#### ABSTRACT

Alkoxy benzalacetone amidinohydrazones and N\*, N\* anhydrobis (2-hydroxyetyl) amidinohydrazones were newly synthesized and antiviral effectiveness of these derivatives against influenza virus was investigated.

Out of 39 compounds, 31 derivatives (79.5 % of total compounds tested) were found to possess the virucidal activity, and 13 compounds (33.3 %) were of antiviral effectiveness against the virus with the chemotherapeutic ratio of 2 or greater. Five derivatives (#283, #284, #286, #299, and #300) have highly virucidal effectiveness to the virus with the minimal concentration as low as 1.6 #7ml or 0.8 f7ml in final. Three(#283, #284, and #300) out of five derivatives have been found to be active with one-sixtyfourth less concentration of their cytotoxic doses.

By the inhibition test, seven compounds) (#268, #274, #275, #276, #279, #280, and #282) have antiviral activity to the virus with the final concentration of 12.5, W/al or less. A final concentration of 6.3 m/ml of #268, and 3.2 M/ml of #275 could completely inhibit the virus replication in the membrane culture system, and those concentrations were found to be a half of their contact- inhibitory concentrations.

#### 1. INTRODUCTION

During recent years we have been investigating the antiviral activities of amidinohydrazones, phenols, azlactones, hydrazones, and miscellaneous compounds against arbo- and myxo-viruses, among which several amidinohydrazones and phenols have been found to possess the inhibitory activity against influenza virus (1, 2, 3). The activity of these amidinohydrazones prompted us to investigate the antiviral effectiveness of newly synthesized alkoxy benzalacetone amidinohydrazones.

During the past year, 39 derivatives were synthesized. Thirtyone derivatives were found to be contact inhibitory (3) and 13 compounds were inhibitory to influenza virus. This final report will describe the results in progressive experiments of antiviral effectiveness of amidinohydrazones against the virus.

#### 2. MATERIALS AND METHODS

Virus; Adachi strain of influenza virus type A2 was used throughout the experiments described herein. One-tenth ml of 10 MID100 (Minimal HA Inducing Dosis of 100 percent) was the inoculum per membrane culture.

Chemical compounds; The compounds tested were synthesized, during the past year, at the Department of Organic Chemistry, Kitasato University School of Hygienic Sciences. A total of 39 amidinohydrasones listed in Table I were quantitatively determined both for toxic and antiviral inhibitory concentrations with the system of Maitland type membrane culture and influenza virus.

Methods and materials for the chorio-allantoic membrane culture, influenza virus titration, and HA test were fully reported eleswhere (1, 2). For the determination method for cytotoxicity of compounds

-1-

was used the same dilution technique as described enerviously. Following two methods for determinating antiviral activity of each commound were employed; 1) Contact inhibition test (formerly named antiviral activity or inhibition in the previous reports) was performed with the same determination technique. The inoculum into membrane cultures was the mixture kent at room temperature for 30 minutes of same volumes of virus and aupropriately diluted commound solution to be tested, and 21 Inhibition test is that one-tenth ml of virus and diluted test samples are simultaneously inoculated into membrane cultures instead of inoculating the mixture. The calculation of the antiviral inhibitory concentration of each derivatives was exactly identical to the contact inhibition test fully mentioned eleswhere (1, 2).

#### 3. RESULTS

Effectiveness of 39 compounds; the hydrochloride was dissolved in 50 % aqueous relycerol and the free base was dissolved in distilled water by addine 1M hydrochloric acid and compound solutions were heated at 121°C for 15 minutes prior to use. The minimal concentrations of 100 % inhibitory and of 300 % cytotoxic activity were determined for each derivative by two-fold serial dilutions. Each concentration was calculated from results with 4 cultures. Appropriate controls were made in marallel with tests. The results are summarized in Table 2. The numbers shown in the column A, B, and C are the minimal concentrations of complete inhibition by the contact inhibition test and the inhibition test, and of 100 % toxicity. The numbers in the column D are indicating the cytotoxic/virucidal ratio of the number at the column A to the column C, and the column E presents the effective ratio of the number in the column B to the

- 2 -

number in the column C.

Commounds listed in Table 2 can be classified by their ratios into 5 groups as shown in Table 3 and in Table 4. As can be seen in Table 3, the numbers of derivatives showing the ratio 1 or less, 2, from 4 to 2, 16 to 32, and 64 or greater were 8(20.5 %), 9(23 %), 13(33.2 %), 5(12.7 %) and 4(10.2 %), respectively. The numbers of  $\pi$ commounds in Table 4 giving the ratio tested by the inhibition test, 1 or less, 2, 4 to 8, and 16 or greater were 19(48.7 %), 8(20.5 %), 4(10.3 %) and 1(2.5 %) in order.

Out of total derivatives, 31 commounds (79.5 %) resulted from the contact inhibition test were found to rousess virucidal action against influenza virus with ratio of 2 dr greater, and only 13 compounds (33.3 %) determined by the inhibition test were completely antiviral inhibitory with the ratio of 2 or greater. One derivative, serial number 275, is effective to the virus with the high ratio of : 16 or greater as demonstrated by both testing techniques.

Two minimal inhibitory concentrations of each compound resulted from the tests by two different procedures were compared. The comparative ratio of virucidal concentration in the column B to the antiviral inhibitory concentration in the column A is withdrawn. All derivatives tested are groups i with reference of the ratio and presented in Table 5. It is worth to note that two derivatives, serial number #268 and #275, inhibited the growth of influenza virus at a final concentration of 6.3  $\gamma$ /ml, respectively, and were found to possess the two-fold higher antiviral inhibitory effectiveness than direct-contact action.

Further studies on the mode of action, chemotheraneutic effect of those fruitful artiviral derivatives in ovo, in vitro, and in

- 3 -

vivo systems to be infected with arbo- and other myxoviruses remain to be done.
