pressure chamber of the U.S. Weather Bureau, Honolulu, prior to being placed on board, and was later compared with the Pacific standard (mercurial barometer). When the instrument was placed on board, the final comparisons, made by Jack Noonan of the Weather

Bureau, Honolulu, showed that a correction of 0.7 mb was needed to assure agreement with the Pacific standard, and that 0.6 mb must be added to obtain sea-level pressure (the barometer was 16 ft above the ship's waterline); thus the total correction, to be added, is 1.3 mb. However, through a numerical error involving the height above the ship's waterline, 1.2 mb was actually added to the observed pressures rather than 1.3; thus 0.1 mb must still be added to *Weather Ship II*'s pressure observations to obtain corrected sea-level pressure.

Wet and dry bulb temperatures were obtained with a ventilated Bendix "psychron" (Model 566-2). Both thermometers are graduated in whole degrees Fahrenheit, with the ventilation being provided by a battery-operated fan. The observations were made on the bridge 16 ft above the water by the ship's personnel.

Observations of wind speed were taken with an anemometer mounted high on the forward mast and read from a dial display on the bridge. The calibration characteristics of this anemometer are, unfortunately, unknown. Upper air instrumentation on both ships consisted of U.S. Weather Bureau radiosondes (Fig. 31). The data were received on board by means of the Bureau's portable receiver No. 66-61. On the *Surveyor* only minor trouble was experienced with the ground equipment, while aboard *Weather Ship II* "no trouble of any kind was experienced and only one ground set was used for the entire trip."

3. Upper Air Instrumentation

With exception of the *Surveyor* and *Weather Ship II*, all radiosonde instrumentation consisted of the standard U.S. Weather Bureau instrument transmitting on 1680 MHz and utilizing the "outrigger" thermistor, carbon humidity elements, and hypsometers (above 100 mb). On the other hand, the two ships used the 403-MHz transmitter, lithium fluoride humidity elements, and no hypsometers.

Ground receiving equipment at all island stations consisted of GMD-1B; shipboard equipment consisted of U.S. Weather Bureau portable receiver No. 61.

4. Aircraft Instrumentation

WV-3 aircraft, U.S. Navy VW-1 reconnaissance squadron. Complete details of all instrumentation are given in the *Weather Reconnaissance Manual* issued by the Airborne Early Warning Squadron One (1965).

Briefly, a continuous digital record of air temperature, humidity, and pressure was provided by the AN/AMQ-17 aerograph set. The data was printed out every minute with tolerances asserted to be $\pm 0.5^{\circ}\text{C}$ on temperature, ± 3 per cent on relative humidity and ± 5 mb for pressure.

The sensing elements, in the case of temperature and moisture, consisted of "a 7-in. probe mounted outside the aircraft's fuselage. The (electrical) resistance of the thermometer and hygrometer elements are varied by changes of temperature and humidity. A continuous-balance servo assembly in each channel maintains the electrical balance of a bridge network." For pressure, "a transducer is connected to the aircraft static pressure system and converts the mechanical energy produced by the changes in static air pressure acting on a bellows to an electrical signal required to operate the pressure servo assembly Changes in pressure unbalance the bridge network . . . which causes the servo motor to drive the balancing potentiometer in a direction to balance the bridge." In addition, pressure was also measured by an aneroid barometer (ML-401/U) connected to the aircraft static line; observations from this instrument were entered on the observing forms.

The ML-313/M psychrometer equipment was not operated on any of the flights, nor was the doppler radar.

During the three flights about 36 dropsondes (AN/AMT-6) were released.

The WV-3 aircraft was equipped with the APS-20E radar for PPI presentation and the APS-45 for RHI. These sets have been standard equipment on Navy weather reconnaissance aircraft for many years. The PPI scope was photographed in 16-mm time-lapse. More detailed specifications of the radar can be obtained on request.

B-47 aircraft, U.S. Air Force (Hickam Field, Honolulu). These aircraft were equipped with doppler radar, a Rosemont temperature sensing element, and, on nearly every flight, a 35-mm camera for (still) cloud photography; no time-lapse cloud cameras were operated on any of the B-47 flights. On most flights, the aircraft radar was photographed in 35-mm time-lapse.

It is not presently known what calibration procedures were normally followed regarding either the temperature sensors or the doppler radar.

WHOI, C-54Q aircraft (Woods Hole). A complete list of all instrumentation aboard the WHOI aircraft has been published by the Facilities Division of NCAR (1965). Additional details can be obtained from the Woods Hole Oceanographic Institution (WHOI), Woods Hole, Massachusetts 02543 (Attention: Andrew H. Bunker).

5. Calibration Procedures

All meteorological equipment supplied by the U.S. Army was calibrated before and after the Experiment at the Army's laboratory in Fort Huachuca; moreover, none of the Army equipment registered any calibration changes during the field program. In particular, Frank C. Harrison informs us that "the barometers were checked in a standard tabletop vacuum chamber (open end 20-in. diam, 34-in. depth, 1-in. glass door) and compared with a Hass barometer (Type MS-2, micrometer standard, 0 to 62 in. Hg, 0.6-in. bore, modified V-tube); the pressure was run up, down, and up, and read optically." Further, "the temperature standards used include a triple-point cell for water and triple-point cell for benzoic acid, and a platinum resistance thermometer; humidity was checked against a Cambridge system dew point hygrometer." The resulting scale corrections, for the pressure range of interest here, are displayed in Table 3; *these corrections have not been applied to the data recorded on forms WBAN 10A-B, nor to the tabulations in Section V.*

Other laboratory tests include the calibration of the Assmann thermometers and the "field test thermometer" -- both in use at Palmyra. All three thermometers were calibrated in a water bath at the University

Table 3

SCALE CORRECTION (mb) AT 75°F FOR U.S. ARMY ANEROID BAROMETER

Station (Serial No.)	Surface Pressure (mb)				
	1000	1005	1010	1015	1020
Christmas (1358)	-0.2	-0.2	-0.2	-0.2	--
Fanning (146)	+0.8	+0.8	+0.8	+0.9	+0.9
Palmyra (2375)	+0.4	+0.5	+0.5	+0.5	+0.6

of Hawaii using an electrical thermometer accurate to $\pm 0.01^{\circ}\text{C}$. Over the range 22° to 28°C , both Assmann thermometers recorded exactly the same temperature, though both were in error by no more than $+0.2^{\circ}\text{C}$ ($+0.4^{\circ}\text{F}$). On the other hand, the field test thermometer was in error by -0.2°C (-0.4°F) over the entire measured range (22° to 28°C). Thus, to correct the Assmann readings *subtract* 0.2°C (0.4°F) and *add* 0.2°C (0.4°F) to correct the field test thermometer.

While at Palmyra, van de Boogaard conducted some field calibrations between the Army screen thermometers, the Assmann psychrometer, and the field test thermometer; these hourly comparisons were conducted at the Army site for six days (22-27 April) and demonstrated that the difference between the test thermometer and the Army screen thermometer on the one hand, and the test thermometer and the Assmann on the other, were both, in the mean, -0.4°C . Stated otherwise: to correct the Army screen thermometer *subtract* 0.4°C (0.7°F). Again, these corrections have not been applied to the data entered on forms WBAN 10A-B, nor have they been applied to the tabulations in Section V.

A "Precision Micro Barometer" (American Paulin System, Los Angeles) was employed in the field to secure barometric comparisons between Palmyra, Fanning, and Christmas. Unfortunately, the instrument was damaged in transit to Honolulu upon the conclusion of the Experiment, and what few comparisons were completed are of doubtful reliability; they have not been utilized in any of the following discussion.

Lastly, the 24 wedge rain gauges (Tru-chek Rain Gauge Division, Edwards Mfg. Co., Albert Lea, Minnesota) were exposed on both Palmyra and Fanning. On Palmyra they were exposed every 0.1 mi along the runway (Fig. 3), while on Fanning the network was wider (Fig. 32) and carefully selected by Frank Robitaille, the observer. These gauges are made of plastic, graduated in hundredths of an inch, and have a capacity of 6.00 in. Huff (1955) has discussed a (favorable) field comparison test between this gauge and four others, including the U.S. Weather Bureau's standard 8-in. gauge.

IV. THE OBSERVATIONS

The listings which follow give the time interval of data collection for the various types of data and for each location. If not specifically stated otherwise, the data may be assumed to be of satisfactory quality or better. Unless otherwise stated, all times are local (150°W) time; all dates 1967. The source of information and/or of copies of the data is NCAR. Virtually all of the data are available on microfilm.

A. PALMYRA

1. Surface Observations

Hourly surface observations (0800 21 February to 1400 21 April; 21 April to 1 May) were recorded on forms WBAN 10A-B, although eight nighttime hours are not available during the last period. Tabulations of most of the data are presented in Section V.

2. Upper Air Observations

Winds and temperatures are available every 6 hr (25 February to 21 April); in addition, serial soundings every 3 hr are available for selected days. A complete list of dates and times is presented in Appendix A. The original records are available at NCAR, with the raw data available on both punch cards and magnetic tape (thermodynamic data at each significant level; wind data each 6 sec for the first 5 min, and every 30 sec thereafter); duplicate card decks or tapes are available. Lastly, two soundings per day (0200 and 1400), hand-worked and uncoded, are immediately available.

3. Photography

Hourly sky panoramas were obtained with a Rolleiflex (70° field lens): good data coverage (2 March to 6 April), spotty coverage (7-17 April), considerable missing data (26-29 March, and after 6 April).

Time-lapse photography (Bolex No. 1, 58° field lens), 12 March to 21 April; considerable missing data on 2, 3, 4, 26 March, and 11, 14, 16 April. On most days, particularly those with active convection, regular photography was liberally supplemented by 35-mm color slides. All original data are available at NCAR; copies (on a limited scale) are available.

4. Radar Scope Photography

There was virtually no interruption of data (2300 2 March to 1400 21 April); the latter consists of 80 rolls of 16-mm Kodachrome II film in 100-ft rolls. Date, time, elevation angle, and range are clearly visible on each frame. In addition, numerous Polaroid prints are also available. Originals are retained at NCAR; copies are available.

5. Stereo Photography

With the exception of 26, 28, 30 March and 4, 5, 10, 14, 16, 18, 20 April, about 15 to 35 stereo pairs per day are available (22 March to 21 April). These data are located at the University of Wisconsin, Department of Meteorology, 1024 Regent Street, Madison, Wisconsin 53706 (Attention: A. Frederick Hasler). A detailed catalogue of all pictures is available upon request.

6. Radiation Data

The Eppley pyrliometer, ventilated radiometer and ATS Zenith pyrliometer were operative between 24 March and 21 April (0730-2030). The ventilated radiometer was operated 24 hr a day on an intermittent basis; the Suomi-Kuhn economical radiometer was flown each evening on the 2000 L sounding between 21 March and 20 April. Additional information may be obtained from the Institute for Environmental Research, ESSA, Boulder, Colorado 80302 (Attention: Peter Kuhn), or from the Department of Meteorology, University of Wisconsin (Attention: James Maynard).

7. Additional Surface Wind Data

The MRI wind set on Barren Island operated from 16 March to 19 April; the MRI wind set on the Causeway site operated from 14 March to 1 May, and the GMQ-12 wind set operated from 16 March to 21 April on the Causeway site with a few short periods of data loss. Microfilm copies of both types of original strip charts are available. Tabulated hourly means from the MRI charts appear in Section V. Additional information on GMQ-12 data may be obtained from the Department of Geophysics and Geophysical Engineering, St. Louis University, P. O. Box 8020, College Station, St. Louis, Missouri 63156 (Attention: Paul Hwang). Tabulated wind speeds at 1-min intervals should be available on duplicate punch cards or magnetic tape on request.

8. Additional Rainfall Data

The Dines tilting siphon rain recorder and the Jardi rate-of-rainfall recorder were operated from 21 February to 1 May. Both records are virtually complete (one chart per day), although there is doubt about some of the Jardi data (under review). Further, the clock spindle on the Dines was apparently bent in transit resulting in a slightly convex ink trace when no rain had fallen. However, this is easily recognized and should not affect the siphoning mechanism.

Additional rainfall data were collected from a network of 14 plastic-wedge gauges exposed at 0.1-mi intervals along the airstrip, with four additional locations roughly at right angles to the west end of the airstrip (Fig. 3). The network operated for 35 days and was usually read three times a day. A summary of totals appears in Section V.

9. Tritium Analysis

About ten samples of rain water and two samples of lagoon water were collected to be analyzed for tritium content. The time of each rainfall -- in some cases an individual shower -- is known, and it is likely that the cloud depth for such cases can be estimated. The analysis is being carried out in the laboratory of Willard Libby, at the University of California at Los Angeles; any significant results will

be reported to NCAR where they will be combined with the appropriate meteorological data and made generally available.

10. Atmospheric Electricity

Stig Rossby obtained numerous measurements of electrical properties of warm clouds in the vicinity of Palmyra, but details are not presently available. Interested persons should contact Rossby at NCAR for further particulars.

B. FANNING ATOLL

1. Surface Observations

Hourly surface observations (0700 1 March to 1400 21 April) were recorded on WBAN 10A-B forms. Most of the data is presented in Section V.

2. Upper Air Observations

Winds and temperatures were taken every 6 hr (4 March to 21 April); in addition, soundings were taken every 3 hr on selected days. A complete list of available soundings is presented in Appendix A2. Other details: same as Palmyra.

3. Photography

Hourly sky panoramas (Rolleiflex, 70° field lens) are available (2 March to 21 April), as well as time-lapse photography (Bolex 58° field lens) during 3 March to 21 April; on some days (12, 15-21 March) there is considerable missing data. Again, on all days, the above record was liberally supplemented by 35-mm color slides. All original records are retained at NCAR; copies are available on a limited scale.

4. Additional Wind Data

The MRI unit on Robitaille's Beach site operated between 28 March and 14 April. Microfilm copies of the original strip chart are available from NCAR. Tabulated hourly results appear in Section V.

5. Additional Rainfall Data

Between Cartwright Point, near English Harbour, and some 4 mi north of the Cable Station, 17 plastic-wedge gauges were exposed; for the most

part, the gauges were read every day (Fig. 32). Robitaille, who organized the network, has provided a photographic record of each gauge and its immediate surroundings. These (35-mm color slides) are available at NCAR, along with copies of the daily results. A summary of totals appears in Section V.

6. Lagoon Surface Temperature

Observations were made by Robitaille and Ralph Coleman during several crossings of the lagoon by small boat piloted by John Fleetwood and Bibou. Tabulations are available at NCAR.

C. CHRISTMAS ATOLL

1. Surface Observations

Hourly surface observations (1700 3 March to 1400 21 April) were recorded on forms WBAN 10A-B, most of which are presented in Section V.

2. Upper Air Observations

Winds and temperatures were taken every 6 hr (4 March to 21 April); in addition, soundings were taken every 3 hr on selected days. A complete list of available soundings is presented in Appendix A3. Other details: same as Palmyra.

3. Photography

Hourly panoramic photographs (Rolleiflex, 70° field lens) are available (7 March to 21 April) with considerable missing data on some days (17 to 20 March, 22 March to 9 April); in addition, time-lapse photography (Bolex, 58° field lens) is also available (14 March to 21 April), again with considerable missing data on some days (15, 18, 20, 25 March; 15, 18 April). This record was occasionally supplemented by 35-mm slides. Original data is retained at NCAR, copies are available on a limited scale.

4. Additional Surface Wind Data

The MRI unit at Bridges Point, London Village, operated during 14 March to 19 April, while a similar unit at Acron Point operated during 24 March to 6 April. The MRI unit at New Camp operated during

8-23 March, while the GMQ-12 wind unit operated during 22 March to 21 April at the main observing site at Northeast Point. Other details: same as Additional Surface Wind Data, Palmyra.

5. Precision Surface Wind Data

The precision totalizing anemometer operated from 22 March to 21 April. The data are in the form of total wind flow in hundreds of miles, totalized continuously from start, on paper tape. The data are continuous over the period of record except for 2.5 hr. On 7 April, the site was shifted from 520 to 22 ft inland from the beach crest at Northeast Point. In each case, the anemometer cups were 39.0 ft above the ground, or 45.0 ft above MSL. Format: punch cards or numerical printouts. Requests for copies of the data should be addressed to the Department of Meteorology and Oceanography, University of Michigan, Ann Arbor, Michigan 48104 (Attention: Gerald C. Gill).

6. Serial Double Theodolite Pibals

These were released at intervals of 20 min for periods of 8 hr. The start time of the serial period varied so as to give all hours of the day equal representation. The ascent rates are unknown, but are mostly near 700-800 ft/min. The theodolites were read at 20-sec intervals; in addition to 501 double theodolite pibals, 11 rawinsonde balloons were tracked by the same method (the rawinsonde printing angles each 6 sec). The baseline was 1,000 m, aligned north-south. The release point of all balloons was about 150 m from the windward coast at Northeast Point. A summary of the observing program appears in Table 4. Location and format: raw data is at the University of Miami; a copy at NCAR. It is probable that the data can be made available on punch cards or magnetic tape in raw or reduced form. For additional information write to the Institute of Atmospheric Science, University of Miami, P. O. Box 9115, Coral Gables, Florida 33124 (Attention: Mariano Estoque).

D. U.S. COAST AND GEODETIC SURVEY SHIP SURVEYOR

The itinerary of the *Surveyor* during the Line Islands program is presented in Table 5. Thus, the highlights of the cruise are a number

1. Surface Observations

Hourly surface observations (0800 16 February to 2300 4 March, and 0700 11 March to 1000 30 March), taken on the ship's bridge, were recorded on forms WB615-5, including hourly (bucket) measurements of sea-surface temperature, and 24-hr rainfall totals from three gauges. The

Assmann psychrometer readings were made on the forward deck in such a manner as to minimize ship effect on the measurements. The wind direction and speed are currently available in real time only. Analysis of the (Aerovane) wind velocity and course recorder charts is in progress at the University of Hawaii, with the goal of more refined estimates. Most of the observations are presented in Section V.

Lastly, surface observations aboard the *Surveyor* were the responsibility of William Curtis, with the generous assistance of Jim Perry.

2. Upper Air Observations

Radiosondes were released every 6 hr (16 February to 4 March, and 10-30 March) and tracked optically with a single theodolite. In addition, soundings every 3 hr were made on selected days. In all, 165 successful soundings were taken, achieving a mean pressure altitude of 25,289 m with the highest reaching 36,031 m. Winds were obtained on 116 soundings, the mean height of the balloons being 1,789 m, with a maximum height of 7,100 m. The complete observational record is presented in Appendix A4.

Raw data are available on either punch cards or magnetic tape (thermodynamic data at each significant level, wind data every 30 sec); duplicates of either are available. These are reduced data tabulations on punch cards or magnetic tape (exact format optional). Two soundings per day, handworked and in coded form, are also available. Original records are retained at NCAR.

Lastly, the upper air program aboard the *Surveyor* was the responsibility of M. Fields (in charge), E. Iverson, and J. Musumeci, whose able services were offered to the Line Islands Experiment by the U.S. Weather Bureau.

3. Photography

Hourly panoramic photographs (Rolleiflex, 70° field lens) are available (22 February to 4 March; 10-29 March) along with numerous 35-mm slides during the whole period. All originals are retained at NCAR; copies are available on a limited scale.

4. Oceanographic Data

The oceanographic program conducted on both cruises has been fully described by Wyrcki (1967).

E. WEATHER SHIP 11

The itinerary of *Weather Ship 11* is displayed in Table 6; briefly, she assisted the Line Islands Experiment during her cruise between Hawaii, the Line Islands, Samoa, the Phoenix Islands, and Hawaii, taking one radiosonde per day and hourly surface observations.

Table 6

Leave Pago Pago	12 "	0830
Arrive Honolulu	1 May	1100

1. Surface Observations

Hourly surface observations (10 March to 1 May) were taken from the ship's bridge and recorded on a form equivalent to WB615-5 used aboard the *Sandogor*. The original observations are available on microfilm.

2. Upper Air Observations

The upper air program consisted of one radiosonde per day (2300 GMT) during the period 13 March to 28 April; no wind observations were made. The 33 completed soundings achieved an average pressure altitude of

23,621 m, with a maximum of 31,240 m. A complete list of all soundings is presented in Appendix A5.

Again, the U.S. Weather Bureau provided both the equipment and the able services of William Sapp, the observer.

F. AIRCRAFT DATA: NCAR QUEEN AIR

1. General

During the Line Islands Experiment the NCAR Research Aviation Facility collected flight data through the operation of a research instrumented Queen Air. Generally speaking, the flight participation amounted to 60 research flights during a period of 53 days for a total of 265 research hours or an average of 5.0 hr per day. Including ferry flights, the total time comes to 310 hr.

The individual flights are summarized by flight track, altitude, and operational instrumentation, in Appendix B. Appendix B1 depicts, by flight number and date, the amount (hours and minutes) and type of data collected, and the aircraft track and altitude over which the data were collected. Appendix B2 lists the various instruments that were used at any time throughout the project. Finally, Appendix B3 depicts the various instruments that were utilized on any given flight.

Through use of these tables it should be possible to determine those flights for which the flight data should be acquired.

Upon requesting any particular Line Islands Experiment aircraft data, the requestor will be furnished with more specific information such as instrument specifications, plus details such as data format and meteorological observations.

2. Infrared Radiometer Operation

The Barnes IT-3 infrared thermometer was flown on the Queen Air on 37 flights, occupying about 138 hr (item 13 in Appendixes B2 and B3). This provided about 18,000 mi of sea temperature data in the region bounded by 2S to 10N and 156W to 165W. The majority of this time was

from an altitude of 500 ft but some data exists for altitudes up to 10,000 ft. An unobstructed view of the ocean surface was afforded through a port in the fuselage for all angles from the vertical to 60° from the vertical. The data format comprises strip charts at the University of Wisconsin, and analog tape records from ARIS at NCAR; analysis is well underway on the latter. For additional information write to the Department of Meteorology, University of Wisconsin (Attention: Robert A. Ragotzkie).

G. AIRCRAFT DATA: WOODS HOLE OCEANOGRAPHIC INSTITUTION C-540

1. General

A series of 12 flights were flown in the Line Islands region between 11 April and 10 May 1967. The departure of the aircraft from Woods Hole was delayed five weeks by maintenance difficulties, so that only the first six flights were made before 21 April, when most of the observations on the Line Islands ceased.

The meteorological parameters observed were: temperatures, humidities, winds, sea temperatures, solar radiation, cloud types and amounts, precipitation areas, turbulence and turbulent fluxes, and dust content of the atmosphere. The temperatures were measured by a thermistor which recorded on an L and N Speedomax recorder, and by the T-6 dropsonde. The humidities were measured by a thermistor covered by a wetted wick, by a dew point hygrometer, and by the carbon element of the T-6 dropsonde.

Winds were measured by the doppler radar installed on the aircraft and by the navigation of the aircraft. The doppler radar was frequently in error during the expedition. It is expected that good wind values can be obtained by checking against navigational winds and using the corrections found by flying 15-mi squares.

Solar radiation was measured by an Eppley pyrheliometer. Vibration of the aircraft broke the wires on the original pyrheliometer and a spare. The last few radiation measurements were made using a light meter, which will have to be calibrated before the record can be reduced.

Clouds were photographed continuously by a Bolex camera on the port side of the aircraft. Photographs were taken every 2 sec. Individual photographs were made with 35-mm cameras and with a Hasselblad camera. Photographs of the weather radar display (X-band) were made every minute to record precipitation areas. Turbulence and turbulent flux data were measured on an oscillograph. The measurements made were: vertical acceleration of the aircraft, airspeed fluctuations, pitch of the aircraft, temperature fluctuations from a platinum wire thermometer, and humidities from a microwave refractometer. A dust counter was used by William Marlatt of Colorado State University during the first three flights.

2. Infrared Radiometer Operation

Radiometric measurements were made on the 12 flights of the WHOI C-54Q. Each flight was about 8-10 hr and nearly half the total flight time was made in the sub-cloud layer at 800 ft. The Barnes IT-3 radiometer has a field of view of 3° . The time response was slowed to 10 sec to eliminate noise and increase sensitivity, so that small temperature changes over large distances could be detected. It is believed that changes of 0.1°C are detectable. The NIMBUS MRIR was operated only in the 10-11 μ channel; the scan mirror was fixed so that it looked straight down at all times. Response time was increased to 15 sec for the same reason as above. This measurement is in question because the aircraft hydraulic fluid was blowing into the scan mirror, and it has not been determined to what extent the readings were affected. The data is available in strip charts. For additional information, write to the Department of Atmospheric Science, Colorado State University, Fort Collins, Colorado 80521 (Attention: William Marlatt).

3. Plans for Reduction of Data

The psychograph, dew point, wind, and shortwave radiation data are being reduced at 2-min intervals throughout the series of flights. Extra observations will be read during climbs and descents and passages through clouds. Most of the reduced data, except the solar radiation data, will be printed out on a single line of computer paper. These

sheets will be sent to NCAR for distribution to meteorologists working on the Line Islands Experiment data.

The cloud movies will be measured and distributed as tabulations of heights of bases and tops of clouds. Cross sections will be drawn.

The short-wave radiation data will be read and printed on computer sheets giving the 2-min values and the computed total for the day at a given spot based on the value at the time of observation.

The original dropsonde data will be sent to NCAR or the University of Hawaii to be checked for errors and recomputation.

The turbulence runs will be reduced at Woods Hole to yield rms vertical velocities, horizontal turbulent velocities, temperature fluctuations, water vapor fluctuations, and fluxes of heat and water vapor. For additional information write to the Woods Hole Oceanographic Institution.

Summaries of the individual flights are presented in Appendix C, while the flight tracks are depicted in Fig. 33.

H. AIRCRAFT DATA: WV-3 AIRCRAFT, U.S. NAVY VW-1 RECONNAISSANCE SQUADRON, AGANA NAVAL AIR STATION, GUAM (FLIGHTS MADE FROM HICKAM AFB, HAWAII)

This aircraft is alternatively identified as the WC-121, or the radar picket ship. Three successful flights were made before the aircraft was recalled to track typhoons in the western Pacific. Routine data collected on each flight include time-lapse photographs of the APS-20 radar scope, height-finding data from the APS-45 radar, and all routine weather reconnaissance observations, but at more frequent intervals than normal (every 15 min). Time-lapse cloud photographs were taken routinely from both sides of the aircraft, supplemented by 35-mm slides. About nine dropsondes per flight were made on the 10,000-ft portion of the flight track.

The itinerary of the three flights is listed in Table 7, while the flight track is depicted in Fig. 34.

Table 7

WV-3 WEATHER RECONNAISSANCE FLIGHT SUMMARY

Flight No.	Local Date	Observations*		Flight Track**	Missing Data (Half flight or more)
		Begin	End		
Alpha	25 Feb.	(Flight aborted during first hour - no data)			
Bravo	27 "	0430	1630	1	Doppler winds
Charlie	1 Mar.	0430	1630	1	" "
Delta	3 "	0500	1800	1	" "

*Total flight duration about 14.5 hr.

**Number refers to track shown in Fig. 24.

All data are available at NCAR and consist of tabulations, strip charts, and photographs. The dropsonde data is still unreduced. Inquiries are invited regarding current status.

I. AIRCRAFT DATA: B-47 AIRCRAFT, U.S. AIR FORCE 57TH WEATHER RECONNAISSANCE SQUADRON, HICKAM AFB, HAWAII

There were a total of 24 flights made by the B-47 aircraft. Routine data collected on each flight include doppler winds, radar-scope photography, and all routine weather reconnaissance observations each 30 min, recorded on AWS forms 24 and 35a (Recco code). It was not possible to mount time-lapse cameras in the aircraft, but the observer carried out a systematic program of still photography with a 58° field 35-mm camera. For most flights, slides were taken every 15-30 min from both sides of the aircraft; because of the altitude (30,000 ft), these slides cover a wide area. All flights were carried out at an altitude between 30,000 and 35,000 ft, mostly at 300 mb (30,000 ft); see Table 8 and Fig. 34. for flight listings and flight tracks. Copies are available from NCAR of standard data, tabulations, and the original photographic data.

J. AIRCRAFT DATA: C-97 AIRCRAFT, AIR NATIONAL GUARD, 146TH MILITARY AIR WING, VAN NUYS, CALIFORNIA (FLIGHTS MADE FROM HICKAM AFB, HAWAII)

These aircraft provided the major logistics support for the field stations in the Line Islands and were not equipped for weather observations. On most flights, however, at least one scientist was on board to operate one or more time-lapse cameras, and to take still photographs, notes on weather conditions, radar echoes, etc. Flight altitude was usually less than 5,000 ft on the short Palmyra-Christmas leg, and usually between 7,000 and 15,000 ft on the Honolulu-Christmas or Honolulu-Palmyra legs. For additional details, exact flight times, or copies of photographic data, write to NCAR. Flights for which significant photographic coverage exists are listed in Table 9 (this is not a comprehensive list of all flights).

Table 8

* U.S. Coast Guard C-130 included here for convenience.

K. SATELLITE DATA: ATS-1

The first ATS-1 picture was taken on 10 December 1966 and successful operation has continued up to the present. The listing in Appendix D is for all dates between 14 February and 10 May 1967, encompassing not only the intensive Line Islands Experiment period proper, but also an earlier period for which some supplementary observations are available from the *USC&GSS Surveyor*, and from Palmyra. Included also is a later period for which supplementary observations are available from Palmyra, from the WHOI C-54Q research flights, and from the USAF B-47 reconnaissance flights.

It is important to note that the listing applies to the hard copy photographs only, and *not* the analog or digital tapes. The photographs are of excellent quality and have a resolution of perhaps 3 mi near the sub-point, including the entire Line Islands area (Fig. 35). The picture ultimately to be derived from the tapes should have substantially superior qualities. The pictures with substantial distortion, occupying most of the period 1-27 March, can only be returned to undistorted presentation through digital methods. Unfortunately, only those for 1, 22 and 23 March have substantial digital tape coverage. On the other hand, the Line Islands region is *not* badly distorted, and the pictures are still of great value in qualitative analysis of cloud systems in the region of greatest interest. The main drawback of these pictures is that accurate gridding presents a more difficult problem.

The best procedure for gridding the ATS-1 pictures is not yet clear. Two sources for grid overlay information are the University of Wisconsin's Space Science and Engineering Center, 601 E. Main Street, Madison, Wisconsin 53706 (Attention: Kirby J. Hanson or Verner E. Suomi), and the University of Chicago's Satellite and Mesometeorology Research Project, Department of Geophysical Sciences, Chicago, Illinois 60637 (Attention: Tetsuya Fujita).

A comprehensive catalogue and users manual on the ATS-1 system is in preparation by Allied Research Corporation, under contract to NASA. Pending its production, additional details on the ATS-1 system or data availability may be obtained from the University of Wisconsin. Limited requests for ATS-1 pictures may be addressed to the University of Wisconsin, to NCAR, or to the ATS-1 Project Office, NASA, Goddard Space Flight Center, Greenbelt, Maryland 20771.

L. SATELLITE DATA: ESSA I

The polar-orbiting ESSA I satellite provided frequent coverage of the Line Islands area. The pictures cover a relatively narrow area (consequently, coverage is incomplete), but are of excellent resolution.

The listing in Appendix D2 includes most, if not all, picture swaths within about 10° of longitude of the Line Islands. For additional information or for the pictures themselves, refer to the appropriate ESSA catalogue.

M. SATELLITE DATA: ESSA III

The polar-orbiting ESSA III satellite provided daily coverage of the Line Islands area. The pictures from a given orbit overlap adjacent orbits to provide complete aerial coverage and are of uniformly good quality. The listing in Appendix D3 includes most, if not all, picture swaths within about 10° of longitude of the Line Islands. For additional information or for the pictures, refer to the appropriate ESSA catalogue.

N. SATELLITE DATA: ESSA V

The ESSA V satellite was launched successfully on 20 April 1967. The pictures are similar to those from ESSA III. Detailed listings are available in the appropriate ESSA catalogue.

O. SATELLITE DATA: ESSA IV AND NIMBUS II (APT SATELLITES)

An Automatic Picture Transmission (APT) receiving station was established on Palmyra. Usable pictures were provided nearly every day between 7 March and 21 April from both APT satellites. For a survey of cloud conditions on a particular day, the ATS-1 and ESSA III coverage is more comprehensive and more easily accessible than the APT pictures. For those interested in details of small-time changes, especially on days of less than complete ATS-1 coverage, or for those who need a picture at the particular time of APT coverage, the APT pictures may be the only ones to fill the gap. APT data is stored on stereo recording tape and on Polaroid prints (4 x 5 in.) at NCAR. Copies are available on a limited basis, and requests should be as specific as possible. A list of available APT pictures is presented in Appendix D4.

P. SATELLITE DATA: RADIOMETRIC

None of the satellites orbiting during the Line Islands Experiment had operative radiometers.

Q. GRAVITY MEASUREMENTS: PALMYRA AND CHRISTMAS

During the Line Islands Experiment, Alexander Malahoff of the Hawaii Institute of Geophysics conducted a gravity survey on both Palmyra and Christmas. Using a Lacoste & Romberg gravimeter, he determined the Bouguer anomalies at several stations on both atolls. His results for Palmyra (east and west ends of the airstrip), and two locations on Christmas (Meteorological Office, London Village, and Northeast Point) are presented in Table 10. These measured values differ by one unit in the first decimal place from those computed by the familiar formula (List, 1958, p. 488) based on the International Ellipsoid of Reference. This is not an insignificant difference for meteorological purposes; indeed, the discrepancy, in the case of Palmyra, leads to a difference of +0.2 mb in the gravity correction for surface atmospheric pressure -- a value comparable to the sea-level correction at most of the atolls in the Line Islands.

Table 10

GRAVITY MEASUREMENTS AT CHRISTMAS AND PALMYRA

Christmas Island (cm sec ⁻²)	
London Village	978.2401
Northeast Point	978.2290
Palmyra (cm sec ⁻²)	
East and west ends of airstrip	978.2542

R. OTHER SYNOPTIC DATA

In addition to the above listed synoptic data collected in the Line Islands, the University of Hawaii is collecting the routine observations taken over the Pacific (130E-80W, 40N-40S) during the Line Islands Experiment. These will include original copies of aircraft reports, additional data taken from the New Zealand Daily Weather Report, synoptic magnetic tapes compiled from RTT intercepts at Fleet Weather Central, Pearl Harbor, and surface and upper air observations taken by EASTROPAC vessels in the eastern Pacific.

Further, a master (unanalyzed) synoptic series of charts (850, 700, 500, and 250 mb), including time and space cross section, aerological diagrams, etc., will be prepared and made available in a variety of ways (e.g., ozalid, microfilm, duplicate card decks).

Lastly, the EASTROPAC vessels conducted extensive cruises during February and March between 20N-20S, and 125W-90W; all vessels took meteorological observations, including rawinsonde (*USCGS Rockaway*) and radiosonde (*Jordan* and *Argo*). Details of the meteorological instrumentation will be discussed in a forthcoming report to be published by Texas A & M University (Department of Oceanography, College Station, Texas 77843). The major ship tracks are presented in Fig. 36.

S. SPECIAL PHOTOGRAMMETRIC STUDY: MAUI, HAWAIIAN ISLANDS

1. General

For the purpose of determining cloud motion and development from ATS-1 picture sequences, a ground-based camera network was established under the direction of Tetsuya Fujita on Mt. Haleakala, Maui, where high peaks on the islands of Maui and Hawaii would serve as gridding anchor points and where an unobstructed view is possible over a very large area from the 10,000-ft elevation vantage point.

2. Equipment and Procedures

The camera network established on Mt. Haleakala consisted of the following: (a) Two 16-mm whole-sky time-lapse cameras taking pictures

at 20-sec intervals. Wind direction and speed, temperature, humidity, and rainfall were also recorded in the photographs. (b) Two 35-mm cameras equipped with 35-mm lenses mounted on a turntable manually rotated 45° after each exposure. A panoramic view was taken at 20-min intervals using slow-speed fine-grain infrared film. (c) Two 16-mm wide-angle time-lapse cameras placed on the highest unobstructed point available, with one camera pointing toward the island of Hawaii and the other toward the south of Oahu, taking in Lanai and Molokai. The pictures were taken at 15-sec intervals. An example of a panoramic view is shown in Fig. 37.

Two camera stations including one camera system each of (a) and (b) above were established about 2 mi apart.

3. Dates of Operation

Whole-sky cameras: 13 March through 3 April 1967, except for several days between 20 and 25 March when weather did not permit operations.

35-mm panoramic infrared camera: 14 March through 3 April on days and times when weather permitted a schedule which coincided with ALS-1 schedule.

16-mm time-lapse camera: 14 March through 3 April on days when weather permitted. (There were some breakdowns during the period due to malfunction of cable releases.),

4. Location of Data

For additional information, write to the Department of Geophysical Sciences, University of Chicago, Chicago, Illinois 60637 (Attention: Tetsuya Fujita).

T. ADDITIONAL FIGURES

Figures 37-50 are included for general interest.

V. SURFACE DATA TABULATIONS

Introduction	65
Palmyra	69
Fanning Island	112
Christmas Island	140
Washington Island	173
<i>Surveyor</i>	174

V. SURFACE DATA TABULATIONS

INTRODUCTION

The hourly tabulations of most of the surface data parameters obtained during the Line Islands Experiment are presented in this section. They have been subjected to a preliminary screening, and many of the more obvious errors have been removed. We have presented the observations here because it is felt that they will be useful for many purposes in their present form. *The user would be well advised, however, to exercise caution in accepting these data uncritically.* In several instances, we are quite certain that errors exist, and these data are under review. Some specific examples of questionable data are mentioned below, but *the user is urged to seek up-to-date information from one of the co-editors if critical evaluation is required in any particular case.*

The wind directions are not to be trusted to better than 10° in an *absolute* sense, although *relative* changes of 10° are quite reliable. The trouble might arise from external and/or internal misalignment of the instruments, with the coarse scale divisions (30°) a contributing factor. It is believed that the application of constant correction increments to each instrument will improve matters considerably. We are attempting to determine these corrections by comparing observed wind directions from different sites on the same island and by comparing all these with the wind directions derived from the rawinsonde observations in the first few tenths of a minute after release. Until this work is completed, the user should *not* draw conclusions from comparing surface wind directions measured at different sites or different islands, although comparing *time changes* of wind directions should be a sound procedure.

The wind speeds can be read easily to the nearest 0.2 mph, and the instruments themselves are believed to be accurate to within 1.5 per cent in both an absolute and a relative sense. The major interpretation problem is the effect of the site. For the most part, this will be left to the

user and to future research, but a few of the obvious influences are noted below.

Palmyra. Barren Island is believed to be most representative of ocean conditions. The Causeway site is excellent, but wind speeds there are about 1 mph less than on Barren Island, and we believe that the difference is real. The U.S. Army surface site has about an equal percentage occurrence of offshore and onshore flow. We are convinced that most of the wind speed differences between the Army and Causeway sites are directly related to the angle of flow relative to the angle of the shoreline at the Army site (85-265°). Onshore flow greater than 30° results in wind speeds at the Army site being very close to those at the Causeway site. Offshore flow of about 15-30°, corresponding to greatest length of trajectory over land results in the greatest difference -- as much as 40 per cent lower than the Causeway site speeds.

Fanning. Robitaille's Beach site more closely approximates ocean conditions, unless winds are north of east-northeast. The wind directions at that site seem systematically high and are under review. The Army surface site has an excellent off-lagoon exposure for all easterly component winds, but the effect of obstructions to the flow downwind has not been determined.

Christmas. This is a large island, and no station on it is completely representative of oceanic conditions. The Northeast Point site seems to approximate oceanic conditions most of the time, excepting days with light winds. We do not understand the lower speeds measured at Southeast Point. The London site is very well-exposed, but is influenced strongly by the land and shallow lagoon areas upwind. New Camp is sufficiently screened by upwind vegetation that it exhibits a continental type diurnal distribution of wind speed.

All moisture parameters have been derived from wet and dry bulb temperature measurements. On the *USC&GSS Surveyor* these were made with an Assmann psychrometer, with care taken to minimize ship influences. On all islands, the shelter and instrumentation were standard (see Section III), and the user should keep the deficiencies of this procedure in

mind. All the sites (see Section III) were exposed to direct onshore flow, whether from the ocean (Christmas), a deep lagoon (Palmyra), or a shallow lagoon (Fanning). As already noted, the Palmyra site does not experience onshore flow for wind directions of 85° or less.

The reader is advised to refer to the section on pressure measurements in Section III before using the surface pressure data.

There is no reason to suspect any of the rainfall data of substantial errors, as sites and instruments were good, and wind speeds were always moderate. Nevertheless, the user will observe that there are differences between rainfall amounts measured at different sites on Palmyra and between the Dines and MRI instruments at the same site. We prefer not to attempt to explain these differences at this time.

Note: additional detail can be inferred from hourly surface weather observations,
available on microfilm.

Fig. 1 Location map, Line Islands Experiment, showing tracks of the USCGSS Surveyor and Weather Ship II, and commercial jet aircraft routes from which routine data are available. During the experimental period, the rawinsonde stations nearest the Line Islands were Honolulu, Canton Island, Nandi, Pago Pago and Tahiti.

Fig. 2 Map of Palmyra, showing the three sites from which surface wind observations were made. (Compiled and drawn by Inge Kendall, based on aerial photos by Bob Kendall)

Fig. 3 Near-vertical aerial view of developed portion of Palmyra, taken from an altitude of 10,000 ft. The runway dimensions are 300 by 6,000 ft. It was cleared of heavy shrubbery in mid-February, 1967. The various observing facilities are located by number: (1-14) locations of rain gauges 1-14; (15) radar and photo tower; (16) second Bolex time-lapse camera, aimed toward west-southwest; (17) second Rolleiflex camera, forming stereo pair with camera on radar tower; (18) radiometer site; (19) U.S. Air Force GMD site; (20) U.S. Army surface site; (21) APT receiving site; (22) atmospheric electricity measurements site; (23) causeway site. (Photo by Bob Kendall)

Fig. 4 Sketch of observing facilities near west end of runway, Palmyra. (Based on a survey by H. M. E. van de Boogaard and A. Pallmann)

Fig. 5 U.S. Army surface observation site, Palmyra, showing (left to right) the MRI, Jardi and Dines rain gauges, instrument shelter, and observers' shelter. All brush was cleared from the area during the first week in March. To the east (left) of the instruments, the nearest palm tree is 400 ft distant. (NCAF photo)

Fig. 6 Causeway site, Palmyra, looking north, showing the MRI set. (SCAF photo)

Fig. 7. Causeway site, Palmera, looking north, showing the GMQ-12 wind sensors on a 40-ft tower, and the MEI of Fig. 6 in the background. (NCAR photo)

Fig. 8 Barren Island site, Palmyra, looking south. (NCAR Photo)

Fig. 9. COM-1B release on Palmyra, looking northeast. (NCAP photo)

Fig. 10 Radar and photo tower, Palmyra. The antenna is 67 ft above ground level. The photography was carried out from the highest platform on the tower, just below the antenna. The radar equipment is in the air-conditioned shack atop the blockhouse. (NCAR photo)

Fig. 11 Piling in Palmyra lagoon serving as radiometer site. The net infrared radiometer is suspended over the lagoon on the extreme left. (NCAE photo)

Fig. 12 Checking the Eppley pyrhelometer atop the piling of Fig. 11. (NCAR photo)

FANNING ISLAND

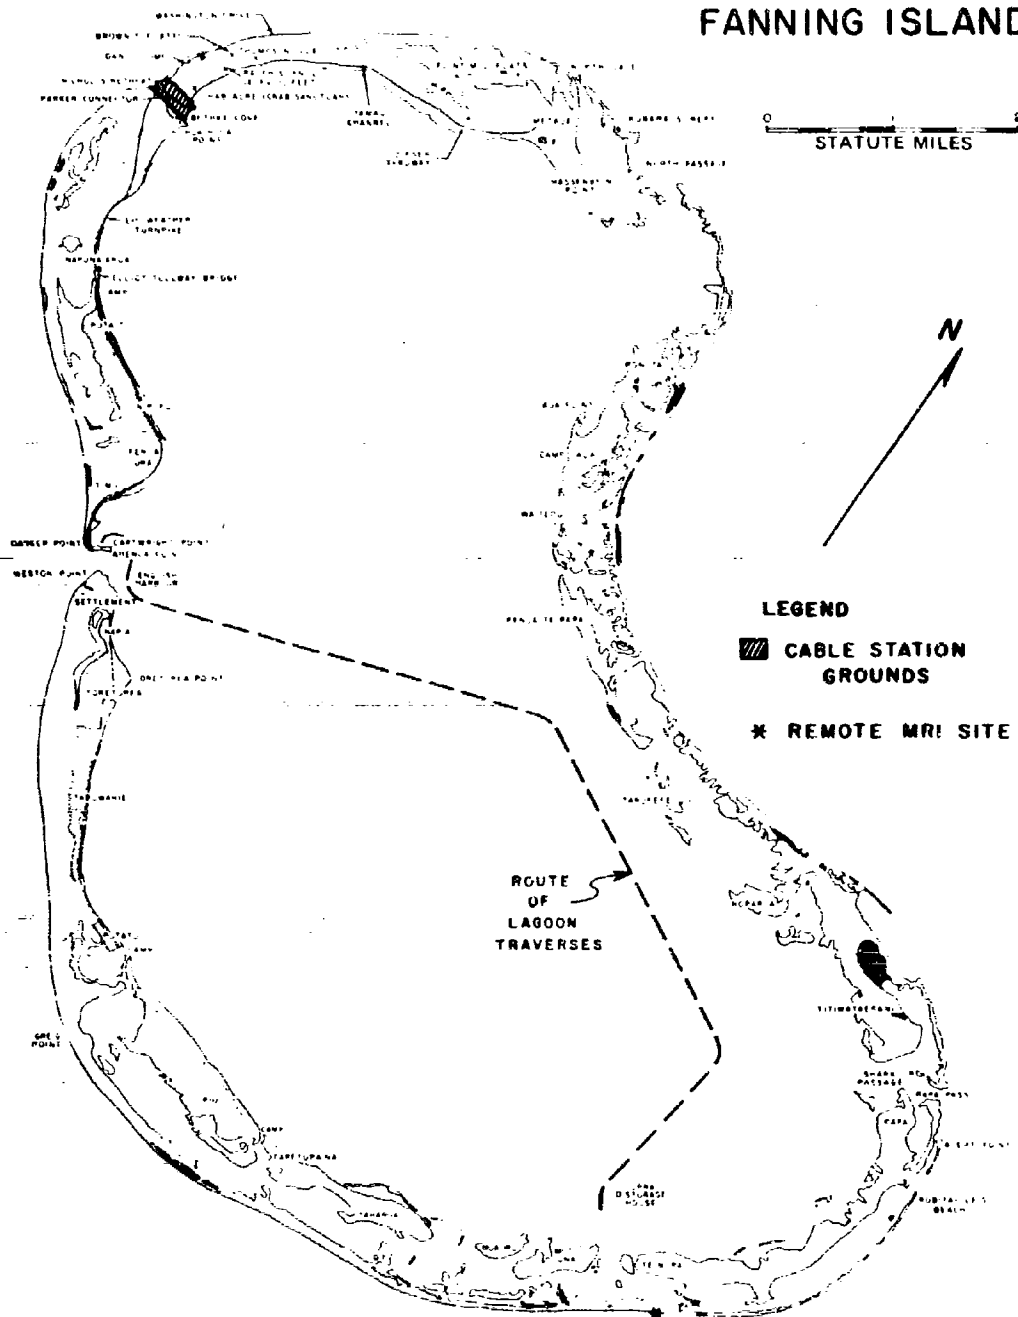

Fig. 13 Map of Fanning Island showing main observing areas in vicinity of Cable Station and remote MRI site. Track of five lagoon cross sections is also shown.

Fig. 14 Fanning Island from 10,000 ft looking south. Army surface site at Huachuca Point and remote MRI site of Robitaille's Beach visible. Route of lagoon traverses shown. (Photo by Bob Kendall)

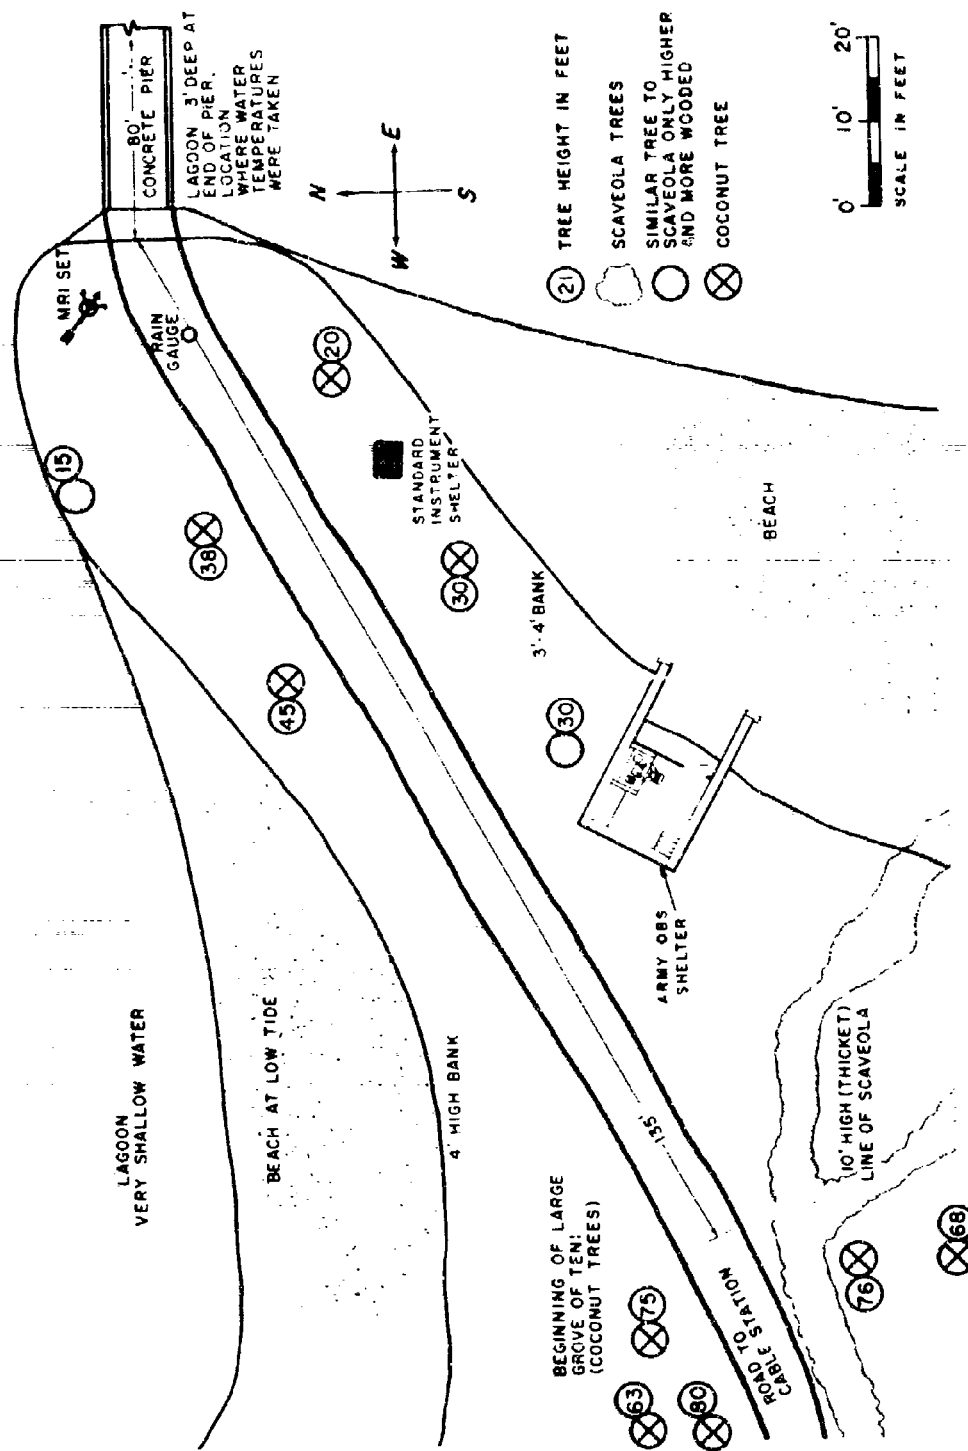

Fig. 15 Sketch of U.S. Army surface observation site at Huachuca Point, Fanning Island. (Drawn by Dick Flint)

Fig. 16 U.S. Army surface observing site, Huachuca Point, Fanning Island. Pier was true east-west. Coconut tree is 30 ft (one and one-half times its height) south-southwest of wind set. (NCAR photo)

Fig. 17 Aerial view of remote MRI site on western end of Rohitaille's Beach, Fanning Island. View is looking northeast from an altitude of 1,200 ft. This site was accessible only by boat, plus wading, and offered excellent off-ocean exposure for all winds except those north of 060 degrees. (NCAR photo)

Fig. 18 Fanning Island ravine release site looking north-northeast. This area is devoid of palms but has considerable lower vegetation. Tracking antenna is on the far right, hydro-gen generators just to the right of center. (NCAR photo)

Fig. 19 Photo tower built atop former administration building, Cable Station, Fanning Island. The cameras are elevated 65 ft above the ground. (NCAR photo)

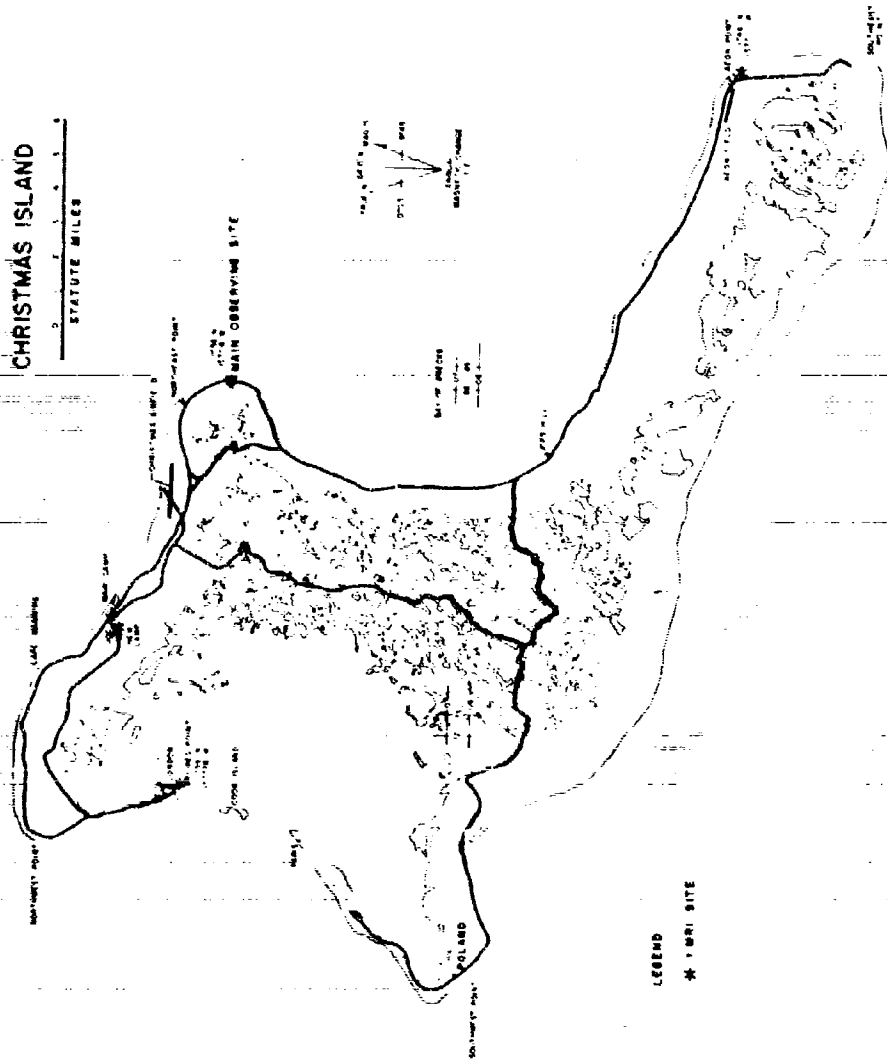

Fig. 20 Map of Christmas Island showing the four surface wind measurement sites (MRI sites). All rain and pibal releases were from Northeast Point -- the main observing site.

Fig. 21 Aerial view of most of Christmas Island, looking somewhat east of due south from an altitude of 9,000 ft. Northeast Point extends into the ocean in the center foreground; Southeast Point is in the far left background; and the airfield shows in the right foreground. (NGAR photo)

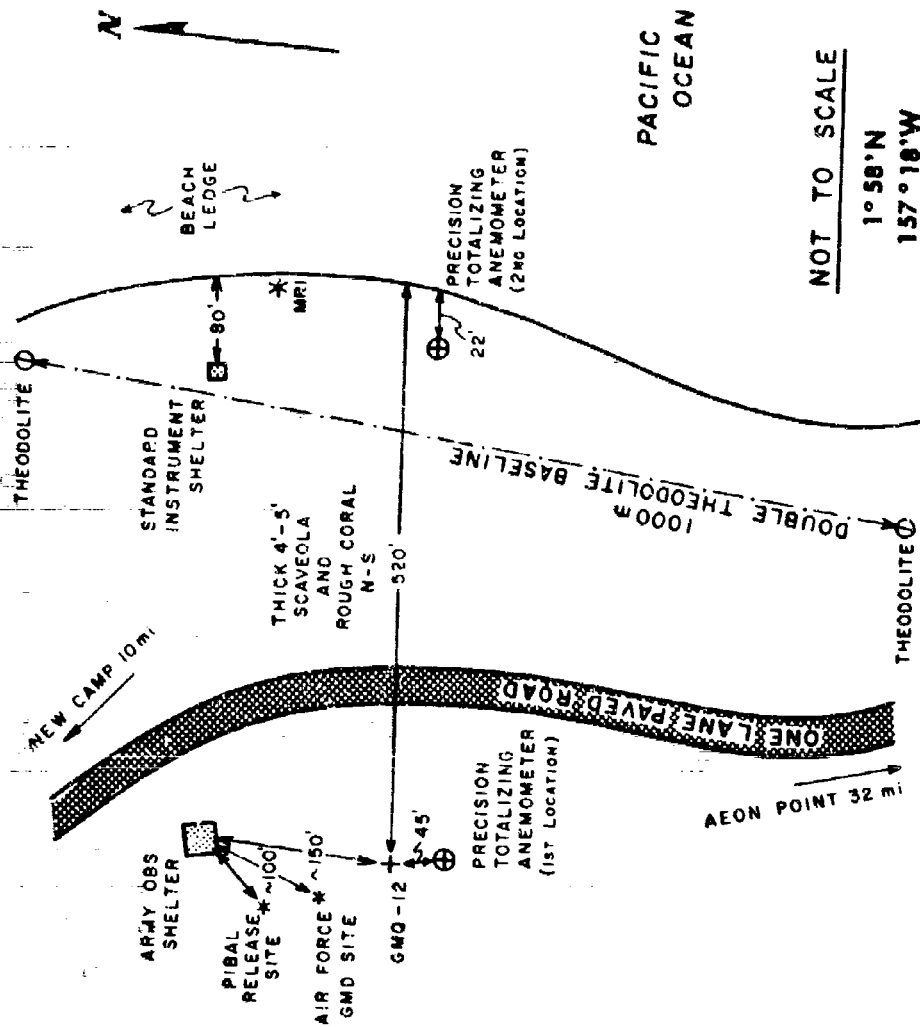

Fig. 22 Main observing area at Northeast Point, Christmas Island.
(Based on sketch by Frank Harrison)

Fig. 23 View of beach ledge looking south toward MRI set at
Northeast Point, Christmas Island. (NCAR photo)

Fig. 24 U.S. Air Force CMD site at Northeast Point, Christmas Island. Tracking antenna is on right, time-lapse and still cameras on roof of shelter on left. Surface instrumentation is visible in the distance. This view is toward the east-northeast. (NCAR photo)

Fig. 25 Christmas Island Bridges Point (London) site. (Sketch by Frank Harrison)

Fig. 76 Conference at the Bridges Point MRI site, Christmas Island. This view is toward the north. (NCAR photo)

Fig. 27 Christmas Island New Camp (JOC) site. (Sketch by Frank Harrison)

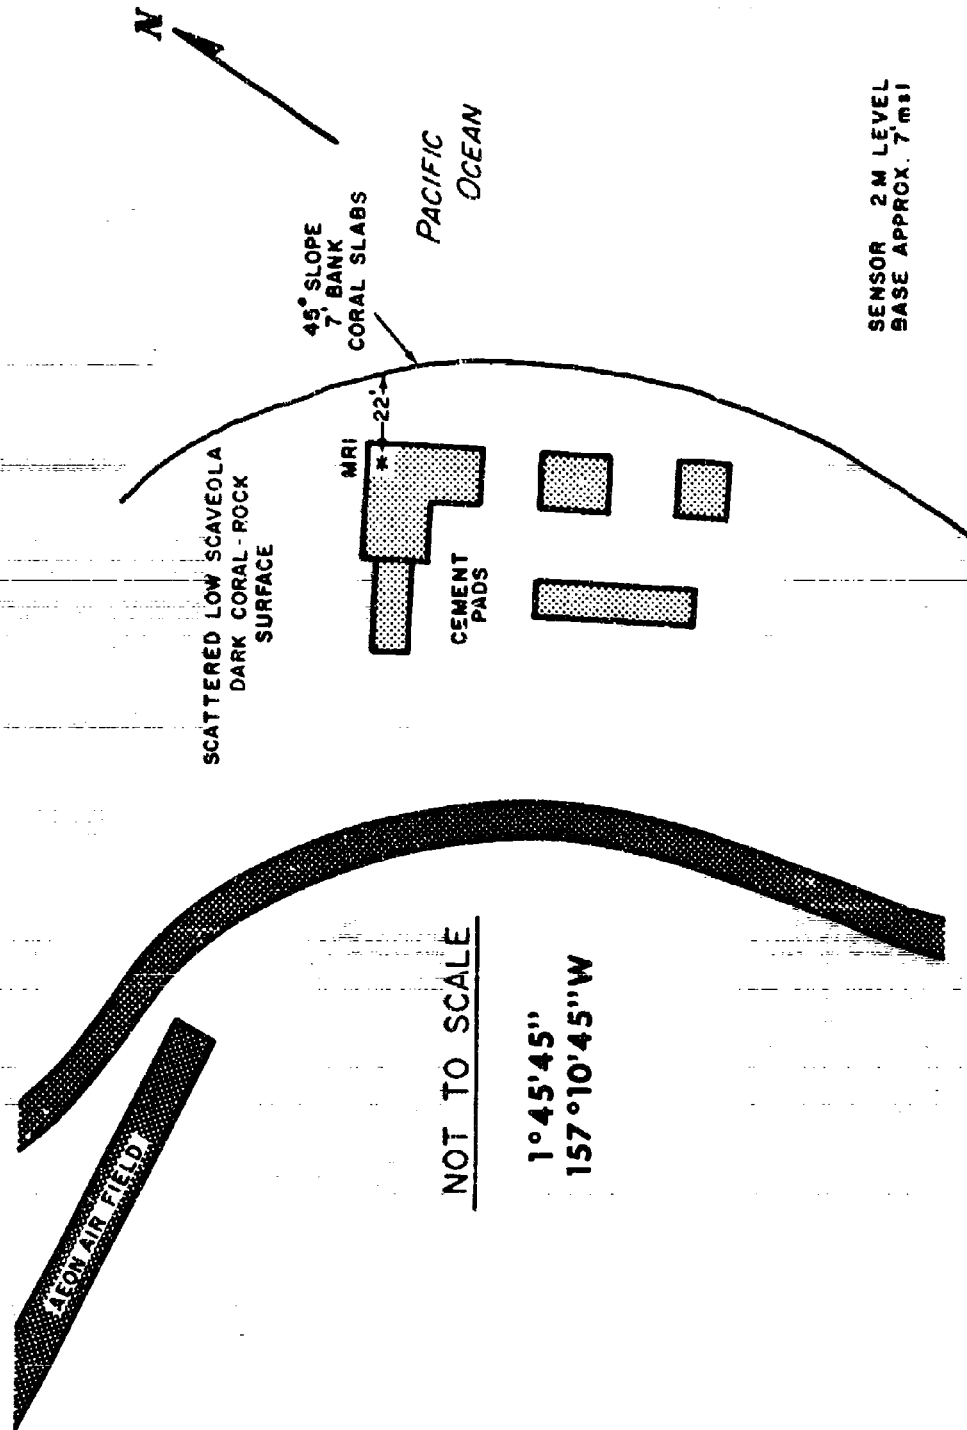

Fig. 28 Christmas Island Aeon Point (VIC 'B' Camp) site. (Sketch by Frank Harrison)

Fig. 29 Looking toward the northeast, Aeon Point, Christmas Island. (NCAR photo)

Fig. 30 *USCGC Surveyor* docked in home port of Seattle before Line Islands Experiment.
Note location of twin anemometers high on the mast. (NCAR photo)

Fig. 31 Shipboard radiosonde release on the *USCGC Surveyor*. (NCAR photo)

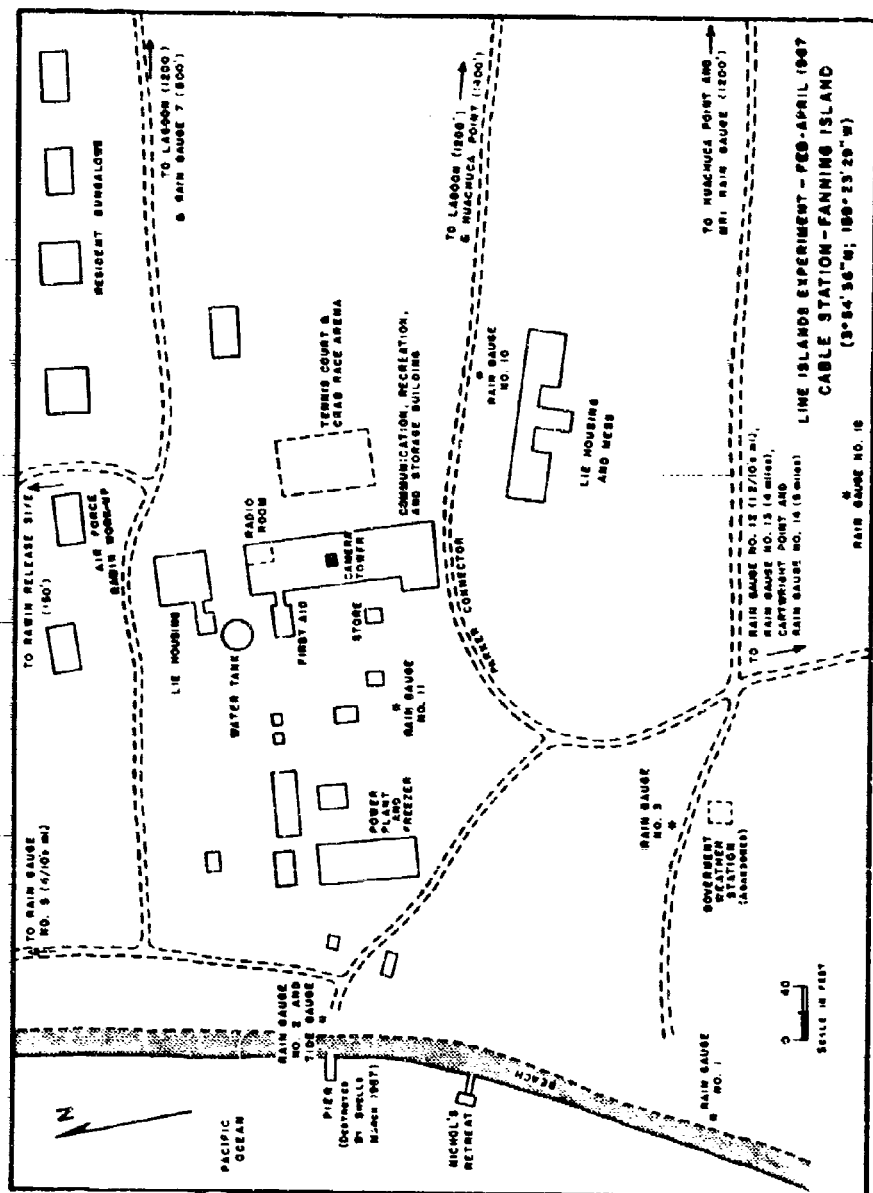

Fig. 32 West part of Cable Station showing part of micro rain-gauge network on Fanning Island. Ground-based photographs were taken from 25-ft tower atop building indicated. Rawinsondes were released from black coral field about 150 ft north of work-up shelter. (Sketch by Gerry Schaeffer and Frank Robitaille)

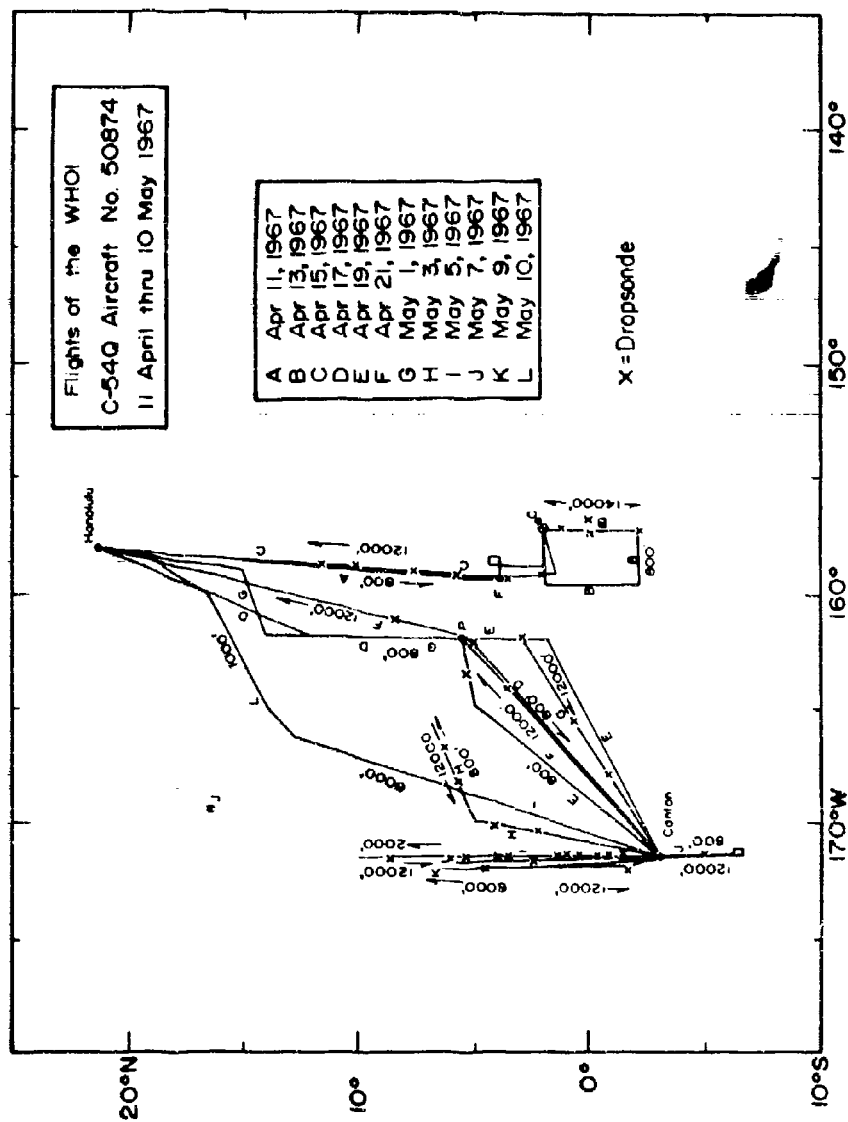

Fig. 33 Map showing tracks flown by the Woods Hole Oceanographic Institution C-540 aircraft during the Line Islands program. The black dots identified as J, P, F and C refer to Johnston, Palmyra, Fanning and Christmas Islands, respectively.

Fig. 34 Map showing tracks flown by military weather reconnaissance aircraft during the Line Islands program. The WV-3 aircraft is from the U.S. Navy VW-1 Reconnaissance Squadron. It flew to Fanning Island at an altitude of 1,000 ft, then climbed to 10,000 ft for the remainder of the track. The B-47 aircraft were from the U.S. Air Force 57th Weather Reconnaissance Squadron. Most of their tracks were flown at 300 mb (30,000 ft).

Fig. 35 Typical ATS-1 photograph taken during period of most intensive coverage. The legend identifies the day (109th day of the year -- 19 April), the year (1967), the time (203823 GMT), and the numerical sequence number (37th picture of the day).

Fig. 36 Major ship tracks of the EASTROPAC program during the period of the Line Islands Experiment. The ships which are identified by name obtained upper air data.

Fig. 37 Example of infrared pictures taken from the summit of Haleakela, Maui, elevation 10,000 ft, pieced together to form a 360° panorama. The observatory dome is west of the camera. To the northwest, Maui narrows to a 6-mi isthmus, behind which are the West Maui Mountains, and in the distance, the islands of Lanai and Molokai. Fig. 38 Aerial view of English Harbour area of Fanning Island from 10,000 ft. North is toward the top. Plantation housing and drying sheds are just south of the channel. Cartwright Point and Ahenca Point extend eastward into the lagoon just north of the channel. Currents in the channel (note standing waves) sometimes exceed 7 kt and are an ever-present threat to safety. Most of the supplies were unloaded near Cartwright Point and taken by truck via 6th Weather Turnpike to the Cable Station some 5 mi to the north. (Photo by Bob Kendall)

Fig. 39 Aerial view of southern approach to Cable Station, Fanning Island, taken from 10,000 ft, north toward the top. The Cable Station grounds extend across the island from ocean to lagoon. The black coral field used for rawinsonde releases is visible at the extreme top, just north of the Cable Station. Huachuca Point is the second point from the top, at the southeast extremity of the Cable Station grounds. This picture includes the area proposed for an airstrip, now crossed by the 6th Weather Turnpike. Note the refracted waves along the west coast. (Photo by Bob Kendall)

Fig. 40 Aerial view of Washington Island looking to the north. This island was not used in the Experiment because it did not afford sites with adequate exposure and because access is extremely difficult. The lake is fresh water and its level is controlled by locks near the south end of the island. (Photo by Bob Kendall)

Fig. 41 Bridges Point, Christmas Island, juts into the lagoon behind the village of London. On Christmas Eve, 1777, Captain Cook anchored *HMS Resolution* in the channel a short distance to the right of the point (see Section II). During the Line Islands Experiment, Bridges Point served as one of the four MRI sites on Christmas Island. (NCAR photo)

Fig. 42 The NCAR Queen Air prepares to take off from Palmyra.

Fig. 43 The Woods Hole Oceanographic Institution C-54Q.

Fig. 44 A U.S. Air Force B-47 flying past Diamond Head, Oahu, Hawaii. During the Line Islands Experiment, these aircraft were flown by the 57th Weather Reconnaissance Squadron.

Fig. 45 The U.S. Navy WV-3. During the Line Islands Experiment, this aircraft was flown by the WV-1 Reconnaissance Squadron.

Fig. 46 The U.S. Air Force C-97 landing at Palmyra, with the PBY in the right foreground. These aircraft made weekly supply flights to Christmas and Palmyra. They were operated by the 146th MAW, Van Nuys, California, and supported by California, Arizona and Utah units of the Air National Guard. (NCAR photo)

Fig. 47 The PBY 5-A, of Catalina Enterprises, Inc., on final approach to a splash landing on the Fanning lagoon. Piloted by Tom or Bob Kendall, it made sixty flights during the Line Islands Experiment. This venerable aircraft, despite the many stories that it served to generate, made the survey trip possible, brought the first personnel into the islands prior to the start of the observing program, and was the main link to Fanning Island.

Philip F. D. Palmer (right), manager of Fanning Island Plantations, Ltd., is completing his 30th year at Fanning and his 47th year in the Pacific Islands of the United Kingdom, including several years during World War II as a coast watcher in the Solomon Islands. During the Line Islands Experiment, he aided by offering food, transportation, communications and other forms of encouragement. His assistant, John Fleetwood, made the remote MRI site and lagoon sections possible, supplying his time and boat to reach this nearly inaccessible part of the island. (NCAR photo)

Fig. 48 Example of routine panoramic cloud photography accomplished during tower on Fanning on 19 April, at 1900, 1920 and 1930 GMT, top to bottom. The "birdhouse" shelters the Bolex cine camera. With relatively minor clouds taken every daylight hour of every day from Palmyra, Fanning, Christmas

accomplished during the Line Islands Experiment. This view is from the photo
d 1930 GMT, top to bottom, or 1 hr prior to the ATS-1 photograph of Fig. 35.
With relatively minor exceptions (see Section IV), similar panoramas were
myra, Fanning, Christmas and the *USC&GSS Surveyor*. (NCAR photo)

Fig. 49 One of the two Bolex cine camera systems on Palmyra is sheltered in the "birdhouse," looking toward the west-southwest across the lagoon where a good horizon is available. Sharks often entered the small cove in the foreground. Time-lapse cloud photography from this and similar systems was accomplished from each island on most days during the program. (NCAR photo)

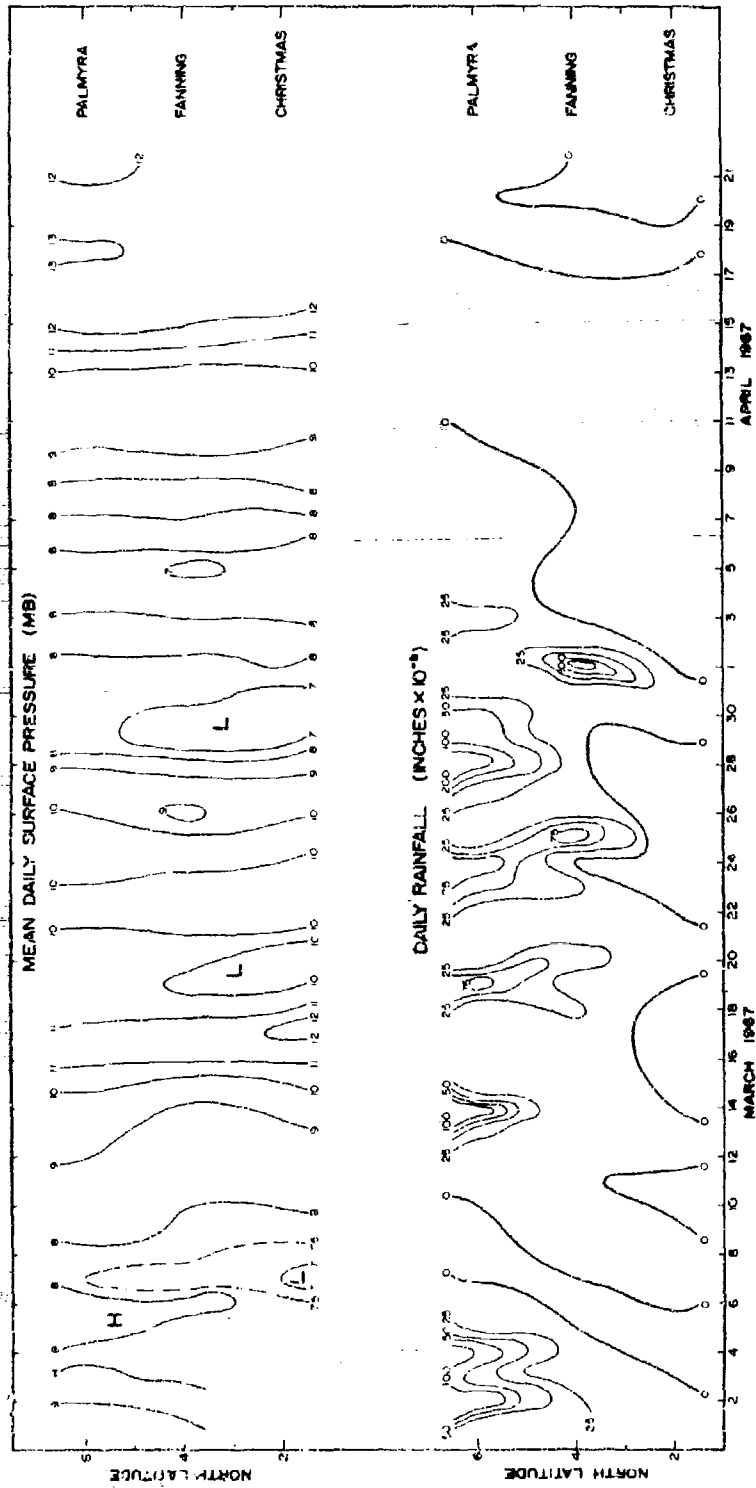

Fig. 50 Space-time analysis of mean daily surface pressure and daily rainfall from the Line Islands from 2 March through 21 April. The presentation is for convenience; the reader may arrive at his own conclusions as to correlations that may exist between the two fields.

INSTRUMENTATION ON NCAR RESEARCH AVIATION FACILITY QUEEN AIR 304D:
LINE ISLANDS EXPERIMENT

<u>Equipment</u>	<u>Parameter</u>
1. Digital clock	Time reference
2. Reverse flow temperature probe	Air temperature
3. NRL axial flow probe	Air temperature
4. Wet bulb probe	Wet bulb temperature
5. Bendix hygrometer	Dew point temperature
6. Pace PIA	Absolute pressure
7. Pace KP-15	Indicated airspeed
8. Johnson-Williams hot wire	Cloud liquid water content
9. Prototype spinning bowl	Cloud liquid water content
10. N-1 compass	Magnetic heading Flight level wind
11. APN-153V doppler navigator	Drift, ground speed Flight level wind
12. Giannini III-B 16-mm camera	Cloud photography
13. Barnes IT-3 infrared thermometer (University of Wisconsin)	Sea surface temperature
14. Air sampling equipment	Aerosols
15. Aircraft Research Instrumentation System	Hybrid data acquisition system

APPENDIX C

SUMMARY OF WOODS HOLE OCEANOGRAPHIC INSTITUTION FLIGHTS

Information for use with Appendix C

All times for the 12 Woods Hole Oceanographic Institution (WHOI) flights are in GMT.

MSw has been used to indicate manual switching of both range and thermistors. The period of switching is irregular and may be as long as 2 or 3 min.

All winds are in knots.

Appendix C

WFOI Flight No. 11

9-10 May 1967

Takeoff 1802 GMT

Landing 0149 GMT

1. Cumulus Study: Canton Island - 6N 172W - Return at 12,000 ft

2. Flight Path and Navigational Winds

<u>Time</u>	<u>Latitude</u>	<u>Longitude</u>	<u>Altitude (ft)</u>	<u>Winds</u>
1848	0105N	17.47W	6,000	065/15
	Square flown to check doppler radar			
2110	0445N	17202W	6,000	083/14
2141	0616N	17159W	6,000	095/11
2155	0537N	17201W	Start study of cumulus	
2240	0537N	17201W	End study of cumulus; start climb to 12,000	
0000	0148N	17152W	12,000	110/16
0100	0058S	17153W	12,000	120/20
0116	Start descent to Canton Island			

3. Observations Taken

	<u>On</u>	<u>Off</u>	<u>Exceptions</u>
Psychrograph	1803	0147	dry only 2253 - 0016
Dew point hygrometer	1814	0147	none
Shortwave radiometer	1805	0147	none
Bolex cloud pictures	1834	0135	none
K-100 cloud pictures (camera pointing forward)	2130	2250	time of operation uncertain
Radar pictures	1827	0149	none
Infrared radiometers	IT-3 and R8		

<u>Dropsondes</u>	<u>Time</u>	<u>Latitude</u>	<u>Longitude</u>	<u>Altitude (ft)</u>	<u>Exceptions</u>

APPENDIX D

LISTS OF SATELLITE PICTURES TAKEN DURING
LINE ISLANDS EXPERIMENT

1. 1967 ATS-1 Photo Inventory 297
2. ESSA I Pictures of Line Islands Area,
15 February to 30 April 1967 325
3. ESSA III Pictures of Line Islands Area,
15 February to 30 April 1967 327
4. APT Satellite Pictures (ESSA IV and NIMBUS II)
Received on Palmyra 330

Information for use with Appendix D1: Quality of ATS-1 prints

<u>Condition</u>	<u>Code</u>
Good, no serious imperfections except at poles where a flattening is acceptable	1
Lateral shift and slight peripheral distortion	2
Distortion of the sphere	3
Severe cropping or interference with parts of picture missing but equatorial area present	4
Cropping or interference which causes sections of equatorial area to be missing	5

Appendix D1

APPENDIX F
METEOROLOGICAL PROGRAMS OF THE PACIFIC ATOMIC TEST SERIES

Appendix F

METEOROLOGICAL PROGRAMS OF THE PACIFIC ATOMIC TEST SERIES

Beginning in 1946 with Operation CROSSROADS -- the first full-scale atomic test at Bikini Atoll -- the United States has conducted seven major tests in the Pacific area. Until 1954, when Operation CASTLE was conducted at Eniwetok/Bikini, the meteorological support for these tests consisted primarily of the information needed to support aircraft operations: in other words, conventional airways weather support.

As a result of the increasing size of shot yields and the increasing hazards from radioactive fallout, tests conducted after CASTLE involved more extensive meteorological programs intended to provide detailed information concerning the structure and development of tropospheric and low-stratospheric flow patterns in the atmosphere.

Operation REDWING, conducted at Eniwetok/Bikini during the spring and summer of 1956, involved, from a meteorological point of view, the establishment of special rawinsonde stations at Eniwetok, Tarawa, Kusaie, Kapingamarangi and Rongerik. Special observations were taken by the regular observing stations at Hawaii, Truk, Kwajalein, Ponape, Wake and Majuro. Additionally, extensive aircraft reconnaissance was flown at 850 and 300-mb levels and special ship observations were obtained in the operational area.

A data report for the period 15 April through 31 July 1956 was prepared following the termination of REDWING operations by Joint Task Force Seven. This report consists of twelve volumes -- one for each island station, one containing the aircraft reconnaissance data and one containing the shipboard observations. Copies of these volumes are available through the Department of Geosciences at the University of Hawaii, from NCAR, or from the Department of Defense in Washington, D.C.

The technique of streamline analysis was used by the Task Force Weather Central during REDWING. Analyses at the surface, and at 10,000, 20,000, 40,000, 60,000 and 80,000-ft levels were prepared four times daily for the operational period and are now archived at the University of Hawaii. Also, a large part of the data obtained during this operation has been reduced to punched-card form by the University of Hawaii, from which it is now available.

During the spring and summer of 1958 a series of atomic tests, known as Operation HARDTACK, was conducted at the Eniwetok Proving Ground by Joint Task Force Seven. Again, special meteorological operations were conducted: stations were established at Tarawa, Nauru, Kapingamarangi, Kusale and Utirik, and special observations were obtained from all regular weather stations in the Pacific area. Intensive aircraft reconnaissance and a shipboard observing program were conducted, as well as pilot observations from the nearby atolls of Ujelang, Wotho and Rongelap. Following the termination of operations, a six-volume weather data report for March through July 1958 was prepared in essentially the REDWING format. It is available from the sources cited above.

The last Pacific test series, Operation DOMINIC, was conducted by Joint Task Force Eight in 1962, partly at Christmas Island (April through July) and partly at Johnston Island (October and November). This series differed from earlier operations in that all test shots were either air-dropped or high-altitude missile-launched. As a consequence, fallout hazards were greatly reduced in comparison with the earlier surface shots and the requirement for detailed fallout prediction was lessened. In a sense, this turned the principal meteorological attention from wind structure forecasting to the exotic problems of making detailed cloud forecasts along the "lines of sight" from instrumentation to the fireball and of making low-level wind-shear forecasts over the missile launch area.

In order to provide adequate weather information for these tests, special observations were taken at certain regular weather reporting stations in the tropical Pacific. In addition, special observing stations were established at Palmyra, Malden, Tutuila, Christmas, French

Frigate Shoals and Johnston Islands. Intensive aircraft weather reconnaissance was conducted, and special ship observations were obtained. In this instance, aircraft weather reconnaissance was particularly aimed at obtaining photographic coverage of the cloud patterns in the test area from U-2 and lower altitudes. Augmenting this photography were satellite photographs obtained from the TIROS satellites.

Joint Task Force Eight has prepared a data report which contains the conventional weather data collected; the five-volume report is available from the sources already cited. Unfortunately, the photographic data obtained have, to a large extent, been scattered; some is available through the University of Hawaii and through the Naval Weather Research Facility at Norfolk, Virginia.

Since 1962, periodic operation readiness tests have been conducted by the Joint Task Force in the Johnston Island area, and in each case a weather data report has been published -- for example, Operation WINDLASS in September 1966.

APPENDIX G
BIBLIOGRAPHY

Appendix G

BIBLIOGRAPHY*

The completeness of the following bibliography is largely the result of our having access to a manuscript bibliography (of books, pamphlets, and articles on the Phoenix and Line Islands -- 4 pp., 124 items, 1940) prepared by H. E. Maude of The Australian National University, Canberra. We are particularly indebted to him for many references prior to 1940, and for sending us other manuscript material dealing with Fanning and Palmyra Islands.

We are also indebted to Bryan's excellent book (1942), which, in many ways, has yet to be equalled in scope of personal experiences throughout the Pacific Islands. We have also benefited from Taylor's standard reference (1965), as well as the very useful compilation of Ida Leeson (1954).

No general narrative of the Line Islands has yet been published. However, the best general discussion is that provided by Tudor (1963) and earlier editions published under the same title. Further, Bryan's book (1942) is rich in personal knowledge of many atolls, drawn from his experiences prior to World War II. Although now somewhat out of date, the discussion provided by the British Naval Intelligence Division (1943-45) is useful, including its many maps, charts, and extensive references.

The Line Islands have been objects of scientific scrutiny for nearly a century, with the major emphasis on their natural history. In this regard, the most complete discussion of Palmyra has been provided by Dawson (1959), while Fanning, Christmas, and Washington have been discussed by at least a dozen investigators (Emory, 1934; Centzler, 1962;

* Includes references in the main text.

Halstead and Schall, 1958; Herms, 1926; Knoch, 1927; Streets, 1877b; Vaughan, 1918; Wentworth, 1931a; Wentworth and Ladd, 1931) although, for the most part, not recently. Geophysical investigations -- largely meteorological -- are provided in a dozen papers (Brooks, 1926; Burns, 1944; Christophersen, 1927; Deberitz, et al., 1967; Freeman, 1957; Harn, 1913; Joint Task Force Seven, 1959; Meteorological Office, 1920; Meteorological Office Discussion, 1959; New Zealand Meteorological Service, 1956; Sadler, 1959; Seelye, 1950) exclusive of recently published data.

We believe the following bibliography contains all major published scientific results for the Northern Line Islands. In addition, several references include historical descriptions of discovery (Bennett, 1840; Bloxam, 1925; Fanning, 1833; Wilkes, 1845), as well as experiences of those who have lived for extended periods on some of the islands (Benson, 1838; Cooper, 1915; Hague, 1902; Herms, 1926; I. Meng, 1923; Ross, 1948; Rougier, 1914, 1915, 1917, 1925; Tresilian, 1838). With one exception (Steele, 1922), all references were personally examined by one of us at either the Bishop Museum or the Gregg M. Sinclair Library at the University of Hawaii, Honolulu.
