INTRODUCTION

The Bibliography on Snow, Ice and Frozen Ground with Abstracts, CRREL Report 12, was first published in 1951 and is the annual publication of a continuing project of the Cold Regions Bibliography Section in the Science and Technology Division of the Library of Congress. It is prepared for the Cold Regions Research and Engineering Laboratory (CRREL) of the U. S. Army Materiel Command, formerly U. S. Army Snow, Ice and Permafrost Research Establishment (SIPRE) of the Corps of Engineers. Volumes 1-15 were issued as the Bibliography on Snow, Ice and Permafrost, SIPRE Report 12. Beginning with Volume 16, the designation was changed to CRREL Report 12, and with Volume 20, the title was further changed to the present form. The current Volume 22 contains abstracts SIP 25201-26000.

The Bibliography provides USA CRREL with a current and comprehensive coverage of basic and applied scientific research on snow, ice, and frozen ground, as well as living and working in polar regions and other cold areas.

Each entry includes a bibliographic citation, code designating the library holding of the abstracted item (see p. vi), assigned call number, Universal Decimal Classification number, and the abstract. The abstracts were written by Jane E. Boerner, Benjamin L. Evans, Wan-Wan Li, Frank M. Marson, Diana M. Niskern, Vladimir D. Pastuhov, Arthur G. Renstrom, Dorine A. Smith, Geza T. Thuronyi, and Natalie S. Voshinin.

Requests for materials abstracted should not be addressed to USA CRREL. Where copyright regulations permit, photocopies of materials in the collection of the Library of Congress may be purchased from the Photoduplication Service, Library of Congress, Washington, D. C. 20540. U. S. Government technical reports, including those designated as located in the Defense Documentation Center may, in most cases, be obtained from the Clearinghouse for Federal Scientific and Technical Information, Springfield, Va. Other materials should be ordered from the publisher or consulted at the designated library.

The volume was prepared by Frank M. Marson, Supervising Editor, Calvin L. Clark and Odessa Swann.

WHEN THE ICE MELTS. *Geogr. Mag.*, 34(11):630-638 incl. illus., diagr., map, March 1962.
DLC, G1.G343

About 10% of the world's land area is covered with ice. If all this ice were to melt and be distributed only over present ocean areas, sea level would rise by about 200 ft. However, the spreading of the water over land, increasing the area of the sea, would have the effect of reducing the rise to 180 ft. The fact that much of Antarctica's ice is already below present sea level further reduces the figure, bringing the rise down to about 150 ft. According to the principle of isostasy, the addition of the extra weight of water would lower the sea floor, and thus the sea level, by about 50 ft. The effective rise in sea level would then be 100 ft over the present level. The current state of knowledge of geophysics is such that it is impossible to do more than make a reasonable assumption about these changes in sea level.
-- DMN

This paper describes the characteristic vegetation types and their ecology in the Yukon Flats Region, Alaska, and associates aerial photographic patterns with these types. The discussion includes the physiographic setting, vegetation patterns, forest fires, bog succession, the selection of sample sites, vegetation sampling, photographic interpretation, composition and structure of vegetation, and radar and thermal imagery. Appendix A lists the scientific and common names of plants, while Appendix B tabulates selected soil samples from vegetation stands. Ground and air reconnaissance were used to select 43 stands representative of the common plant communities. Ten individual trees were harvested by meter increments, and stem, branch, and leaf components were weighed. Three kinds of vegetation type maps were constructed from an examination of aerial photography by application of the ground data to photo interpretation. -- BLE

ALBUM OF ICING FORMS ON WIRES. (Atlas obledeneniia provodov; Text in Russian). Leningrad, Gidrometeorologicheskoe Izdatel'stvo, 115p. incl. illus., table, diagrs, 1966. 4 refs.
DLC, TK3231.B82

The enlarged edition of the Album, initially published in 1955 (see SIP 13432), contains a detailed classification and description of the forms and diversities of icing on transmission and communication lines. The meteorological phenomena determining the formations are described. New data shows icing effects on network wires. Selected photographs show typical icing deposits including cross-section views and details of the microstructure. -- VDP

PROBLEMS OF AVALANCHE RESEARCH. p. 15-22 incl. diagrs. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 18 refs.
DLC, GB651.163

The questions to be answered about avalanches may be classified under: (1) types, location, and frequency of occurrence, (2) reason and manner of formation, and (3) movement process and effects. Two branches of genetic studies must be distinguished; (1) the problem of the genesis of certain types of snow or certain strata, and (2) the pure mechanics of avalanche formation. The most complex problem in avalanche genesis is probably the influence of temperature, be it conductive or radiant heat. Other basic factors are fresh snow deposits, stratification of the old snow cover, and wind action. A definition of avalanche velocity is given and different types of friction involved in moving snow are described. -- BLE

METEOROLOGICAL CONDITIONS OF AVALANCHE FORMATION IN THE Khibiny. p. 35-42 incl. graphs, diagrs. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 3 refs.
 DLC, GB651.163

Information is presented about the number of avalanches and their distribution on slopes with different exposure, numerical characteristics of the possibility of avalanche formation of different volume in avalanche deposits, and relationships between avalanches and transfer and wastage of snow. A diagram is given for estimating the onset of snow drift avalanches. The role of solid precipitation and air temperature in the formation of avalanches are discussed, and a brief classification is given. (Author's abstract)

SNOW COVER DENSITY CHANGES IN AN EXPERIMENTAL WATERSHED. p. 43-52 incl. tables, graphs, map. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 5 refs.
 DLC, GB651.163

Factors influencing the accumulation and properties of snow are investigated in an experimental mountain water shed. As the area comprises a slope with a frequent occurrence of avalanches, the obtained results may also be applied to the problem of avalanches. Although a great variability in the total snow deposit was observed, there is a consistent occurrence of the deepest snowpacks in one place with avalanche danger. The gradual increase in the snow density during the winter season was measured and a method of calculating it derived. As the density differences between the layers of a snowpack diminish with time, special apparatus must be used to determine layers of different structure to indicate avalanche conditions. On the basis of measurements of the effect of air temperature and wind velocity on changes in the water content, the weight of a snowpack was determined by a radioactive snow gage and by weighing snow samples. Zingg, Th.
RELATION BETWEEN WEATHER SITUATION, SNOW METAMORPHISM AND AVALANCHE ACTIVITY. p. 61-64 incl. table. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966).
 DLC, GB651.163

The weather acts especially on the surface layer of a snow cover. The poor heat conductivity of snow is responsible for the thermal instability of a snow cover. This instability produces moisture transport in the upper levels and at the same time a metamorphism of the snow crystals into new shaped grains. This changes also the mechanical and physical properties of the snow cover. The phenomenon depends very much on the depth of the new fallen snow and the whole snow cover. The temperature gradient and the effective temperature of the snow determine the structure and grain shape of the snow. Avalanche activity depends on the stratigraphy and on the current weather. Important are: amount and kind of snowfall, wind action, (separately or in connection with snowfall), temperature, radiation, and rain (especially early in the winter and in spring. AVALANCHE ACTIVITY AND FREE WATER CONTENT OF SNOW AT OBERGURGL (1980 m a. s. l., SPRING 1962). p. 65-72 incl. illus., graphs., diagr. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966).
 DLC, GB651.163

The free water content of snow was determined daily by measuring the dielectric constant of the snow at different depths. Other climatological data were also taken. Free water content was measured with a new instrument, a plate capacitor, which is rammed into the snow. The capacitor consists of 7 plates (13 x 13 cm) spaced 2 cm apart, so that its average volume is about 1500 cm³. The capacitance depends on the dielectric constant of the snow. A small amount of free water causes a significant rise in the capacitance due to the high value of the dielectric constant of water and the low value of snow. The evaluation of the measurements is facilitated by means of a nomograph which also includes the dependence of the readings of snow density. Accuracy is ± 0.5 vol. per cent of free water. High avalanche activity was found to be correlated with a high value of the free water content, caused by large positive values of the heat budget. -- BLE

THE HYDROLOGICAL ROLE OF AVALANCHES. (Le rôle hydrologique des avalanches; Text in English with French title). p. 73-77. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 15 refs.
 DLC, GB651.163

The necessity for studying the avalanche factor in the hydrological investigations of highland regions is advanced in this report. The role of the avalanches in the nourishment of glaciers, the disturbance of the winter regime of river run-off, and the formation of floods by mudflows is pointed out. The main hydrological role of avalanches is their creation of avalanche snow deposits, the hydrolog-

ical processes (melting, evaporation, infiltration) which differ sharply from the same processes inherent in snow cover. Some specific examples show that even in regions with weak avalanche activity, about 10-30% of the snow cover is carried away by avalanches, whereas in regions with abundant avalanches, meltwater from avalanche deposits can produce about 50% of the average annual runoff of the catchment area. (Author's abstract)

Sosedov, I. S. and I. V. Seversky
ON HYDROLOGICAL ROLE OF SNOW AVALANCHES IN THE NORTHERN SLOPE OF THE ZAILIYSKY ALATAU. p. 78-85 incl. tables, graphs. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz. Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 10 refs.
 DLC, GB651.163

The paper is based on quantitative field observations. On the northern slopes of the Zailiysky Alatau range, snow deposits are extensive and well developed. In the zone of rugged topography (1600-3000 m) they are formed by snow avalanches and fill the lateral valleys and revines in ribbonlike form. Avalanches are formed mainly in the spring on the northfacing slopes. They scour considerable areas and transport up to 20% of the total. On the avalanche slopes the infiltration properties of the ground is changed. Avalanches increase the runoff to such a degree that the coefficient of thaw water runoff is less than one. This increase appears to be small, as it is only a few per cent of the annual runoff and flood flow. The controlling effects of the redeposited snow is also insignificant. It is concluded that the use of artificial avalanching under these conditions is inexpedient. (Authors' abstract)

VARIATIONS OF THE STRENGTH OF SNOW. (Les variations de la résistance de la neige; Text in French with English summary). p. 86-99 incl. tables, graphs, diagrs. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 4 refs.
 DLC, GB651.163

A general relation is given to determine the influence of a change of temperature (below freezing) on the tensile strength of snow. From a series of shear tests in which the snow was subjected to different pressures, perpendicular to the shear plane, the intrinsic strength curves of various types of snow have been established. Successive measurements of the shear strength of different layers with-

CRREL BIBLIOGRAPHY

in the snow cover show how it varies with time. It increases under pressure of new snowfall and is reduced by metamorphism and/or a rise in temperature. The relation between the shear strength parallel to the stratification and the tensile strength (measured in the same direction) varies greatly between strong and weak layers. This stems from the anisotropic qualities of snow which change with time and prevailing natural conditions. (Author's abstract)

MECHANICAL PROPERTIES OF SNOW AND FIRN. p. 114-118 incl. graphs. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966).
 DLC, GB651.163

General methods are given of studying the physico-mechanical properties of snow and firn. Emphasis is placed on principles of densification and peculiarities of the deformation of snow and firn, concepts of hardness and bearing capacity, methods of determination of these characteristics, and the dependence of the strength of snow and firn on its hardness, temperature, and structure. The results can be used for the analysis of the processes of formation of the snow-firn cover and its stability on mountain slopes. (Author's abstract, modified)

SINTERING OF SNOW AS A FUNCTION OF TEMPERATURE. p. 119-127 incl. table, graphs. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 19 refs.
 DLC, GB651.163

This paper shows that both the sintering of snow and the rate constant as a function of temperature can be represented satisfactorily by an exponential equation. The findings will probably apply over the entire density range from freshly fallen snow to about 0.55 gm/cm³. The sintering process will also be affected strongly by densification. From the apparent activation energy obtained, it appears that the most probable mechanism is the one of evaporation, diffusion through the ambient atmosphere, and condensation. There is no indication that another mechanism takes over at any particular temperature. -- BLE

CONSIDERATION OF THE CRITICAL SLOPE AND THE PRESSURE COEFFICIENT OF A SNOW COVER. (Considérations sur la pente critique et la coefficient de pression au repos de la couverture de neige; Text in French with English abstract). p. 141-153 incl. table, graphs, diagrs. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 10 refs.
 DLC, GB651.163

For the critical slope, the second primary stress becomes 0 by definition. Its main value is a function of the so-called parameter of creep, which can be measured and expressed by the relative density of the snow layer. Furthermore, it is shown that there exist simple but only approximate relations between the critical slope and the pressure at rest of the horizontal snow cover on one hand and the pressure at rest of the inclined snow and ice layer on the other hand. The values of the latter are calculated and it appears that they are always smaller than those of the pressure at rest of the horizontal snow and ice-layer. Finally, the application of these theoretical relations to the problems of the state of stresses of the neutral zone of the snow cover and the formation of loose snow avalanches are discussed. THE STABILITY OF SNOW LAYERS. (Stabilité des plaques de neige; Text in French with English abstract). p. 170-181 incl. graphs, diagr. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 2 refs.
 DLC, GB651.I63

The comparison of the stresses in the weakest layer of snow with the corresponding critical curve in the Mohr plane allows one to define a primary stability. Primary stability is investigated as a function of the slope angle and of the distributed load, and it is shown that it is absolute in certain cases (independent of the load). Secondary stability characterizes the absence of sensitivity to perturbations, especially to a localized rupture of the critical layer. Different shapes of the broken zone are considered, and also the influence of a vertical concentrated force applied to the surface. (Author's abstract)

ON THE MECHANISM OF THE FORMATION OF WET SNOW AVALANCHES, p. 196-198. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966).
 DLC, GB651.I63

This paper considers the equilibrium equation of a snow layer subjected to water seepage. Among the factors considered in the calculations are the apparent friction angle, free water in the snow layer, porosity of the snow, and shearing strength. In all of the equations presented, the water equivalent includes the full amount of water in the snow sample after its free water has flowed down in the snow gage. The latter must be thrust vertically into the snow cover for its full depth. For quick estimation of possible wet avalanche hazards it is sufficient to know the average density of the snow cover and the ratio of the thicknesses of the aquifer to the whole snow cover. -- BLE

THE RELEASE OF AVALANCHES. (Les Déclenchements d'avalanches; Text in French with English abstract). p. 182-195 incl. tables, graphs, diagrs., map. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 8 refs.
 DLC, GB651.I63

An approximate indication of the stability of a snow cover on a slope can be established by the stability index. This is the strength parallel to the slope of the weakest stratum, divided by the shear stress within the stratum. The angles of static and of kinetic friction are measured in disaggregated crystals of different kinds of snow. It gives an idea of the amount of resistance left in a layer after its structure has been broken and once the crystals are in movement. Measurements at the rupture line of slab avalanches show that avalanches can start when the stability index is as high as 4. An attempt is made to show that a rupture due to tension stresses in the convex part of a slope is the most likely cause of a slab avalanche release when the stability index is higher than 1. It is found that the higher the stability index, the more compact and resistant the slab must be for an avalanche to be released. Several examples are given. (Author's abstract)

CONTRIBUTION TO AVALANCHE DYNAMICS. p. 199-214 incl. table, graph, diagrs. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 8 refs.
 DLC, GB651.I63

Snow in motion is considered to consist of clods of snow. Among the clods appear friction forces. The three components of these friction forces are: a force not depending on velocity, a force proportional to the velocity, and a force proportional to the square of the velocity. It is shown that surface waves cannot propagate in a flowing avalanche. The avalanche velocities are calculated for arbitrary cross section and for all three components of the friction forces. The phenomena of moving snow depend on the Froude's and Reynolds' numbers. The runout distance for flowing avalanches is calculated, and it is shown that under a certain condition, it is impossible to stop an avalanche by means of artificial obstacles. (Author's abstract)

DLC, GB651.I63

Experimental studies on the dynamics of avalanching snow were carried out during the winters of 1959-1962 on a test slope, some 500 m long and 35° in mean gradient, using artificially released avalanches which made it possible to obtain positive and confirmable data on moving avalanches for the first time in Japan. To understand the mechanism of avalanches which is affected by many factors it is most necessary to first observe and record the motion accurately and then to attempt a qualitative classification. Therefore, this paper presents such a classification and points the way to more quantitative approaches. (Author's abstract)

BEHAVIOUR OF AVALANCHES IN AREAS CONTROLLED BY SUPPORTING STRUCTURES.
p. 243-250 incl. illus., tables, graph, diagrs., map. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 4 refs.
DLC, GB651.I63

Observations suggest that avalanches occur more often in areas controlled by supporting structures than is commonly believed. Two problems which arise regarding avalanche prevention are (1) the structure has to stabilize the snowpack and prevent avalanches from starting, and (2) the structures must resist the quasistatic snow pressure and the impact of the sluffs. A large number of case studies show that under unfavorable conditions structures cannot completely stabilize the snow cover nor can they catch all the sliding snow once movement has started. -- BLE

SNOW GLIDING AND AVALANCHES. p. 230-242
incl. illus., graphs, diagrs. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 12 refs.
DLC, GB651.I63

The slow, downhill gliding of the entire snow cover along the ground leads on uneven slopes to the formation of cracks and sluffs. While the cracks form as a result of the gliding, such a relationship for the sluff release is not clear. As a result of field investigations over several years, the influence of ground surface roughness, terrain shape and snow characteristics has been determined. The snow cover always glides on a wet snow boundary layer several millimeters thick and in all cases reaches a steady glide velocity. A method for measuring the glide velocity is described. A glide velocity equation is derived for these relations, assuming a free-gliding snow block and a simplified friction model. Field observation of the spatial and temporal coincidence of sluffs running on the ground with rapid glide motion lead to the influence that snow gliding participates in the release of the sluffs. THE SNOW RESISTOGRAPH AND SLAB AVALANCHE INVESTIGATIONS. p. 251-260 incl. graphs, diagrs., appendix. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966).
DLC, GB651.I63

Certain types of snow avalanches, notably deep slab avalanches, appear to be initiated by the catastrophic disruption or collapse of the snowpack under its own load. Hence, field measurements of snow strength and snow load are fundamental to the prediction of such avalanches. Snow loads are easily measured with a standard snow coring tube. For the measurement of snow strength, the Earth Sciences Department at Montana State College has developed a new field instrument called a Snow Resistograph which gives a vertical strength profile of the snowpack. Highly consistent results may be obtained. Weekly resistograms taken in the Bridger Range of Montana during the winter of 1963-1964 illustrate the methodology and potential usefulness of the resistograph in avalanche and other snow research. Laboratory tests have identified chemicals, principally aldehydes, which inhibit snow recrystallization and the formation of depth hoar. This inhibition is accompanied by gains in strength of bulk snow samples. Several investigators have noted this phenomenon of crystal poisoning of ice. Comparison of these observations and those of the authors indicates that the effect of a given chemical depends on experimental conditions, prevailing temperatures, and possible other unidentified factors. Practical application of this phenomenon to avalanches has been tested in the field. Test plots at Berthoud Pass, Colorado, where natural depth hoar formation is common, were sprayed with selected chemicals. Later, pit excavations showed strong depth hoar suppression and snow cover strengthening next to the ground on those plots sprayed with benzaldehyde and N-heptaldehyde. Chemical hardening extended 15 cm above the ground, while above this level depth hoar developed with some crystal alteration. Depth hoar suppression by ethylene glycol was tested on a small avalanche path. No avalanche fell, although others did nearby, but enough depth hoar formed to make the snow dangerously unstable.  DLC, GB651.I63

Slush avalanches are rapid mass movements of water-saturated snow that are most prevalent in regions where negative temperatures below the surface inhibit infiltration of rain and melt waters. Along stream courses they may comprise an important part of the process of stream break-up. On open slopes in the melt zones of sub-polar glaciers and ice caps, they may be a kilometer or more in

length, up to several hundred meters wide, and may move on slopes as low as 2°. In some cases they entrain significant volumes of rock material into the moving mass, and thus become important geomorphic agents. The interrelationships between all types of rapid mass movements may be effectively visualized by plotting the approximate bulk composition of the moving mass on a triangular diagram utilizing end-members of water, snow, and rock fragments. This approach results in consideration of dry snow avalanches, land slides, and streamflow as being extremes in a continuum, with such features as slush avalanches and mudflows as intermediate types. **A WET SNOW AVALANCHE ON A SLOPE OF 12
 DEGREES.** p. 273-275. (In: International Symposium
 on Scientific Aspects of Snow and Ice Avalanches,
 April 5-10, 1965, Davos, Switz., Publ.
 No. 69, Int. Assoc. Sci. Hydrol., 1966).
 DLC, GB651.I63

Spring wet snow avalanche activity is not an uncommon occurrence in the Cascade Mountain Range, but due to the unusual combinations of weather that prevailed during the winter of 1963-64, the snowpack on south slopes, when exposed to the spring warming trend, reached a higher degree of instability than is normal. Wet snow avalanche activity is not necessarily confined to the spring season and can occur at any time during winter when a cold, unconsolidated snow pack is exposed to a sudden warming trend.  DLC, GB651.I63

This paper discusses the results of studies on the height variations of temporary snow lines in the Italian Western Alps. The results indicate that the snow line moves downward at a speed of 170 m per week in autumn, and moves upward 115 m per week in spring. The variations in height depend on anomalies due both to the quantity of snowfall at the various levels and to the orographic conditions. (Author's abstract, modified)

SNOW COVER AND ITS MEASUREMENT ABOVE THE TREE LINE (IN AVALANCHE REGIONS). (La couche de neige et sa mesure au-dessus de la zone forestière (dans la région des avalanches); Text in French with English abstract). p. 286-293 incl. illus., table, graphs. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966).
 DLC, GB651.I63

The tree line in the climatic zone of Czechoslovakia is situated about 1500 m above sea level. Above this line snow cover conditions are favorable for the formation of avalanches. Research in the area suggests that it is advantageous to determine snow cover conditions in mountain ranges by the genetic snow measuring method. Its features are: (1) snow parameters are measured by snow measuring pictures with contour lines; (2) a snow measuring line has equal morphometric parameters, i. e., slope orientation, absolute elevation, and vegetative cover; (3) the length of the snow measuring line is given by the number of measuring points and their spacing and by terrain configuration; and (4) minimal point spacing is given so the values of the snow cover parameters will not be interdependent. THE HUASCARAN AVALANCHE IN THE SANTA VALLEY, PERU. p. 304-315 incl. illus., graph, map. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 7 refs.
 DLC, GB651.I63

The avalanche, the first one known in the country, occurred on Jan. 10, 1962, and fell from one of the country's highest and most beautiful peaks. It was caused by the breaking off of the west front of the hanging glacier on the summit of North Huascarán at the approximate altitude of 6300 m. The amount of ice involved is estimated at 2.5 to 3 million m³, and the avalanche included a great volume of granodiorite blocks from the cliff. It travelled 16 km, descended 4000 m in elevation, and destroyed and demolished everything in its path. The average speed was 60 km/hr. More than 4000 human lives were lost and nine small towns were destroyed. Cultivated fields were devastated, thousands of animals were killed, and great destruction was caused in an area famous for its fertility and beauty. (Author's abstract, modified)

DLC, GB651.163

Descriptions are given of ice avalanches and cases of unusual glacier growth which occurred between 1892 and 1962. It is pointed out that it is not always easy to distinguish ice or glacier avalanches from unusual glacier growth which can take on the characteristics of an avalanche. A classification of ice avalanches is proposed which considers the type of rupture, the condition of the sliding surface, the nature of the avalanche trail (ice or terrain), type of movement, and the type of deposited material. National organizations are encouraged to intensify the defense against the danger of ice avalanches by serious control and international collaboration.

AVALANCHES CAUSED BY THE ALASKA EARTHQUAKE OF MARCH 1964. p. 326-331. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 16 refs.

DLC, GB651.163

The 27 March 1964 earthquake in south central Alaska caused less snow avalanching in the upper glacier basins than might be expected and does not appear sufficient to have a significant effect on glacier regimen. The validity of the Tarr and Martin earthquake advance theory is therefore being questioned. However, avalanches induced by rock falls occurred on a number of glaciers and are expected to modify their regimen by insulating the underlying ice from normal ablation. One of the largest avalanches of this kind was on Sherman Glacier near Cordova and measures 7.7 km in length and about 13 km² in area. Its average thickness has been estimated to be 3 m. At the end of the 1964 ablation season the lower end of this avalanche was already on a pedestal some 7 m above the surrounding exposed surface of the glacier. Detailed observations of this avalanche and its effect on glacier regimen are being planned in 1965 and succeeding years. (Author's abstract)

Avalanches are generated by structural weaknesses

CRREL BIBLIOGRAPHY

In the snow cover. Some of these weaknesses can be observed and measured by investigating snow stratigraphy in pits or with instruments. This method offers reliable data from direct observation, but it is time consuming. It is most effective when forecasting climax avalanches caused by snow metamorphism or a consequence of snowfalls. Many avalanches fall during or immediately after a storm. Time usually does not permit stratigraphic investigation, which is difficult in fresh snow. These direct action avalanches can be forecast by an analysis of meteorological factors prevailing during the period of snow deposition. This indirect evidence is less reliable, but can be more easily obtained and is often the only forecasting guide available. The accuracy of such forecasts is checked by practical field tests. This determination is illustrated by examples from different climate zones in the western U. S. (Author's abstract, modified)

GENETIC CLASSIFICATION OF AVALANCHES.
p. 394-398 incl. table. (In: International Symposium on Scientific Aspects of Snow and Ice Avalanches, April 5-10, 1965, Davos, Switz., Publ. No. 69, Int. Assoc. Sci. Hydrol., 1966). 4 refs.
DLC, GB651.I63

A scheme for genetic classification of avalanches is suggested which takes into account the effects of meteorological factors and the processes within the snow cover on their formation. Avalanche types may be distinguished as those associated with snowfalls, snow drifts, rapid fall of temperature, rainfall, advection thaw, radiation thaws, spring warming, depth hoar formation, and snow cover strength reduction caused by the continuous action of load. These avalanche types are simple, but in nature complex types occur. Further development of the classification should be directed towards quantitative characteristics of avalanches and definition of those complex types that occur most often in nature.

CRREL BIBLIOGRAPHY

Ice wedges lie at levels partly just a few meters under the highest limit of the late-glacial sea and partly 30-40 m above this limit. The glaci-fluvial deltas in which the ice wedges were observed are part of the so called Gothenburg-moraine or lie a few kilometers to the west of this ice recession line. The ice wedges occur only in the northeastern part of the deltas and are so wide and deep in the glaci-fluvial sands that they must have taken considerable time to develop. The ice-wedge areas in West Sweden are not in age relation to each other. They may have developed just as the ground was exposed to the cold arctic climate in connection with the regression of the land ice and/or have arisen during several periods in gothiglacial and finiglacial times. THE ELECTRIFICATION OF AN ICE SPHERE MOVING THROUGH NATURAL CLOUDS. *J. Atmos. Sci.*, 23(6):757-763 incl. illus., tables, graph, Nov. 1966. 7 refs.
DLC, QC851.A283

Measurements have been made of the electric charge acquired by an ice sphere as the result of whirling it through various types of natural cloud and snowfall. The sphere received an appreciable charge only if ice were present in the air. In the case of an ice crystal cloud or a fall of snow crystals, the charge on the sphere was generally negative provided that the air temperature was -4°C or less. Simultaneous measurements of the charge on the ice sphere and the number of ice crystals colliding with a sphere of similar size yielded a value for the charge on the sphere of -2×10^{-3} esu per ice crystal collision. When the air temperature was above -4°C , the charge on the sphere was erratic but was found to have the same sign as the charge on the particles in the air. If graupel particles were present the ice sphere always received a large positive charge. The presence of supercooled droplets in the air caused a considerable reduction in the charge accumulated on the ice sphere. When the sphere was whirled through a cloud consisting entirely of supercooled droplets, negligible charge was separated. This result is in disagreement with the laboratory measurements of Latham and Mason, and casts doubt on the mechanism of thunderstorm electrification proposed by these workers. (Authors' abstract)

HEAT EXCHANGE OF FREEZING AND THAWING GROUND AND THE ATMOSPHERE. (Teploobmen promerzafushchikh i protaivafushchikh gruntov s atmosferoy; Text in Russian). Moscow, Izd-vo "Nauka", 254p. Incl. map, tables, diagrs., graphs, 1965. 309 refs.
DLC, TA713.P3

Results of long research on the heat balance in regions with seasonally freezing and thawing ground are summarized. Components of heat balance of the ground during the year, characteristics of heat exchange of ground and atmosphere, processes of heat exchange in ground and snow cover, and the heat regime during seasonal freezing and thawing are studied. On the basis of theoretical research checked by field observations, recommendations are made regarding methods of calculating freezing depth, moisture migration and ground heaving. A mathematical formula for the determination of subsoil freezing is set up. Mathematical derivation for the depth of ground thawing takes into account the heat influence in the processes occurring between the active layer and the atmosphere. It is recommended that limiting values be established in engineering computations of freezing and thawing depths and also of temperature fields of the ground on the basis of the thermal regime of the ground, the snow cover, and the atmosphere. -- VDP

THE USE OF MEMBRANE FILTERS IN MEASUREMENTS OF ICE NUCLEUS CONCENTRATION. I. EFFECT OF SAMPLED AIR VOLUME. J. Appl. Meteorol., 5(4):474-480 Incl. graphs, Aug. 1966. 16 refs.
DLC, QC851.A66

The membrane filter technique for detecting ice nuclei in atmospheric air has the disadvantage that the measured concentration decreases with the volume of air sampled. Various possible causes are investigated. The effect is found to be due to the presence of small numbers of ice nuclei on the filters prior to use, which give a spurious "background count," and to the presence of other particles, sampled simultaneously with the ice nuclei, which prevent the latter from being detected. SOLID WATER-INSOLUBLE PARTICLES IN HAILSTONES AND THEIR GEOPHYSICAL SIGNIFICANCE. J. Appl. Meteorol., 5(4):481-492 Incl. tables, graphs, diagrs., Aug. 1966. 7 refs.
DLC, QC851.A66

By melting concentric layers of ice, the size distribution, and concentration of solid water-insoluble particles accumulated in hailstones were determined for three hailstorms in Colorado. It was found that in approximately 50% of the hailstones analyzed, particle concentration increased with radial distance. Following an equation derived for this category of hailstones, a relationship is shown among liquid water content of a cloud, concentration of solid particles in cloud droplets, speed of the hailstone, and its residence time in the atmosphere. Spatial distribution of solid particles in hailstones was also determined by slicing hailstones and subsequently separating particles from the ice by sublimation under low pressure. It was found that some of the hailstones analyzed were oriented during their growth. (Author's abstract)

Mossop, S. C. and others
THE USE OF MEMBRANE FILTERS IN MEASUREMENTS OF ICE NUCLEUS CONCENTRATION: II. COMPARISONS WITH CLOUD CHAMBERS. J. Appl. Meteorol., 5(5):703-709 Incl. tables, graphs Oct. 1966. 23 refs.
DLC, QC851.A66

Comparisons between ice nucleus concentrations as measured by membrane filters and cloud chambers show good agreement when natural ice nuclei are being sampled. Wide discrepancies in the case of other test aerosols, particularly silver iodide, bring to light differences in the mechanisms by which various substances nucleate. The experimental technique is described. Comparisons were made in atmospheric air, using silver iodide aerosols, organic ice nuclei, and clay minerals.

FORMATION OF CRYSTALLOGRAPHIC ETCH PITS ON ICE, AND ITS APPLICATION TO THE STUDY OF HAILSTONES. J. Appl. Meteorol., 5(5):710-714 Incl. illus., diagrs., Oct. 1966. 8 refs.
DLC, QC851.A66

CRREL BIBLIOGRAPHY

The principle of formation of etch pits with crystal faces on ice crystals is explained as a natural consequence of evaporation (or any sort of dissolution) at concave surfaces of crystals. A new technique of ice etching using perforated metal foil is described, which is useful for determining grain orientations in hailstones. In etching hailstones, a funnel is used as a vacuum chamber. The hailstone is cut and a flat surface is frozen onto the center of a four inch square glass plate. The other side of the glass plate is placed on a thick metal plate (a heat sink), and an ice layer is built up to the desired thickness by dropping cold water onto the glass around the hailstone with a medicine dropper. The entire section of the stone is covered with the perforated foil, and the funnel is sealed to the surrounding, built-up ice. In the application of crystallographic etch pits for crystal orientation measurement of hailstones, one plots the difference between c-axis orientation and the growth direction as a function of frequency and looks for preferred growth orientations. -- BLE

A CALORIMETRIC METHOD FOR MEASURING WATER CONTENT OF HAILSTONES. *J. Appl. Meteorol.*, 5(5):715-721 incl. illus., graphs, diagr., Oct. 1966. 5 refs.
DLC, QC851.A66

A calorimetric method for measuring the liquid water content of hailstones has been developed. When parameters such as the radiative losses of the system and the changes in heat capacity of the apparatus are eliminated by performing all measurements under identical conditions, the temperature drop is linearly related to the mass of ice melted. For equal masses the temperature drop is smaller if water is present, and there is a linear relationship between the changes in temperature drop and the amount of water present. The water content of hailstones can then be determined from a calibration of plot of the changes in temperature drop as a function of the water content of ice. (Authors' abstract)

NOTE ON RECORDING HAIL INCIDENCES. *J. Appl. Meteorol.*, 5(6):899-901 incl. graph, map, Dec. 1966. 5 refs.
DLC, QC851.A66

A means of recording hail occurrences with existing field facilities has been found. Standard weighing-bucket raingages without evaporation funnels will record the incidence of hail, and dense networks of such gages can provide data for portraying the areal extent, movement, and the time of hailstorms and their cells. Likewise, useful climatological data on hail could be obtained through the dense hydroclimatic network of recording raingages operated by the U. S. Weather Bureau throughout the nation. In Illinois, unusual vertical marks, or 'spikes,' which occurred on the rainfall traces at several raingages, were determined to be a record of the time and incidence of hail. -- BLE

SLIDING OF NON-TEMPERATE GLACIERS. *Res. Rept. 216*, U. S. Army Cold Regions Research and Engineering Laboratory, 4p. incl. diagrs., Dec. 1966. 5 refs. (Also: *J. Geophys. Res.*, 72(2): 521-523, Jan. 15, 1967)
CRREL files; DLC, QC811.J6

It is shown that the temperature gradient normal to the bed is an important parameter in determining whether sliding can or cannot occur in a glacier whose bottom surface is at the melting point. Only if a large temperature gradient exists will sliding be prevented. Since the temperature gradient of a glacier whose bottom surface is at the melting point is expected to be small, it is concluded that sliding usually will occur in such a glacier even if obstacles in the bed may protrude into cold ice. WATER YIELD FROM SNOW. Meteorol. Mag., 92(1096):332-335 incl. illus., table, graphs, Nov. 1963. 4 refs.
DLC, QC851.M18

This paper presents the relationship between snow depth and water yield which has been found from snow samples taken in Scotland. Each morning rain gage stations measured snow accumulation on a flat board laid on the ground or on top of previously fallen snow near the rain gage. Using the inverted funnel of the rain-gage, a cylindrical snow sample was cut from the full depth of measured snow on the board. The sample was melted and measured in the glass rain measure to obtain the water yield. A total of 381 snow-depth observations were made at 7 stations. The equivalent snow depth was calculated and tabulated against the mean daily temperature. The large standard deviation of the equivalent snow depths (nearly 4 inches) shows the imperative need to obtain the actual water equivalent by melting wherever possible. -- BLE

Z. Geomorphol., 10(4):346-368 incl. illus., diagrs.,
Dec. 1966. 36 refs.
DLC, G1.Z47

Aapamoors and string bogs hitherto explained by soilfluction and vegetation, are derived from normal fen and moss with permafrost that is broken when the meltwater in the subsoil drains off. The underflow of moving water and mud turned the still frozen surface layers so that their steep borders are in the direction against the underflow. The occurrence of string bogs is restricted to the border zone of permafrost in all the northern hemisphere. Aapamoors and string bogs are developed by collapse of permafrost. Its structure controls the differentiation of the vegetation cover. (Author's abstract)

SOIL FREEZING AND SOIL WATER CHARACTER-
ISTIC CURVES. Soil Sci. Soc. Amer. Proc., 30(6):
680-685 incl. graphs, Nov.-Dec. 1966. 16 refs.
DLC, S590.S64A13

An earlier paper (SIP 24852) suggested that the soil
water characteristic (SWC) of soil should have an
analogue to be called the soil freezing character-
istic (SFC) that could be obtained by freezing satu-
rated soil in an apparatus functionally related to the
pressure plate apparatus. The analogy for granular
soil, free of colloids, is on a different basis (capil-
lary effects) than for soil that is wholly colloidal
(absorption effects). Different rules are needed to
demonstrate the analogies for the respective types.
Apparatus was devised to permit SFC and SWC data
to be obtained, in turn, with each material placed

in the apparatus. Two silt fractions, a sodium-
montmorillonite paste, and a whole soil were used.
The results confirm the expected analogies and in-
dicate that, in these experiments, the ratio of the
specific surface energy of an air-water interface
at 20°C to that of an ice-water interface near 0°C
was as 72.7:33.1. The results demonstrate signif-
icant mobility for unfrozen water at temperatures
as low as -0.15°C even in clean silt fractions. It
is concluded that the inherent instability of some of
the residual water in soils during drying does not
significantly affect the SWC in the range 0 to 4 bars
of matric suction. (Authors' abstract)

SIMILITUDE CONDITIONS FOR MODELING ICE-
BREAKER OPERATIONS. Nav. Engr. J., 78(6):
1039-1044 incl. tables, Dec. 1966. 4 refs.
DLC, VM1.A5

Structural and dynamic similitude are considered
for modeling icebreaker operations. The ice-
breaker must perform at least 3 separate functions:
it must provide impact forces, provide gravity
forces, and disperse the broken segments. Model
tests should involve all three functions. The pre-
sented analysis is mostly concerned with the im-
pact forces which must precede the gravity forces
and will therefore govern as well most of the con-
ditions which follow the impact. Particular em-
phasis is placed on dimensional analysis and the
principles of similitude by which model experiments
provide data on full scale performances. -- BLE

Karev, Mikhail
THE PLANETS' ICE SPHERE. APN Newsletter, Sci. & Eng. (Moscow), No. 7:6-8, Feb. 25, 1967.
DLC, Unbound Periodical

The Earth's stone sphere (the lithosphere) is accompanied by the hydrosphere which is increased by the great masses of water vapor from volcanic eruptions. Where the temperature drops below zero, there appear short term, seasonal, and perennial zones of frost. What is known as permafrost has been proved to exist not only in the extreme North but all over the globe, its temperature

differing according to geographic latitude and altitude above sea level. Usually temperature increases by 3-4°/100 m of depth to the level of thawed ground. The inclination of the Earth's axis towards the plane of the Earth's rotation about the Sun promotes glaciation but the area of glaciation is always smaller than that of persistently frozen rock. This rock forms earlier and disappears later than does the surface ice. The permafrost sphere on Mars must be very thick all over because Mars is a greater distance from the Sun and half as well heated as the Earth. -- BLE

TWO-DIMENSIONAL NUCLEATION OF ICE. Nature, 213(5074):384-385 incl. graph, Jan. 28, 1967. 11 refs.
DLC, Q1.N2

This paper shows that the first stage in the nucleation of ice on organic nucleators is the growth of monolayer patches of ice on the nucleator surface. The properties of the monolayer of ice can be investigated by studying the effect of pressure on the nucleation of ice I by organic nucleators. The described experiments show that once ice has been formed on phloroglucinol dihydrate, a monolayer persists at temperatures up to 0°C. In general, it may be stated that at all pressures the nucleation temperature of bulk ice is the temperature at which the monolayer becomes sufficiently well developed to act as a nucleator for bulk ice at the ambient bulk supercooling. -- BLE

ICE-FORMING NUCLEI IN THE ATMOSPHERE. Nature, 211(5054):1164, Sept. 10, 1966. 5 refs.
DLC, Q1.N2

Three years of investigations and experiments on the 'Millipore' filter method of measuring ice nuclei concentration have given results better than those obtained by Bigg (SIP 21758). The main differences between the two techniques are in the means of providing the water vapor and in the method used to observe the ice crystals when they have formed. In the present method, before the filter is cooled it is placed on molten petroleum jelly, which partly fills the pores, so that water vapor cannot pass. The filter is then exposed to air which has been saturated with respect to the ice at the bottom of the chamber, and, by cooling the filter further, the air in contact with the filter can be made saturated with respect to water. The filter is kept under these conditions for 30 min. The ice crystals in the central portion of the filter (about 40% of the total area) are observed with a microscope. Preliminary results show that the ice crystal count does not depend on the length of time the filter is exposed to air at water saturation. The count becomes constant after 15 min. -- BLE

ICE NUCLEATING PROPERTIES OF METEORITIC
MATERIAL. *J. Atmos. Sci.*, 24(1):46-49 incl.
illus., Jan. 1967. 15 refs.
DLC, QC851.A283

A description is given of an attempt to duplicate the small particles formed by evaporation and recondensation during the flight of meteors in the atmosphere by heating meteors at low pressure. A metallic meteorite produced entirely shiny spherules, almost all of which were in the size range 5 to 25 μ diameter, while a stony meteorite produced only irregular aggregates of tiny particles whose maximum dimensions were 0.1 to 0.2 μ . At water saturation and -10°C , it is estimated that the iron meteorite creates about 10^5 - 10^6 ice nuclei per gram and the stony meteorite about 10^8 - 10^9 . It is concluded that sufficient ice nuclei active at -15°C are produced to explain observed concentrations in the troposphere. (Authors' abstract)

spheres with spherical roughness elements designed to simulate hailstones with rough rime coats exhibit an unexpectedly sharp drop in drag coefficient at critical Reynolds number. For a spherical hailstone with roughness elements as large as 0.02 in., the transition to the lower drag coefficient could occur when the stone is as small as 1.6 in. in diam. (for a smooth sphere the corresponding transition does not occur unless its diameter exceeds 4 in). (Authors' abstract)

NATURAL CONVECTION IN ICE MELTING FROM
BELOW. Res. Rept. 211, U.S. Army Cold Regions
Research and Engineering Laboratory, 13p. incl.
illus., tables, graphs, diagrs., Dec. 1966. 12 refs.
CRREL files

An experimental technique has been successfully developed to study the effect of natural convection (thermal instability) on the melting rate of ice. Reproducible results were obtained by using homogeneous, bubble-free ice samples for the melting process. The problem of volume change due to phase transition or separation of the ice-water interface encountered when melting from below was solved by continuously adding water at the same temperature as the constant temperature bath which supplied the heat for melting. Under certain temperature conditions irregularities in the interface, a result of convective motion, became very apparent and could be observed visually. By periodically measuring the amount of water added and varying the initial temperature of the ice sample and that of the heat source, extensive results were obtained demonstrating the effects of these temperatures on the melting rate which could be expressed in terms of dimensionless parameters. The results from this experimental investigation are compared with those obtained from an analytical solution of the same problem. (Author's abstract)

THE ANALYSIS OF SNOW LOADS WITH APPLICATIONS TO SNOW LOADS IN BRITISH COLUMBIA. *Trans. Eng. Inst. Can.*, Paper No. EIC-65-CIV 6, Vol. 8, No. A-2, 10p. incl. tables, graphs, map, May 1965. 31 refs.
DLC, TA1.C22

The paper discusses factors influencing snow loads, forms of statistical solutions, choice of distribution for snow loads, selection of a return period for a design load, the present snowfall situation in Canada, mountain snow loads, theoretical load distribution functions, and snow load-elevation relationships. Climatic or meteorological factors influence both ground and roof cover: wind velocities, wind direction and variability, temperature, solar radiation, rain and the seasonal snowfall characteristic. It is uncertain whether the factors to be used to determine roof loads in low lying areas can be directly transferred for use in mountainous districts. This difficulty arises not only because the factors may change when transposed from high to extremely high snow loading conditions, or due to an areal variation of the meteorological influences, but because of certain unique features of snow loads in mountains. -- BLE

SOME THERMODYNAMIC RELATIONSHIPS FOR SOILS AT OR BELOW THE FREEZING POINT: I. FREEZING POINT DEPRESSION AND HEAT CAPACITY. Res. Rept. 222, U. S. Army Cold Regions Research and Engineering Laboratory, 18p. incl. tables, graphs, appendixes A-B, Dec. 1968. 16 refs.

CRREL files

An extended equation was derived relating the relative partial molar free energy of water in a soil to its freezing point depression and relative partial molar heat content. The equation was used to prepare a table from which each of these 3 quantities can be ascertained if the other 2 are known. The table was used with experimental data to obtain a curve of freezing point depression vs. water content for Na-Wyoming bentonite. Provided the activity of the liquid water in the clay is a single-valued function of the liquid water content and that the ice has the properties of pure bulk ice, this curve also represents the relationship between freezing point depression and unfrozen water in the partially frozen clay. An equation for the heat capacity of a partially frozen soil was also derived. This equation was employed to calculate the heat capacities of the clay at different water contents and sub-zero temperatures. A comparison of the calculated unfrozen water contents and heat capacities of the partially frozen Na-Wyoming bentonite with the available experimental data indicated satisfactory agreement, especially as regards the unfrozen water contents. Lilboutry, L.
DISCUSSION OF PAPER BY J. WEERTMAN, 'SLIDING OF NONTEMPERATE GLACIERS.' J. Geophys. Res., 72(2):525-526, Jan. 15, 1967. 5 refs.

DLC, QC811.J6

A refined theory of glacier sliding, worked out during 1965-66, abandons the idea of "controlling obstacle size." In a realistic model of a glacier bed, the biggest bumps are not juxtaposed to smaller ones, but are covered with them. The hillocks, covered with small bumps, protrude into the cold ice, and ice cannot overflow even the minute bumps. This is true because the melting-point isotherm must follow the mean profile of the bedrock, and not the exact profile of the hillocks.

INERTIAL OSCILLATIONS OF FLETCHER'S ICE ISLAND (T-3). J. Geophys. Res., 72(4):1165-1174 incl. graphs, map, Feb. 15, 1967. 10 refs.
DLC, QC811.J6

Observations with improved Roberts current meters, tethered drogues, and fathogram highlights are used to show that Fletcher's Ice Island (T-3) in the Arctic Ocean often moves in clockwise circles with a diameter of about 1 km and a period of about 12 hours. The motions are inertial oscillations which represent the transient response of a floating ice mass to changing wind stress. Since the winds are often fluctuating, T-3 responds often with inertial motion. The following arguments indicate that these motions are inertial oscillations: (1) the period of the motions is closer to the inertial period at this latitude of 12.05 hr than it is to the lunar semidiurnal tidal period of 12.42 hr; (2) the amplitude of the periodic motion and the local wind speed are closely correlated; (3) the phase of the motion changes irregularly with time; and (4) the motion is restricted to the ice and to the uppermost layers of water. STUDIES OF PARTICLES FOR EXTRATERRESTRIAL ORIGIN. 5. COMPOSITIONS OF THE INTERIORS OF SPHERULES FROM ARCTIC AND ANTARCTIC ICE DEPOSITS. J. Geophys. Res., 72(4):1404-1406 incl. illus., table, Feb. 15, 1967. 5 refs.

DLC, QC811.J6

Previous papers in this series have reported results of chemical analyses of the surfaces of microscopic particles of several origins (See SIP 22174, 22175, 22176, and 23402). The present paper reports results of chemical analyses of the sectioned and polished interiors of some of these particles. Among the particles are 2 from the South Pole and one designated only as Antarctic. Contrary to expectations, there are few significant differences in composition between the surface and the interior of a spherule, and the particles are rather homogeneous. The interiors of the spherules cannot be determined from the data available.

INTERACTIONS OF H₂O MOLECULES IN ICE. I. THE DIPOLE MOMENT OF AN H₂O MOLECULE IN ICE. Proc. Roy. Soc. (London), 291A(1427):445-453 incl. tables, diagrs., April 26, 1966. 15 refs.
 DLC, Q41.L7

The dipole moment of an H₂O molecule in ice is greater than the moment of an isolated H₂O molecule, 1.84 D, owing to the electric fields of neighboring molecules. The magnitude and direction of the field arising from the nearest 85 neighbors is computed in this paper by representing each molecule as a series of electric multipoles. It is found that the field has the direction of the dipole moment of the central molecule and is sufficiently strong to increase its total dipole moment to about 2.60 D. (Authors' abstract)

 DLC, Q41.L7

The energy of interaction of H₂O molecules in ice is calculated by representing each molecule as a series of multipoles. This energy is found to increase when the mutual polarization of the molecules is taken into account. It is also found to depend significantly upon interactions of a molecule with its second and further neighbors. The interaction energy of molecules in the cubic form of ice is found to be essentially the same as that of molecules in the ordinary hexagonal form. (Authors' abstract)

ON THE ACCUMULATION AND THE DECREASING
OF SNOW IN PINE DOMINATED FOREST IN FIN-
LAND. *Fennia*, 86(1), 51p. incl. illus., tables,
graphs, diagrs., maps, 1961. 39 refs.
DLC, G23.G4

An investigation has been conducted to determine the effect of forest density and tree distribution on snow accumulation and ablation. The data used are from snow course stations in which a part of the measuring route includes pine dominated forests, and stake stations with fixed measuring stakes established in groups in such forests. Snow accumulation in forests is compared with accumulation in open areas and factors causing the decrease of snow in forests are outlined. -- BLE

Artificial snowstorms were created inside a large cold room by blowing snow crystals over a snow surface. The charges acquired by the visible blown particles and the residual snow surface and the electric fields and concentrations of positive and negative ions produced in the air above the snow surface were measured as a function of the wind velocity, the relative humidity, the amount of snow introduced into the air jet, and the temperature of the jet and the snow surface. The charging was found to increase with an increase in wind velocity, and was slightly reduced as the relative humidity was raised. The measured electrification at temperatures below 0°C is shown to be entirely explicable, quantitatively and qualitatively, in terms of the temperature-gradient effect. The primary source of the charge carried by air is shown to be point discharge between highly charged particles. The contributions to the measured electrification of the Workman-Reynolds effect, the Dinger-Gunn effect and the evaporation of ice are shown to be minimal. (From authors' abstract)

THE OCCURRENCE OF BENTHIC MARINE ALGAE
UNDER SHORE FAST-ICE IN THE WESTERN ROSS
SEA, ANTARCTICA. In: *International Seaweed
Symposium, 5th, Halifax, August 25-28, 1965,
Proceedings*. Oxford, Pergamon Press [1966],
p. 217-231, incl. illus., tables, map. 23 refs.
DLC, QK564.I5

Diving surveys along the western coast of the Ross Sea during Jan. and Feb., 1964 revealed the presence of large algal beds at depths between 6 and 35 m. The dominant species were red algae. Investigations of these same localities in Oct. through Dec. 1964, when the area was covered by up to 6 m of sea ice, again showed a luxuriant growth of the rhodophycean species. Adult and fruiting specimens were found in abundance during both surveys, so it is likely that the algae in this part of the Antarctic are present for at least 8 mo. of the year. If they are present throughout the year, they may be inactive during some of the months when there is no sunshine. In contradiction to previous work, the present study shows that the algae under consideration are capable of photosynthetic production under fast ice with a coverage of 9 to 10 mo. FINNISH STUDIES ON SNOW FENCES IN 1947-1959.
(Kinostintutkimuksia Suomessa vuosina 1947-1959;
Text in Finnish with English summary). Tielehti,
34(3):13-17, 97-98 incl. graphs, 1964. 6 refs.
DLC, TE4.T5

Results are presented of snow fence studies in Finland. Snow fences are generally placed in one or two rows with about 100 m between rows. The fences generally come in 7 sections. Snowdrift depth was measured 3 to 6 times in winter depending on snowfall and drift accumulation. On the basis of the measurements, longitudinal sections have been graphed, and the length and maximum height of drifts have been determined. Also, the cross-sectional area of drifts above the actual snow surface was calculated. (From author's summary)

which a d. c. current is passed through the junction of 2 dissimilar semiconductors. The thermoelectric element can remove up to 40 watts of heat. In a laboratory soil column of 6 in. diam., this would correspond to a frost penetration of about 8 cm/hr. The apparatus was found to be very convenient. The sample did not have to be enclosed in a cabinet and better control of the rate of heat removal was obtained. -- BLE

MOISTURE, PORE SPACE, AND BULK DENSITY
CHANGES IN FROZEN SOIL. Soil Sci. Soc. Amer.,
Proc., 28(3):422-425 incl. illus., tables, graphs,
May-June 1964. 11 refs.
DLC, S590.S64A13

This paper reports a study of the changes in moisture and physical properties which occurred during winter freezing of soil under two cover conditions. The two test plots, forty feet apart, were located 6 mi north of Lansing, Mich. One was on bare soil that had been plowed and packed 7 weeks before continuous freezing began. The second was under a full, mature stand of alfalfa. In the upper 15 in. of the two plots, moisture contents usually exceeded prefreeze field maximum. Total pore space was always above that before freezing; bulk density was predominantly less than the lowest expected prefreeze bulk density. Moisture changes in the frozen soils are attributed solely to internal moisture movement. -- BLE

CREEP OF SNOW AND ICE. Res. Rept. 220, U. S.
Army Cold Regions Research and Engineering
Laboratory, 13p. incl. tables, graphs, Dec. 1966.
23 refs.
CRREL files

Constant load creep tests in uniaxial unconfined compression were performed on samples of sintered snow and bubbly polycrystalline ice. Nominal axial stresses were in the range 0.1 to 1.0 kgf/cm² for snow, and 0.5 to 20 kgf/cm² for ice. The range of temperatures investigated was from -0.5 to -34.5°C. Assuming creep to follow the Arrhenius relation, values of apparent activation energy for secondary creep under a nominal axial stress of 0.5 kgf/cm² varied from 10.7 kcal/mole for ice of density 0.83 gm/cm³ to 17.8 kcal/mole for snow of density 0.44 gm/cm³. The creep of polycrystalline ice depends on dislocation damping for the process dominant at high stress, and drift of dislocations pinned by stress-induced order for the low stress mechanism. If each mechanism has its own characteristic activation energy, the apparent activation energy measured in creep experiments may well vary with stress level. In snow subjected to a given nominal stress, such an effect should be reflected in variation of apparent activation energy with bulk density, since true stress in the ice matrix will increase as density decreases when the nominal applied stress is fixed. The effect of bulk density on strain rate and the possibility of predicting creep rates for snow from data on creep of polycrystalline ice are discussed. (Authors' abstract)

CRREL BIBLIOGRAPHY

Investigations have been conducted to (1) determine the extent to which open mesh metal panels will accumulate snow, and (2) to devise methods for controlling or eliminating accumulation and adhesion. Methods investigated include electrical resistance heating, forced air movement, icephobic surface coatings, infrared heating, mechanical vibration, fluid flow, and power broom sweeping. The influence of meteorological parameters on unheated panel tests was also investigated. It is concluded that passive methods alone are incapable of keeping a perforated steel panel free of snow and ice accumulation under all conditions. Forced air moving at a minimum speed of 300 to 500 ft/min through the panels can prevent accumulation of snow. Near the freezing point, however, and with slight precipitation of snow or ice, forced air can result in ice accretion. Mechanical vibration will remove dry snow but not wet snow or ice. Fluid flow over the panel cannot prevent snow accumulation at moderate rates of fall. Resistance heating using the perforated panel as the resistance element is an effective and practical method. THE SINTERING PROCESS IN SNOW. Res. Rept. 226, U.S. Army Cold Regions Research and Engineering Laboratory, 4p. incl. graph, Feb. 1967. 12 refs.

CRREL files

The growth of bonds between snow grains or ice spheres has been variously attributed to surface diffusion, volume diffusion, and evaporation-condensation. To distinguish among these possible mechanisms the unconfined compressive strength of 2 groups of snow samples was determined as a function of time. One group was allowed to sinter under atmospheric conditions while the other group was kept immersed in silicone oil. The much lower rate of strengthening of the latter group suggests that evaporation-condensation must be the major mechanism of mass transport in snow under atmospheric conditions. The possible magnitudes of the various mass transfer coefficients are discussed. (Authors' abstract)

CREEP-VELOCITY BOUNDS AND GLACIER-FLOW PROBLEMS. J. Glaciol., 6(46):479-488 incl. table, graphs, Feb. 1967. 7 refs.
DLC, GB2401.J68

A general result due to Martin can be used to find upper and lower bounds on velocities in steady-

creep problems. This method can be applied to glacier flow if ice can be assumed to satisfy a power-law, stress-strain-rate relation. Bounds on the mean velocity over the glacier cross-section and on the mean velocity on the surface are determined for a particular example (a uniform parabolic channel, with power-law exponent 3) and they are shown to bound quite closely the exact solutions due to Nye. Bounds can be found rapidly by hand calculation. The method can be applied to real glacier cross sections measured in the field. (Author's abstract)

AN EXAMINATION OF THE LILBOUTRY THEORY OF GLACIER SLIDING. J. Glaciol., 6(46):489-494 incl. illus., Feb. 1967. 8 refs.
DLC, GB2401.J68

A review is presented of Lilboutry's theory of glacier sliding, which assumes a glacier bed that is rough in only one direction. The equation contains 2 unknown parameters--the water pressure, and the thickness of the water layer; their values cannot be determined from the theory in its present state of development. Therefore, it is claimed, the theory is incompletely developed and cannot be used to make meaningful predictions of sliding velocities.

 THE ADHESION OF ICE SPHERES IN ELECTRIC
 FIELDS. *J. Glaciol.*, 6(46):505-514 incl. graphs,
 diagrs., Feb. 1967. 12 refs.
 DLC, GB2401.J68

The force F required to separate two ice spheres was measured as a function of environmental temperature T , relative humidity H and the strength E of the external electric field in which the spheres were situated. It was found that over the entire attainable range of T and H , F increased rapidly with increasing E . The increased adhesion was not accompanied by an increase in the rate of growth of the ice bridge between the two spheres and is explicable in terms of Davis's (1964) calculations of the purely electrostatic forces between two spheres situated in an electric field. The experiments indicate that the rate of growth of snowflakes in a cloud by means of ice crystal aggregation will be markedly enhanced if the cloud is highly electrified. (Authors' abstract)

 INTERNAL STRUCTURE OF SANDY GLACIER,
 SOUTHERN VICTORIA LAND, ANTARCTICA.
J. Glaciol., 6(46):529-540 incl. illus., map, Feb.
 1967. 10 refs.
 DLC, GB2401.J68

Sandy Glacier is a narrow, 600-m-long cirque glacier. It is apparently composed throughout of alternating layers of ice and sand that strike parallel to the edge of the glacier and dip into the glacier at an angle of 82°. The thickness of the sand layers averages 10 cm, and that of the ice layers, 20 cm. The sand layers are generally composed of thin parallel laminations, but micro-crossbedding is present locally. The layers have been broken into angular blocks 0.5 to 3.0 m long, separated by ice columns connecting adjacent ice layers. The ice layers show thinner zones of contrasting bubble content; these bend into the columns separating the sand blocks. The sand was probably blown into the cirque from the floor of Wright Valley 6 km SW and 1100 m below. Each pair of sand and ice layers may record a year's accumulation. The steeply dipping, yet otherwise undeformed layers, clearly prove that rotational movement has occurred. The breaking of the sand layers into blocks is the result of plastic extension within the glacier. (Author's abstract, modified)

 PRELIMINARY STUDIES ON SEA ICE IN McMurdo
 SOUND, ANTARCTICA, DURING "DEEP FREEZE
 65." *J. Glaciol.*, 6(46):515-528 incl. illus.,
 graphs, maps, Feb. 1967. 16 refs.
 DLC, GB2401.J68

Studies were made of the bearing strength of the ice at McMurdo Sound, in order to determine the safety of logistics activity on the ice. During the summer of 1964-65, shear strength decreased from 9.8 kg/cm² in Oct. to 6.3 kg/cm² in late Jan., then it increased to 8.0 kg/cm² by Feb. 10. The salinity of collected brine decreased from 125 ppt in Nov. to 43 ppt in Jan. Thickness of the ice increased until mid-Dec., then decreased rapidly by bottom melting until break-out in Feb. In the Cape Armitage shoal area, thickness decreased from 2.5 m in mid-Dec. to 36 cm in late Jan. Snow cover significantly affects the degree of internal deterioration and the amount of strength lost during the summer. Sea ice with more than 6 cm of snow cover is consistently stronger than unprotected ice, and deterioration is less. Bearing strength of the sea ice is sufficient for most ordinary loads throughout the period of greatest use. (Authors' abstract, modified)

METAMORPHISM OF AIR BUBBLES IN A SNOW
CRYSTAL. *J. Glaciol.*, 6(46):561-564 incl. illus.,
graph, Feb. 1967. 6 refs.
DLC, GB2401.J68

Observations have been made of the modification produced by a temperature gradient in the shape of air bubbles in natural snow crystals, and also of the shrinkage of the bubbles with time. The rate of shrinkage is governed by a constant which is strongly temperature dependent with an activation energy of about 15.1 kcal/mole, a value sufficiently similar to the activation energy for diffusion of tritium and dielectric and mechanical relaxation to suggest that atomic diffusion processes may be responsible for all of these phenomena. To observe air bubble shrinkage rate, a snow crystal was soaked in ice-saturated kerosene to keep it from sublimation. This shrinkage rate was measured at temperatures of -5, -15, and -34°C. The time dependence of the shrinkage could be expressed by a given formula. It is pointed out that the shrinkage can be explained also in the same manner as that of voids in metals.

ON THE DISTURBANCE OF SURFACE ELECTRIC
FIELD CAUSED BY SNOWFALL. *J. Meteorol.
Soc. Jap.*, 44(5):260-279 incl. tables, graphs,
diagrs., maps, Oct. 1966. 27 refs.
DLC, Orientalia Div.

The results of observations on the atmospheric electric field pattern, the electrical charge on falling snow crystals, and the intensity of snowfall indicate that: (1) in the case of light snowfall

CRREL BIBLIOGRAPHY

from altocumulus clouds, snow crystals are charged negatively by the Wilson induction mechanism, and a steady positive atmospheric surface electric field is increased by the downward transportation of negative charge on the snow crystals; (2) In the case of heavy steady snowfall from stratocumulus or successive nimbostratus clouds, graupel or rimed snow crystals are charged positively by the friction with non-rimed snow crystals which are charged negatively, and then a negative surface electric field is established by the removal of the positive charge on graupel or rimed snow crystals from the cloud layer where a negative space charge is left due to the negative charge on non-rimed snow crystals with a low fall speed. This negative electric field of the atmospheric surface corresponds to the negative area of the graph pattern; (3) sharp peaks in the surface electric field pattern are produced by the passing of local space charges near an observation point due to falling graupel. -- BLE

MODELS OF CHARGE DISTRIBUTION IN AND UNDER CLOUDS DURING SNOWFALL. *J. Meteorol. Soc. Jap.*, 44(5):280-285 incl. graphs, diagrs., Oct. 1966. 1 ref.
DLC, Orientalia Div.

Several models of charge distribution in and under snowy clouds were proposed, based on the mechanism in which falling rimed snow particles or larger snowflakes are electrified positively by the frictional contact with non-rimed snow crystals or smaller snowflakes in temperatures warmer than -10°C. The models explain the surface electric field patterns very well, particularly the rapid change in the field. In the models, it is assumed that the surface electric field is influenced by the space charge only vertically above the observation point. However, in actuality the rapidly changing surface electric field during snowfall is influenced by the space charge both just above and at the observation point. -- BLE

CHARGE TRANSFER ASSOCIATED WITH THE EVAPORATION OF ICE IN ELECTRIC FIELDS. *J. Meteorol. Soc. Jap.*, 44(5):286-290 incl. graphs, diagrs., Oct. 1966, 11 refs.
DLC, Orientalia Div.

Experiments are described which were designed to investigate the possibility that the electrification which accompanies the evaporation of ice may be drastically modified in the presence of an electric

field, and to provide information enabling a reevaluation of the importance of evaporation processes in atmospheric electricity. The mechanism of evaporation and electrification of ice in the absence of an electric field has been discussed earlier by the authors (SIP 24586), who demonstrated theoretically that energetic limitations preclude the possibility that individual charged molecules escape from the ice surface. In the present work the mechanism of charge transfer is obscure. The possibility that the electrification was a consequence of the splintering of microscopic protuberances on the evaporating surface is inconsistent with the observed dependence of the charging on pressure, temperature, and, more conclusively, the sign of the electric field. -- BLE

DLC, VM451.A8

The development of icebreakers, beginning with the "Yermak" built in 1899 in England for the Russian government is briefly reviewed. To increase 20-40 day cruising capability, the first atomic powered icebreaker, the "Lenin" was designed to navigate one year without refueling and built at the Admiralty yard in Leningrad in 1956-1958. Technical characteristics of this atomic turboelectrical ship are given. The low ratio between length and width ensures high maneuverability in ice, and careful stern design provides reliable protection for propellers and rudder, and ensures a smooth reverse motion across ice. The steam generating plant, mechanical systems, fire prevention system, and the electrical circuits are described. Diagrams of the reactor, the total power system and steam generator and cooling systems are given. -- VDP

THE UTILIZATION OF TELLUROMETERS UNDER ANTARCTIC CONDITIONS. (Primeneniye radiodol'nomerov v usloviyakh Antarktity; Text in Russian). Antarktika: Dokl. komis., 1965, Moskva, Izd-vo Akad. nauk SSSR, 1965, p. 59-64 incl. tables, graph, diagrs. 4 refs.
DLC, G576.A65

Specifications are given for a new continuous operation phase tellurometer which was used in Antarctica during the 1963-64 summer season with increased speed and accuracy. The measurable distance ranges from 0.15 to 30 km. The carrier frequencies may vary from 2700 to 3000 Mc/s, with a wavelength of ~10 cm. Formulas are given for the calculation of the length of a side, taking into consideration the temperature and atmospheric pressure. The accuracy of the tellurometer was tested on a geodetic quadrangle at the Pole of Inaccessibility, one vertex of which was set on a class-4 astronomical point. The relative error of a side was 1:160,000 without taking possible systematic errors into consideration. It has been proven, however, that tellurometer measurements can achieve great accuracy on the Antarctic ice cap as a result of the extremely low humidity. -- DAS

SCREW PROPELLERS OF ICE NAVIGATING VESSELS. (Grebnye vinty sudov ledovogo plavaniya; Text in Russian). Leningrad, Izd-vo Sudostroenie, 114p. and 6 annexes, incl. illus., tables, diagrs., graphs, 1966. 19 refs.
DLC, VM755.I33

Icebreakers in escort often change speed and direction and hence must have high maneuverability. The icebreaker screws require sufficiently high torque in forward and reverse, the latter being of great importance. Experience acquired in operating icebreakers and transport vessels in arctic ice conditions shows a high percentage of damage to the propulsion machinery, which sharply decreases the ice-cutting capacity. Therefore, in specifications for propellers (diameter, number of blades, profile of the blades, etc.) special attention must be paid to production reliability to ensure the necessary strength of propellers and shafting. Although the use of theoretical methods for the calculation of screw propellers has recently increased in practice, the most reliable method is calculation on the basis of continuing tests made with small scale models. Numerous mathematical formulas, graphs, and diagrams are given to calculate required strength and optimum torque of screw propellers on icebreakers and ice-navigating vessels under various conditions of design, ice distribution, power, load, etc. -- VDP/FMM

PECULIAR FEATURES OF TEMPERATURE DISTRIBUTION IN THE LOWER LAYER OF THE TROPOSPHERE OVER ANTARCTICA. (Nekotorye osobennosti raspredeleniya temperatury v nizhnem sloye troposfery nad Antarktidoj; Text in Russian). Antarktika: Dokl. komis., 1965, Moskva, Izd-vo Akad. nauk SSSR, 1966, p. 73-81 incl. tables, graphs. 5 refs.
DLC, G576.A65

The most probable explanation for a high surface inversion (as high as 3-4 km) is the conjunction of a surface radiation inversion with a subsidence inversion in an anticyclone. The results of the present paper confirm this hypothesis, and at the same time it is found that a conjunction of a radiation inversion and a frontal inversion may occur. Tables show the

CRREL BIBLIOGRAPHY

frequency of various upper boundaries of surface inversions as observed by radiosonde ascents at Mirnyy and Vostok Stations in 1958 and 1959. An analysis of synoptic maps and vertical profiles, constructed for cases of high inversions at these stations in 1958, leads to the conclusion that the specific characteristics of surface inversions on the Antarctic coast and on the ice cap are determined by the conditions under which they are formed. On the coast the greatest activity of synoptic processes takes place in winter; only with these intensive processes are the significant descending movements and thick frontal zones possible which lead to the conjunction of several inversions to form high inversions to 3-4 km. Further inland, where only the peripheries of cyclones and ridges arrive, the height of inversions does not exceed 2 km. -- DAS

THE DISTRIBUTION OF ATMOSPHERIC DENSITY OVER ANTARCTICA. (Raspredelenie plotnosti vozdukh nad Antarktidoj; Text in Russian). Antarktika: Dokl. komis., 1965. Moskva, Izd-vo Akad. nauk SSSR, 1966, p. 87-94 incl. tables, graphs, 4 refs.

DLC, G576.A65

The more reliable data on atmospheric density are analyzed for Mirnyy, Vostok, Amundsen-Scott, Ellsworth, Hallett, and McMurdo Stations. The results show that at the isobaric surfaces the maximum mean-monthly values are observed from June to Sept. in the troposphere, and in Aug. and Sept. in the stratosphere. Minimum values are observed in Dec. and Jan. in the troposphere, and from Dec. to Feb. in the stratosphere. A vertical profile above the continent, showing isopycnals and isotherms, permits a comparison of the latitudinal distribution of densities at various altitudes. The monthly density values to an altitude of 28 km above Mirnyy Station are graphed. An evaluation is made of the effect of pressure and temperature factors on the atmospheric densities above Mirnyy. Vertical gradients ($g/m^3/km$) are graphed in the form of isolines. -- DAS

INVESTIGATION OF ATMOSPHERIC TURBULENCE IN ANTARCTICA BY THE RADIOSONDE METHOD. (Issledovanie atmosfernoj turbulentnosti v Antarktide radiozondovym metodom; Text in Russian). Antarktika: Dokl. komis., 1965. Moskva, Izd-vo Akad. nauk SSSR, 1966, p. 82-86 incl. graphs. 6 refs.

DLC, G576.A65

The turbulence-measurement apparatus consisted of an ordinary radiosonde, suspended by a spring from a sounding balloon and possessing an attachment which converted the overload on the balloon caused by vertical gusts into radiofrequency impulses. Temperature, pressure, and humidity measurements could be made simultaneously. Approximately 100 ascents were made at Mirnyy Station in Sept., Oct., and Dec., 1963, at 1200 and 2400 hr. The frequency of turbulence per kilometer, its mean-monthly variation with height, and the turbulence distribution relative to the tropopause and level of maximum wind speed are calculated. The turbulence shows two maxima: between 6.5 and 11.5 km (63%), related to the tropopause and the maximum wind velocity, and at 21 km (54%), possibly related to a secondary wind maximum. High turbulence is distributed symmetrically to the axis of a stratospheric jet stream, with calmer winds on the axis. Turbulence in the lower troposphere is evidently related to dynamic, rather than thermal, factors. -- DAS

 DLC, QE575.A45; CFSTL, TT 65-50144

The study is based primarily on Soviet research in the Antarctic in 1957 and 1958 and secondarily on data of other expeditions. The climatic and meteorological factors causing the formation of the snow cover in Antarctica are discussed. The following aspects of snow cover formation are described: precipitation, snow transport, dynamics of the microrelief, snow accumulation during the year, development of the snow surface in warm and cold seasons, and the mass balance of the surface layer. Development of the snow-firn layer is treated. Some properties of Antarctic snow, its classification and characteristics for distinguishing the annual and seasonal layers are presented. A description is given of features of the snow cover in various geographic zones of the continent. The thickness and age of the snow-firn layer and the development of recent Antarctic glaciation are discussed. -- DAS

REMNANTS OF QUATERNARY GLACIATION ON THE TIBETAN PLATEAU. (Text in Chinese with English summary). Acta Geographica Sinica, 31(1):63-72, March 1965.
 DLC, P/B106.4 T43

On the Tibetan Plateau, remnants of the Quaternary glaciation are of general occurrence. Cirques, U-shape valleys, glacial-scoured lakes, till plains, terminal moraines, and drift boulders are widespread features down to 4200 m in altitude. The authors believe that there was once a fairly continuous ice cover on the Tibetan Plateau in late Pleistocene. Subsequently the snow-line was higher and the glaciers retreated gradually to their present positions. The reasons are two-fold: a general warming of the world climate, and desiccation of

Tibet due to further uplift. The latter is evidenced by the obvious shrinkage of many lakes on the plateau. By correlating the moraines of this glaciation with the terrace of Zi-Ling Tsangpo and Yamdrok, it is concluded that this great ice cover was late Pleistocene. Since that time the glacier retreated in three stages forming: 1) Yamdrok Lake (4400 m. 2) terminal moraines in Cano Chu Valley (4650 m.); 3) moraines on Cano-La Col (4950 m.). Recessional moraines are also present in the valley of Drokar Chu on the northern slope of Chumulanna. (Authors' abstract, modified)

ICE OR FROZEN EARTH ANCHOR. U.S. Patent
3,304,671, [5]p. incl. diags., Feb. 21, 1967.
CRREL files

An ice or frozen earth anchor is described which has maximum holding power, is simple, relatively inexpensive to manufacture, has a minimum number of operating parts, is very strong, and has a long operating life despite continued rough use. The tubular anchor is installed into ice or frozen ground by lighting a combustible material such as thermite placed in the lower portion of the anchor after the unit is placed in a hole made specifically for it. The thermite container is insulated from the upper portion of the anchor tube by a circular disk of low-strength refractory material. Above the refractory disk in the central portion of the tube are ground engaging cables, rods, and corner anchors attached to it and to an ignition wire along the outside of the anchor tube. When the thermite is expended, the spring forces the ground gripping elements out of the anchor tube. The ice or frozen earth reforms around the holding components. -- BLE

DETERMINATION OF WATER CONTENT IN SNOW.
(Określenie zasobów wodnych śniegu; Text in Polish).
Przegląd Geofizyczny, 7(4):245-254 incl. tables,
maps, 1962. 11 refs. (Engl. transl.: TT 65-50500,
Central Institute for Scientific, Technical and Economic
Information, Warsaw, 1967)
DLC, QC851.P72; DLC, Tech. Rept. Collection

Investigations of snowfall conditions in the Dunajec Basin are discussed which resulted in a new method enabling day-by-day measurements of the water content in snow and consequently current determination of the decrease in the snow cover and the formation of both water levels and flows. This method is better than previous ones because (1) it produces charts of constant coefficients of water content in the snow cover based on observational data; (2) it requires only measurements of the thickness of the snow cover for current computations; (3) it reduces the up-to-date computations to the basic rule of multiplication (of constants); (4) it is rapid and gives the results within the limits of accuracy adopted for computations of this kind; and (5) it gives the possibility of observing the changes in water content of snow from day to day. -- BLE

FEASIBILITY STUDY OF BURIED ANCHORS IN POLAR SNOW. Spec. Rept. 107, U. S. Army Cold Regions Research and Engineering Laboratory, 41p. incl. illus., tables, graphs, diagrs., appendix, March 1967, 8 refs.
CRREL files

The load resistance behavior of buried anchors in polar snow was investigated to determine the feasibility of using them as part of a reaction system for containing the forces generated by pile test loading devices. The test program was conducted at Camp Century, Greenland. Ten anchors were load-tested: eight in quick extraction and two under sustained long-term extraction. Ultimate load capacities of the anchors to resist quick extraction forces and their ability to hold sustained loads have not been definitely established, and no mathematical solution has been brought forward to predict the unit load creep rate or the ultimate load vs. embedment depth of an anchor in snow. The results of this exploratory study established the feasibility of using buried anchors in polar snow for the pile test program. (Author's abstract)

A PHYSICAL STUDY OF SOLID PRECIPITATION FROM CONVECTIVE CLOUDS OVER THE SEA: PART IV. IMPORTANCE OF GIANT SEA SALT NUCLEI IN FORMATION OF SOLID PRECIPITATION. J. Meteorol. Soc. Jap., 44(6):308-319 incl. illus., tables, graphs, Dec. 1966, 16 refs.
DLC, Orientalia Div.

Observations over the Japan Sea revealed that: (a) the amounts of sodium and chlorine in graupel pellets were several times as large as those in snowflakes, and the ratio of sodium to chlorine in the graupel was very close to that in the sea water, (b) a number of supercooled large cloud drops (several tens of microns in diameter) were present in the clouds over the sea near the coast where graupel showers occurred often, (c) there was a positive correlation between the daily amount of snowfall and the concentration of giant chloride particles in the air, (d) the relation between NH_4^+ content and Na^+ content of snow showers from convective clouds over the sea was different from that of snow showers from orographic cells at an inland area. The results suggest that giant sea salt particles play an important part in the formation of snowfall from convective clouds over the sea. The giant salt particles probably enhanced the growth of rimed snow crystals. -- BLE

STRESS AND WAVE PATTERNS IN SOILS SUB-
JECTED TO DYNAMIC LOADS. Res. Rept. 120,
U. S. Army Cold Regions Research and Engineering
Laboratory, 52p. incl. tables, graphs, diagrs.,
appendixes A-B, March 1967. 44 refs.
CRREL files

The report is divided into four parts: Parts I and II cover investigations of the reliability of shear stress measurements in soils subjected to vibratory loads for biaxial and triaxial systems, respectively. Part I is a summary only (See SIP 21834 for detailed treatment). Part III is a study of three-dimensional "principal" stress patterns produced in soil subjected to vibratory loads. Part IV is a theoretical analysis of some aspects of soil wave propagation in stratified soil. From the measurements of five shear stresses and one normal stress, the stress distribution of a triaxial system can be determined. In noncohesive soils triaxial stress fields due to vibratory loads can be determined by recording six independent stress components. Sinusoidal force excitation and impact excitation yield time-distance graphs which can be used to determine reflection and refraction techniques in stratified soils. (Author's abstract)

offered for calculating the necessary moment for propellers to break ice caught in the blades. The formulas are based on specific pressure necessary for breaking ice by crushing and cutting, mean thickness of blade, depth of blade cut into ice, moment of power application, diameter of propeller, speed of vessel, number of blades, angle between fracture planes and propeller blade, mean width of blade, pitch angle of blade section, angle of normal blade section determined by actual vessel speed and propeller revolutions, and rotating speed of propeller. -- VDP/FMM

DLC, VM4.M6

The greatest strain on screw propellers and shafting of an icebreaker occurs when the propeller blades are striking the ice and the propulsion unit stalls. This leads to frequent damage of propeller and shaft and often makes the vessel inoperative. The importance of determining the ice forces on propeller blades is emphasized in designing the main propulsion machinery and insuring adequate engine torque to overcome stalling. Mathematical formulas are

 PERMAFROST DEPTHS, LOWER MACKENZIE VALLEY, NORTHWEST TERRITORIES. Arctic, 20(1):21-26 incl. graphs, map, March 1967. 6 refs.
 DLC, G600.A695
- Ground temperature records in the Lower Mackenzie Valley have been obtained for seven sites during the 1965-1966 period by installing thermistor cables in seismic shot holes drilled for the purpose. From the initial measurements, permafrost thickness is estimated at about 350 ft for Arctic Red River and 400 ft for a site 14 mi west of Fort McPherson. In the south central part of the Mackenzie Delta, in an area of gradually shifting channels and infilling lakes, the depth is 350 ft, or possibly more. In the distal part of the Delta, where new islands are growing, permafrost is aggrading downwards in the saturated alluvial soils. At four sites within 2 ft of sea level, permafrost may be only 60 to 100 ft deep. The permafrost in this area should continue to aggrade for many centuries. (Author's abstract)

ICE SURFACE MOVEMENT ON THE TUTO RAMP
IN NORTH GREENLAND. Tech. Rept. 164, U.S.
Army Cold Regions Research and Engineering Lab-
oratory, 28p. incl. tables, graphs, diagrs., maps,
appendixes A-B, March 1967. 6 refs.
CRREL files

As part of a study of road construction on glacier ice, a program of measurements of the horizontal and vertical movement of the surface of the ice has been conducted. This report covers measurements from 1956 through the 1963 thaw season. The measurement procedure is described, and the movement data are tabulated. Appendixes A and B present short-term horizontal movement measurements and station elevations, respectively. The rate and direction of both the vertical and horizontal movement on the Tuto ramp are fairly consistent on an annual basis. The upward vertical movement from Station 20+00 to 58+00 on the original Ramp Road is probably caused by the ice upthrust over a stagnant wedge of ice at the edge of the glacier. The existence of this wedge is evidenced by the small amount of horizontal movement at the edge of the glacier and the upward vertical movement of the ice in the area in front of the wedge. -- BLE

PERMAFROST AND ITS EFFECT ON LIFE IN THE
NORTH. Corvallis, Ore. State Univ., 1966, 40p.
incl. illus., tables, diagrs., map. 152 refs.
DLC, GB641.P4

Permafrost is actively forming in the north, and most perennially frozen ground is in equilibrium with the existing climate, although a few occurrences of permafrost are relics of a colder climate. The effect of permafrost in the biological field is perhaps most evident on vegetation. Underlying frozen ground seriously modifies surface drainage, which in turn affects the distribution of vegetation. Ground water distribution in many parts of the north is affected by the distribution of perennially frozen ground. In many places, it may be found only below permafrost; elsewhere, however, it may occur above the frozen ground and also in thawed zones within the permafrost. Engineering structures are seriously influenced by permafrost if the ice content of the ground is greater than the available pore space in the sediments. Intense seasonal frost heaving of the ground is common because of the rigorous climate and great areas of poorly drained fine-grained sediments. -- BLE

EFFECT OF BUOYANCY ON THE MELTING AND
FREEZING PROCESS. Trans. Amer. Soc. Mech.
Engr., 89(1):81-89 incl. tables, graphs, diagrs.,
Feb. 1967. 17 refs.
DLC, TJ1.A7

Measurements were made of interfacial velocities and transient and steady-state temperature profiles during the freezing and melting of water in a 0.5 x 0.5 x 2-in. high test chamber. Heat flow was one-dimensional, up and down. Tests both included and excluded the density-inversion temperature of 4°C. Freezing at the top and at the bottom, melting at the top, and at the bottom, all were achieved by selection of cold-end temperatures between -50 and -5°C and hot-end temperatures between 3 and 97°C. Tests included conditions with buoyancy forces in the liquid, with buoyancy forces existing but insufficient to cause convection, and with natural convection occurring at all times. With no natural convection the results agreed with predictions found by use of the numerical technique of Murray and Landis developed originally for cases with no convection. The onset of natural convection was found to be at a Rayleigh number of about 1700. Proper selection of the significant length, the ΔT [temperature], and coefficient of expansion for the Rayleigh number is described. The effective thermal conductivity for Rayleigh numbers up to 10^7 agreed with prior correlations obtained with free convection but with no phase change. The numerical calculation procedure was modified successfully by use of the effective k [thermal conductivity]. At the highest Rayleigh number, an unusual case of oscillations in the interface velocity is reported. (Authors' abstract)

This report summarizes the findings and conclusions drawn from a survey which was conducted at Alaskan bases. The purpose of the survey was to secure necessary information for making recommendations on the nature and level of effort of research program which could be directed toward minimizing the disruptive effect of ice fog on air operations at Eielson Air Force Base. The ice fog phenomenon, its principal causes at Eielson, and the nature and extent of its effect on air operations to the solution

CRREL BIBLIOGRAPHY

of ice fog problems and their influence on the apparent trend during the past ten years toward a decreasing frequency of occurrence. A recommendation is made for engineering designed to minimize pollutions from what is considered to be the primary source. Finally, there is a discussion of the feasibility of establishing an applied research program designed to provide operationally useful solutions to the ice fog problem. (Authors' abstract)

The use of helicopters by the Geographical Branch in its continuing Baffin Island Research Project is discussed. Mountain top landings are being made to test the Nunatak Hypothesis (which reasons that some Canadian mountain tops have never been ice covered and remained a refuge for certain plant species during the Ice Age). Samples of finely weathered materials were collected for chemical analysis and a particularly careful investigation was made of the many large "foreign" boulders that were found on some of the high mountain tops. Equally valuable was the access afforded by the helicopter to many other landforms and deposits under study at all levels. Information is given on flying time and general rules for operating helicopters in Arctic regions. -- BLE

APPROXIMATE EVALUATION OF THE STATIC ICEBREAKING POWER OF VESSELS. (Prblizheniia of Senka staticheskoi ledokol'noi moshchnosti sudov; Text in Russian). *Morskoi Flot*, 26(10):32-33 incl. graphs, Oct. 1966.
DLC, VM4.M6

Vessels for ice navigation are designed in terms of static icebreaking power, i. e., capacity to overcome the greatest thickness of ice in steady progress without churning. This phase of design is determined when writing basic specifications and as required by ice conditions in the area of navigation which govern the vessel displacement and installed power. A new simplified method of approximate evaluation of the static icebreaking power enables designers to establish a direct relationship between vessel dimensions, installed power and ice thickness. It is assumed that the width of ice channel made by the icebreaker equals the width of the vessel. Therefore calculations are made in terms of $q = N/B = k\sqrt{\delta^3}$, where q is screw power proportional to 1 m of vessel width, N is screw hp, B is width of vessel, k is an empirical value of 0.55, and δ is the ice thickness in cm. Graphs show that the results obtained agree closely with those obtained in field observations aboardship and those obtained by an elaborate 5-term equation. A nomogram enables the navigator to determine the screw power depending on the ice thickness and width of vessel.

MECHANICAL STABILIZATION OF A GRAVELLY SAND FROM THE BEACH AT POINT BARROW, ALASKA. Progress Rept., Proj. 320-S, Iowa Eng. Exp. Station, 57p. incl. illus., tables, graphs, maps, appendix, July 1, 1955. 22 refs.
DLC, Tech. Rept. Collection

Laboratory experiments indicate that the stability of the gravelly beach sand in the Barrow area may be substantially improved by mechanical stabilization using locally available materials. The stability may be increased approximately tenfold. However, the stability still is not adequate for permanent base or surface course construction, largely because of the highly rounded nature of the beach materials. Because of possible beneficial affects to be realized by the use of other materials or modifications to the mechanical stabilization treatment, further work seems to be justified. -- BLE

PROPERTY STUDIES OF ALASKAN SILTS IN THE MATANUSKA VALLEY, BIG DELTA, AND FAIRBANKS AREAS. Progress Rept., Proj. 320-S, Iowa Eng. Exp. Station, [57]p. incl. illus., tables, graphs, diagrs., maps, Dec. 1, 1955. 8 refs.
DLC, Tech. Rept. Collection

The silty materials of the Matanuska Valley, Big Delta, and Fairbanks regions are being studied as part of an Office of Naval Research project. This report covers work done during the first year, most of which concerns the Matanuska Valley. The silts overlie a variety of glacial and alluvial deposits in the Matanuska Valley as a surficial deposit. Five and possibly six volcanic ash layers are present in the thick silt, but only remnants are to be found in the thin silt sections. Mechanical analyses and consistency limits of all 91 samples showed 92% classified texturally as silty loam, and 85% had an engineering classification of A-4(8). Only a preliminary survey of the Big Delta region was made. Here the principal silt deposits (which are highly

micaceous) lie on what may be terraces. The Fairbanks silts, which are a surficial deposit found on the hills, are also micaceous but are generally finer-grained. Numerous illustrations, graphs, diagrams, and maps are appended. -- BLE

Blank, H. L. and others
MILITARY TRAFFICABILITY OF SOILS IN THE MATANUSKA VALLEY, ALASKA. Progress Rept., Proj. 320-S, Iowa Eng. Exp. Station, 42p. incl. illus., tables, graphs, map, Feb. 1, 1957. 24 refs.
DLC, Tech. Rept. Collection

Most soils in the Matanuska Valley appear to provide good trafficability for most military vehicles. Many areas of swamplands, which are classified as untrafficable in this study, may, if further tests are conducted, prove to be trafficable for many military vehicles. In this area, cultivated soils provide better trafficability than adjacent virgin tracts of the same soil. This increase in trafficability is due both to densification of the top soil and to better surface drainage. All tests conducted in hay fields produced very high trafficability ratings. The report presents a review of the literature and suggests a simplified procedure for tactical trafficability mapping and interpretation by military field units. -- BLE

GEOLOGY AND BITUMINOUS STABILIZATION OF SOIL MATERIALS AT BARROW, ALASKA. Final Rept. III, Proj. 320-S, Iowa Eng. Exp. Sta., 86p. incl. illus., tables, graphs, maps, June 30, 1958. 56 refs.
 DLC, Tech. Rept. Collection

Investigations were made in the southwestern portion of the Matanuska Valley, the area south of Big Delta, Fairbanks and vicinity, and the region near Point Barrow to determine the areal extent, geologic and engineering properties and the trafficability characteristics of the soil materials in these areas. Correlation of this data is to be used to determine the feasibility and most practical method of soil stabilization for use in road and runway construction. This report deals with the Point Barrow area. The results indicate that the stability of the beach materials can be satisfactorily increased by mechanical stabilization. The available crude oil can be used in bituminous stabilization of base and surface courses only after blowing to increase its cohesive properties. The consideration of subgrade behavior on thawing is very important in pavement design when working in an area of continuous permafrost. Prevention of ice saturated silts from thawing is very important. Generally, the beach is the most favorable location for roads and runways.

RADAR MEASUREMENTS OF ICE FORMATIONS. (Radiolokatsiia lednikov; Text in Russian). Zh. Tekh. Fiz., 37(4):781-788 incl. illus., tables, graphs, 1967. 12 refs.
 DLC, QC1.Z48

A description is given of the results of systematic measurements of the thickness of the ice cover made along a 100-km sector between the Mirnyy Observatory and the Pionerskaya Station during the 10th Soviet Antarctic Expedition. Measurements were made at 36 points whose geodetic coordinates had been fixed by GDR scientists. The sounding and reflected pulses were recorded on an electron beam tube. On the basis of a two-year cycle of investigations the following conclusions were drawn: (1) The amplitude of the reflected signal is practically constant when measuring the distance from the antenna to the snow surface within a 1 to 500-cm range. Should the active antennas of the vibrators come in contact with the snow, the signal amplitude decreases by 6 to 10 db. Penetration of the entire antenna into snow weakens the amplitude of the recorded signal by 6 to 20 db. (2) No regular amplitude variations of the reflected signal were detected when measuring the temperatures of the snow-cover surface between -2 and -12°C. (3) It was possible to measure the angle of inclination of the base of the glacier relative to the horizontal plane with an error of ±15°. (4) The most probable values of $\tan \delta$ for $f = 213$ mc for a glacier with a snow layer is in the range $(4.2 \text{ to } 7) \times 10^{-4}$. (From ATD abstract)

CRYSTALLOGRAPHIC STUDIES OF SEA ICE IN McMURDO SOUND, ANTARCTICA. U. S. Nav. Civ. Eng. Lab., Proj. Y-F015-11-01-026, Tech. Rept. R-494, 31p. incl. illus., graphs, map, Nov. 1966. 23 refs.
 CFSTL, AD642432

Sea ice is a crystalline solid with physical properties that are highly temperature-dependent between -1.8°C and -10°C. This dependence becomes less with decreasing temperatures. A detailed study of the crystal structure and other internal features of sea ice is necessary for an understanding of the relationship of these properties with strength properties. Horizontal banding in the McMurdo Sound ice sheet was studied to determine the effect of temperature fluctuations on band frequency, and various

CRREL BIBLIOGRAPHY

crystal parameters were measured from photographs of thin sections. Subcrystal platelet width increased with depth from about 0.5 mm at the surface to about 1 mm at 2.8 m. The length-width ratio of single crystals increased from 2 to 1 near the surface to more than 5 to 1 at depths greater than 2 m. The number of crystals per unit area decreased with depth. Strained ice from a pressure ridge showed preferred c-axis orientation and wavy extinction similar to that observed in strained quartz. There is apparently no correlation between strength and crystal structure in a mature isothermal ice sheet. (Author's abstract, modified)

ARE THE STRUCTURES OF THE CARIBBEAN AND SCOTIA ARC REGIONS ANALOGOUS TO ICE RAFTING? *Earth & Planetary Sci. Let.*, 1(5):335-338 incl. illus., diags., Sept. 1966. 11 refs.
DLC, Unbound periodical

The structures of the Caribbean and Scotia Ridge regions appear to be geometrically similar to "finger-raftering" of ice. Simple overlapping, such as occurs in ice sheets, is not likely to occur in the mantle. However, the oceanic crust could have been forced down in trenches in front of the arcs, and reabsorbed into the mantle. Conclusions based solely on the general similarity in geometry seem to indicate a possible explanation for the thicker crust, wider range in crustal velocities, more gradual change from crustal to mantle velocity, and greater thickness of derived materials overlying the crust.

THE OCCURRENCE AND DISTRIBUTION OF HAIL IN AFRICA. *Meteorol. Mag.*, 95(1128):212-218 incl. table, maps, July 1966. 12 refs.
DLC, QC851.M18

Hail is virtually unknown over Africa between 20°N and 30°N , on the Atlantic coast north of 25°S , and on the Indian Ocean coast north of 15°S . However, hail has been reported at Mauritius (20°S), where there is a reliable report of a hailstorm occurring over the sea, and at the Grande Comore Island (12°S) in the Mozambique Channel. There have been occasional reports of hailstorms in West Africa even at fairly low elevations, but on the east coast, where thunderstorms are much less common, hail is extremely rare north of Mozambique. In most areas the peak hail frequency does not necessarily occur in the wettest month, but more often towards the beginning and end of rainy seasons, or at the end of a dry spell in the rainy season. Geographical and topographical features undoubtedly lead to the existence of certain favorable hail "breeding areas." The problem of forecasting hail in tropical Africa is not likely to have a simple solution, but it seems probable that the best results will be obtained by using some form of stability index. -- BLE

ICEBREAKERS TO THE FORE, Finnish Trade Review, 134(2):38-39, 56 incl. illus., 1963.
DLC, HF25.F5

The modern shipyard Sandvikens Skeppsdocka of Wärtsilä-koncernen A/B is the world's foremost shipyard for icebreakers. Of the icebreakers delivered to the USSR the 22,000 shp polar icebreakers "Moscow" and "Leningrad" are the largest and most powerful icebreakers in the world with conventional machinery. After extensive modernization during the last few years the yard now fulfills all modern requirements. A fitting out pier over 100 m long with a 25-ton gantry crane was completed some years ago. For repair work there is a floating dock of 2500 tons capacity and a graving dock measuring 465 x 65 x 21 ft. Finland's biggest icebreaker "Volma" (Power) is Wärtsilä-built with shaft hp of 10,500. Orders in hand include a polar icebreaker, a sister ship to the "Moscow" and "Leningrad," and two 12,000 shp sea-going icebreakers for the Swedish and Finnish Governments. -- BLE

ICE-BREAKER EXPORTED TO SWEDEN. Finnish Trade Review, 104(2):63 incl. illus., table, 1958. DLC, HF25.F5

On Nov. 9, 1957, the Sandvikens Shipyards (Finland) delivered the "Oden," a 10,500 shp icebreaker to Sweden. This was the fifth icebreaker built at the shipyard. The first European vessel to be designed especially for ice breaking was the "Eisbrecher I," built in Hamburg in 1871. The Finnish "Sampo," built in 1898, was the first ship built in Europe with a propeller in the bow. The use of diesel-electric propulsion was introduced with the Swedish icebreaker "Ymer." One of the advantages obtained was improved maneuverability. The latest development is the use of 2 bow propellers on the "Voima," the prototype of the class to which the "Oden" belongs. The "Oden" has 2 continuous decks and an extended forecastle. Nine transverse bulkheads divide the vessel into 10 watertight compartments. Two heeling tanks are situated amidships on each side between the lower and main decks. The hull's ratio between length and breadth is 4.14 and the angle of the stem at the water line, 22°. The propellers are made of cast Ni-steel. Two diesel engine rooms form independent units, both of which have three 9-cycle single-acting 2 stroke diesels, each connected to a generator. The tag winch is fully automatic. Normal crew size is 63 persons. -- BLE

Oelsner, Chr. SEISMOACOUSTICS, A NEW MEASURING TECHNIC FOR GLACIER MECHANICS. (Seismonakustik, eine neue Messmethode für die Gletschermechanik; Text in German). Polarforschung, 6(1/2):19-27 incl. illus., graphs, diagr., map, 1965, publ. Jan. 1967. 17 refs. DLC, G600.P6

The expedition program of the German Spitsbergen Expedition (1964/65) of the National Committee for Geodesy and Geophysics of the DDR included glaciology, geodesy, hydrological meteorology, periglacial morphology, and geophysics. This paper describes the seismoacoustical measurement technique and equipment used in the Kingsbay area of West Spitsbergen. The seismoacoustic method was originally a geophysical technique used to study vibrations in mines, based on dynamic stress equalization in rock formations which produces elastic waves whose tonal components can be heard as pistol-shot noises or explosions, depending on the intensity. By calculating energy spectra, it was determined that a reverse glacier movement prevails which is caused by a lubricating water layer beneath the ground. -- BLE

Brockamp, B. and H. Kohnen A CONTRIBUTION TO THE SEISMIC INVESTIGATIONS ON THE GREENLAND ICE CAP. (Ein Beitrag zu den seismischen Untersuchungen auf dem Grönländischen Inlandeis; Text in German with English abstract). Polarforschung, 6(1/2):2-12 incl. tables, graphs, map, 1965, publ. Jan. 1967. 21 refs. DLC, G600.P6

The compressional and the shear wave velocities in the Greenland ice sheet are derived from seismic records of the EGIG 1959. Also, the variation of velocities in the firn and the dependence of Poisson's ratio are determined. At Station Centrale, two P-waves are recorded from underground layers. Their velocities show that the ice base consists of crystalline rocks. The P-wave velocities derived from reflections agree well with those obtained by refraction shooting. This indicates that the ice is ± homogenous and ± isotropic for P-waves. The elastic constants for isotropic ice are calculated, and the temperature dependence of the velocities is discussed. A WEATHER STATION TO BE CONSTRUCTED ON BOUVET ISLAND? (Errichtung einer Wetterstation auf Bouvet Øya?; Text in German). *Polarforschung*, 6(1/2):38-41 incl. map, 1965, publ. Jan. 1967. 9 refs.

DLC, G600.P6

One of the most isolated areas of the Earth is to become accessible to scientific research and at the same time be brought into the large international network of meteorological observation stations. This is the result of the short, but meaningful "South African Bouvet Island Expedition, Feb. - March 1966," which staked off an area of the island on which a manned weather station could be built. Many expeditions have been made to the island, the first being in 1739 by Lozier Bouvet. In 1966, measurements were made on the plateau as well as on the ice free rock ridges of the crater. The scientists present included geologists, geophysicists, meteorologists, geodesists, and biologists. Neither ice thickness nor ice movement could be determined during the 7 days of research, but other glaciological observations were made. Direct radio contact is foreseen between the weather station, South Africa, and Mawson and SANAE Stations in Antarctica. -- BLE

A PRELIMINARY STUDY OF THE OCCURRENCE OF ICE CRYSTALS IN LAYER CLOUDS. *Meteorol. Mag. (London)*, 96(1134):23-27 incl. table, graphs, Jan. 1967. 2 refs.
DLC, QC851.M18

Flights have been made to investigate the occurrence of ice crystals in layer clouds, using an icing rod to collect samples of the cloud particles. Concentrations down to 1 ice crystal per cubic meter can be detected by this method. From a study of 26 layers of cloud, it has been found that ice crystals can occur in stratocumulus cloud, whose lowest temperature is -7°C , and also that some altocumulus clouds with temperatures below -20°C contained only supercooled water drops. A PHYSICAL STUDY OF SOLID PRECIPITATION FROM CONVECTIVE CLOUDS OVER THE SEA: PART I. DEUTERIUM CONTENT OF SNOW CRYSTALS WITH RESPECT TO CRYSTAL SHAPES AND THEIR RELATION TO ORIGINS OF THE WATER VAPOUR OF SNOWFALL. *J. Meteorol. Soc. Jap.*, 44(3):178-184 incl. tables, map, June 1966. 35 refs.
DLC, Orientalia Div.

On the basis of the isotopic analysis of deuterium content in snow crystals and graupel pellets which fell on the coast of Japan facing the Japan Sea, the following results were obtained. (a) The D/H ratios of snow were large (mean value 150 ± 2 ppm) when the snow flakes consisted of nonrimed crystals having the same shape of crystal habit. (b) The D/H ratios were small (mean value 146 ± 3 ppm) when the precipitation consisted of graupel pellets, rimed crystals, or a mixture of 2 different shapes of snow crystals. (c) It is likely that the difference between (a) and (b) was due to the difference in the vertical development of precipitating clouds. (d) Temperatures of the sea surface from which snowfall water had evaporated were estimated from the D/H ratio of snow samples. As the horizontal water temperature gradient in the Japan Sea was very steep, the geographic location of this vapor source could be specified. (Authors' abstract)

A PHYSICAL STUDY OF SOLID PRECIPITATION FROM CONVECTIVE CLOUDS OVER THE SEA: PART II. RELATION BETWEEN ICE NUCLEUS CONCENTRATION AND PRECIPITATION. J. Meteorol. Soc. Jap., 44(4):218-226 incl. graphs, diagrs., map, Aug. 1966. 7 refs.
 DLC, Orientalia Div.

Ice nucleus concentrations in cold air which came from the continent of Asia to the northwest coast of the main island of Japan in the northwest monsoon season was observed. A close relation has been found between the fallout rate of snow crystals or graupel pellets and the concentration of atmospheric ice nuclei active at the temperature at the top of the clouds. It is concluded that ice nuclei actually play an important role in the formation of snow crystals and graupel pellets and that their concentration controls the rate of precipitation, at least in the case of cold convective clouds. (Authors' abstract)

developed anomalously and broke out towards the Japan Sea. The heavy snowfall area was found at the northwest side of the jet stream where positive vorticity prevails. While in the lower layer, some smaller scale lows move to the Hokuriku district and cause heavy snowfall at the coast. A three-dimensional structure of the disturbance which would produce coastal heavy snowfall was studied. From the horizontal distribution at each level and zonal and meridional cross sections of vorticity, divergence and temperature fields, it was noticed in the cases of coastal heavy snowfall that there exist descending currents above the cold dome and ascending currents in the lowest layer and, thus in the middle layer, there is a divergent wind field in which the southerly wind at about the 700 mb level over Wajima seems to be important. LONG-RANGE ICE OUTLOOK, ANTARCTIC (1966-67). Spec. Publ. 100(66), U.S. Nav. Oceanogr. Off., Mar. Sci. Dept., Wash., D. C., 11p. incl. maps, Nov. 1966.
 DLC, Tech. Rept. Collection

Oceanographic and climatic data for the Ross Sea and McMurdo Sound areas were analyzed in terms of sea ice growth during the preceding austral winter. These analyses, combined with observed ice conditions for Oct. 3-8, 1966, and a comprehensive study of historical ice and climatic information, formed the basis for the outlook from mid-Nov. 1966 through mid-Jan. 1967. Evaluation of this information indicates that ice conditions were similar to those observed during the 1964-65 season. Compared to the 1965-66 season, ice conditions are expected to be slightly heavier in the Ross Sea, with less fast ice to be broken in McMurdo Sound. (Authors' abstract, modified)

THE SYNOPTIC CONDITIONS ATTENDING AN
OCCURRENCE OF FREEZING DRIZZLE. Meteorol.
Mag., 96(1137):112-115 incl. maps, April 1967.
DLC, QC851.M18

The widespread occurrence of freezing drizzle over southern England on Jan. 20, 1966 (see SIP 25384), was accompanied by an easterly stream of cold air from western Europe, while milder Atlantic air was crossing France from the Bay of Biscay. Available evidence suggests that the drizzle was produced at freezing or near-freezing temperature and, falling through a shallow freezing layer, readily froze on contact with the ground or other surfaces. Surface charts indicate that the very weakness of the low pressure area was a main factor in the extent of the icing. -- BLE

SIGNY ISLAND, SOUTH ORKNEY ISLANDS: II.
TEMPERATURE REGIMES IN THE ACTIVE LAYER.
Brit. Antarctic Surv. Bull., No. 10:71-83 incl.
tables, graphs, Dec. 1966. 14 refs.
DLC, Unbound periodical

Soil temperatures were recorded by electric resistance thermometers over a 2-yr period at 2 sites on Signy I. Resistance readings were converted to temperatures by a computer, which also calculated monthly means and standard deviations. Analysis of these records shows rates of freezing and thawing throughout the year, frequency of freeze-thaw cycles at different depths, and the difference in regime between the stones and fines of a sorted pattern. Results suggest that, in this case, there is no uneven descent of a freezing plane in a manner which would induce cryostatic pressure and the consequent movement of fine material. A considerable difference is noted between freeze-thaw cycles inferred from meteorological data and actual freezing and thawing in the soil, suggesting that air temperatures are an inadequate indicator of soil conditions unless information on snow cover, soil moisture, and radiation is available. 12(1):101-102 incl. illus., March 1966. 4 refs.
DLC, QR1.J63; DNAL, 448.3 J824

The fifth Japanese Antarctic Research Expedition took samples of plankton-ice, sea water around icebergs, icebergs, and phytoplankton from Lützow-Holm Bay in Jan, 1961. The samples were frozen and stored for about 6 mo., and then thawed for analysis. Microorganisms were isolated on sea water agar plates. Viable bacteria in the plankton-ice consisted of about 70% *Brevibacterium minutiferula* and about 20% *Achromobacter aquamarinus*. Algae in this ice consisted mainly of *Fragilariopsis curta* and *Charcotia australis*. In the sample of phytoplankton collected by pumping, *Corentron cryophila* predominated. Predominant organisms in the surface sea water were *Pseudomonas azotogena*, *Achromobacter aquamarinus*, and some flavobacteria. Only a few *Brevibacterium minutiferula* were isolated from the sea water samples. The *brevibacteria* and diatoms in the plankton-ice might be ecologically connected. -- DMN

Propane is an effective agent causing glaciation of supercooled fog droplets and subsequent improvement of visibility. When wind is less than 5 or 6 knots and steady with respect to direction, two or three dispensers, each emitting 2.5 to 3 lb/min. of liquid propane, could probably keep an airfield open to air traffic at a cost of about 20 dollars per hour. The propane system is easy to use, inexpensive, requires neither preparation nor personnel standby time after the initial installation, and is effective at temperatures higher than the effective temperature of the more commonly used agents. No combustible mixture has been found beyond 8 ft from the discharge nozzle of the propane-air mixture. On airports with short runways, the reduced aircraft braking index caused by snow accumulation might be sufficient to render the system unsuitable unless the dispensers could be positioned far enough from the airport to allow the snow to fall upwind of the runway. -- BLE

NUCLEATION OF FREEZING BY CAVITATION IN SUPERCOOLED LIQUIDS. *Nature*, 214(5086):379, April 27, 1967. 3 refs.
DLC, Q1.N2

In a recent paper (SIP 23211) the author has proposed that the nucleation of freezing by cavitation is caused, in all supercooled liquids, by the high compression generated near the surfaces of collapsing cavitation bubbles. It was assumed that the compression is isentropic. Hunt and Jackson have suggested that this assumption is erroneous and that Rankine-Hugoniot relations across a shock wave front are a more realistic representation of the thermodynamic behavior of the liquid during cavity collapse. The Rankine-Hugoniot relations are based on the belief that shock waves occur during the collapse of cavitation bubbles. Shock waves, however, cannot occur at this stage of the bubble wall motion, because the conditions for generating shock waves do not arise. There seems to be no reason to believe that the isentropic condition is not a suitable assumption. -- BLE

 fossila iskilpolygoner; Text in Swedish with English
 summary). Svensk Geogr. Arsbok, 42:145-162 incl.
 illus., tables, graphs, diagr., 1966. 4 refs.
 DLC, G25.S8

As the result of photo interpretation, a relict pattern of ice wedge polygons was identified in a cultivated area on the Swedish west coast. In this paper the moisture conditions have been studied to get an idea of the actual difference in water content causing the crop pattern, and to determine if the polygon lines could be detected on the ground surface itself because of their moisture properties. In vertical sections a fossil ice wedge often stands out very clearly some time after the excavation because of its higher moisture content. However, on the ground surface the polygon lines can be detected very seldom. On early summer mornings a clear moisture contrast was visible on the surface of a thin humus layer on the polygon line. A junction of 2 lines could be mapped in detail. Freezing makes the polygon lines visible on ground surfaces where the humus layer is removed. The photographs that were used were made with panchromatic film. More details could probably be obtained by using infrared film. -- BLE

DLC, TD201.A12

Some of the methods in which heat is used in com-
bating freeze-up of elevated tanks are (1) hot water,
and (2) the pump and liquid medium. Several com-
binations of the heat, pump, and coiled type of
energy dissipation are used in one form or another.
The types of freeze-up that occur in tanks usually
result in an ice wedge forming in the riser pipe at
the junction of the riser pipe and the bowl. Ice in
tanks forms in layers which form plugs that are dan-
gerous if precautions are not taken to preclude the
piston action of a falling ice chunk. Thawing out of
all riser pipes and tanks should be done from the
top end. One of the most effective methods is to
use the steam jenny. Where steam jennies are not
available, a method of heating a large tub with
butane gas torches to obtain hot water is used.
Basically, the concept of movement of water must
be kept in mind for the prevention of freezing.

INVESTIGATION OF THE WATER BUDGET OF A
SNOW COVER. (Untersuchung des Wasserhaushalts
der Schneedecke; Text in German). Umschau, 67(8):
256, April 15, 1967. 1 ref.
DLC, AP30.U5

Snow storage on the ground surface and its melting
and evaporation are closely related to the meteor-
ological situation which therefore determines how
much of the winter precipitation will actually con-
tribute to the water economy. To determine the
quantitative relationships between these components
of the water budget of a snow cover, a large sur-
veying apparatus was constructed several decades
ago in Obernachtal, south of Walchensee (Ober-
bayern), at the present Research Establishment for
Water Works of the Munich School of Technology.
It consists primarily of a platform 2.5 x 2.5 m which
operates at ground level and rests on a 3-ton scale.
The scale is situated on a topless concrete bunker
which can only be entered from the side. Snow and
meltwater accumulate naturally on the platform and
surrounding area and can be weighed regularly. By
observing and evaluating weight changes as a result
of melting and evaporation, insight can be obtained
into the processes within the snow cover. To de-
termine the general applicability of the results, a
similar surveying station was erected under dif-
ferent climatological conditions in 1965. -- BLE

Experiments have been conducted with a particular
layer lattice silicate, montmorillonite, in order to
study the interaction of water and ice with silicate
surfaces. The structural features of this class of
silicate minerals are described, and other aspects
which have a particular bearing on interfacial phe-
nomena are discussed. Emphasis is placed on the
nature of water and aqueous solutions, mechanisms
of clay-water interaction, physical and thermody-
namic properties of clay-adsorbed water, freezing
point depression and supercooling, the existence of
unfrozen interfacial water, spatial distribution of
unfrozen water, the nature of the ice phase, and
phase relationships. -- BLE

ALASKA'S MIGHTY RIVERS OF ICE. *Nat. Geogr.*,
131(2):194-217 incl. illus., maps, Feb. 1967.
DLC, G1.N27

This paper presents a colorfully illustrated description of Alaska's glaciers and the investigating methods to gain new insights into past and present climate and hints about the future. The survey was part of the National Geographic Society's Alaskan Glacier Commemorative Project, a five-year field study begun in 1964. Much information is given also about the aspects of operating Michigan State University's Summer Institute of Glaciological and Arctic Science with emphasis on transportation and logistics. The results of the investigations back up the solar-climate theory of weather cycles. Glacier fluctuations over the past 200 yr show a correlation to recorded cycles of sunspots. -- BLE

GLACIER SURVEYING AND MAPPING PROGRAM
OF THE OHIO STATE UNIVERSITY. *Can. J.
Earth Sci.*, 3(6):849-861 incl. illus., graph, maps,
Nov. 1966. 18 refs.
DLC, QE1.C17

Ohio State University's extensive program of glacier mapping and associated glaciological research has studied glaciers in the western United States, Alaska, the Yukon Territory, Greenland, and Antarctica. Ground surveying and aerial triangulation have been used, and the mapping has been performed stereophotogrammetrically by means of first- and second-order instruments. Surveying and mapping phases of the work are described, and data on glacier structure, volume variations, and surface ice velocity are presented to illustrate the value of photogrammetric techniques in glaciological studies. The Antarctic glaciers considered are Byrd Glacier and the continental ice sheet between Byrd Station and the Whitmore Mts. (Authors' abstract, modified)

METHOD OF EVALUATING SUBSTATION RECORDS
OF HAIL AND THUNDER. *Monthly Weather Review*,
95(4):209-212 incl. maps, April 1967. 8 refs.
DLC, QC983.A2

Cooperative substation records of hail and thunder incidences have been used as a source of data to develop more accurate and detailed average patterns of these phenomena. Since the accuracy and completeness of records by volunteer observers are generally considered questionable, a method of determining accurate substation records of thunder and hail was devised. The evaluation method relies strongly on comparisons of substation data with those from nearby first order stations. The number of stations with accurate hail records was found to be greater than the number with accurate thunder records. Reliable records of both events in Illinois and surrounding States have provided very useful information. (Author's abstract)

METHOD OF CALCULATING PROBABLE DEPARTURE DATE OF ICEBREAKERS FOR UNINTERRUPTED PASSAGE THROUGH CONTINUOUS ICE. (Metod rascheta srokov vozmozhnogo nachala nepreryvnogo dvizheniia ledokolov v sploshnykh l'dakh; Text in Russian). *Prob. Arktiki Antarktiki*, No. 22:66-74 incl. graphs, diagrs, 1966. 2 refs.
DLC, G575.L422

Uninterrupted icebreaker passage through continuous ice is determined by the design parameters of the icebreaker and by the ice cover resulting from local physicometeorological conditions. In the basic equation used for the study,

$$F(v) = R(v) = k_2 B v^{\alpha} h + k_3 B v h^2 + k_4 B^2 \frac{1}{\eta} h v^{\gamma} + r(v),$$

$F(v)$ is propeller traction in tons, at speed, v ; $R(v)$ is shearing force of ice cover and water in tons during icebreaker motion; B is vessel width in meters; μ, η are dimensionless coefficients of hull configuration at bow waterline; $k_2, k_3, k_4, \alpha, \gamma$ are empirical coefficients; $r(v)$ is water resistance in

CRREL BIBLIOGRAPHY

tons during the vessel motion; v is icebreaker speed in m/sec.; h is ice thickness in meters; and σ is the temporary ice resistance to bending in tons/m². An example of navigation scheduling is given which shows a gain of 17 days passage time when the icebreaker forces the ice. During the forcing, the speed of the icebreaker increases from 1 to 8 knots in 15 days. Formulas are derived from the basic equation to determine the factors for evaluating departure dates. VDP/FMM

Zagirov, F. G.
FORMATION OF ANCHOR ICE ON BODIES OF
VARIOUS STRUCTURE. Soviet Hydrology: Selected
Papers, No. 1:99-101 incl. graph, 1966. 2 refs.
DLC, Unbound periodical

Experiments are described which have been conducted to investigate the formation of ice in canals, the freezing over of grids, floodgates, the crests of weirs, and the underwater parts of hydraulic structures. The study concludes that (1) a concrete surface is subject to significant icing at a water temperature of 0.05°C; (2) materials subject to icing in various degrees may be classified in terms of the time taken for formation of the initial layer of ice on their surface, after which the subsequent icing conditions become the same; (3) only absolutely water-repelling materials can have reliable protective properties against icing, e.g. polyethylene films. Coating the parts of metallic constructions that freeze in winter with polyethylene film may significantly improve their winter performance, and coating the bottom and sides of a canal might prevent the formation of anchor ice. WATER SUPPLY AND WASTE DISPOSAL IN
ALASKA NATIVE COMMUNITIES. Civ. Eng.,
37(4):66-68 incl. illus., graph, diagr., map, April
1967. 3 refs.
DLC, TA1.C452

The 43,000 native Alaskans of 3 ethnic groups, Indians, Eskimos, and Aleuts are spread over an area about one fifth the size of the 48 contiguous United States. Beginning in 1961, the U.S. Public Health Service initiated a construction program in cooperation with the Alaskan natives to improve environmental sanitation facilities. In a community which has no electricity, no roads, a site underlain by permafrost, and primitive living conditions, a central watering point is a practical solution. Thus to provide potable water, a well has to be drilled, a heated building must be provided, facilities for treatment are needed, a means to prevent the well water from freezing is necessary, and a system of maintenance and operation must be developed. Under these conditions, batch treatment in wood stave tanks of about 500 gal capacity is used. The cost of a 4-in. well ranges from \$10.00 to \$100.00 per ft with an average of about \$50.00. The distribution system to put running water in homes is described with emphasis on heating costs and sewage disposal.

DLC, G575.L422

The primary effect of the wind's tractive action is a simple drift component of currents; the secondary effect, caused by wind inhomogeneity and the influence of coastlines, develops purely gradient currents. A means of separating these components is necessary to determine current development and physical constants. An experiment conducted on drifting Arctic ice from May to Oct. 1964 included

measurements of wind speed, currents at various horizons, and tilting of the plane surface. Instruments embedded in an ice floe of 1-km diameter and 220-460-cm thickness measured meridional and latitudinal components of inclination. The following conclusions were obtained: (1) local sea-level inclinations resulting from inhomogeneous wind fields are the sources of waves with periods ranging from tens of seconds to several minutes; (2) the superposition of waves in an ice-covered open ocean creates deformations in the ice which, under anomalous conditions, lead to fracturing; (3) in the Arctic fast-ice zone the effect of these waves is strengthened by interference phenomena and by wave transformation in shallows; and (4) these fluctuations are a basic factor in fracture formation in ice in which there are no visible signs of deformation.

COMPARATIVE CHARACTERISTICS OF THE RADIATION REGIME OF THE ARCTIC AND ANTARCTIC. (Sravnitel'naya kharakteristika radiatsionnogo rezhima Arktiki i Antarktiki; Text in Russian). Prob. Arktiki Antarktiki, No. 24:30-34 incl. maps, 1966.
DLC, G575.L422

In the Arctic, scattered radiation accounts for 70-80% of the total radiation, while over the central Antarctic continent direct radiation comprises 80% or more. Total radiation in summer in high Arctic latitudes attains 17-19 kcal/cm²/mo., and in central Antarctica, 25-30 kcal/cm²/mo.; total yearly values are 75-80 kcal/cm² and 100-120 kcal/cm², respectively. The highest values on earth are observed in summer in the elevated region near the Pole of Inaccessibility. The monthly total radiation values decrease rapidly with distance northward from the Antarctic coast as a result of dense cloud conditions. The lowest yearly totals in the Southern Hemisphere are found between 65° and 50°S. On the surface of the Antarctic ice cap, the radiation balance is positive (about 2 kcal/cm²) only in the 2 months of the year during which the sun is 18-20° below the horizon. The lowest negative balance is observed on the high Antarctic plateau, where strong surface inversions significantly increase counter-radiation in winter.

DLC, G575.L422

The intensity of radiational and thermal processes in the atmosphere is partially dependent on the content of absorptive gases, the thermal stratification of the atmosphere, astronomical factors, etc. The vertical trend of water vapor density at varying temperatures at Mirnyy and Argentine I. Stations is calculated, and the zonal distributions of temperature and water vapor intensity and volume in the Antarctic atmosphere are tabulated. Equations are derived for computing the absorption of direct and reflected radiation by water vapor, carbon dioxide, and the permanent gases; the calculated values are tabulated in cal/cm²/day for each month at 70°S, 80°S, and 90°S. Water vapor accounts for the greater proportion of absorption, in spite of its infinitesimal volume in the Antarctic atmosphere. In summer, the intensity of absorption remains relatively constant with latitude. The annual cycle of the components of the long-wave radiation balance are graphed for various latitudes. Monthly and annual values of the short-wave, long-wave, and total Antarctic radiation balance are tabulated.

manns Geogr. Mitt., 110(4):284-285 incl. graph,
map, 1966. 5 refs.
DLC, G1.P43

An ice thickness profile was made gravimetrically in the summer of 1964 by members of the German Spitzbergen Expedition 1964-65 of the National Committee for Geodesy and Geophysics of the GDR. At the end of the Polar night in March 1965, the nearly constant advance of the glacier at 1.5 m/day had caused calving and shattering of the ice cover of the fiord immediately near the front of the Kongsvegen Glacier. Fiord ice and ice from calving were constantly being pushed forward, causing a compression and broken-ice zone whose course reflected the velocity profile. This zone extended within 1 m of the glacier front. Soundings at 31 profile points along the entire front in this complex ice field came within 100 and 450 m of the glacier front. An average ice thickness of 85 m was obtained, which agrees with earlier estimates. -- BLE

CROSS SECTIONS OF ICE NUCLEUS CONCENTRA-
TIONS AT ALTITUDE OVER LONG PATHS. J.
Atmos. Sci., 24(2):226-229 incl. graphs, March
1967. 4 refs.
DLC, QC851.A283

CRREL BIBLIOGRAPHY

Measurements of ice nucleus concentrations using Millipore filters at altitudes of about 4 and 11 km over lengthy paths are described. Bands of ice nuclei between latitudes 23S and 30S were frequently found at both altitudes, narrower and of higher concentration than those observed at the ground. Broad regions at 10-12 km markedly deficient in ice nuclei were found near the equator on each of two flights. There was no conspicuous difference in ice nucleus concentrations in the two hemispheres and no obvious change was found at the northern boundary of the pall of volcanic dust then present. CONSIDERATION OF THE NATURAL CHARACTERISTICS OF CONTINUOUS ICE IN THE EVALUATION OF ICEBREAKER PROGRESS. (Uchet prirodnykh kharakteristik sploshnogo l'da pri ot'senke ego prokhodimosti ledokolom; Text in Russian). Prob. Arktiki i Antarktiki, No. 22:75-81, 1966.
DLC, G575.L422

The extension of navigation periods in the far north is occurring more often, pointing to the growing importance of icebreaker capability in making progress through continuous ice. Up to recently, this capability was computed by the Arctic and Antarctic Institute formula on the basis of tests with models in experimental water ways: $R = 0.004B\sigma Bp\mu + 3.25Bh^2\mu + 0.25B^{1.65}h\nu / \eta^2 + R_B^1$, where R is total ice resistance in tons; B is vessel width in m; σBp is temporary resistance of ice to bending in tons/m²; h is ice thickness in m; ν is vessel speed in m/sec.; μ and η are coefficients of hull configuration effects on the resistance of the ice; R_B is the vessel resistance in open water in tons. This formula, however, takes into consideration only thickness and strength of the ice cover (temporary resistance to bending). Closer study points to the fact that continuous ice thickness possessing fracturing and hummocking properties has a substantial effect on the vessel progress, whereas temporary resistance of ice to bending has little effect. For the additional factors of ice thawing and hummocking, five-point scales have been devised by Volkov and Somov and by Gordienko, respectively. Nomograms with the above characteristics are given to improve the A. A. I. formula, showing effects on thrust capability and speed of the icebreaker.

MAIN FEATURES OF RECENT GLACIATION OF THE EASTERN DZHUNGAR ALATAU. (Osnovnye cherty sovremennogo oledeneriia vostochnoi chasti severnogo sklona Kirebta Dzhungarskii Alatau; Text in Russian). Glatsiologicheskie issledovaniia v Kazakhstane, Vyp. 6:5-28, Alma-Ata, 1966. 11 refs.
DLC, QE575.A4

During a survey of the Tentek and Tastau river basins, the features of recent glaciers in the area under general alpine climate characteristics are shown in connection with hypsometry, orography, exposure, and mechanical factors. Morphologic and morphometric characteristics of basin, valley, train, corrie, hanging, and flat-summit glaciers are distinguished. The role of hypsometry in the development of glaciation in the eastern part of the range is revealed, based on the dependence of mean height of upper firn line from the area of glaciers of different types. Peculiarities of firn line distribution on the glaciers of different types are described in connection with bed exposure. Glaciation elements are explained, such as distribution of degree of glaciation according to exposure; structure of glaciers of various types in per cent of their general area; distribution of glaciation in high zones in per cent of the general glaciation area. They are presented separately for all basins as a whole and for every type. (From author's summary)

(Ablatsiya lednikov bassejna reki Aganakty Tentek-
skoi v khrehte Dzhungarskiy Alatau, Text in Russian).
Glasologicheskie issledovaniya v Kazakhstane,
Vyp. 6:50-68, Alma-Ata, 1966. 7 refs.
DLC, QE575.A4

The ablation seasons during 1960 to 1963 ranged from 75 days in 1962 to 50 days in 1963, the mean duration being 61 days, from July 9 to Sep 8. Ice melted near the Krasovskiy Glacier terminus during the ablation seasons as follows: 1961 - 159 cm (water equivalent), 1962 - 263 cm, and 1963 - 134 cm. Compared to a glacier surface free of moraine, the thawing of ice on moraines 5 cm thick was 70% and on moraines 50 cm thick was 6%. Determination of precipitation in the glacial areas by means of calculations and direct observations yielded similar results - for 1960-61, 963 mm; 1961-62, 795 mm; and for 1962-63, 922 mm. The gradient temperature change, dependent on general cloudiness, ranged from May, 0.68; June, 0.72; July, 0.73; Aug, 0.70; to Sep, 0.63. Mean daily temperature was obtained by extrapolation of temperature gradients. The relationship between ice thaw and mean daily air temperature was used as the basis of calculation to obtain ice thaw during periods of no observations.

WEATHER AND RADIATION CONDITIONS IN THE
DZHUNGAR ALATAU RANGE GLACIAL ZONE.
(Meteorologicheskie i radiatsionnye usloviya glatsial'noi zony khrehta Dzhungarskiy Alatau; Text in Russian). Glasologicheskie issledovaniya v Kazakhstane, Vyp. 6:69-81, Alma-Ata, 1966. 2 refs.
DLC, QE575.A4

Weather and actinometric investigations in the altitude of 2940 and 3180 m were carried out during ablation season 1961-1963 on the Krasovskiy Glacier in the Aganakta-Tentek River basin. During the period of observation the glacier surface changed very little. The maximum albedo occurs after snow-fall (A = 60 to 90%) and decreases as the snow becomes compact and dirty, down to 30 to 50%. When the solar altitude and the air temperature increases and glacier meltwater appears, the albedo decreases to 12 to 15%. The effective radiation depends on the temperature of the underlying surface, air water content and on cloudiness. Mean magnitudes of effective radiation at cloudless sky at various values of steam pressure and air temperature, and mean values of cloudiness were calculated at different amounts of clouds. When the cloudiness changes from 0 to 10 points, the effective radiation decreases by 0.100 cal/cm²/min. At night the magnitude of the radiation balance is negative, being in the ranges of -0.2 to -0.1 cal/cm²/min. Daily amounts of radiation balance from six thirty to eighteen thirty change in wide ranges from 30 to 500 cal/cm². Maximum frequency was observed in the ranges from 100 to 250 cal/cm²/day. Radiation balance during one month (August) in 1962 was 8 kcal/cm², in 1961 and 1963, 6 kcal/cm². (From authors' summary)

MASS BALANCE OF SOME SMALL GLACIERS IN
THE ZAILIISKII ALATAU. (Balans massy nekotorykh malykh lednikov v Zailiyskom Alatau; Text in Russian). Glasologicheskie issledovaniya v Kazakhstane, Vyp. 6:82-92, Alma-Ata, 1966. 8 refs.
DLC, QE575.A4

Glaciers in the Zailiysky Alatau Range range from 0.1-0.2 to 40 km², and from 0.1 to 10-12 km in length. Mass balance observations were made on 6 small (< 2 km²) glaciers, Igly Tuyuksu (valley type), Molodezhnyy Glacier (trail type), Mametova's Glacier (corrie hanging type), and valley-hanging type, Shokalskiy's Glacier, and the TEU Northern and the TEU Southern Glaciers. Their unique feature is the high elevation of the tongue terminus, 3450-3720 m, or 100 m or more higher than the terminus of the larger valley glaciers nearby. Comparative mass balance data is given for the glaciers. (From author's summary)

CHARACTERISTICS OF INTERRELATIONSHIPS IN THE HYDROLOGICAL REGIME OF A CENTRAL TUYUKSU GLACIER. (Kharakteristika nekotorykh bzaivosv'язey v gidrologicheskom rezhime T'sentral'nogo Tuyuksuiskogo lednika; Text in Russian). *Gliatsiologicheskie issledovaniya v Kazakhstane*, Vyp. 6:93-111, Alma-Ata, 1966. 8 refs.
 DLC, QE575.A4

The interrelationships of the hydrological regime of the glacier are determined by precipitation and air temperature measurements taken at an altitude of 3030 m from 1937 to 1964 and discussed in sections under weather conditions and run-off; run-off and hydrological balance; weather conditions and hydrological balance; and climatic conditions of zero and extreme balance. Formulas are used which relate precipitation, air temperature, and precipitation together with air temperature to height of the névé line. Meltwater run-off is related to precipitation and air temperature. The hydrological balance is divided into tongue balance, névé basin balance, and total glacier balance given in terms of water, cm/km² of corresponding area. The most suitable of the above relationships may be used to establish similar relationships in glaciers under other physico-geographical conditions and facilitate solutions to problems involving regularities in nature and in glacier regimes. -- VDP/FMM

very important. On the average, considering the northern and southwestern slopes the time difference in formation and breaking up of the snow cover was about two months at altitude 2000-2500 m. On the southern slopes stable snow cover is absent. In higher altitudes the orientation is less significant. Influence of altitude is significant. With higher altitude, the snow cover on northern slopes sets 0.7 day earlier for each 100 m., while for the southwestern slopes the gradient is several times more, being on the average three days for each 100 m. Influence of orientation change from the southwest to the north according to the time of snow cover deposition is equivalent to the influence of altitude increase from 800 to 3400 meters in accordance with different characteristics. Thus in the areas with lesser altitude ranges the influence of the orientation may be greater than that of the altitude. (From author's summary)

INFLUENCE OF AVALANCHES ON RUN-OFF FORMATION IN AREAS OF MODERATE ELEVATION IN THE ZAILIISKIY ALATAU. (Vliyanie shezhnykh lavin na formirovaniye stoka v srednegornoj zone Zailiyskogo Alatau; Text in Russian). *Gliatsiologicheskie issledovaniya v Kazakhstane*, Vyp. 6:123-132, Alma-Ata, 1966. 13 refs.
 DLC, QE575.A4

The report is based on the quantitative indices obtained as a result of special field investigations. Névé basins are widely developed on the northern slopes of the Zailiysky Alatau range. In the zone of the deeply dissected topography (1600-3000 m) they are formed by avalanches and fill talwegs of the side valleys and ravines in a shape of long bands. Avalanches occur mostly in the spring on the northern slopes. They strike considerable areas and carry away up to 20 per cent of snow reserves. Hence ground permeability on the slopes stricken by avalanches, varies greatly. Avalanches increase the run-off to the same degree in which the coefficient of snow run-off on slopes is less than one. This increase appears to be rather small, and is expressed in % units of the annual and flood run-off. The regulating effect of névé basins is also not very great. It is concluded that artificial increase of avalanche activity under the above mentioned conditions would be inexpedient. (From authors' summary)

ACCUMULATED RADIATION IN THE ZAILIISKII
ALATAU RANGE ALPINE ZONE. (Summarnaiā
radiatsiā v vysokogornoj zone khrebtā Zailiyskogo
Alatau; Text in Russian). Glābiologicheske is-
sledovaniā v Kazakhstane, Vyp. 6:133-139, Alma-
Ata, 1966. 5 refs.
DLC, QE575.A4

Accumulated radiation is the most important component of the input of radiation balance. Low latitudinal position as well as great height of the glacier result in considerable flow of short-wave radiation. The daily heat amount in June reaches 943 cal/cm². Maximum intensity of the accumulated radiation of 1.98 cal/cm²/min has been observed frequently. The magnitude of the incoming short-wave radiation changes depend on the condition of the Sun. The medium- and upper-level clouds do not have much influence on the intensity of the accumulated radiation. In the annual heat cycle, the maximum may occur in May - August depending on the annual cycle and transparency of the atmosphere. The minimum accumulated heat radiation, as a rule, occurs in December. (From author's summary)

STRATIGRAPHIC ANALYSIS OF A DEEP ICE CORE FROM GREENLAND. Res. Rept. 77, U. S. Army Cold Regions Research and Engineering Laboratory, 133p. incl. illus., tables, graphs, diagr., maps, appendixes A-D, May 1967. 403 refs.
CRREL files

A deep rotary core drilling project in 1957 at Site 2 on the Greenland ice sheet (76°59'N, 56°04'W) provided ice core to a depth of 411 m. The vertical variation in bulk density, macroscopic structure, oxygen isotope ratios, ionic constituents, and extraterrestrial dust (black spherules) were analyzed using both field and laboratory techniques. These data permit the direct estimate of annual accumulation layers in the core. The average total ionic concentration in the ice sheet ranges between 0.65 and 1.35 mg/liter. The annual global mass deposit of black spherules as calculated from these studies varies from 2.10 x 10⁵ metric tons in 700 year old ice to 6.57 x 10⁵ metric tons in 12 year old firn. The oxygen isotope ratio variation provides the best means of estimating accumulation at depth. Results of the investigations indicate rates of net snow accumulation of 42.3, 34.2, 37.4, 41.1 and 41.6 g/cm²-yr at the surface, A.D. c. 1773, c. 1513, c. 1233 and c. 934, respectively. Accumulation data and other physical and chemical evidence allow climatological inferences to be made over the 10-century profile. The ice core record shows that snow accumulation and temperature in A.D. 934 were similar to today, followed by a gradual decrease in accumulation to a minimum around the late 13th century and an increase in both accumulation and temperature from A.D. 1773 to 1957 and following.

DLC, G576.A65

Knowledge of the Antarctic continent's subglacial structure is obtained from a combination of seismic and gravimetric investigations. Beginning with mean sea level at the Davis Sea, elevations sufficiently accurate for the purposes of gravimetry, were determined by trigonometric leveling for 250 points along the oversnow traverses from Mirnyy to Vostok, Pionerskaya, Komsomol'skaya, and Sovetskaya Stations and to the Pole of Inaccessibility. The Faye (free-air) anomalies were determined by SN-3 and Worden gravimeters at 350 points along this route; these anomalies are mapped and lines are drawn connecting regional maximum and minimum values between adjacent traverses. The subglacial relief, as reflected by the free-air anomalies and indicated by other data, is mapped and isohypses are drawn at 500-m intervals. The crustal thickness is estimated from the Bouguer anomalies in accordance with known empirical relationships, and is found to increase from 33-35 km at the coast to 40-55 in the area of the subglacial Gamburtsev Range.

THE PROBLEM OF THE ANTARCTIC PENEPLAIN. (Problema poverkhnosti vyravnivaniya Antarktity; Text in Russian). Antarktika: Dokl. Komis., 1964. Moskva, Izd-vo Akad. nauk SSSR, 1965, p. 61-66 incl. illus, 18 refs.
DLC, G576.A65

Descriptions of various leveled rock surfaces found in Antarctica are compiled, and their geneses are discussed. Peneplained peaks range from 500 to 3700 m in elevation. The peneplain had probably been created through water denudation by the end of the Mesozoic; the present differences in its elevation are due possibly to Neogenic faulting. That Quaternary glacial processes account for part of the peneplanation is indicated by glacial striae and polishing of leveled rock now cropping out far above the icecap. -- DAS

THE PERIMETER OF ANTARCTICA AND THE BUDGET OF THE ANTARCTIC ICE CAP. (Perimetr Antarktity i byudzhet Antarkticheskogo lednikovogo pokrova; Text in Russian). Antarktika: Dokl. Komis., 1964. Moskva, Izd-vo Akad. nauk SSSR, 1965, p. 67-75 incl tables. 30 refs.
DLC, G576.A65

A new calculation of the ice budget for the entire continent of Antarctica is made. For the purpose of accurate determination of the discharge through formation of icebergs, a careful measurement of the coastline was made which showed the length to be 30,030 km. The iceberg discharge is calculated for each type of glacial coastline (outlet glaciers, ice shelves, and continental ice barriers), the total of which is 1180 km³/yr. Other sources of discharge are underwater melting from ice shelves (250 km³/yr) and bottom melting in the central part of the ice cap (20 km³/yr). The total rate of ice accumulation, 2420 km³/yr, is compiled from the value calculated by the present authors for the Antarctic Peninsula and that given by Dolgushin, Evteev, and Kotl'akov (1964) for the remaining part of the continent. A positive ice budget of 970 km³/yr is obtained from these figures. The problem of establishing the accuracy of ice-budget calculations is discussed. The mean quadratic error for this determination is ± 170 km³/yr, or 20%. -- DAS

an attempt is made to compare the various charge-generating mechanisms operant during snowstorms, and to evaluate their relative significances. An equation is given for Q_{max} for a spherical snow particle with radius r . Factors in the equation represent: (1) the charge acquired as a result of collision with larger or smaller particles; (2) electrification of the crystal during its disintegration; (3) charge from random capture of atmospheric ions; (4) charge resulting from friction; and (5) charge arising during phase changes. After evaluation of these factors, the equation is represented in a simplified form with the elimination of (3) and (5) because of their relative insignificance. Likewise, charge losses due to atmospheric electric conductivity and corona discharge currents were not considered. -- DAS

(1963) that the Antarctic icecap is receding, are answered. Zhantuarov and Markov express the opinion that the past 50-yr atmospheric warming trend would not have been sufficient for the warming of a glacier to any significant depth; Shumskii feels they have neglected to account for such factors as convection in calculating heat transfer. The method of determining icecap retreat or advance by calculating the total ice budget, which Zhantuarov and Markov feel has correctly indicated growth of the Antarctic icecap, is not considered sufficiently accurate. Further data are presented which may indicate glacial retreat within the 20th century, for instance, Lady Newnes and Amery Ice Shelves have decreased in area by 2500 km² and 11,000 km², respectively; an 80-km ice tongue has disappeared from the Weddell Sea; and the Astrolabe and Zélée Glaciers have retreated significantly. -- DAS

DYNAMICS OF THE ANTARCTIC ICE SHEET. (O dinamike Antarkticheskogo lednikovogo pokrova; Text in Russian). Antarktika: Dokl. Komis., 1964. Moskva, Izd-vo Akad. nauk SSSR, 1965, p. 138-154 incl. table, graph. 46 refs.
DLC, G576.A65

Criticisms are made regarding the calculations made by P. A. Shumskii and S. A. Evteev (1963), based mainly on evidences from Drygalski I. and Gaussberg, which they believe prove the existence of a general ablation trend for the entire ice sheet. It is felt that various calculations of the total Antarctic ice budget, which have generally indicated that the ice sheet is growing, are more likely to reflect the true situation. Recent investigations have shown that glacial retreat in one area is not necessarily accompanied by retreat elsewhere on the earth, and in particular that warming trends are not uniform over the entire Antarctic. Furthermore, a warming trend beginning only in the 20th century would not be sufficient to warm the Antarctic ice sheet to any significant depth. -- DAS

SOME MECHANICAL PROPERTIES OF ALPINE SNOW, MONTANA 1964-66. Res. Rept. 227, U. S. Army Cold Regions Research and Engineering Laboratory, 56p. incl. illus., tables, graphs, diagrs., appendixes A-F, March 1967. 36 refs.
CRREL files

Data on the physical properties of seasonal alpine snow have been collected from the Beartooth Mountains near Cooke City, Montana, and the Bridger Range near Bozeman, Montana. Systematic measurements of snow density, temperature, structure, ram and Canadian hardness, centrifugal tensile strength and shear strength measured with a shear box and several types of shear vanes are included. Test results were grouped according to gross snow types and whether the snow was wet or dry. Interrelations between the different test parameters were studied. Experiments were also conducted to study the sources of error in making in-situ mechanical tests on snow without utilizing a pit wall. The main factor contributing to the experimental scatter is lateral inhomogeneity in the snow cover. However, the standard deviation of a group of strength tests is shown to be directly proportional to the mean value of the group. The systematic relations between snow properties invariably become obscured when different snow "types" are indiscriminantly grouped together. (Authors' abstract)

DLC, Q115.S686; Q115.S6862

Ten-day measurements at Pionerskaya (Jan. 30, 1957, to Jan. 1, 1958) and Lazarev (March 31, 1959, to Feb. 20, 1961) stations and measurements from snow-measuring cables at Lazarev for the same period are used to determine the accuracy of snow measurements. Both areas are 100 x 100 m and have 41 stakes arranged in checkerboard fashion. The measuring cable consists of legs 40 m long, and measurements are made every meter. The accuracy with which average snow accumulation can be computed increases with the length of the observation period. Accuracy also increases rapidly as the number of stakes in the area is increased to 25; beyond this, the number of stakes has relatively little effect on the percentage of error. The accuracy of stake measurements is taken as 1 cm, and the square error in the computation of the average value from 41 stakes over 2 yr as 3 cm. This error increases by a factor of several tens with a smaller number of stakes and especially when the measurements are made from single stakes. The same applies to single borehole and pit measurements. -- JEB

DLC, Q115.S686; Q115.S6862

CRREL BIBLIOGRAPHY

Geodetic and gravimetric observations were made along the Komsomol'skaya-Sovetskaya-Vostok-Komsomol'skaya traverse from Nov. 12, 1961, to Jan. 11, 1962. Simultaneous geodetic leveling observations were made from opposite ends of consecutive 5.5-km intervals. A relief map of the glacier surface and a table of the elevation of the stations above sea level are given. To investigate the effect of the refraction coefficient on the results of geodetic leveling, systematic observations were made for 24 hr at one 5.5-km interval. Preliminary values of the gravitational and magnetic anomalies indicate that the interior of the continent is a single, very slightly dissected block. The mean annual snow accumulation between Sovetskaya and Vostok was 11 cm. According to the snow stakes at Sovetskaya, the 3-yr snow accumulation there was 60.3 cm.

MAGNETOMETER SURVEY OF THE WEST ICE SHELF. (Magnitometricheskaya s'emka Zapadnogo shel'fovogo lednika; Text in Russian). Sovet. Antarkticheskaya Eksped., Inform. b'ull., No. 43:45-47 incl. map, 1963. 2 refs. (Eng. transl. in: Soviet Antarctic Expedition, Information Bulletin, Vol. 5, Issue No. 1:22-23, 1965).
DLC, Q115.S686; Q115.S6862

During the Fifth Continental Expedition, measurements of the vertical component (Z) of the magnetic field were made at 90 stations on the West Ice Shelf simultaneously with seismic and gravimetric measurements. The values of ΔZ relative to the absolute datum at Mirnyy were obtained from preliminary analysis of the data. The map of these values generally shows a normal field, with intensity increasing gradually from east to west (1500 to 4500 γ). The region of the West Ice Shelf is characterized by a relatively quiet magnetic field with anomalies of 0 to 500 γ . The magnetic field of the ice shelf does not show a clear relationship to the subglacial relief, but individual peculiarities of the bedrock relief may be reflected on the Z_2 map. -- DMN

ABSORPTION OF LONG RADIO WAVES BY THE ANTARCTIC ICE CAP. (Pogloshchenie dlinnykh radiovoln lednyam massivom Antarktity; Text in Russian). Sovet. Antarkticheskaya Eksped., Inform. b'ull., No. 43:49-52 incl. tables, 1963. 2 refs. (Eng. transl. in: Soviet Antarctic Expedition, Information Bulletin, Vol. 5, Issue No. 1:23-25, 1965).
DLC, Q115.S686; Q115.S6862

The field intensity of long-wave radio stations was measured at Byrd Station from March 11-19, 1961, and the results were used to compute the average field for 120°W at noon. The Austin equation was applicable for all radio links except those of the region from the coast to Byrd. Absorption values of 16 to 20 kcs and 1.2 to 2.0 db/100 km were obtained for the Antarctic ice cap. Darkness leads to the greatest increase in field intensity on the Balboa-Byrd line, where the equatorial section comprises a large part of the entire link. Antarctica is south of 65°S and therefore the maximum solar depression angle is 48.5°. Taking into account only the changes in the illumination of radio links, 6 db can be adopted for the index of long waves at night or in winter.

CORROSIVE EFFECT OF MELTWATER ON THE COOLING SYSTEM OF TYPE 7D-12 DIESELS DURING OPERATION IN ANTARCTICA. (Korrodiruyushchee vliyanie taloi vody na sistemu okhlazhdeniya dizelei tipa 7D-12 pri ekspluatatsii ikh v Antarktide; Text in Russian). Sovet. Antarkticheskaya Eksped., Inform. b'ull., No. 43:53-54, 1963. (Eng. transl. in: Soviet Antarctic Expedition, Information Bulletin, Vol. 5, Issue No. 1:26, 1965).
DLC, Q115.S686; Q115.S6862

Meltwater in the closed 2-circuit cooling system of 7D-12 diesels causes the block walls to corrode, apparently from the combined action of electrochemical corrosion and cavitation erosion. Typical corrosion control methods, such as the addition to the cooling water of 0.3 to 1% potassium bichromate, 50 to 100% sea water, or soap, drying oils, or paint, are unsuccessful. During the third Soviet expedition, the cast iron blocks were replaced by aluminum blocks, and even after 4000 hr of operation there was no sign of hole formation. -- JEB

Vol. 5, Issue No. 1:41-43, 1965).
DLC, Q115.S686; Q115.S6862

The sea bottom west of Molodezhnaya Station is a continuation of the structural relief forms of the coastal oasis. Two small islands, 2 to 3 m high, are covered with continental ice that probably was recently continuous with the mainland. A good natural berth 250 m long exists at the edge of the continental ice barrier which rises 3 to 4 m above sea level. Observations of sea level fluctuations in Alasheyev Bight were used to determine the theoretical zero datum of 67 cm in gage readings, established relative to the tidal gage bench mark and the center of the Molodezhnaya astronomical station. The volume of fresh water lakes in the vicinity of the station was also investigated and found adequate to meet any needs of a wintering party. -- JEB

DLC, Q115.S686; Q115.S6862

Off the coast of East Antarctica, polynyas persist throughout the year. They occur on the west side of any ice shelf or northward-projecting cape or peninsula. Their formation and existence are determined by the influence of strong drainage winds and prevailing SE winds on the water surface. Intense evaporation of the open water in these areas restores to normal the dry air arriving from the continent and thus is one of the main factors in cooling or supercooling the water in polynyas. The transport of the supercooled water to coastal regions causes the formation of a large amount of ice under the shore ice. Also, evaporation is accompanied by strong salinization of a thin surface layer which inhibits ice formation and promotes the conservation of open water areas. -- JEB

No. 44:39-42 incl. tables, graph, 1963. 3 refs.
(Eng. transl. in: Soviet Antarctic Expedition, In-
formation Bulletin. Vol. 5, Issue No. 1:52-54,
1965).
DLC, Q115.S686; Q115.S6862

Analysis of a diurnal series of observations yielded the harmonic constants of 4 principal tides. These constants were used to compute the variation in sea level at Lazarev Station Sept. 26 and 27, 1960. The highest spring tide at maximum lunar declination may reach 210 cm. The minimum tide during quadrature and when the moon is located near the equatorial plane decreases to 30 cm. The tides have a mixed, predominantly semidiurnal character. The cotidal hour of the semidiurnal tide is 4.0 hr and that of the diurnal tide, 22.0 hr. The age of the semidiurnal tide is 13.8 days and that of the diurnal tide, 13.4 days. Because the tides in the Lazarev Station region are complex, the harmonic constants obtained from a one-day series of observations are approximate. -- JEB

SUBGLACIAL RELIEF AND THICKNESS OF THE
LAZAREV ICE SHELF. (Podlednyĭ rel'ef i mosh-
chnost' shel'fovogo lednika Lazareva; Test in Rus-
sian). Sovet. Antarkticheskaja Eksped., Inform.
b'ull., No. 44:43-48 incl. diagr., maps, 1963. 2
refs. (Eng. transl. in: Soviet Antarctic Expedition
Information Bulletin. Vol. 5, Issue No. 1:55-58,
1965).
DLC, Q115.S686; Q115.S6862

Fifteen seismic and 150 gravimetric observations were made on the Lazarev ice shelf in 1960-61. The surface relief is generally smooth at 37 m above sea level and slopes gently from southeast to northwest. The ice shelf is 170 to 190 m thick in the western and northern parts. It increases to 375 m in the south and southeast and decreases to 140 m in the marginal area near the station. The ice shelf is located over a relatively deep part of the ocean. Bedrock depth ranges from 90 to 1170 m below sea level. It is suggested that the ice domes on the shelf were formed by icebergs grounded in the shallows, and that the shelf is associated with the development of shore ice which formed and persisted under the protection of the icebergs. -- JEB

DLC, Q115.S686; Q115.S6862

A comparison of surveys of the Princess Martha
Coast between 0° and 3°W (the Trolltung Ice Shelf)
indicates that the tongue of the shelf has a dynamic
front. Instability results from the very ample re-
plenishment of the tongue by ice flowing into the sea
along the Penck Trough and from the lack of support
for the ice. On the basis of various charts, it is
concluded that the shelf advanced at an average rate
of about 1.1 mi/yr from 1939 to 1955. Between 1939
and 1959, the shelf was displaced about 10 mi to the
west. -- DMN

formation Bulletin. Vol. 5, Issue No. 1:60-63,
1965).

DLC, Q115.S686; Q115.S6862

The computations of the mass balance of the Ant-
arctic ice cap by various authors are compared.
It appears reasonable to assume that from 1.70 to
2.30 x 10¹⁸ g/yr of snow are accumulated, while
more than 1.70 x 10¹⁸ g/yr of ice are lost in the
calving of icebergs and about 0.55 x 10¹⁸ g/yr of
ice are lost by the melting of the lower surface of
ice shelves. Using the average values, the mass
balance of the Antarctic ice cap is less than
-0.4 x 10¹⁸ g/yr. -- JEB

SPRING-SUMMER TEMPERATURE REGIME OF THE
SNOW AND FIRN LAYER AT VOSTOK STATION.
(Vesenne-letnĭĭ temperaturnyĭ rezhim snezhno-
firnovoy tolshchi na stanĭtsii Vostok; Text in Russian).
Sovet. Antarkticheskafā Eksped., Inform. bŕull.,
No. 44:63-67 incl. tables, graph, 1963. 2 refs.
(Eng. transl. in: Soviet Antarctic Expedition, In-
formation Bulletin. Vol. 5, Issue No. 1:66-68,
1965).

DLC, Q115.S686; Q115.S6862

The temperature regime of the snow and firn layer
at Vostok Station was studied from a 40 m hole for
100 days in the spring and summer of 1961. Only
the upper 2 m are subject to sharp fluctuations.
Annual temperature fluctuations attenuate at a
depth of 25 m, where a temperature of -57.2°C was
recorded. Below 25 m, the temperature is apparent-
ly subject to long-period fluctuations only. The
temperature gradients decrease with depth as tem-
perature fluctuations attenuate. They vary greatly
with time. The lowest temperatures are recorded
in winter near the surface and in summer, at a
depth of 5 m. The average annual air temperature
for 4 yr (1958-61) were -55.4°, -55.4°, -57.4°, and
-54.2°C, respectively. The difference between the
mean annual air temperature and the firn tempera-
ture at the level of zero annual fluctuations is small
and depends mainly on the upward heat flux and the
presence of radiational heat exchange at the snow
surface. -- JEB

Vol. 5, Issue No. 1:69-73, 1965).

DLC, Q115.S686; Q115.S6862

CRREL BIBLIOGRAPHY

The following investigations of the upper snow layers were conducted during the Komsomol'skaya--Amundsen-Scott traverse of the fourth Soviet expedition:

1) determination of the shear strength of snow under various normal loads and temperatures corresponding to natural conditions of deposition, 2) descriptions of snow structure in pits and determinations of its density, and 3) determinations of the average annual snow accumulation. The equipment and methods used in the determinations are described. Snow density varied little along the route, but its strength varied sharply, apparently due to texture. Snow strength is considerably greater in the Mirnyy region than in central Antarctica; it reaches a minimum between Komsomol'skaya and Vostok, and increases beyond Vostok. The average thickness of annual layers decreases toward the interior. Crystal sizes increase sharply with depth. As the intensity of snow accumulation decreases, the enlargement of snow particles occurs at a lesser depth.

BLACK ICE IN THE ANTARCTIC. (Chernyĭ led v Antarktike; Text in Russian). Sovet. Antarktičeskaja Eksped., Inform. biull., No. 44:82-84 incl. illus., 1963. (Eng. transl. in: Soviet Antarctic Expedition, Information Bulletin. Vol. 5, Issue No. 1:78-79, 1965).

DLC, Q115.S686; Q115.S6862

In 1956 a large area of black ice was seen in the wall of the coastal ice barrier at the head of McDonald Bay, about 12 km SW of Mirnyy Station. It is probable that a huge block of continental ice had turned over, exposing the morainic material embedded in its lower surface. In addition to the usual igneous and metamorphic rocks of central East Antarctica, a flat boulder was found which consisted of calcite-dioptase-acetinolite rock dissected by a calcite sheet vein up to 0.15 m thick containing radiated aggregates of actinolite crystals in the center. This led to the conclusion that greenstone slate facies of regional metamorphism are widespread south of Mirnyy. -- JEB

THE SOVIET'S NEWEST ICEBREAKER LENINGRAD. (NL:n uusin polaarijäänmurtaaja Leningrad, Sovjets nyaste polarisbrytare Leningrad; Text in Finnish and Swedish). Volma ja Käyttö; Kraft och Drift, 60(1): 8-15 incl. illus., table, Jan. 1962.

DLC, TJ4.S73

The diesel-electric icebreaker "Leningrad," a sister ship to the "Moskva" (launched January 1959 and de-

livered June 1960) was launched October 1959 and delivered to V/O Sudimport of Moscow on October 30, 1961. The principal dimensions and characteristics of the "Leningrad" and "Moskva" are presented in a table together with comparative data for the Russian atomic icebreaker "Lenin." The design features, accommodations, and the main and auxiliary equipment and machinery including the three propellers and engines, are described. The 122-m-long "Leningrad" accommodates a crew of 120 men, comprising 40 ship's officers, 24 petty officers, and 56 seamen. The speed of the icebreaker, 18 knots, is the same as that of the "Lenin." The hull is made of high-tensile special steel and is completely welded. It is designed to withstand both the forces suffered during passage through the ice and those caused by the pressure of drifting ice masses. The shell plating has a maximum thickness of 5 cm. The living quarters are heated by warm air radiators to maintain a normal inner temperature at -35°C outer temperature. The mechanical ventilation system permits the maintenance of normal inner temperatures down to -10°C outside temperature. -- AGR

THERMOPHYSICAL PROPERTIES OF FROZEN GROUND. (Teplofizicheskie svoĭstva merzlykh gornykh porod; Text in Russian). Moscow, Izd-vo Nauka, 1965, 72p. incl. tables, graphs, diagrs. 65 refs.

DLC, QE431.5.B

Data on thermal properties of frozen friable rocks (sands, loams, clays, and sandy loams) are compiled and systematized. Basic concepts are reviewed regarding the forms and coefficients of heat transfer in thawed and frozen ground and in that undergoing freezing or thawing. Relationships of volume/heat capacity and temperature and thermal-conductivity coefficients on moisture, density, and temperature are shown analytically and graphically. The thermophysical properties of snow and ice are discussed in terms of their physico-mechanical properties, such as porosity, structural characteristics, and temperature. The effect of lowering the coefficient of thermal conductivity in rock in the first stage of thawing is demonstrated. The influence of cryogenic textures on the thermophysical properties of frozen ground, particularly of laminated and reticulate textures is discussed. The temperature dependence of the coefficients of bound-water transfer in frozen ground is treated, and fundamental methods for determining thermophysical properties of rock in various frost stages are presented. -- DAS

SNOW REMOVAL FROM RAILWAY SWITCHES.
 (Ochistka strelok ot snega; Text in Russian). Moscow, Tranzheldorizdat, 1962, 36p. incl. illus., tables, diagrs. Ref.
 DLC, TF542.O2

Specifications and recommendations are given for operation and maintenance of pneumatic devices and electric heaters for snow removal at switch points. A semi-automatic device with electrical startup consist of a control unit, air tank, and electropneumatic valves; compressor; and a 24-v energy source. Intermittent blasts of air not exceeding 400 ml between the switch point and the rail clean a switch in 1 to 3.2 sec or 51 switches in 3 min. A similar device consists of an automatic valve, a switch, and 2 air distribution pipes with outlets. A hand operated blower with 30 mm³ nozzle area is recommended for use on lines with low traffic. An electric heating device is also described which uses a helical nichrome wire coil stretched in a seamless steel tube packed with magnesium oxide powder. It is used as a straight tube 5800 mm long and 16 mm in diameter, placed between the switch point and the rail, or as a bent tube 9400 mm long, placed around the switch base. A safety device automatically controls short circuits and excessive heater amperage.

EXPERIMENTAL CONSTRUCTION OF A FROZEN-TYPE DAM IN YAKUTIA. (Opyt stroitel'stva plotiny merzlogo tipa v Yakutii; Text in Russian). Yakutsk, Yakutskoe knizhnoe izd-vo, 1964, 70p. incl. diagrs. 19 refs.
 DLC, TC543.L9

An experimental dam was constructed on the Ireliakh River at Mirnyy in central Yakutia, using the method of natural winter freezing of the anti-filtration core integral with the permafrost foundation and river valley walls. The lower facing wall was built of loose frozen rock which subsequently compacted and settled after spring thawing; the upper facing wall was constructed in spring of partially and completely thawed rock by mechanical compaction. The operating and temperature regimes of the dam and spillway were observed for over a year, and the following conclusions were drawn: 1) the construction of this type of dam is much more economical in the Far North than the non-frozen or the artificially frozen types; 2) due to its monolithic, permanently frozen core, the dam has fewer weak points than the non-frozen type; 3) the frozen state of the core can be maintained naturally year-round in climates similar to that of Mirnyy and artificially in warmer climates; 4) an inlaid stone spillway is the most economical, is sufficiently reliable, and can be used even when a talik has formed in the stream bed. Recommendations are given for organization of construction of frozen dams in permafrost regions. -- DAS

STRENGTH AND STABILITY OF FROZEN GROUND. (Prochnost' i ustoychivost' zamorozhennykh gornykh porod; Text in Russian). Moscow, Izd-vo Nedra, 1965, 78p. incl. illus., tables, graphs, diagrs. 30 refs.
 DLC, Slavic Div.

A variety of soil types -- clays and medium, fine and powdered sands -- from various mining regions were subjected to laboratory tests for compressional and shear strength in the frozen state. The strength was found to depend on the temperature of freezing, physico-mechanical properties (i. e., moisture, porosity, and granulometric composition) and on load duration. Creep occurs in all samples and under constant stress reduces strength by several factors. Strength ratings and their parameters are de-

termined for instantaneous and continuous stress. Under a continuous load the decrease in overall value of shear resistance takes place only as a result of a decrease in the cohesive coefficient, with the angle of internal friction remaining constant. Results of field observations on the temperature regime of shaft walls stabilized by freezing are presented. A proposed method for determining the depth and stability of an artificially frozen bare rock wall is based on the plastic, elasto-plastic, and elastic zones in a cylindrical shaft. Depth calculations are related to strength of the frozen rock or to deformation of the frozen rock wall.

INFLUENCE OF SURFACE CONDITIONS ON GROUND TEMPERATURE. Can. J. Earth Sci., 4(2):199-208 incl. graphs, April 1967. 8 refs.
 DLC, QE1.C17

Ground temperatures were measured under two parking lots, one of which was cleared of snow in winter, and monthly and annual average surface temperatures were estimated by extrapolation. The surface temperatures were compared with monthly and annual surface and air temperatures measured at a nearby grassed site. A dependence of the difference between the monthly average surface and air temperatures on snow cover and convective loss was observed. A correlation was found to exist between the monthly average of the daily global solar radiation and the difference between monthly average air temperature and monthly average parking lot surface temperature. It was demonstrated that, because of a change in surface conditions, there was a change in annual average ground temperature beneath a parking lot. The observations are discussed with reference to the formation of sporadic permafrost. (Author's abstract)

SOME TRACE ELEMENTS IN LAKES OF McMURDO OASIS, ANTARCTICA. Geochim. Cosmochim. Acta, 31(5):731-736 incl. table, map, May 1967. 24 refs.
 DLC, QE351.G425

In order to study the origin of a number of highly saline lakes in the Taylor and Wright Valleys, the concentrations of Zn, Pb, Bi, Fe, Mn, and Mo were determined by a combined spectrochemical and solvent extraction procedure. From the measurement of ionic ratios, it was concluded that there was some evidence for Lake Bonney having had a sea water origin. It was also deduced that Lake Fryxell may have contained sea water in the past. (Authors' abstract, modified)

SNOWPLOW: CLEARING MOUNTAIN RAILS.
 Berkeley, Howell-North Books, 1966, 119p. incl.
 illus., tables, graph, diags., map, appendix.
 DLC, TF542.B4

This book presents an illustrated history and development of the battle against snow on the railroad which crosses the Sierra Nevada between Sacramento, California and Reno, Nevada. Emphasis is placed on equipment used by the Central Pacific and Southern Pacific railroads, snowshed construction, methods to prevent fires in the sheds and forests, the Bucker snowplow, rotary snowplows, and notable snowstorms and attempts to overcome them. The appendix has rules for operating the rotary snowplow, lists snowplows giving basic information such as builder, date built, dimensions, purchaser, status (in use or out of use), etc. Diagrams are given of snowshed types. -- BLE

 DLC, QE575.A43

Most snow-accumulation features are of the drift type. They consist mainly of firm and infiltration ice and can be characterized as seasonal or intra-seasonal formations. Those which survive the summer may cover 5 to 7% of the ice-free rock area and attain dimensions of 80 x 200 x 15 m. Seasonal snow strips and ridges are formed in valley bottoms and hollows. The melting of snow deposits causes intensive nivation and in some cases leads to the formation of solifluction terraces and rudimentary cirques in small valleys. Rock deposits are rare at the glacier edge but increase in area toward the north. Nival processes occurring on the moraine surface create moraine-nival deposits--usually represented by viscous loam--and accumulations of eolian aleurite. Melting of snow beds plays an important role in forming cement ice, segregation ice, and vein ice in the layer of friable Quaternary deposits. -- DAS

THE MEANING OF THE TERM "ANTARCTIC OASIS."
 (O sodержanii ponĭatiā "Antarkticheskiĭ oazis"; Text in Russian). Akad. nauk SSSR. Inst. geogr., Mater. glaciol. issled. Khronika, obsuzhdeniā, No. 12: 255-257, 1966. 7 refs.
 DLC, QE575.A43

The term "Antarctic oasis" entered the literature in the works of the British Antarctic Expedition of 1934-37. In view of the confusion which has characterized the use of the term in the Antarctic literature to date, clarification is considered imperative, and the following definition is proposed: those ice-free portions of the marginal zone of the continent that have a comparatively smooth, hummocky topography. The oases are distributed within the limits of the glacial accumulation area and possess a specific complex of landscape elements: 1) local frigid desert climate; 2) a hydrological regime dominated by undrained lakes and temporary streams; 3) irregularly distributed vegetation, consisting mainly of epilithic, scablike, and bushy lichens; and 4) an animal population represented by several species of penguins, petrels, and skuas.

SOME RESULTS OF 10 YEARS OF SOVIET GLACIOLOGICAL RESEARCH IN ANTARCTICA. (Nekotorye itogi sovetsskikh glatsiologicheskikh issledovanii v Antarktide za 10 let; Text in Russian). Akad. nauk SSSR. Inst. geogr., Mater. glatsiol. issled. Khronika, obsuzhdeniia, No. 12:283, 1966.
DLC, QE575.A43

Results are summarized from papers presented in 1966 at a meeting of the Geographical Society of the USSR and institutes participating in Antarctic research. Snow accumulation studies indicate a rate varying from 50 to 70 g/cm²/yr in coastal and some shelf areas to 5 to 15 g/cm²/yr on the plateau. The thickness of the snow-firn layer is 10 to 20 m at the coast, 100 m at Pionerskaya Station, and 150 m in the interior. The time required for snow to transform into ice is calculated. Studies of East Antarctic bedrock relief reveal extensive depressions 1500 m below sea level and a 2500-km-long mountain system which rises in some areas to 3000 m above sea level. From temperatures at the 20 to 25-m level in boreholes, the mean annual temperatures of the surface air layer at Vostok Station, the Pole of Inaccessibility, and the highest point of the plateau are determined to be -57.0°, -57.2°, and -59.2°C, respectively. The rate of movement of the ice sheet edge is 100 to 200 m/yr, while that of large outlet glaciers is 1000 to 1200 m/yr, -- DAS

DLC, QE575.A43

The Antarctic ice shelf theory of Pleistocene glaciations proposed by A. T. Wilson (See SIP 21931) is summarized, and critical comments are added. The strong point of the theory is its use of modern geographical and geophysical data. Very recent mass balance calculations, however, cast doubt on the basic premise, which involves mass increase of the Antarctic ice cap at present and during interglacial periods in general. Recent observations indicate much higher rates of ice movement and iceberg calving in marginal regions than those utilized in earlier mass balance calculations. Wilson's hypothesis still deserves attention because of its emphasis on the interaction of natural processes accompanying glaciation and the possibility of their autoregulation.

PHASE COMPOSITION OF FROZEN MONTMORILLONITE-WATER MIXTURES FROM HEAT CAPACITY MEASUREMENTS. Res. Rept. 218, U.S. Army Cold Regions Research and Engineering Laboratory, 14p. incl. tables, graphs, diagr., May 1967. 15 refs.
CRREL files

Equations are presented which form the basis of a method for determining the unfrozen water content of frozen clay-water mixtures from heat capacity measurements. The heat capacity of frozen sodium-montmorillonite water mixtures was determined at -4.7 and -9.6°C with a Calvet Microcalorimeter. The data were then used in conjunction with the method described to obtain the unfrozen water content of these clay water mixtures. The data obtained indicate that the method is applicable at temperatures below about -5°C. The amount of unfrozen water found in the frozen clay-water mixtures at -5 to -10°C is equivalent to an interfacial surface layer of water of from one to two molecular diameters in thickness. Most of this water can be accommodated and is thought to be located in interlamellar regions. (Author's abstract)

The "Moskva" has eight 3250 hp diesel engines, 4

CRREL BIBLIOGRAPHY

each in separate compartments, turning the GM 434/80-80 generators to produce power for 3 electrical screws. The power is distributed among the shafts in the ratio 1:2:1, and with varying switching arrangements of the diesel generators, necessary power can be obtained in different combinations up to a 100% capacity. The Woodworth constant speed electro-mechanical hydraulic regulators enable engine operation at 3 rates: 330, 300, and 260 rpm. Load tests were carried out at the 3 operating rates. The power of each diesel engine was determined. Fuel consumption was determined at different speeds for 4 loadings at 25, 50, 75 and 100% of nominal load. Graphs show the amount of power and hourly fuel consumption relative to the vessel speed in open water and to various engine speeds. An analysis shows that 330 rpm is the optimum rate to develop main engine power beyond 21,000 hp. When working with less power, 300 rpm is more economical, and reduces piston wear. Operation at 260 rpm is not effective because scavenging and combustion deteriorate which results in increased scale formation. Smooth functioning and control of diesel fuel flow by maintaining constant pressure of the scavenging air is described and related to exhaust gas analysis. -- VDP/FMM

ABOUT THE SELECTION OF THE INJECTION PUMPS OF THE MAIN DIESEL-ENGINES FOR ICEBREAKERS WITH ELECTRIC POWER TRANSMISSION TO SCREW PROPELLORS. (O vybore toplivnykh nasosov glavnykh dizelei dlia ledokolov s elektropredachei na grebnye vinty; Text in Russian). Sudostroenie, 28(11):33-35 incl. table, graphs, Nov. 1962.
 DLC, VM4.S8

Icebreaker operation requires that the power generators provide constant engine speed despite frequent and sharply changing shaft torsion moments. The required engine speed reaction to load variations is insured by a constant speed governor which varies fuel injection pump rate. The control of fuel injected into the cylinders is accomplished in 3 ways: by modifying 1) starting or 2) closing time of injection into the cylinder or 3) modifying both. Opinion is that the second way is the best for diesel engines driving electric generators; the third way is possible. The first way is not recommended, but may be desirable in other cases. The main technical characteristics of the diesel engines on the "Moskva" are tabulated. Curves of the engine performance at varying loads and speed are provided. -- VDP/FMM

DETERMINATION OF THE DIAMETER OF THE RUDDERSTOCK OF ICEBREAKERS AND OF ICE NAVIGATING VESSELS. (Opredelenie diametra ballera rullia ledokolov i sudov ledovogo plavanija; Text in Russian). Sudostroenie, 28(12):13-15 incl. tables, graphs, Dec. 1962.
 DLC, VM4.S8

The experience of operating icebreakers and ice navigating vessels in Antarctica has proved that the rudder mechanism is often damaged. The most frequent and important kind of damage results from rudderstock torsion caused by ice force compression or stern ramming of the ice channel edge. The rudderstock for Class L ships of the Register of USSR (the Register of USSR lists the standard specifications for sea and river boats of the merchant marine; Class L (Class III of the Register) is the lowest class of ice navigating vessels), are subject to large residual torsion damage. The most successful rudder construction has come from ordinary castings with horizontal ribs. Mathematical formulae are proposed for the computation of the torsion moment for the rudderstock under ice compression. A formula is proposed for determining a conventional value (k) for measuring relative rudderstock strength taking into consideration the material, dimensions, and the Register standards (N). Tables provide the value k for the rudderstock of 1) a series of icebreakers and ice navigating vessels cited by name, and 2) for vessels of Class UL (Class I and II) classified according to value N. A mathematical formula, which includes factors k and N, is proposed for computing the rudderstock diameter. -- VDP

PENDULUM STEERING FOR THERMAL PROBES IN GLACIERS. Spec. Rept. 116, U. S. Army Cold Regions Research and Engineering Laboratory, 8p. incl. diagrs., July 1967.
 CRREL files
- Pendulum steering, a new concept of attitude stabilization for thermal probes or coring drills in ice, eliminates instability. The center of support is placed above the center of gravity. A lower and upper hot point produce melt penetration. The ratio of their power levels is the basis for stabilization, which is provided by the automatic control of the heater in the upper hot point. This feature makes possible a single thermal probe design that is suitable for all ice cap temperatures and a wide range of penetration rates (i. e., applied power levels).
- The simplicity of a thermal probe with pendulum steering suggests availability at modest cost and versatility as a widely applicable tool. -- BLE

REPORT OF THE ANTARCTIC ICE OBSERVING AND FORECASTING PROGRAM- 1965. Spec. Publ. 80(65), 26p. incl. illus., tables, maps, appendix A, Jan. 1967.
DLC, Tech. Rept. Collection

This report describes the ice program conducted by the Naval Oceanographic Office principally in support of Deep Freeze 66 Antarctic operations. Methods of data collection and dissemination, ice forecasting, and various allied ice projects are discussed. A summary of ice conditions in the Ross Sea and McMurdo Sound is given graphically for the period Oct. through Dec. 1965. Ice concentrations were near normal during the Deep Freeze 66 operation, but they were somewhat heavier than those experienced during Deep Freeze 65. Rapid disintegration of the ice during late Nov. resulted in nearly ice-free conditions in the Ross Sea by mid-Dec. Because of persistent northerly winds that prevented the ice from drifting northward into warmer waters, McMurdo Sound remained congested until mid-Jan. (Author's abstract modified)

CONCRETE WITH HIGH RESISTANCE TO FROST AND DE-ICING SALTS. (Beton mit hohem Frost- und Tausalz-widerstand; Text in German). *Beton*, 15(11):469-474 Nov. 1965 and 15(12):509-515, Dec. 1965 incl. illus., tables, graphs. 38 refs. + 71 refs.
DLC, TA680.B36

The paper discusses the mechanics of damage to concrete roads and sidewalks as a result of frost action and de-icing salts. Particular emphasis is placed on aggregate type and the influence of air pores on frost and salt resistance. The composition of an ideal young concrete with a high resistance to frost is described, and data are given on the results of investigations. Continuation of the paper discusses the manufacture of high frost resistant concretes with emphasis on various types of cement and aggregates. Standard mixtures are given for concrete blocks for streets and sidewalks, and testing processes for determining freeze-thaw durability are described. It is concluded that best resistance will be obtained if the aggregate is free from clayey and micaceous particles, and if the water-cement ratio, air pore content, and particle size are kept within a prescribed range. Very young concrete can be made completely resistant to salt damage by saturating it with diluted linseed oil or with epoxy resin solutions. -- BLE

THE HEIGHT OF THE GLACIATION LIMIT IN SOUTHERN BRITISH COLUMBIA AND ALBERTA. *Geografiska Annaler*, 48A(3):126-138 incl. illus., graph, maps, 1966. 31 refs.
DLC, G25.G4

A number of methods for determining the climatic snowline are described. The firn line on glaciers will normally lie slightly lower than the climatic snowline; however, most previous methods for its determination are connected with observations on glaciers. From a study of the distribution of glaciers and the altitudes of surrounding mountain summits, it is possible to determine a critical height (the "glaciation limit") which has normally to be exceeded if glaciers should form. This height is about 100 m above the climatic snowline. The glaci-

CRREL BIBLIOGRAPHY

ation limit was determined on a large number of topographic maps, the results plotted on a small-scale map, and contour lines were drawn showing its regional variation in southern British Columbia and Alberta. The source material and possible errors in the determinations are discussed. A comparison is made with different maps showing precipitation, continentality, land surface elevation, and the 1961 firn line altitude on glaciers. It is concluded that the height of the glaciation limit is inversely connected with the precipitation distribution. (Author's abstract)

Kim, Dong-Yun and V. Hugo Schmidt
SEMICLASSICAL THEORY OF PROTON TRANSPORT IN ICE. *Can. J. Phys.*, 45(4):1507-1516, April 1967. 15 refs.
DLC, QC1.N332

A method is described for calculating proton or other ion mobility which is applicable if mobility is limited by lattice scattering rather than by barrier jumping. The Boltzmann transport equation is used, with the collision term calculated from the electrostatic interactions between the mobile ion and the vibrating lattice. In particular, the proton mobility in ice is calculated. The lattice vibrations are approximated by a Debye spectrum for translational vibrations of water molecules, plus an Einstein spectrum for modes in which protons vibrate almost as independent particles. Scattering by phonons somewhat below the Debye cutoff frequency is of the greatest importance in determining the mobility, and the proton modes have negligible effect. The calculated mobility agrees reasonably well with the experimental value. (Authors' abstract)

Lennon, Joseph T.
FIGHTING SNOW IN URBAN AREAS REQUIRES GOOD COMMUNICATIONS. *Better Roads*, 37(7):25-27 incl. diagr., July 1967.
DLC, TE1.B27

Experience in New York City has shown that a central communications network is indispensable in a snow and ice control organization. The variance of local snow situations demand timely information and progress reports of weather forecasts and direct reports from various scenes of actual operations. Only with such information can personnel, equipment, and material be used efficiently. In the past several years, New York City's communication facilities have been expanded to include a two-way radio system of nearly 140 units installed in vehicles of field supervisors, which give almost instantaneous contact with the heads of the 57 sanitation districts into which the city is divided. Plans are made to expand the radio system by installing two-way sets in some of the operational vehicles. The present system of teletype communications has been in use for more than 25 years. It does not provide over-all two-way communications but it has served well. Telephones will always be a basic component of the system, especially for confidential conversations and unavoidably lengthy exchanges of ideas. The main shortcomings of the radio network lies with the people who use it. -- BLE

Mueller, Don R.
HOW TO CHOOSE THE RIGHT SPREADER. *Better Roads*, 37(7):33-35 incl. illus., July 1967.
DLC, TE1.B27

Spreading equipment for ice control work can be divided into two categories: tailgate type and hopper type. Tailgate spreaders are less expensive to maintain and can be mounted on smaller more maneuverable trucks. The most common power sources and control means available for tailgate spreaders are: (1) chain drive from rear wheel of truck, (2) straight hydraulic drive, and (3) variable control hydraulic drive. Most tailgate spreaders are classified as the tailgate-replacement or the under-the-tailgate type. Hopper spreaders usually have a greater capacity than tailgate spreaders and larger trucks can be used. They can be used in low clear-

CRREL BIBLIOGRAPHY

ance areas and the spreading disc remains about the same height from the pavement throughout the spreading operation. Hopper spreaders are designed with variations in width and slope, variations in conveyors, and variation in drives. Usually the hydraulic pump that drives a spreader is large enough to handle any other hydraulically controlled device which may be mounted on a truck. By planning ahead, one can buy a truck that will receive a power take-off and pump and then buy the other hydraulic accessories, less their pumps. -- BLE

THE CASE FOR RUBBER SNOWPLOW BLADES. Better Roads, 37(7):35, incl. illus., July 1967. DLC, TE1.B27

A rubber snowplow blade that underwent two winters of testing in Canada has been introduced by Goodyear Tire and Rubber Co. In one test, the rubber blade was worn only 2 in. along its entire length after removing snow from 3500 miles of highways. The blade can be turned over so that a new plowing edge is available when one side wears. It flexes during plowing and its entire bottom edge is in contact with the surface to be plowed. The blade passes over or bounces off obstacles such as frozen ruts, stones, and manhole covers. Two city street departments have experienced very good results with the blades. Directions are given for mounting the rubber blades. -- BLE

Bradie, Richard A. SLAR IMAGERY FOR SEA ICE STUDIES. Photogram. Eng., 33(7):763-766 incl. illus., July 1967. 6 refs. DLC, TA593.A2P5

The process of obtaining aerial photographic coverage of Arctic regions has been hampered by inclement weather, cost, and amounts of imagery necessary for adequate coverage. Recent studies utilizing Side-Looking Airborne Radar (SLAR) imagery have illustrated its value for collecting imagery during day or night, during periods of bad weather, and covering large amounts of land and water masses on relatively small amounts of film. The value of timely and continuous ice observations is evident for military and commercial applications. A brief historical background to the ice-observation program includes a

comparison of radar versus conventional imagery acquisition and graphic examples of ice interpretation from radar flights. Key sea ice features commonly associated with the physical process of formation, growth, drift, deformation, and disintegration are readily identified by SLAR. (Author's abstract, modified)

Kamb, Barclay, Anand Prakash, and Carolyn Knobler. STRUCTURE OF ICE V. Acta Crystallogr., 22(Pt. 5):706-715 incl. tables, diagr., May 10, 1967. DLC, QD801.1523

Ice V, the high pressure ice phase stable at pressures of about 3 to 6 kbar, density 1.23 gm/cm³, has a structure involving 28 H₂O molecules in a monoclinic cell. The structure is a single tetrahedral framework, rather than a "self clathrate" as occurs in the denser forms ice VI and VII. Each oxygen atom is hydrogen bonded to 4 near neighbors at distances of 2.76-2.87 Å, and the shortest next-nearest neighbor distance is 3.28 Å. Distortion from ideal tetrahedral coordination is rather large, bond angles (at oxygen) ranging from 84 to 128°, with an rms deviation of 18° from 109.5°. There is no indication of bifurcated hydrogen bonds. Proton ordering is not possible in the space group A2/a indicated for the oxygen atoms. A proton-ordered structure is possible in space group Aa, but is considered unlikely on the basis of comparison with X-ray evidence for proton order in ice II. For the ice V structure to remain proton disordered on quenching to 120°K (the experimental conditions), the ordering energy must be less than 0.14 kcal/mole. (Authors' abstract, modified)

Schwerdtfeger, W. ANNUAL AND SEMI-ANNUAL CHANGES OF ATMOSPHERIC MASS OVER ANTARCTICA. J. Geophys. Res., 72(14):3543-3547 incl. table, graphs, July 15, 1967. 12 refs. DLC, QC811.J6

The annual march of atmospheric pressure at the surface is analyzed for 15 Antarctic stations. For a combined series, weighted so that it represents pressure changes over the whole continent, the first and second harmonics are significant. The most pronounced rise, of almost 13 mb, occurs between the end of Sept. and the middle of Jan., concomitant with the partial filling of the southern circumpolar vortex. This rise corresponds to an increase of about 2 x 10¹⁸ g in atmospheric mass over the continent. Variations of such magnitude can affect

CRREL BIBLIOGRAPHY

meridional mass-exchange in high southern latitudes and sea-level changes in Antarctic waters; they also slightly affect the moment of inertia of the Earth. (Author's abstract, modified)

Payne, F. A.
FURTHER MEASUREMENTS ON THE EFFECT OF ICE COVER ON SHALLOW-WATER AMBIENT SEA NOISE. J. Acoust. Soc. Amer., 41(5):1374-1376 incl. graphs, May 1967. 6 refs.
 DLC, QC221.A4

The results are presented of shallow-water ambient-noise measurements made during the 1963-64 winter under open water and ice cover conditions at Prince Edward Island. Through the use of improved equipment, measurements were made that covered a greater range in frequency (3-3200 cps) and noise levels than previously reported for this area. The results have generally corroborated those obtained in 1961-62. The 1963-64 measurements have extended the spectra toward lower frequencies, where both the open-water and under-ice spectra exhibit interesting features. It appears that there may be more than one source of ambient noise contributing to the low-frequency levels. While no data have been gathered to establish the existence of second-order pressure variations in the present investigation, they cannot be ignored as a possible source of low-frequency ambient noise. Some support for the hypothesis that turbulent pressure fluctuations are the source of the low-frequency noise is suggested by the lowest spectrum level curve below 20 cps in the under-ice spectrum. The relationship of wind speed to shallow-water ambient noise has not yet been clarified. -- BLE

ELECTRICAL RESISTIVITY MEASUREMENTS ON ICE SHEETS. J. Glaciol., 6(47):623-633 incl. tables, graphs, June 1967. 15 refs.
 DLC, GB2401.J68

Several D. C. electrical resistivity measurements have been made on the Greenland Ice Sheet and on Roosevelt I. and the Ross Ice Shelf in Antarctica. These measurements were made in order to study the variation of the specific resistivity with depth and to investigate the existence of low resistivity layers at the bottom of the ice sheet. The results show that the electrical resistivity of firn and ice of ice sheets is a function of the "base" resistivity, the contact resistance between the grains, and the temperature. At greater depths, temperature is the predominant influence, and observed resistivity curves can be explained by temperature variations that agree in part with the theories of heat conduction in ice sheets. LABORATORY MEASUREMENTS OF THE RESISTIVITY OF ICE. J. Glaciol., 6(47):643-650 incl. illus., graphs, June 1967. 9 refs.
 DLC, GB2401.J68

An attempt has been made to measure the D. C. resistivity of ice directly by placing plane-parallel samples between two electrodes with guard rings. Very strong polarization effects were observed which were most pronounced in ice from an ice-cored moraine, lesser in glacier ice, and least in artificially frozen ice. The electric resistivity of ice varies with time when current is flowing through

CRREL BIBLIOGRAPHY

the ice. The resistivity drops during the first few minutes, then it rises again and will reach its first observed value within 30 to 60 min. It is possible that free ions in the interstices between ice crystals are responsible for this effect, as the amplitude of the variation is less at lower temperatures. Variations in the electrical resistivity of ice samples seem to depend on the direction of the current.

GROWTH MODES OF ICE CRYSTALS IN SUPERCOOLED WATER AND AQUEOUS SOLUTIONS, *J. Glaciol.*, 6(47):651-662 incl. illus., graphs, diagr., June 1967. 17 refs.
DLC, GB2401.J68

The growth modes of ice crystals in supercooled water and various aqueous solutions were studied at different supercoolings by a motion picture technique. In pure water contained in plastic capillary tubes, ice dendrites formed which at supercoolings between 1 and 4°C grew parallel to the tube axis. At supercoolings larger than 4°C, the direction of growth was inclined to the tube axis such that the dendrites hit the tube wall and afterwards proceeded growing in a new direction. As a result it appeared that the ice crystals grew in a zig zag or screw fashion. This growth mode became enhanced when the supercooling was increased or salts were dissolved in the water. In large water drops, ice dendrites formed which at supercoolings smaller than 1°C were co-planar with the seed crystal and between 1° and 5°C split into 2 dendritic segments. At supercoolings larger than 5°C, multiple splitting of the seed crystal was observed and this became strongly enhanced when salts were dissolved in the water. Tentative explanations for these results are given. (Author's abstract)

ICE-BRINE DENDRITIC AGGREGATE FORMED ON FREEZING OF AQUEOUS SOLUTIONS, *J. Glaciol.*, 6(47):663-679 incl. illus., graphs, diagrs., June 1967. 13 refs.
DLC, GB2401.J68

Dendritic aggregates of ice and brine formed on freezing of aqueous solutions have been studied. Chlorides of sodium, potassium, lithium, and hydrogen were used as solutes, and the structures produced on freezing of binary, ternary, and quaternary solutions were examined. Effects of freezing rate, solute concentration, solute diffusivity, mixing of solutions, and magnetic fields are reported. The spacing between ice platelets or dendrites was found to be proportional to the square root of the freezing time when the freezing rate was

constant from beginning to end of solidification. During unidirectional freezing from a constant temperature chill, the solution at each location is subjected to a spectrum of freezing rates; dendrite spacing increases linearly with distance from the chill surface and it is inversely proportional to the square root of the maximum freezing rate. In binary solutions, dendrite spacing increases linearly with solute concentration; above a critical solute concentration, ice platelets develop side branches. At a given solute concentration, spacing between ice dendrites increases linearly with solute diffusivity. In ternary and quaternary solutions, dendrite spacing is a function of the concentration and diffusivities of each of the constituent solutes. (Authors' abstract)

ICE LENSING, THERMAL DIFFUSION AND WATER MIGRATION IN FREEZING SOIL, *J. Glaciol.*, 6(47):681-694 incl. illus., graphs, diagr., June 1967. 18 refs.
DLC, GB2401.J68

When a surface layer of the soil freezes, both heat and water diffuse from the unfrozen soil beneath to the frozen region. Often the soil does not freeze homogeneously but distinct ice lenses form. An analysis of the diffusion and ice nucleation processes suggests conditions under which ice lensing can be expected; in particular, it is shown that multiple ice lenses cannot form unless the soil thermal diffusivity is greater than the water diffusion coefficient. Analysis of a simple one-dimensional case (a semi-infinite mass of homogeneous soil whose surface temperature is suddenly lowered) gives the temperature and water-content fields as functions of time; these agree with those observed in an experimental study of freezing clay. PLASTICITY SOLUTION FOR A GLACIER SNOUT, *J. Glaciol.*, 6(47):695-713 incl. table, graphs, diagrs., appendixes A-C, June 1967. 9 refs.
DLC, GB2401.J68

The flow near the end of a glacier in a steady state is investigated by using a theoretical model: a plastic rigid material with a constant flow stress resting on a rough horizontal bed. Starting from an appropriately chosen slip-line far from the end, the slip line field is constructed numerically and continued to the end of the glacier. The field rapidly settles down to a form independent of the precise starting conditions. In the region of small surface slope it agrees with the approximate analytical solution reported earlier. To avoid a breakdown in the method it is found necessary to modify the bed by a

CIREL BIBLIOGRAPHY

trivial amount over the final 3 m. In practice the ice can lose contact with the bed very near the end, and the effect of this on the solution is discussed. The velocity field is computed for a uniform ablation rate. Other distributions of ablation rate could be accommodated, but there appears to be a critical gradient of ablation rate beyond which the slip line field falls. (Author's abstract)

TUBULAR ICE CRYSTALS. *Nature*, 215(5098):271-273 incl. illus., diagr., July 15, 1967. 8 refs.
DLC, Q1.N2

A simple method is described for growing hollow ice tubes or needles of controlled size for physical testing. Some of the crystallographic characteristics are reported, and evidence is presented which supports and extends Dorsey's mechanism. Dorsey assumed that needle growth occurred when, because of an increase in volume during solidification, water in an open container is forced through an opening in the ice surface. He suggested also that a tube formed through which water flowed and which "grew" at the tip. The apparatus used in the present experiment consisted of a cell, a cold trap, and a rotary vacuum pump. Crystallographic orientation was determined in polarized light and with an etch pit technique. Microscope observation showed that the tube wall was clear, but the frozen core occasionally contained small bubbles of air or vapor. Visual observation was made of the formation of the ice cover, water flow through the tube, and growth at the tip. It is pointed out that in practice the process is made feasible only by the high surface tension of water and the apparently low polarity of the ice surface which prevents overflow. It is concluded that tubes from substances other than water could be grown if an experimental technique could be devised to create suitable conditions. -- BLE

SPIRAL AIR BUBBLES IN ICE. *Nature*, 214(95):1324-1325 incl. illus., diagr., June 24, 1967. 4 refs.
DLC, Q1.N2

Air bubbles and brine inclusions in intercrystal boundaries in ice polycrystals are illustrated and discussed which were grown slowly from a 0.1% solution of NaCl. Direct observation of the formation of the spiral air bubbles is difficult, but from a few observations of the formation of less perfect spirals, their origin appears to be as follows. First, an air bubble nucleates within an intergranular brine film. As the bubble grows it tends to become surrounded by ice-ice contact, i.e., the brine film "shrinks" away from it, cutting off its air supply. When the rates of growth of the air bubble and the ice-ice contact have just the right ratio, the spiral bubbles form. After growth, no brine is in contact with the spiral bubbles. The spiral shape can not have any relation to dislocations and, even though they form in thin films rather than on free surfaces, the principles of their formation may apply to the spirals on metals. Many if not all of the patterns expected from pairs of screw dislocations are expected from this mechanism also, though the spiral air bubbles are so infrequent in ice that no interacting spirals have been found. In the etching of crystal surfaces, spirals of this sort may form by precipitation of a new phase at the edge of an adsorbed surface layer which is either forming radially or breaking up radially. -- BLE

ON ETCHING OF SNOW CRYSTALS. (Yuki no kesshō no fushoku; Text in Japanese with English summary). *Telon-kagaku* (Low Temp. Sci.), Ser. A, 24:57-80 incl. illus., diags., 1966. 5 refs. DLC, Orientalia Div.

Chemical etching was applied to natural snow crystals to observe surface structures. When a fresh surface of a snow crystal was etched, typical hexagonal pyramidal etch pits (dislocation etch pits) and etch channels were observed. Surface density of the etch pits was found to be different for every crystal. The results suggest that aerosol particles are captured by a developing snow crystal, producing dislocations. An ice crystal containing PbI_2 particles was etched to demonstrate the etch pit formation by entrapped foreign particles. In the

course of etching snow crystals, two interesting etch patterns were observed. Patterns of frozen clouds droplets showed a different orientation (30° in angle) from that of the base crystal. A fine step-like structure, produced on a snow crystal surface placed on the surface of the viscous etchant, was produced by the surface migration of the film of the etchant. The formation of both patterns was caused by the etching processes. (Author's summary, modified)

GAS ENCLOSURES IN SNOW CRYSTALS. (Yuki no kesshō no naka no kihō; Text in Japanese with English summary). *Telon-kagaku* (Low Temp. Sci.), Ser. A, 24:81-89 incl. illus., 1966. 5 refs. DLC, Orientalia Div.

The existence of gas enclosures in natural snow crystals was proved by (1) replicating their surface structures, (2) allowing them to sublime in an atmosphere almost saturated with water vapor, and (3) melting them in kerosene. Several interesting phenomena were observed. The gas enclosures are usually oriented in $\langle 1120 \rangle$ directions. Some of the long and hairlike gas enclosures split into spheres in an isothermal condition and vanished after twenty days or so. When a thermal gradient was applied to a snow crystal by heterogeneous sublimation, the gas enclosures were modified in shape showing crystal faces on their warmer sides and rounded faces on their colder sides. This phenomenon is similar to that of vapor figures produced by internal melting in ice. (Author's summary, modified)

AIR BUBBLES IN ICE, NUCLEATED AND TRAPPED AT AN ICE-WATER INTERFACE. (Suihyō kaimen ni okeru kihō no hassei to hosoku; Text in Japanese with English summary). *Telon-kagaku* (Low Temp. Sci.), Ser. A, 24:91-109 incl. illus., graphs, diags., 1966. 13 refs.

DLC, Orientalia Div.

The formation of air bubbles at an ice-water interface was observed with a microscope. Air bubbles were nucleated along a scratch made by a fine glass rod on the ice surface and also on surfaces of foreign solid particles placed on the ice-water interface. The nucleation abilities were investigated using various substances such as carborundum particles, glass or metallic beads, and droplets of mercury and water-insoluble organic liquids. While

CRREL BIBLIOGRAPHY

air bubbles were formed on contaminated solid surfaces no air bubbles were produced on clean ones, on the smooth surfaces of organic liquids or on mercury. The shape of an air bubble trapped in ice is determined by rates of freezing and modes of diffusion of air molecules along the ice-water interface. When an air bubble formed between a carborundum particle and a developing ice surface, it was immediately captured by the ice surface. The carborundum particle, however, migrated upward with the advancing ice-water interface. (From author's summary)

COMPRESSION OF SNOW PARTICLES BY TAPPING.
(Sekisetsu ryūshi no tappingu asshuku; Text in Japanese with English summary). Teion-kagaku (Low Temp. Sci.), Ser. A, 24:111-131 incl. illus., tables, graphs, diags., 1966. 2 refs.
DLC, Orientalia Div.

Snow particles were compressed by dropping their cylindrical container repeatedly from a height of 4 cm, and a correlation found between "strain of volume" and the number of drops. To apply greater compression, the containers were dropped from heights of 85 and 154 cm. The results indicate that when samples were dropped from 4 cm the final strain of volume was almost independent of the grain size of the snow. However, the velocity of compression of large-grain snow was found to be smaller than that of small-grain snow. Compression velocity increased in the order: granular > compacted > newly fallen snow. The internal structure of compacted snow by tapping was investigated by making a cross section or thin section of each sample and is discussed in connection with tapping processes. THIN PLATE OF SNOW THINNED WITH HOT METAL PLATES. (Netsuban ni yoru sekisetsu usuita no sakusei; Text in Japanese with English summary). Teion-kagaku (Low Temp. Sci.), Ser. A, 24:133-137 incl. illus., diag., 1966. 7 refs.
DLC, Orientalia Div.

The process and equipment are described for making thin sections for the observation of the structure and texture of deposited snow. A sample cut from a snow cover is made into a plate 2 cm thick and is placed on a glass plate which is in turn placed on a metal plate which has been heated on an oil stove or electrically. When the snow plate is thinned to about 1 cm by melting, it is covered with another glass plate and inverted so as to be melted on the other side. Immediately after the inversion, the glass

plate on top is taken off. When the snow plate is thinned to about 2 mm, it is sandwiched between two polaroid plates and placed on a wooden table. The snow plate continues to melt because of the light source and, after a while, the single crystals composing the snow plates become distinguished from one another due to different colors which are caused by interference of polarized light. STUDIES OF FIRN ON MT. DAISETSU IN SUMMER, II. (Daisetsuzan no sekkei chōsa; Text in Japanese with English summary). Teion-kagaku (Low Temp. Sci.), Ser. A, 24:201-210 incl. illus., table, graphs, diagr., 1966. 7 refs.

DLC, Orientalia Div.

Firn studies were made from Sept. 2-5, 1966, on the "Yukikabe" snow near the top of "Yanbetappu" valley of Mt. Daisetsu, Hokkaido. Main emphasis was placed on snow metamorphism and melt, and the creep of firn down the slope. These phenomena proceed rapidly in summer because of the high water content of the snow and firn. The firn area observed was 55 x 60 m and 8-m thick in the center. Firn volume was 8658 m³, eleven times what it was the previous summer. The snow structure was almost homogeneous except for a bottom layer of ice. Density was about 0.7 gm/cm³. Other observations showed a daily mean snowmelt of 6 cm/day at the end of Aug., and 2.8 cm/day in the middle of Sept. (Authors' summary, modified)

THE MAGNITUDE OF AVALANCHE. (Nadare no kaisyū; Text in Japanese with English summary). Teion-kagaku (Low Temp. Sci.), Ser. A, 24:211-220 incl. table, graphs, 1966. 8 refs.

DLC, Orientalia Div.

To assist in the measurement of avalanches, a tentative definition of avalanche magnitudes has been proposed using a simple snow slide model. Energy diagrams for three cases with constant slope are presented with (1) no destruction along the course, (2) destruction at the upper part of the slope, and

(3) destruction at the lower part of the slope. The study was conducted under the assumption that resistance to snow movement can be expressed as an increasing function of velocity. Three magnitude scales are proposed for describing an avalanche: (1) mass magnitude (the quantity of avalanched snow), (2) potential magnitude (total work done by an avalanche consuming its potential energy), and (3) destructive magnitude (maximum destructive power for a given mass of snow and slope. Examples of classifying avalanches by mass magnitude and potential magnitude are given. It is pointed out that more research should be conducted on the destructive power of avalanche wind. SATSUNAI-GAWA AVALANCHE, 1965. (1965-nen Satsunai-gawa nadare chōsa hōkoku; Text in Japanese with English summary). Teion-kagaku (Low Temp. Sci.), Ser. A, 24:221-238 incl. illus., tables, graphs, diagrs., maps, 1966. 8 refs.

DLC, Orientalia Div.

A surface, dry-snow avalanche is described which buried and killed 6 members of the Academic Alpine Club of Hokkaido University on March 14, 1965. Noteworthy features of the avalanche were the extremely wide front and destructive effect of the avalanche wind along the path, and ice shells, composed from newly formed ice sheets, found in the debris. The major diminution of the debris was solar radiation and wind. Surface melting was accelerated by a thin layer of soil on the debris. But a thick layer of soil acted as a thermal insulator. Bottom melting along the water stream was very active in the summer and resulted in more rapid collapsing and diminution of the debris. (From authors' summary)

VIBRATIONS OF A SEA ICE SHEET ON THE OCCASION OF ITS BREAKING. (Kaihyōban no hakai ni tomonau shindō; Text in Japanese with English summary). Teion-kagaku (Low Temp. Sci.), Ser. A, 24:239-248 incl. graphs, 1966. 6 refs.

DLC, Orientalia Div.

Vibrations of a sea-ice sheet on the Okhotsk Sea coast of Hokkaido were observed when a cantilever type of sea-ice beam deflected and broke. Three types of transducers were used to detect the vibrations: an electro-magnetic detector of the moving-coil type of 2 c/s for vertical components; an accelerometer of the U-gage type for lateral vibrations; and a piezoelectric transducer detected internal stress during flexural loading. The results are presented and discussed in relation to tensile stress and flexural loading of the ice beam. (From author's summary)

THERMAL PROPERTIES OF SEA ICE. III. ON THE SPECIFIC HEAT OF SEA ICE. (Kaihyō no netsuteki seishitsu no kenkyū. III. Kaihyō no hinetsuni tsuite; Text in Japanese with English summary). Teion-kagaku (Low Temp. Sci.), Ser. A, 24:249-258 incl. illus., graphs, 1966. 3 refs.
DLC, Orientalia Div.

This paper presents a practical formula for the specific heat of sea ice calculated as a function of chlorinity and temperature. Another method uses the observed values of the thermal conductivity (K) and density (ρ) for sea ice in situ. The good agreement in specific heats (c) obtained by the different methods proves that a K/cp-value is useful and the specific heat of sea ice can be measured in situ. (From author's summary)

STUDIES OF THE MECHANICAL PROPERTIES OF SEA ICE. IX. MEASUREMENT OF FLEXURAL STRENGTH IN SITU (3). (Kaihyō no rikigakuteki seishitsu no kenkyū. IX. Genjō ni okeru mage kyōdo no sokutei (3). Text in Japanese with English summary). Teion-kagaku (Low Temp. Sci.), Ser. A, 24:259-268 incl. table, graphs, 1966. 7 refs.
DLC, Orientalia Div.

Cantilever beam tests were conducted at Monbetsu Harbor on the Okhotsk Sea at Hokkaido from Feb. 18-20, 1965. The ice was about 24 cm thick, 30-40 cm wide, and 1.5 m long. The bending force was applied manually, measured with an electric load cell, and recorded with an oscillograph. The vertical acceleration at the free end of the beam was also measured and recorded. Maximum and minimum values of the temperature profile of the ice were measured with thermocouples. Data are presented on the deflection and flexural strength of a beam, the relation between the obtained flexural strength and maximum tensile stress, the relation between maximum tensile stress and Young's modulus, and the relation between flexural strength and the square root of the relative volume of brine. It is concluded that the flexural strength of a sea ice beam increases with an increasing rate of tensile stress because Young's modulus increases with an increasing rate of tensile stress. Flexural strength decreases with increasing ice temperature, and decreases in proportion to an increasing square root of the relative volume of brine. (From author's summary)

OCEANOGRAPHIC OBSERVATIONS ON THE DRIFTING STATION ARLIS-II, JUNE-NOVEMBER 1964. (Hyōtō Arisu II ni okeru kaiyō kansoku; Text in Japanese with English summary). Teion-kagaku (Low Temp. Sci.), Ser. A, 24:269-284 incl. tables, graphs, maps, 1966. 11 refs.
DLC, Orientalia Div.

Results are presented of oceanographic observations made in the Arctic Ocean in the area of Greenland. Arlis-II drifted from 86°25'N, 35°31'W to 83°50'N, 14°32'W covering a total of 150 oceanographic stations. Three main water masses are identified as the Arctic Surface Water, Atlantic Water and Arctic Bottom Water. The vertical distribution of temperature, chlorinity, and density in each season are shown. In the dilution processes, there are two different kinds of fresh water in this region, the fresh water transported from other localities and that supplied by melting of sea ice. The processes of concentration take place due to ice formation, the vertical convection being deduced from chlorinity distribution. The amount of sea ice formed is estimated from the deviation of the depth of the vertical convection layer. (From author's summary)

HEAVING FORCE OF FROZEN GROUND. II. ON THE RESULTS OF FIELD RESEARCH. (Tōjōryoku II: Genjō no sokutei kekka ni tsuite; Text in Japanese with English summary). Teion-kagaku (Low Temp. Sci.), Ser. A, 24:285-297 incl. illus., tables, graphs, diagrs., 1966. 5 refs.
DLC, Orientalia Div.

Direct measurements of heaving force have been made since the 1961-62 winter, using a load cell mounted on an iron disc, 12 cm in diameter and attached to a rigid beam, which was placed as a receiver of the force. The beam was supported by 2 iron rods fixed to a large concrete foundation 2 m below the ground. The maximum force measured was 5300 kg. The average pressure applied to the disc was 47 kg/cm². A cyclic change of the heaving force was observed frequently, although the heaving and frost penetration were continuous during winter. Heaving force decreased with time when the heave ceased increasing. A vertical section made at the end of winter revealed no ice beneath the disc but many thin layers below the heaved ground surface. Measurements with a 30-cm-diam disc indicate that heaving force is proportional to disc size, suggesting the stress distribution under the disc is similar to that in a semi-infinite elastic medium where its boundary is compressed by a rigid disc. SOME POSSIBILITIES OF USING RADIATION DATA TRANSMITTED BY SATELLITE IN SYNOPTIC ANALYSIS. (Nekotorye vozmozhnosti ispol'zovaniā radiatsionnykh dannykh so sputnika v sinopticheskom analize; Text in Russian). *Meteorologifā i gidrologifā*, No. 7:20-28 incl. graphs, maps, Aug. 1967. 11 refs.
DLC, QC851.M27

CRREL BIBLIOGRAPHY

The results of radiation measurements transmitted by satellites are discussed in relation to determining heat inflow in statistical forecasting and synoptic analysis. The characteristics of the radiation measurements obtained by "Kosmos-122" are tabulated and discussed for three different types of surfaces: 1) the surfaces of the Pacific and Atlantic oceans, land surface of tropical and sub-tropical latitudes (Africa and Australia), land surface of temperate latitudes (Asia), and 2) three states of sky: clear, cloudy with the prevalence of cumulus clouds, and overcast when layered clouds predominate. A graph relating radiation temperature to that of soil and air is presented and the way of calculating the temperature of an underlying surface (soil, ocean surface) is explained. Heights to the upper boundaries of clouds are calculated according to true temperature of the upper cloud boundary, the underlying surface, and the vertical temperature gradient. The relationship between radiation fields and weather fronts, cyclones, and anticyclones is discussed and illustrated by practical examples.

ON THE MEASUREMENT OF SNOW COVER DENSITY. (Ob izmerenii plotnosti snezhinogo pokrova; Text in Russian). Meteorologiya i Gidrologiya, No. 7:105-107 incl. table, Aug. 1967. 3 refs.
DLC, QC851.M27

The height of snow cover and its density were registered during the five year period 1960-1965 over the European territory of the USSR and the northern Caucasus. The results tabulated show differences between the snow density values obtained near the permanent measuring rods and along the 1-km long survey strips. Repeated control measurements sustained a sufficient accuracy of these data; the results of both kinds of measurements were quite close. It is concluded that the snow density values obtained at the permanent measuring rods are sufficient for the solution of practical problems, such as the estimation of water content in snow for a thawing period, so there is no need of repeating measurements when surveying along 1-km strips. -- NSV

Meteorologiya i Gidrologiya, No. 7:96-97 incl. graph, Aug. 1967. 1 ref.
DLC, QC851.M27

Observations have revealed that the impounding of the reservoir waters has affected the conditions of icing and temperature variation in the lower Volga during the fall-winter seasons in the following ways: 1) normal temperature increase from north to south was reversed; 2) ice was formed in the south 15 to 26 days later than under normal conditions and proceeded upstream; 3) water supply inlets located in the tail-water area were affected by bottom ice and slush, regardless of their depth and structure, at temperatures of -8° to -10°C, dependent on the wind direction. Massive bottom ice was formed mainly by slow progress of the ice edge from Astrakhan' to Volgograd and an intensive heat transfer from open water surface. The ice edge was growing in the direction of the dam by holding back the ice brought by the free part of the river. Its position with respect to the dam and the possible intensity of bottom-ice formation were calculated according to formula offered, as well as determined graphically from a curve relating the position of ice edge to the negative temperature of air. -- NSV

MIGRATION OF AIR BUBBLES, VAPOR FIGURES,
AND BRINE POCKETS IN ICE UNDER A TEM-
PERATURE GRADIENT. J. Geophys. Res.,
72(16):4093-4100 incl. graphs, Aug. 1967, 23 refs.
DLC, QC811.J6

Equations are derived for the speed and direction of migration of air-, vapor-, or brine-filled triaxial ellipsoidal cavities of any orientation, and expected velocities are computed for the spherical, cylindrical, and discoidal cases that have been investigated experimentally. In the case of air bubbles agreement is only fair for approximately spherical bubbles trapped during freezing and is somewhat better for drilled cylindrical holes open to the atmosphere. The lack of agreement and the considerable scatter in the data are probably due to uncontrolled variations in pressure and shape and to the slow accumulation of frost. In the case of discoidal vapor figures the agreement is much poorer and the scatter is much greater, probably because of large uncontrolled variations in shape, air content, and temperature of the figures. Calculation of the effect of small size, for which viscous flow of the vapor is important, shows it to be negligible for the figures used in the experiments. For spherical brine pockets at temperatures a few degrees or more, below freezing agreement is fairly good, considering the uncertainties in the diffusion coefficient, but at the ice point the predicted speed is about 5 times that observed, probably because the brine concentration in the pockets at this temperature was not in fact zero as required by the theory. (Author's abstract)

Values of compressive viscosity vary from 10^6 to 10^9 gm/cm² per second which is an order of magnitude less than the lowest values for polar snow. Plots of specific volume against overburden reveal a sharp discontinuity at a specific volume of about 3.0 cm³/gm. The persistence of this discontinuity from location to location indicates that it may reflect a real phenomenon. It is suggested that it may be accounted for by extremely high strain rates at low densities. (Author's abstract)

odnorodnom more, pokrytom l'odom; Text in Russian).
Akademii Nauk SSSR, Doklady, 167(2):338-341 incl.
illus., 1967. 10 refs.
DLC, AS262.S3663

Mathematical solution of a problem concerning the effect of ice-cover on the vertical variation of water velocity in a tidal flow below the ice is presented and discussed. It is assumed that the sea is homogeneous and its ice cover can be simulated by an elastic film, which reacts to the vertical movements of water by assuming the form of the wave passing underneath and slowing down its horizontal movement. Two boundary layers are distinguished in the velocity cross-section of a tidal wave during its motion under the ice; one near the sea-bottom and another immediately below the ice. When the sea is shallow the upper and lower layers may close producing a turbulent mixing. Formulas are derived which can be used for the calculation of a vertical velocity profile of a tidal wave. -- NSV

ALPINE SNOW COVERS. Tech. Rept. 197, U.S.
Army Cold Regions Research and Engineering Labo-
ratory, 16p.incl. tables, graphs, appendix A, July
1967. 15 refs.
CRREL files

Through pit measurements on selected deep seasonal snow covers, observations have been made on the densification rates of dry snows. The variation between rates has been compared with such physical characteristics of the snow as temperature, grain size, and loading rate. The rate of densification does not appear to be affected by temperature in the -1 to -10°C range but it is inversely proportional to grain size and sensitive to rates of loading during the formative stage of any particular snow layer.

DLC, TA775.A45

Observations made of the majority of structures in Magadansk Oblast erected on gravelly ground of moisture content ranging from 13 to 20% by weight, indicate that an irregular thawing of the ground during subsequent use of the building results in a relative sag of 0.023 in the foundation and cracking of the walls and basement floor. Three types of cracks are described; the nature of their distribution indicates that a building during ground thawing behaves in very much the same way as a beam resting on two supports or as a cantilever beam subject to bending. The deformation is based on the calculation of beams by ultimate design which accounts for the time factor and for variable settling of the ground dependent on full load of the building and irregular thawing of the basement. Its application is illustrated by the case of a building strengthened by tie beams placed at the floor levels and along the edge and bottom of the basement. -- NSV

DLC, TA775.A45

Determination of normal forces developing during freezing of the bearing ground requires the knowledge of relative normal forces, which are the stresses acting in the zone of intensive frost heaving of grounds. An attempt is made to develop a phys-

ically substantiated procedure for the evaluation of relative normal forces and obtaining data for the most common types of soil in the Moscow region. An apparatus for measuring these forces in artificially mixed and undisturbed natural soil samples is described in detail and observational procedures are outlined. It is concluded that the values established were mainly dependent on the degree of preliminary soil compaction and temperature of the freezing process. Maximal heaving forces are revealed when the sample is frozen along its entire depth. For the Moscow region the relative normal forces of frost heaving range from 0.5 to 3 kg/cm², reaching their maximum in finegrained moist soil. The data obtained may be used for computing heaving forces acting on any type of supports located within the zone of seasonal freezing. -- NSV

ARTIFICIAL AIR COOLING FOR BUILDING PILE FOUNDATIONS IN PERMAFROST. (Iskusstvennoe vozdušnoe okhlazhdenie pri ustroystve svaynykh fundamentov na vechnomerzlykh gruntakh; Text in Russian). Moscow. Nauchno-issledovatel'skiy institut osnovaniy i podzemnykh sooruzheniy. Osnovaniya i Fundamenty. Sbornik trudov, No. 55:103-115 incl. tables, diagrs., 1964. 14 refs.
DLC, TA775.A45

An air-cooling technique is discussed which was developed for accelerating the freezing of piles when building foundations and sinking shafts in frozen ground by using steam jets or drill bits. A mathematical procedure for air cooling is developed and a formula relating the duration of the process to atmospheric temperature is derived. The computations are illustrated by practical examples. According to tabulated data the preliminary cooling of frozen ground in shafts takes little time, especially when the ground is sandy. The theoretical results closely correlated with field testing data obtained in May and December for grounds of different physical properties and moisture contents. This technique permits the erection of pile foundations at zero ground temperature, thus broadening the geographic areas for such construction. In permafrost regions it can be used during six months of the season. -- NSV

DLC, TA775.A45

CRREL BIBLIOGRAPHY

The results of preliminary experimental studies of the relationship between the composition of exchange ions, soil heaving intensity and water migration in freezing soils indicated that the last two factors depend on the isobar potential of soils or their free energy, the variation of which is expressed through the change of particle sizes, their mineralogical composition, and the composition of exchange ions in the exchange complex of soils; the possibility of controlling soil heaving by varying the composition of exchange ions was proved. An attempt is made to find such cation pairs which can be used for decreasing soil-heaving intensity by varying their ratios in the exchange complex of the soil. Potassium ion was chosen for the experimental study of this process in different soil samples. Also the aggregation and destruction of soil particles from different fractions was studied to establish the regularities governing moisture redistribution when soil freezing is accompanied by moisture inflow. The introduction of potassium into a soil lowers its heaving because it decreases the surface energy of soil particles by changing the size and quality of their surface. -- NSV

EFFECT OF HEATED BUILDINGS ON DEPTH OF NATURAL FREEZING OF SOIL. (K voprosu o vliyanii otaplivaemykh zdaniĭ na glubinu promerzaniia grunta; Text in Russian). Moscow, Nauchno-issledovatel'skiĭ institut osnovaniĭ i podzemnykh sooruzheniĭ, Osnovaniĭ i Fundamenty. Sbornik No. 56:78-87 incl. illus., graphs, diagrs., 1966. 9 refs.

DLC, TA775.A45

It was established by observation that the depth of ground freezing decreases nearer to a heated building and is mainly determined by temperature inside the building and the structure of the surrounding fence touching the ground. These observation data are used in the analytical discussion of the dynamics of frozen ground near heated buildings, in plotting graphs relating the depth of freezing to the distance from the cellar wall, and in diagrams showing the position of frozen ground boundaries at various periods of the freeze-thaw cycle during the years 1962-63. Formulas are derived for the coefficient of thermal effect (m_t) of a heated building on the frozen ground accounting for seasonal variations in the depths of ground freezing and the time of the year when the heating of the building begins. It is concluded, that actual m_t values may vary within a broad interval depending on the type of the first-story floors, the building dimensions in plan, depth of the cellar, and temperature inside the building. -- NSV

STUDY OF CONSOLIDATION OF THAWING ICE-SATURATED GROUNDS. (Issledovaniĭa konsolidatsii ottaivaĭshchikh l'donasyshchennykh gruntov; Text in Russian). Moscow, Nauchno-issledovatel'skiĭ institut osnovaniĭ i podzemnykh sooruzheniĭ, Osnovaniĭ i Fundamenty. Sbornik No. 56:97-141 incl. tables, illus., graphs, diagrs., 1966. 10 refs.
DLC, TA775.A45

Consolidation of thawing ice-saturated grounds is discussed with relation to the calculation of deformation limits for a foundation erected on permafrost. The discussion is presented in two parts: experimental study of thawing clayey ground and theoretical analysis of primary and secondary consolidation. It is concluded, that at the same moisture content the highly frozen grounds thawing under load are more compressible than thawed grounds; after thawing they become overdense, their porosity changing stepwise in this process and remaining almost constant with depth. Within the limits studied the consolidation process is practically independent of load, its course being determined by rate of thawing. An increasing thawing rate increases soil compressibility and decreases its porosity, moisture content, and strength in a stabilized state. Regardless of thawing rate the ground settling under any load proceeds during the thawing period in proportion to the square root of time and amounts to 92-99% of the full stabilized settling for the soils studied. In the same samples this process occurs at high pore pressure which remains about constant during the whole thawing period, rapidly dropping to zero at the end. -- NSV

"FUJI": A JAPANESE ANTARCTIC RESEARCH AND SURVEY VESSEL. Shipbldg. & Shipp. Rec., 106(11):348-350 incl. illus., Sept. 9, 1965.
DLC, VM1.S4

Japan's new diesel-electric vessel, the "Fuji", in Japan's 7th expedition to south polar regions will reopen Showa Station 3 yr after closing in Feb. 1962. The 328-ft "Fuji", built in icebreaker form, displaces 7760 tons, travels at a service speed of 15 kn., and has a range at this speed of 15,000 mi. It has a cargo capacity of 400 tons which, in addition to stores and general expedition equipment, includes hangar space and flight deck for 3 helicopters and a tracked snow vehicle. The well-rounded reinforced double-hull section is designed to assist the "Fuji" in rolling free of ice. The "Fuji" will carry a crew of 182 in addition to its scientific staff. Each heli-

CRREL BIBLIOGRAPHY

copter holds 24 persons and crew or 4 tons of cargo. Boat-form hulls provide for amphibious operations; the helicopters are instrumented for night-flying. In addition to a launch, 2 lifeboats, and 6 liferafts, the vessel's fleet includes a whaler. Meteorological and many other observational installations are situated throughout the vessel; a large communications room is included. -- FMM

SOME RESULTS OF MICROMETEOROLOGICAL MEASUREMENTS IN ANTARCTICA. Arch. Meteorol., Geophys. Bioklimatol., 16(1):31-43 incl. graph, 1967. 12 refs.
DLC, QC857.A73

Measurements at Norway Station indicate that the exchange of sensible heat between air and snow is effected by aeration. Therefore, the existence of a laminar sub-layer over permeable snow is questionable. The zig-zag profile of the mean vertical distribution of temperature near the surface indicates that turbulence in the area considered is systematized. The vertical displacement of the elements is estimated from the temperature profile, and heat transfer in the air is calculated in relation to measurements of the frequency of temperature variations near the surface. The expression derived for the eddy heat transfer coefficient contains fairly well defined quantities and proportions. (Author's abstract, modified)

ICE FLORA (BOTTOM TYPE): A MECHANISM OF PRIMARY PRODUCTION IN POLAR SEAS AND THE GROWTH OF DIATOMS IN SEA ICE, Arctic, 20(2): 114-133 incl. tables, illus., diagrs., June 1967. 16 refs.
DLC, G600.A95

A field survey off Barrow in the summer of 1964 revealed that sea ice in the Arctic develops a layered structure through the growth of diatoms. The diatoms increase in brine solutions which occur in the microfissures between fine crystals of sea ice and form a brown-coloured layer near the bottom. The chlorophyll content of the layer studied was 120 µg/l, or one hundred times greater than that of the sea water under the ice, leading to the hypothesis that the most important production of the Arctic is in sea ice, especially in spring and in early summer. Studies were also made of the flora of diatoms and of the mechanism of sea-ice degradation as related to its biological effects. In this paper arctic and antarctic conditions are compared. A HARBOR ICEBREAKING FERRY-BOAT. (Portovoi ledokol'nyi parom; Text in Russian). Sudostroenie, 31(8):3-6 incl. illus., diagrs., 1965.
DLC, VM4.S8

The main specifications of the ice navigating ferry-boat "Kanonerefs" are: total length 39.8 m., length between perpendiculars 36 m., breadth at guards 10.2 m., rated breadth 9.7 m., rated board height 4.2 m., mean draft 2.5 m., loaded displacement 516, lifting capacity 65. The vessel is equipped with bow and stern platforms for loading and unloading of motor cars and similar vehicles. Accommodations are at the bow, the stern and in the deck superstructures for 135 passengers. The strake is made of shipbuilding steel, 09G2 reinforced by intermediate frames. The diesel electric propulsion machinery consists of three DG 200 diesel engines. The 4-blade screw propellers, made of one-piece stainless steel, have the high strength calculated for ice navigation. Speed in clear water attains 7.5 knots with one propeller operating, and 10.5 knots with 2 propellers. In broken ice the speed reached is 3.0 to 3.5 knots. The shape of the vessel and the rational placement of deck machinery and equipment ensures speedy loading and unloading. The building design has provided good maneuvering qualities to the vessel. A photograph of the boat, general layout of the vessel, and diagrams of the midship frame, the strake, and stern structure are given. -- VDP

Samoflov, IŪ, S.
ICEBREAKER'S SIDE SCREW SHAFT. (Bortovoi grebnoi val ledokola; Text in Russian). Sudostroenie, 31(9):35 incl. diagr., Sept. 1965.
DLC, VM4.S8

Conical fitting of the screw propeller on the drive shaft is the most frequent type. According to statistics most of the screw failures occur precisely in this section. The side screws of the icebreakers "Moskva" and "Leningrad" have removable blades which together with the hull configuration permits dismantling of the propellers in the direction of the long axis. The shaft and the hub are made from a single forging with a fillet radius larger than is usually recommended. (According to the USSR Register this radius must be not less than 1/8 of the shaft). The shaft is simple to build, and permits, with the same outside diameter of the hub (and the same dimensions of the removable blades) an increase in the strength of the shaft. -- VDP

EVOLUTION OF USES OF CLOUD-SEEDING TECHNOLOGY. Proc. Amer. Soc. Civ. Engr., J. Irrig. & Drain., 93(IR3):187-197 incl. graphs, diagrs., Sept. 1967. 11 refs.
DLC, TC801.A4

The evolution of uses of cloud-seeding technology is reviewed to determine the factors responsible for introduction of this new technology into operating systems for water resources management. There is a time lag between recognition of the possibility of beneficial use of this technology and its general acceptance. Factors promoting this time lag include not only physical and economic evaluations of the technology, but also the attitudes of management and its willingness to innovate. In contrast to attitudes of the recent years, a consensus now exists on the importance of cloud seeding as a tool in management of water resources. This portends substantial increases in weather modification activity, and attempts to evolve operational systems of weather modification to further exploit the technology as a water resources management tool. Experience to date indicates the importance of providing latitude for innovators in developing the technology.

MATHEMATICAL MODEL OF THE INTERACTION BETWEEN THE SCREW PROPELLER AND ICE. (Matematicheskoe modelirovanie rezhima vzal'model'stviã grebnogo vinta so l'dom; Text in Russian). Sudostroenie, 30(3):32-36 incl. diagr., graphs, March 1964. 3 refs.
DLC, VM4.S8

When planning new icebreaker machinery, the computation of the elements of the interaction between the propeller and ice depends on the solution of a system including numerous non-linear differential equations. An electronic computer study gave the relationship of the electrical screw propulsion system of the "Moskva" and the conditions of stalling the propellers and of optimal working conditions during an ice passage. Computer output based on input derived from the electrical characteristics of the power generators, moments of the screw, flywheel, and drive shaft, and water resistance was used to plot curves showing the transformation of energy. Oscillograms obtained from field tests and model experiments indicate that the mathematical model is reliable for determining screw behavior in ice. -- VDP/FMM

HIGH TEMPERATURE BORING IN GLACIERS UNDER HIGH-MOUNTAIN CONDITIONS. (Ognevoe burenie lednikov v vysokogornyykh usloviãkhi; Text in Russian). Izvestiã vsesoiuznogo geograficheskogo obshchestva, 99(2):147-148 incl. illus., diagr., Mar.-Apr. 1967. 2 refs.
DLC, Slavic Div.

An assembly for drilling in ice under summer conditions was designed and tested by the A. V. Brichkin Laboratory of the Kazakh Polytechnic Institute. It includes a tripod, a torch-drill of the rocket type, pressure hoses, a light pile-driver, a hand-operated hoist, the oxygen, air, and kerosene tanks, and a water pump. Ice is destroyed by a jet of gasses heated to 3000°C escaping from the burner at a supersonic speed (2000 m/sec.). The rocket-burner, weighing 3-4 kg and suspended from a steel cable, is lowered into the bore-hole together with the fuel and air supplying hoses. During testing, the kerosene pressure in the main line was 12 atm., that of oxygen - 11 atm., drilling speed - 140 meters per hour, remaining the same with depth. The advantage of this device, compared to mechanical drilling, is a higher penetration speed and a considerable saving of working time since it does not require lifting of instruments for removing ice cuttings, which in this case are melted and evacuated by the exhaust gasses. The simplicity and low operation cost make this method especially suitable for deep drilling in difficultly accessible high-mountain regions. -- NSV

ORIGIN OF UNDERGROUND ICE LAYERS IN THE LOWER YENISEY VALLEY. (Proiskhozhdenie plastovykh zalezhei podzemnogo l'da v nizov'iyakh r. Eniseya; Text in Russian). Izvestiya Akademii Nauk SSSR, Seriya Geograficheskaya, No. 2:108-115 incl. map, illus., Mar.-Apr. 1967. 8 refs.
 DLC, Slavic Div.

A discussion is presented on the recent origin of ice layers 1 to 4 meters thick, outcropping in the lower Yenisey Valley at different depths from the surface. The horizontal layering of the ice bodies, their position at the contact between two lithologically different formations, limited extent, and occasional boulder and rock pieces found within the ice, indicate their recent origin through repeated water injections into taliks formed between the underlying water-resistant shales containing boulders and the irregularly frozen water-permeable overlying sands. It is believed that they originated at the end of Middle Pleistocene when ground freezing and the formation of the injection ice occurred at the same time with the emergence of the deposits from the sea. In this case, it was an epigenetic permafrost, the taliks (closed water-bearing pockets) being formed at different depths in proportion to a gradual freezing of water-bearing zones in the ground.

ICE STOREHOUSES. (Lednyye khranilishcha; Text in Russian). Akademiya Nauk SSSR, Sibirskoe Otdelenie, Institut Merzlotovedeniya. Moscow, Izd-vo "Nauka", 118p. incl. tables, diagrs., graphs, 1967. 72 refs.
 DLC, Slavic Div.

Problems concerning the erection of different structures built of ice are discussed taking as an example building of ice storehouses. The progress of ice-building technique during the last 12 years is covered and the material is presented in four chapters: 1) Ice as a structural material, its physical properties, and the production of ice for structural purposes. 2) General information on ice storehouses; different types of structures, their advantages and shortcomings are discussed. 3) Deformative and thermal

stability of ice storehouses is evaluated from a new standpoint concerning the insignificant role of winter cooling of the whole ice mass in the general thermal balance of the structure. The design of insulating cover is outlined, an optimal procedure for its freezing during construction is recommended, and a new method of calculating thermal stability of seasonal storehouses is explained. 4) Certain peculiarities of the organization and execution of work are analyzed which have to be accounted for when building an ice structure. The monograph gives practical recommendations for building small storehouses which can be followed by the untrained staff of a kolkhoz or a trade center, and at the same time, presents the theoretical justification and the methods of designing large ice structures with an account for their thermal and deformative stability.

CALCULATION OF THE FREEZING DEPTH OF SOIL COVERED BY SNOW ACCORDING TO GIVEN AIR TEMPERATURE. (Raschet glubiny promerzaniya pochvy, pokrytoy snegom, po zadannoy temperature vozdukh; Text in Russian). Izvestiya Akademii Nauk SSSR, Fizika atmosfery i okeana, 3(6):602-610 incl. graphs, 1967. 8 refs.
 DLC, Slavic Div.

The depth of soil freezing under a snow cover and temperature distribution in the soil and calculated by numerical solution of a system of equations describing the heating of a multilayered medium on the basis of a model at a given air temperature. The theoretical results, illustrated by practical examples, closely approached the observation data because variation of the following factors in time was considered: snow cover thickness, water vapor in air, albedo of the underlying surface, solar radiation, and heat inflow from lower layers of thawed soil. For these calculations it is desirable to have exact data on thermal and physical characteristics of soil and snow, and the coefficients of air turbulence for the atmospheric boundary layer. The calculation procedure was programmed for electronic digital computers EVM M-20. -- NSV

CRREL BIBLIOGRAPHY

Six main 385 kva synchronous generators, one 213 kva generator and one 62.5 kva emergency generator are included in the power plant of the "Moskva" type icebreakers built by the Siemens and Schukert Co. All the generators have a static exciting system with compound phase amplitude. Four hundred volts is the generators' normal voltage, and a stabilization in the 388-395 volts range is ensured by a self-exciting system. The machinery is insulated by a double layer of glasscloth. The main and stationary generators have 2-cycle, 600 rpm diesel engines with the following specifications: K58E, 412 hp, 8 cylinders; K55E, 258 hp, 5 cylinders. The engines have a "Wooldworth UG8" precision regulator with a remote control servodrive, to modify speed within $\pm 5\%$. The generator feeder, switching, interruptor, and overload systems with 5 kg/cm² pneumatic pressure, electromagnetic controls are described. The emergency power plant, the distribution panel, and control instruments are located in a separate location on the lifeboat deck. The generator motor is a RHS548D, 4-cycle, 3-cylinder diesel engine of 87 hp and 1500 rpm. The 62.5 kva synchronous generator differs only slightly from the main generators.

DYNAMICS OF THE ELECTRICAL PROPULSION SCREW OF AN ICEBREAKER DURING INTERACTION BETWEEN THE SCREW AND ICE.
(Dinamika grebnoy elektricheskoy ustanovki ledokola pri vzaimodelstviy grebnogo vinta so l'dom; Text in Russian). Sudostroenie, 29(9):31-35 incl. diag., graphs, Sept, 1963. 3 refs.
DLC, VM4,S8

Modern recorders enable designers to study the complicated phenomenon of the interaction between the screw propeller and ice and variation in motor torque for propeller thrust or stall. The results of tests carried out on the "Moskva" are discussed and a line diagram of the main electrical power variation on the ship is provided. The dynamic load can at certain times increase to a magnitude which is dangerous not only for the blades of the screw propeller but also for other parts of the screw. The moment of rotation resistance in such cases can exceed the nominal torque of the electrical machinery 2 to 4 times. Results from the study of graphs of variations occurring during the action between the screw and the ice pressure show that for a short time, not exceeding 15 sec, the high-speed control system of the screw must ensure the increase of the nominal value of the screw moment up to 3-4 times.

DLC, TA713.A439

Short cyclic variations of mean aestival and mean annual soil and atmospheric temperature were registered in sub-arctic regions of the USSR; the temperature variation of 5 to 6 year periods was expressed by a simple near-sinusoidal harmonic curve. Steady temperature increases over the half-periods of 2 to 3 years have increased the depth of soil thawing by 30 to 45 cm or 50 to 60% of the normal depth, sometimes accompanied by a decrease in mean annual air temperature. According to mean annual temperatures, the directions of temperature variation are determined by different types of the snow-cover effect on the mean annual temperatures of soil and the boundary air layer. The law of latitudinal zonality and thermokarst is discussed in terms of total heat received by the soil, depths of soil thawing and annual increments, and the intensity of heat exchange between soil and atmosphere in warm seasons. The short-period increments in the depth of thaw exceed 25 cm, so are believed to be responsible for increased intensity of present thermokarst and soil slides on the slopes. -- NSV

DLC, TA713.A439

The lower reaches of the Viliya River are a part of the Central Yakutia lowland -- an alluvial plain consisting of a series of Quaternary terraces characterized by a widely developed thermokarst relief which indicates large masses of subsurface ice filling rock fractures and cavities. In this area ice is found in the flood plain deposits and above them, mostly in peat bogs or peaty silts. Because of great ice thickness, the nature of rock bending near contact with ice, and its cryogenic structure, it is believed that ice is syngenetic to the enclosing rock. It is concluded that it should be referred to the class of vein ice rather than limnetic. In this region the climatic conditions were more frigid during the lower Pleistocene when the forest-tundra landscape prevailed, and the permafrost which appeared at that time is still preserved. -- NSV

tion about 250 mm. An analysis of the maximum and minimum rock temperatures measured at different depths indicated a wide variation of the absolute temperatures, depending on the combinations of natural conditions, and a similarity in their relative changes with respect to time and depth. Down to 15 meters, temperatures ranged from about -1° on the water-divides and populated gentle slopes, to -2° in the forested areas, and to -3° to -4° on the northern slopes. A mean geothermal gradient of 0.6°/100 m was typical of the depth interval 70-590 m but the variation itself was irregular, increasing from 0.6°/100 m to 1.3°/100 m in the interval 20-400 m and suddenly dropping to 0.5°/100 m below 420 m. In the permafrost zone the rock temperatures ranged from -1.6° to -1.8°, but below it they increased to 0° due to the effect of highly mineralized ground waters. The thickness of the permafrost zone depended on the degree of surface cooling and on water mineralization. -- NSV

DLC, TA713.A439

In 1869 A. F. Middendorf calculated the depth of permafrost for the Yakutsk city territory from the geothermal gradient established by him according to mean temperatures of shaft walls in the Shergin Mine. Similar studies were conducted in the mine by other investigators in 1939, and by the author during the four year period 1958-62 in a well drilled at a 30 meter distance from the mine. The comparison of all data has shown that the mean annual temperatures of permafrost obtained by Middendorf for the first 15 meters of the ground were much lower, compared to the subsequent data and about the same at depths of 30, 45 and 61 m. From there to 116 m they were higher by 0.2 to 0.8°C, and in complete agreement with the subsequent measurements beyond this depth. This temperature increase was explained by disturbance of the thermal regime during shaft sinking and its gradual reestablishment through the subsequent years, while the discrepancy of the upper 15 meters was referred to a convective heat-exchange between air and shaft walls during cold seasons. -- NSV

 DLC, TA713.A439

Drilling of numerous wells near lakes and rivers in different parts of the territory revealed the lithological effect of river-bed deposits on the thawing depth of frozen ground under the channels of major non-freezing rivers and lakes. In the presence of water resisting formations the depths of thawing zones were restricted to certain limits depending on the degree of conductive heat-exchange, thermal conductivities of rocks, and the geocryological conditions of the region; when the river-bed deposits were permeable the underlying permafrost was not preserved under the river channels. Another cause of increased thawing zones was the presence of interconnected taliks below the river channels which conducted warm water deep into the frozen ground; this was typical for limestone formations and for faulting zones. The relationships described were important for designing dams and large water reservoirs, and calculating the depth of permafrost thawing during different periods of their exploitation.

HEAT EXCHANGE BETWEEN ROCKS AND ATMOSPHERE AND THAWING OF FROZEN GROUND. (Teploobmen mezhdu atmosferoy i gornymi porodami i protalvanie merzlykh gornykh porod; Text in Russian). Akademiya Nauk SSSR, Sibirskoe otdelenie, Institut merzlotovedeniya, Sovremennye voprosy regional'noy i inzhenernoy geokriologii (merzlotovedeniya), Izdatel'stvo "Nauka", p. 147-166 incl. tables, 1964. 14 refs.
 DLC, TA713.A439

The temperature field of frozen ground and the thawing-freezing processes are usually analyzed separately from the phenomena of heat and moisture transfer in the air, taking the surface temperature as a boundary condition; consequently, all formulas for calculating depths of thawing are based on the surface temperature, which is unstable and difficultly measurable. An attempt is made to determine the temperature field of permafrost and its thawing depths in relation to heat exchange in the air by solving a system of thermal-conductivity equations for a rock layer and the boundary layer of air in the absence of water phase transformation in rocks. The mathematical solution is then used for deriving formulas for thawing depths and for the calculation of time required for a full freezing of a rock layer thawed during the summer season. Rocks with an irregular moisture distribution with depth are separated into layers assuming a constant moisture content in each layer and the thermal coefficients obtained as average values for the whole thawed zone. -- NSV

EXPERIENCE IN APPLYING ACOUSTICAL AND SEISMIC METHODS OF PERMAFROST EXPLORATION. (Opyt primeneniya akusticheskikh i seismicheskogo metodov issledovaniya merzlykh gornykh porod; Text in Russian). Akademiya Nauk SSSR, Sibirskoe otdelenie, Institut merzlotovedeniya, Sovremennye voprosy regional'noy i inzhenernoy geokriologii (merzlotovedeniya), Izdatel'stvo "Nauka", p. 167-180 incl. illus., graphs, diagrs, 1964. 23 refs.
 DLC, TA713.A439

CRREL BIBLIOGRAPHY

Three methods of permafrost exploration are described with a schematic illustration of instruments and their working principles: the impulse ultrasonic, sonic, and seismic techniques, all designed for shallow sounding. The first is used for determining elastic properties of rocks and the variation of physical and chemical processes in frozen grounds. By measuring acoustic wave attenuation dependent either on the relaxation phenomenon, or Rayleigh scattering, or thermal processes, it is possible to establish the coefficient of thermal conductivity of rocks without disturbing their initial thermal state. The second method is in principle the same as the navigational echo ranging technique; its advantages are the speed of measurement and a detailed presentation of complicated permafrost cross-sections. The seismic method is based on the construction of travel time curves for reflections. Its data are used for an accurate determination of the permafrost depth, dimensions of thawing ground under buildings, lithological subdivisions of a cross-section, and other problems. -- NSV

STEPWISE NATURE OF PERMAFROST HEAVING. (O skachkoobraznosti puchenija promerzafushchikh gruntov; Text in Russian). Akademija Nauk SSSR, Sibirskoe otdelenie, Institut merzlotovedeniya, Sovremennye voprosy regional'noy i inzhenernoy geokriologii (merzlotovedeniya), Izdatel'stvo "Nauka", p.181-185 incl. table, graph, 1964. 5 refs. DLC, TA713.A439

According to observations permafrost heaving under laboratory and field conditions is an intermittent, incremental and steady, stepwise process. Because freezing of soil may be regarded as water crystallization in pore spaces or in the presence of a large quantity of insoluble particles, the stepwise heaving reflects a discontinuous water crystallization produced by the following factors: intermittent inflow of water to the growing ice crystals, the soil particle effect, and the separation of salts from freezing water resulting in water overcooling. In the second case the regular growth of ice crystals is interrupted by periodical accumulations of close-lying mineral particles on the crystal surface. In the third case, a gradually increasing precipitation of salts near the growing ice crystals lowers the water freezing temperature causing a pause in water crystallization. In some cases the intermittency of the heaving process may be due to a stepwise deformation of an externally loaded permafrost layer under the action of compressive and shear forces. -- NSV

CALCULATION OF GROUND HEAVING WHEN DESIGNING PREVENTIVE MEASURES AGAINST FOUNDATION HEAVING. (K raschetu puchinihosti gruntov osnovanii pri proektirovanii meroprifitii protiv vypuchivaniya fundamentov; Text in Russian). Akademija Nauk SSSR, Sibirskoe otdelenie, Institut merzlotovedeniya, Sovremennye voprosy regional'noy i inzhenernoy geokriologii (merzlotovedeniya), Izdatel'stvo "Nauka", p. 186-193, 1964. 1 ref. DLC, TA713.A439

The calculations offered are based on the hypothesis of a stationary heat-separation process in the ground, which produces a dynamically balanced relationship between water in the thawed and frozen zones. Ice is formed in a certain boundary layer of the freezing ground limited by a definite temperature gradient the lower limit of which is the temperature of water crystallization and the upper -- a certain extreme temperature at which the water-movement, capable of ground heaving, ceases. Because the forces causing water migration cannot be evaluated, the analytical calculation of specific moisture accumulation in frozen ground can be conducted according to the moisture gradient in the thawed and frozen layer, i. e., the quantity of migrating water in the frozen layer will depend on the temperature of the ground freezing process as well as its initial moisture and other physical and mechanical rock properties. In some cases it is possible to assign the depth of ground freezing by calculating the values of normal heaving forces according to the procedure described. -- NSV

DLC, TA713.A439

The process of rock failure as the result of temperature increase and repeated freezing-thawing of the ground is discussed and illustrated by practical examples. Maximum deformation of supporting walls in mines was observed in the ventilation shafts, the main causes being moisture condensation near walls in summer and its evaporation during

CRREL BIBLIOGRAPHY

the cold season. The areas of intensive moisture accumulation moved progressively from their near-surface position at the beginning of a warm season to some 500 meters below it in August, resulting in a periodical successive moistening-drying of the ground within one warm period. This effect combined with repeated heating-cooling and freezing-thawing of rocks leads to their rapid destruction and consequently an increased pressure on supporting walls. It is recommended that the thermal conditions of mines located within the permafrost zone be regulated to reduce to minimum the thawing zone behind the supporting walls and the variations of air temperature in the mine. -- NSV

Akademiā Nauk SSSR, Sibirskoe otdelenie, Institut merzlotovedeniā, Sovremennye voprosy regional'noi i inzhenernoi geokriologii (merzlotovedeniā), Izdatel'stvo "Nauka", p. 203-209 incl. table, diagr., 1964. 6 refs.

DLC, TA713.A439

Concrete supporting walls in the shafts of the Vorkuta coal-mines were showing signs of deformation after a sufficiently thick layer of thawed rocks was formed around them. Typically for these mines, the failure of concrete was associated with the air-supplying shafts, while the exhaust shafts remained undamaged although a similar thawing zone was formed around them. All these effects were explained by the consequences of blowing hot dry air through the shaft: an increased moisture evaporation, desiccation of thawed ground behind the concrete, and excessive vertical stress exerted on the concrete by the settling ground. This process was studied in a model of an air-supplying shaft, which is described and illustrated schematically; a formula for the minimum radius of rock thawing sufficient for the onset of deformation is derived, and the measures preventing ground desiccation behind the concrete are recommended. -- NSV

DLC, TK1509.A7

Thickness, strength, and structure of ice cover on a water reservoir is discussed in relation to use in the winter as a road or an air-field. Specific thermal conditions affect the formation and destruction of the ice-cover, which differs from river ice in homogeneity and regularity of crystalline structure through the whole thickness and lesser stability due to a rapid loss of mechanical strength in the spring. The scale factor is of utmost importance in the experimental strength evaluation, the limit of which is determined from a curve relating strength to the size of ice-sample cross-section and ice sheet thickness. It is recommended that the periodic occurrence of multiple temperature fractures of different width and direction, growing in numbers after sudden drops of temperature, especially in the snow-free ice, be taken into account when calculating the carrying capacity of ice cover. -- NSV

DLC, TK1509.A7

General regularities governing the formation of ice stoppage in Siberian rivers are discussed and the degree of channel clogging is analyzed in relation to

the conditions of river freezing in the fall, temperature variation during winter, and the intensity of spring season development. The problems concerning river hydraulics, river-channel conditions, and the temperature/ice regime during ice-breaking are analyzed for the Yenisey River in Spring 1958. A method of calculating the degree of obstruction is given. It is stressed that building of hydro developments, particularly power plants, leads to essential changes in the ice regime dealing with ice thickness, and the time and character of ice breaking. Since the elimination of ice jamming is costly and not always effective, the following preventive measures are recommended: the use of ice-breakers and ice cutting machines, weakening of ice by accelerated radiation or chemical methods, and building of dams further upstream. -- NSV

A METHOD OF DECREASING SLUSH FORMATION ON THE HYDRO PLANT CASCADE. (Metod umen'sheniâ shugobrazovanîâ na kaskade GES; Text in Russian). Novosibirsk, Izd-vo Akademii Nauk SSSR, Sibirskoe otdelenie, Sibirskiy nauch. issled. institut energetiki, Metody Bor'by s Ledovymi Zatrudneniâmi na Gidrostançîfâkh Sibiri, p. 72-82 incl. table, maps, diagr., 1965. 8 refs.
 DLC, TK1509.A7

The mathematical analysis of slush origin and its dynamics indicated the major role of water velocity in determining the direction and development of the ice and slush formation processes. Velocity control by the regulation of cascade flow is discussed. Regarding the improvement of the winter regime conditions the conclusion was reached that building of the plants in downstream succession, or covering the entire stretch of the cascade by the basic stations at once, will diminish ice jamming. When the hydro plant development is gradual it is desirable to decrease the water stream velocities in the lower reaches during the periods of spring and autumn ice-drifts to the limits when the edge of a slush-cover moves rapidly upstream preventing further formation of floating ice and furthering the development of an ice cover. The feasibility of these recommendations is illustrated by practical examples.

TEMPERATURE AND FREQUENCY DEPENDENCE OF THE VELOCITY OF SOUND IN DIELECTRIC CRYSTALS. Phil. Mag., 16(140):331-340, Aug. 1967. 9 refs.
 DLC, Q1.P5

CRREL BIBLIOGRAPHY

The temperature and frequency dependence of the velocity of sound in dielectric crystals have been calculated to lowest order in anharmonic terms by using the quasi-harmonic approximation and the phonon Boltzmann equation. It is assumed that the quasi-harmonic approximation for the stress in a deformed crystal in microscopic equilibrium may be generalized to non-equilibrium situations in a simple way. It is found that at very low frequencies the velocity is determined by the adiabatic elastic constants in agreement with classical continuum theory. At high frequencies, however, the classical isothermal result is not obtained, and in contrast to the classical result it is found that there is a change in velocity in going from low frequencies to high frequencies for pure shear waves. A rough estimate is made of the magnitude of this effect and it is decided that it should be observable under suitable conditions. (Author's abstract)

REVERBERATION UNDER ARCTIC SEA-ICE. *J. Acoust. Soc. Amer.*, 42(1):78-82 incl. diags., illus., July 1967. 8 refs.
DLC, QC221.A4

Backscattering strengths were obtained from polar pack ice in the Beaufort Sea during April 1965. The ice surface in the experimental area consisted of 10%-15% of pressure ridges separating random patches of 1 yr ice. The results cover a frequency range of 40 to 10240 Hz and a grazing-angle range of 5°-85°. Comparison with earlier results obtained with the same equipment and methods but limited to frequencies of between 1280 and 10240 Hz indicates a strong relationship between surface roughness and scattering strength. The variation with frequency of scattering strength is small over the 8-oct range examined. However, at grazing angles below 20° and frequencies below the 320-640-Hz band, scattering strength falls with decreasing frequency. (Authors' abstract)

CONDITIONS OF BREAKING ICE JAMS ON THE MALAI SEVERNAI DVINA RIVER IN THE REGION OF KOTLAS. (Ob usloviakh proryva zatorov l'da na r. Maloi Severnoi Dvine v raione g. Kotlasy; Text in Russian). *Izvestiya vsesoiuznogo geografi-cheskogo obshchestva*, 99(3):239-240, May-June 1967.
DLC, G23.G16

Ice jams at the river junction were caused by narrowing of the channel at Pustoi I, located in the middle of its course. Decreasing stream velocity and water transmission capacity sharply increased the upper water level, forcing water to escape through the river branches. Expensive ice cutting and blasting produced little effect because the ice jams practically reached the river bottom. A detailed analysis of the morphometric, hydrological and hydraulic conditions at the jamming area has indicated that local broadening of the channel until it is sufficient for an unobstructed ice passage, and increasing the water level to maximum probability of a break-through will eliminate ice jamming. This measure proved very effective during Spring 1966 ice breaking at the river junction. -- NSV

DLC, QC851.A2732

A mathematical analysis is presented of the case when ice cover starts moving under the action of shearing stress originating at the ice-water boundary, acquiring certain finite velocity in accordance with the given external parameters. The velocity and direction of ice drift are obtained as a particular solution of the general problem concerning the structure of a tidal flow in the sea covered by floating ice. Proceeding from the solution of a system of equations describing such a flow, formulas are derived for the velocity and direction of the drifting ice, the oscillations of tidal level, the profile of tidal flow velocity, and the turbulence coefficient in the boundary layers of water adjacent to ice and the sea-bottom. The calculation results are illustrated by a practical example. -- NSV

FROZEN GROUND ZONING IN MINE FIELDS OF THE PECHORA COAL BASIN. (Merzlotnoe mikrofonirovanie shakhtnykh polei v Pechorskome ugol'nom bassejne; Text in Russian). Vsesoiznoe geograficheskoe obshchestvo, Komi filial, Izvestiia, Vyp. 10:40-51 incl. tables, diagrs., map, illus., Syktyvkar 1965. 4 refs.
DLC, G23.G2625

A map was compiled showing a detailed subdivision of mine fields in the Pechora coal basin area into smaller zones according to the characteristic features of their seasonal freezing and thawing layers of soil, serving as a basis for the engineering, geological, and cryogenic evaluation of the terrain. General and particular regularities governing the formation of this layer were established and the division based on certain zonal distinctions reflecting the influence of climate, topography, lithology of ground, its moisture content and cryogenic structure, mean yearly temperature of the ground, mean velocity of its freezing and thawing, and the amplitude of temperature fluctuation at the soil surface. Types and sub-types of seasonally freezing and thawing grounds were distinguished and the areas of their development mapped. This procedure is explained in detail and illustrated by the practical example of the Tun'-Iagin coal field. -- NSV

PROBLEMS OF COLD-RESISTANCE OF TECHNICAL DEVICES IN SIBERIA AND THE EXTREME NORTH. (Problemy khladostokosti tekhnicheskikh ustroystv v Sibiri i na krainem severe; Text in Russian). Akademiya Nauk SSSR, Gosplan SSSR, Problemy Severa, Ikonomika Lzd-vo "Nauka", p. 121-129, Moskva, 1965. 14 refs.
 DLC, GB395.P7

Excessive break-down of transportation vehicles under conditions of the extreme north is analyzed. Low temperature is the principal cause of engine malfunction since it affects the performance of the basic units and the mechanical parts, changes the properties of lubricants, makes more difficult the starting of an internal-combustion engine, and increases the brittleness of steel. It is recommended that special types of cold-resistant steels be used in fabricating the engines and vehicles intended for use in the extreme north to diminish the tendency of metal toward brittle failure by taking the cold-factor into consideration when designing separate details, and avoiding technology omissions in the process of fabricating these details. The performance of a vehicle can be improved by good practice, which is based on the knowledge and understanding of the nature of cold-brittleness of metals, and depends on the degree of qualification of the servicing personnel. -- NSV

CONSTRUCTION AND USE OF UNDERGROUND COLD STORAGE. NORTHERN AND NORTH-EASTERN SOVIET UNION. (Stroitel'stvo i ekspluatatsiya podzemnykh kholodil'nikov. Sever i severovostok sovet'skogo soyuza; Text in Russian). Akademiya Nauk SSSR, Bibrskoe otdelenie, Trudy Severo-Vostochnogo kompleksnogo nauchno-issledovatel'skogo instituta, Izd-vo "Nauka", Vyp. 15, 69p. incl. illus., tables, graphs, diagrs., Moskva, 1967. 34 refs.
 DLC, QE699.A55

This monograph was written to fill gaps in the technical literature, which concerned the economic advantage of building underground coolers, and the solution of problems related to protection from ground-water penetration, to stability of roofs, and to the temperature regime. General information on the types of coolers, structural properties of frozen ground and buried ice, and the regions suitable for such structures are described. The design of underground cold storage chambers, the calculation of dimensions, volume, roof stability, and ground works is discussed and the formulas derived for the radius of cooling zone for single- and multi-chambers. The thermal regime of such structures and their advantages over surface coolers built for use under northern conditions are evaluated. -- NSV

ELECTRIC PROPELLER DRIVE OF THE ICE-BREAKER "KIEV". (Grebnaya elektricheskaya ustanovka ledokola "Kiev"; Text in Russian), Morskoy flot, p. 29-31 incl. diagrs., July 1967.
 DLC, VM4.M6

The ice-breaker "Kiev" is the third ship of the "Moskva" series built in Finland on the USSR order. Its electric propeller drive includes 8 main, irreversible, two-stroke, trunk diesel-generators of the type 9MN-51/55, their effective power being $N_e = 3250$ hp and the step control of the diesel rotation speed: 260, 300, 330 revol./min. The ice breaker has 3 aft rotors the middle one activated by two identical propeller drives coupled by a clutch. The scheme of its electronic control generator shows three separate principal circuits, which provide for different ways of connecting the main generators to the electric propeller drives. The activation system for the electronic control generator differs in many points from that in the previously built ice-breakers in this series. -- NSV

Trudy Irkutskogo politekhnicheskogo instituta, seriya mekhanicheskaya, Vyp. 26:13-27 incl. graphs, illus., Irkutsk 1966.
 DLC, T4.I72

Cold-resistance of cast steel items was studied by testing metal samples for impact bending at temperatures 0, -10, -20, -30, -40, -50, -60, and -70°C. The testing results are discussed separately for each detail and indicate that increased content of phosphorus, sulfur, nitrogen and oxygen in steel as well as non-metallic inclusions and pores lower its strength at minus temperatures. Coarse-grained steels are especially susceptible to cold destruction and their qualities could not be improved by additional normalizing and tempering. Hardening of steel in water followed by tempering at 600-650°C brought the critical temperature down to -50°C and the impact viscosity to 2 kg-m/cm². Steels treated this way are recommended for coupling devices of rolling stock. -- NSV

USE OF VEGETATION AS AN INDICATOR OF PERMAFROST CONDITIONS. (Ispol'zovanie rastitel'nosti v kachestve indikatora merzlotnykh usloviy; Text in Russian). Vestnik Moskovskogo Universiteta, Geografiya, 5(4):54-58 incl. table, July-Aug. 1967.
 DLC, G1.M68

Plants growing on permafrost ground in the valleys of major Siberian Rivers are studied at the Department of Geocryology of the Geological Faculty, Moscow State University. Because the depth of seasonal thawing and freezing of ground depends on temperature, lithology and moisture content of rocks, thickness and density of snow cover, and on mean yearly amplitude of air temperature, the vegetation cover affects the freezing depth of ground and at the same time is a product of the same factors. General aspect of plant communities in all parts of permafrost regions is similar; it is characterized by thin forest of a low quality and yield index devoid of seedling growth, large numbers of swamp plants, and widely developed peat moss. -- NSV

TRANSFORMATION OF THE NEAR-SHORE TEMPERATURE FIELD IN THE PROCESS OF THERMAL ABRASION. (Metamorfizatsiya pol'ya temperatur pribrezh'ia v protsesse termicheskoy abrazi; Text in Russian). Vestnik Moskovskogo Universiteta, Geografiya, 5(4):104-106 incl. graphs, July-Aug. 1967.
 DLC, G1.M68

Similarly to a flow of dissolved substances accompanying a chemical abrasion, a thermal abrasion transforms the temperature field near the eroding shore forming a flow of relatively cooler water along the shore. The parameters of this stream were measured by thermistors at the northern shore of Mostakh I., the Laptev Sea, in a direction perpendicular to the shore. Results indicated in all cases a gradual rising water temperature in the direction away from shore behind a cool flow zone 15 to 20 m wide. In this zone temperature gradients were reaching 1 to 2°C/m of water depth, while along the course of the flow they amounted to 0.1 to 0.01°C/m of flow movement along the shore, the temperature being quite stable within the zone. It is believed also that water-salinity in the cool stream may differ from its background values. -- NSV

PECULIARITIES OF HEAT-EXCHANGE DEVELOPMENT IN ACTIVE SOIL LAYER IN EASTERN SIBERIA. (Osobennosti razvitiya teploobmena defatelnogo sloya pochvy v Vostochnoy Sibiri; Text in Russian). Vestnik Moskovskogo Universiteta, Geografiya, 5(4):83-90 incl. table, July-Aug. 1967. 9 refs.
 DLC, G1.M68

In Eastern Siberia the thickness of the thawing-freezing soil layer is quite often less than that of the layer with seasonal temperature variations; the upper 2-3 meters of soil absorb more heat during warm seasons releasing it during the cold period than the whole underlying layer with the yearly temperature fluctuation. Thermal exchange (B) in soil was calculated according to the variation of heat content in this yearly "active" layer using formula

$$B = \int_0^z C(T_2 - T_1) dz,$$

(where C - is thermal capacity by volume), the integral of which is divided into two parts expressing both layers separately:

$$B = \int_0^z c(T_2 - T_1) dz + \int_0^z C(T_2 - T_1) dz,$$

and the formula is further transformed to account for the quantity of heat used for phase transitions. The advantage of this method is its applicability to multilayered media and the possibility of characterizing seasonal variations in the thermal regime of soils. -- NSV

PROBLEMS OF ARTIFICIAL ACCELERATION OF GLACIER MELTING IN TIEN SHAN. (Voprosy iskusstvennogo usileniya taniya lednikov na Tian-Shane; Text in Russian). Akad. Nauk Kirg. SSR, Frunze. Tian'shan, Vysoko, Fiziko-geogr. Sta., Roboty, Vyp. 11:14-26 incl. illus., tables, graphs, diagrs. Frunze, Izd-vo "Ilim", 1965. 13 refs.
 DLC, GB2401.A55

An investigation into methods of accelerating the melting of ice and snow by artificial dusting was conducted on the Semenov and Kara-Batkak Glaciers with the conclusion that natural pollution of glaciers is so strong that an additional recommended 5 g/m² of coal dust cannot substantially decrease the reflection factor of ice; even when 400 g/m² was used the effect was insignificant and short-lived. Considerable additional melting was obtained by repeated dusting during the entire ablation period which was economically unjustified. The conclusions reached were of a local nature, the justification of glacier dusting in other Tien Shan regions required further study. -- NSV

 DLC, GB2401.A55

This report is based on data obtained in 1962-1963 in connection with studying daily regimes of the Semenov Glacier movement using the optical theodolite TB-1 to measure progress every 2 hours. Glacier velocity was changing stepwise its increase beginning at 10-12 AM and lasting to the evening with subsequent gradual decrease toward the next morning. Variations in ice movement were noticed not only between the 2 hour observation intervals but also between successive days. In 1962 the general ice displacement per 24 hours was 10 cm while in 1963 it was 13.5 cm and 16.5 cm during the first and second observation days, respectively. Such variations are explained by changes in meteorological conditions; therefore, an attempt is made to establish a relationship between the variation of surface velocity of ice movement and air temperature. -- NSV

 DLC, GB2401.A55

Temperatures of the Grigor'ev Glacier were measured in several bore-holes 10, 20 and 30 m deep arranged along its longitudinal profile. Five temperature zones were distinguished in the ice but regularities governing temperature distribution with depth could not be established from short-term observations. The first zone 0.5 to 1.0 m in depth showed a sharp temperature variation from -6.8°C on the surface to -4.3°; the second zone of almost stationary temperature was between 1.0 and 2.5 m, temperature changing from -4.3° to -3.5°; in the cold middle zone temperature was constantly dropping from the 2.5-m depth reaching -5.8° at 10° m depth; the fourth zone between 10 to 30 m was characterized by a gradual temperature leveling and increase to -3.1°; in the fifth zone 40 to 50 m temperature was about -1.0° and almost stationary. The conclusion was reached that the upper 40 to 50 m of glaciers located on flat summits are the coldest due to rigid climatic conditions and moderate precipitation. -- NSV

EFFECT OF GLACIER MELTING ON RIVER DRAINAGE IN ALA-ARCHA BASIN. (Vliianie taianifa lednikov na stok rek Ala-Archinskogo Basseina; Text in Russian). Akad. Nauk Kirg. SSR, Frunze. T'ian'shan. Vysoko. Fiziko-geogr. Sta., Roboty, Vyp. 11:46-56 incl. tables, graphs. Frunze, Izd-vo "Ilim", 1965. 7 refs.
 DLC, GB2401.A55

An attempt was made to calculate thicknesses of seasonal ablation layers for each glacier in this basin as well as the intraglacial and subglacial melting produced by heat flow toward the ice body from the bottom, heat generated by ice friction against the rocks, high internal pressures, and heat released by melt water and air penetrating into a glacier along fissures and cavities. Two methods are given for calculating the amount of glacial discharge per season accounting for the above factors. The results obtained are tabulated and the relations among different factors are presented graphically. They indicate that the volume of glacial melt water was not equal to that of the run-off from the glacier surface due to the controlling effect of intraglacial cavities, moraines, trapping of water in pot holes on the surface, its freezing on the ice surface during temperature drops, and partial penetration of melt water into the ground. A general mathematical procedure for computing the components of water-balance in glacial regions is described and illustrated by practical examples. -- NSV

EVAPORATION FROM THE SURFACE OF A MOUNTAIN DRAINAGE SYSTEM. (Isparenie s poverkhnosti gornogo vodosbora; Text in Russian). Akad. Nauk Kirg. SSR, Frunze. Tiān'shan. Vysoko. Fiziko-geogr. Sta., Roboty, Vyp. 11:57-76 incl. tables, graphs, diags. Frunze, Izd-vo "Ilim", 1965. 7 refs.

DLC, GB2401.A55

Evaporation from the surface of the Ala-Archa drainage system was measured to evaluate this component of the total water balance in relation to the problem of artificial irrigation of mountain pastures in northern regions. The total figure represents the sum of moisture evaporation from different exposed surfaces: grassy slopes, hillside waste, snow cover, ice, etc.; values from derived formulas equalled 140, 180 and 166 mm for the years 1960, 1961 and 1962 respectively. The amount of evaporation is dependent on air temperature and on the amount of precipitation during summer seasons; low temperatures were responsible for the evaporation figure in 1960, and increased precipitation combined with high air temperature accounted for its value in 1961. -- NSV

DLC, 236.A4

The quantity of talus moving along the slopes of the gorge during a dry-weather period was measured in five areas differing by the angle, lithology, and surface of the slope, with simultaneous observation of the temperature regime, air humidity, velocity and direction of winds. The tabulated results indicate that maximum material was accumulating during evening hours due to temperature fluctuation and the winds blowing downwards from the mountains to the river valley. The largest quantity of debris was moving along the precipitous bare slopes of south-eastern exposure, and the smallest, along the grass-covered 15-25° slopes facing north-west. Total quantity of talus moving over the whole area of the gorge in 24 hours varied from 49 to 202 kg, and from 945 to 5249 kg for one month, maximal quantities moving during August due to strongest temperature fluctuation and the largest number of rainless days. -- NSV

FORESTLESS TUNDRA IN NORTH-EASTERN SIBERIA AND ITS CAUSES. (Bezlesie tundrovoĭ zony severo-vostochnoĭ Sibiri i ego prichiny; Text in Russian). *Izvestiĭa Akademii Nauk SSSR, Seriiĭa geograficheskaiĭa*, No. 4:94-103 incl. illus., July-Aug., 1967. 32 refs.
 DLC, G23.A35

Relationships among the type of vegetation, lithology, and thawing depth of soil in tundra were studied to explain the presence of localized arboreal growths in the marsh-tundra of northeastern Siberia in which the northern boundary of vegetation passes through the near-shore plain built of alluvial deposits containing 50-60% buried ice to a depth of 50-100 m. Hummocky marsh tundra was associated with clayey and loamy soil cut by vein ice, its maximum thawing depth ranging from 45 to 80 cm. In the southerly direction it passed into the forest-tundra in which the northern boundary of arboreal vegetation followed the line of 50 cm thawing. Separate islands of trees found in the marsh area were located about 100 km north of this boundary. They were always associated with sandy soils or bed-rock outcrops the thawing depth of which ranged from 60 to 80 cm. -- NSV

WAYS OF SOLVING THE PROBLEMS OF GLACIER MOVEMENT. (Puti resheniĭa problemy dvizheniĭa lednikov; Text in Russian). *Izvestiĭa Akademii Nauk SSSR, Seriiĭa geograficheskaiĭa*, No. 4:118-121. July-Aug., 1967. 15 refs.
 DLC, G23.A35

A critical review is presented of different methods for solving the problems concerning rheological properties of ice and of their study in various models. Since the main difficulty for a theoretical solution lies in two kinds of ice movement in a glacier: the block movement and the visco-plastic flow, it is believed that the most promising technique is the modeling of this process on the basis of mechanical similarity by choosing the materials rheologically similar to ice and shaping them into a geometric model of a glacier, using the corresponding formulas of the similarity theory for the choice of material. This way, it is possible to study the glacier movement mechanism, verify the existing theories, determine the feasibility of other modeling methods, check the applicability of known numerical solutions of the differential equations for the case of glacier movement, and to verify the hypotheses concerning the origin of some structural features of glaciers. -- NSV

STRUCTURE OF SLOPE DEPOSITS IN ZABAĪKAL. (O stroenii sklonovykh otlozheniiĭ Zabaikal'ĭa; Text in Russian). *Vestnik Moskovskogo Univ., Ser. 5. Geogr.* No. 6:54-61 incl. illus., tables, diagrs., 1961.
 DLC, G1.M68

The talus accumulations described differ in thickness but are similar in structure and composition resembling moraines. They consist of sandy loam with large quantities of rounded and striated boulders and gravel, the peculiar feature being linear veins of relatively compacted fine material cutting the main body of the deposit (which is in places disturbed by cryoturbations) in all directions. Such accumulations were formed by slow movement of waste material, its velocity depending on the slope steepness and variable hydrothermal conditions. Four structural layers are distinguished; the surface layer produced by sliding of the seasonally thawing part along the deeper frozen material, and the also active layer beneath whose movement is characterized by successive sliding of separate layers in proportion to the depth of seasonal thawing. One of the causes of this well defined layered structure was frost heaving of separate zones with subsequent melting and sliding down the slope. -- NSV

DLC, QH301.M566

Active rock waste and the deposits closely resembling rock glaciers were studied on the valley slopes of mountainous taiga in relation to development of special morphological maps for engineering purposes. Different types of deposits moving by creep or solifluction are described, classified, and the yearly rate of their advancement evaluated. It is concluded that because rock streams consist of an upper layer of loose material and a dense lower layer their movement is of a complex differentiated nature, the upper layer progressing faster and sometimes in discrete increments, its velocity depending mostly on slope steepness, water saturation, and the intensity of weathering processes. For rock streams the yearly speed of movement does not exceed 1.5 to 2 m for the slope angles of 20 to 30°, while the maximum advancement of rock glaciers developing in permafrost regions on much gentler slopes does not exceed 0.5 m. -- NSV

DLC, GB236.A4

The movement of rock debris along mountain slopes under forces of gravity were studied in several talus cones produced mostly by physical weathering. The results indicated that the degree of mobility at different parts of the same cone-surface differed widely, the maximum movement for large Tien Shan cones being restricted to the upper levels

and depending on the degree of material cohesion and on its slope angle. The talus movement was more intensive in the spring, less so in summer and fall, and almost extinct during winter. Depending on the speed of moisture penetration, slope, physical composition of the talus, and other factors, three forms of its movement were distinguished: rolling of separate boulders, general creep of material for short distances down the slope, and rapid band-like movement of debris along the slope for long distances (rock streams). The temperature factor was important only for separate smaller rock pieces oriented in a special way, the basic factors being the impact of falling blocks and the penetration of melt and rain water into the waste material. -- NSV

CRRREL BIBLIOGRAPHY

Dorogi", 1956. The author was studying talus in the Far East, Mongolia, Kirgizia, the Caucasus, the Urals, and other regions, and reached the conclusion that the majority of hillside waste, be it granite, slate, limestone, marl, or sandstone had a characteristic slope suggesting the conditions of its accumulation: an angle of $35^{\circ} \pm 2^{\circ}$ was indicative of its formation under dry conditions. The author also observed and photographed crumbling of limestone mylonite during heavy rain; its slope after a few hours was 28° . It is believed, that the $14-18^{\circ}$ slopes of the porphyritic debris observed in Safany indicated crumbling of iced material falling from a great height rather than "dying out" of a formerly steep hillside pile as assumed by P. T. Pushkin. From the engineering standpoint talus is believed to be a good quality dam material with good water-transmission properties, the problem being in shaping it and making it stable. -- NSV

RECENT RELIEF-FORMING PROCESSES IN THE ORULGAN MOUNTAINS (WESTERN YANA RIVER). (Sovremennye rel'efobrazovushchie protsessy v gorakh Orulgana (zapadnoe Verkhofan'e); Text in Russian). *Izvestiia Akademii Nauk SSSR Seriia Geograficheskaiia*, No. 6:58-65 incl. illus., map., 1966. 3 refs.

DLC, G23, A35

Recent talus deposits formed in young mountains are described and the rate of rock destruction processes evaluated for the conditions of a sharply continental climate and the permanently frozen ground of polar and sub-polar regions. The Orulgan mountains are devoid of vegetation and entirely covered with talus from summits to river-beds; it is constantly moving along the steep and gently sloping sides, all over the alluvial fans, and even along the river terraces and their thalwegs with a speed sufficient to prevent the appearance of any vegetation. The typical elevations for physical rock destruction were 1000 to 1200 m., and those for temporary waste accumulations with subsequent reworking by frost-solifluction were 500-1000 m. -- NSV

CERTAIN PECULIARITIES OF ROCK STREAMS LOCATED IN THE SOUTH-EASTERN CHITA REGION. (Nekotorye osobennosti razmeshcheniia kurumov na fugo-vostoche Chitinskoii oblasti; Text in Russian). *Geograficheskoe Obshchestvo SSSR. Zabaikal'skii otdel, Zapiski. Vyp. XXI:189-191, 1963.*

DLC, Slavic Div.

Different types of rock streams observed in this area are described and the mechanism of their origin discussed. They were found in the form of talus aprons associated with the levels of ancient or recent denudation, the layers of coarse debris covering slopes of varied steepness and exposure, separate bands, or filling the bottom of valley heads. Sometimes there was no visible source of their origin, or the bedrock occurred deeply below the debris. Quite often they formed entire landscapes the origin and dynamics of which is explained. Because frost weathering was the principal factor in their origin, their irregular distribution was explained by the peculiarities of water movement through fractured rocks and the conditions of its freezing. Thalweg zones are believed to be especially favorable for their development when the depth of seasonal freezing exceeds that of the loose deposits. -- NSV

ROCK GLACIERS IN KHAMAR DABAN MOUNTAIN RANGE. (Kamennye gletchery v khrebtke Khamar-Daban; Text in Russian). *Izvestiia Vsesoiuznogo Geograficheskogo Obshchestva*, 97(1):80-81, Jan.-Feb. 1965.

DLC, G23.R6

In the Khamar-Daban range stone glaciers are associated with cirques of north exposure, valley heads, and elevation range from 1700 to 2000 m. They are narrow bodies 700 meters to 1 km long displaying all stages of their development: from talus creep to foothill benches to lobate forms and to spatulate tongues, their micro-relief becoming progressively more complicated. By their form and position in the cirque they strongly differ from the crescent-shaped moraines which have no visible relation to the waste movement along the cirque slopes. The rock glacier development depended strongly on the lithology of the source and the degree of rock fracturing in close contact with granitic bare mountains and tectonically weakened zones. -- NSV

DYNAMICS OF ICE COVER. (Dinamika ledianogo pokrova; Text in Russian). Gidrometeorologicheskoe Izd-vo., Leningrad, 215p. incl. tables, graphs, diagrs., 1967. 109 refs.
DLC, GB2403.K5

A mathematical theory is presented of wave processes developing in a floating ice sheet under the action of gravity and internal elasticity forces, hydrodynamic water pressure, and the disturbance produced by external forces. The scope of the work includes the purely oceanological side of the problem as well as strength problems in which the action of a system of dynamic loads on an ice sheet is analyzed. The previously published information on theoretical solutions and experimental results are considerably supplemented by the author's own investigation data and utilized. It is assumed that the reader is familiar with the fundamentals of hydrodynamics, theory of elasticity, Fourier series and integrals, and the functions of complex variables. -- NSV

ROCK-GLACIERS IN THE SWISS NATIONAL PARK OF BASSE-ENGADINE. (Coulées de blocs (Rock-glaciers, Rock-streams) dans le parc national suisse de la Basse-Engadine; Text in French). Compt. Rend. Soc. Phys. et D'Hist. Natur. Genève, 36(1):12-15, Jan.-Mar. 1919.
DLC, Q67.G35

Three rock glaciers at elevations below 2000 m were studied in the National Park; one located in the Sassa Valley is briefly described. A regular glacier occupies almost the whole length of this valley and is bordered by two lateral moraines. In place of the frontal moraine the glacier channel ends in a kind of earthwork which overtops the moraines and represents a most typical part of a rock glacier. Its complicated surface relief appears to be identical to those in the U. S. A. described by Whitman, Cross and Howe. Borings into the glacier to a depth of 1 m 20 cm revealed material gradation from coarse angular stones to smaller gravel and to black-gray earth mixed with gravel. -- NSV

ACCOUNTING FOR ALBEDO IN CALCULATING ICE THAW. (Uchet al'bedo pri raschetakh tafanii l'da; Text in Russian). Leningrad. Arkticheskii i Antarkticheskii Nauchno-Issledovatel'skii Institut, Trudy, 269:71-78 incl. table, graph, 1966.
DLC, G66u.L4

Starting with the heat balance equation for ice and considering the cited results of the research work of the drift stations "Severnyi Polius" 4 and 5 and the changes in albedo with the thickness and surface characteristics of the ice (shown graphically) the following equation is derived for the computation of ice melting: $h_t(n) = D(n) + C(n) + F(n)$, where $D(n)$ is the least melting for a critically large thickness of ice and of snow or of ice crumbs on it; $F(n)$ = additional melting considering the actual thicknesses, and $C(n)$ = additional melting considering the floating snow on the ice. A nomogram is given for the computation of $F(n)$ and $C(n)$. A sample computation of the change in the ice thickness resulting from melting is given in a table. (Meteorol. & Geostrophys. Abstract)

ROCK GLACIERS OF THE SWISS NATIONAL PARK, NEW MEASUREMENTS AND COMPARISON WITH THE "ROCK STREAM" OF THE SIERRA NEVADA IN CALIFORNIA. (Les coulées de blocs du Parc National Suisse Nouvelles mesures et comparaison avec les "rock stream" de la Sierra Nevada de Californie; Text in French). Le Globe, 82:121-128 incl. illus., tables, 1943.
DLC, G29.S5

The results of recent observations of two out of three rock glaciers occurring in the following valleys: Sassa, l'Acqua, Val Tantermozza, of the Swiss National Park are tabulated and discussed. The yearly rate of movement measured from 1918 to 1919 and in 1920 was 1 m 35 cm for the central part and correspondingly, 20, 40, 50 cm for the margins. New measurements in 1942 showed that the central mass of the Sassa glacier has been advancing at the rate of 1 m 36 cm per year, the same for l'Acqua being 1 m 58 cm. A more rapid movement of l'Acqua was explained by its greater volume. The yearly movement of the lateral parts ranged from 11 to 15 cm (Sassa) and from 57 to 1 m 24 cm (l'Acqua). The similarity between the structural and the surface-relief features of these rock glaciers and the rock streams of the Sierra Nevada are discussed. -- NSV

 NEW OBSERVATIONS OVER THE MOVEMENT OF THE NIZKOMORENNYI ROCK GLACIER IN DZHUNGARSKIY ALATAU. (Novye nabludeniya nad dvizheniem kamennogo gletchera Nizkomorenogo v Dzhungarskom Alatau; Text in Russian). Akad. Nauk Kazakh, SSR, Vyp. 8:200-204 incl. tables, diagrs., 1961.
 DLC, G23.A34
- The data obtained during the 6 year period 1953-59 and a short review of the measurement technique are presented. According to the results the advancement of this rock glacier during that period was slower compared to the 5 year period of 1948-53, the explanation being the leveling of the slope, a decrease in the amount of talus and moraine material inflowing into the glacier from the cirque sides, and certain changes in the dynamics of the main glacier (Nizkomorenniy) the rock glacier being its lower extension. The double row of measurement points running across the glacier indicated that the upper row was moving faster than the lower, its mean advancement being 120 and 92 cm compared to 89 and 68 cm of the lower row during the 5- and 6-year periods respectively. -- NSV

 ON THE FORM AND ORIGIN OF MORAINES IN MOUNTAINS. (O forme i proiskhozhdenii moren v gorakh; Text in Russian). Moskovskiy Universitet, Uchenye Zapiski, 119(2):59-74, 1946. 10 refs.
 DLC, Q60.M868
- Two types of morainic deposits were observed in the Pamirs: stationary moraines, and accumulations consisting of similar material but moving under their own weight and increased plasticity acquired by water absorption. The second type occurred in two forms depending on topography: aprons on gently sloping ground and long spatulate tongues moving along river valleys or cirque gorges. Local

CRREL BIBLIOGRAPHY

to the Pamirs the conclusion was reached that moraines are the product of glacial activity to a very small degree, because in this case the glacial erosion was insignificant compared to that by running water, but glaciers were acting as a transporting agent by transferring rock waste on their surface and saturating the already accumulated bodies with water thus helping them to flow. The mobile "moraines" are compared to the rock glaciers of Zailiiskiy Alatau several types of which are described. -- NSV

CRYO-GEOLOGICAL PROCESSES IN A POLAR DESERT AS A CONSEQUENCE OF SEASONAL ICING OF ACTIVE LAYER. (Merzlotno-geologicheskiye protsessy v pol'arnoy pustyne kak sledstvie sezonnogo l'dobrazovaniia v deiatel'nom sloe; Text in Russian). Vestnik Moskovskogo Univ. Ser. Geograf., 5(2):67-71, 1965. 3 refs. DLC, G1.M68

Regularities governing the movement of hillside waste, solifluction, sorting, and orientation of rock debris in permafrost regions were studied by observing the sinking of metal rods and rock fragments into ice due to their lower light reflection. This process is complicated by the variation of heat absorption within the same rock fragment and by heat inflow from the side of the ice-free ground, and resulting in a much longer horizontal than vertical displacement, which increases with the steepness of the slope and the amount of ice surrounding the rock fragments. This is considered to be most characteristic of talus creep in permafrost regions when the rock debris is devoid of fine-grained material filling spaces between individual stones. -- NSV

PERMAFROST IN INNER TIEN SHAN. (Vechnaya merzlota vo vnutrennem Tian'-Shane; Text in Russian). Vestnik Moskovskogo Univ. Ser. Geograf., 5(3):75-77 incl. map, 1965. DLC, G1.M68

Cryogenic features of the high-mountain southern regions are described and the mechanism of their formation explained. The permafrost zone in Tien Shan is developed at altitudes exceeding 3000 meters, its lower boundary fluctuating between 3000 and 3300 m depending on local climatic differences. At lower altitudes there is a thin and unstable snow cover. A number of taliks associated with faults cutting through the permanently frozen ground were evident on land and assumed to be present under larger lakes. Other characteristic features were thermokarst topography formed in moraines by thawing of ice-lenses, seasonal frost heave hummocks up to 30 m. in diameter, and the solifluction processes which in this region are restricted to the permafrost zone. -- NSV

 Izvestiia Vsesoiuznogo Geograficheskogo Obshche-
 stva, 99(1):67-70, 1967. 17 refs.
 DLC, G23.R6

A critical review is presented of the literature published on this phenomenon with the conclusion that two types of ice luminescence have been established: a lasting green glow appearing in separate spots, and momentary blue flashes. The first is believed to be of a biogenic origin its manifestation depending on the activity and yearly life-cycle of glowing organisms; the second is of an electrical nature depending less on the surrounding medium, geographical location, and ice age than on the intensity of ice destruction, its thickness, and the solidity of ice cover. The first type prevails in the primary forms of young sea-ice where water salinity exceeds 10%, the second in all types of ice regardless of water salinity. It is recommended to try applying the well known method of luminescence analysis, used for studying admixtures in minerals, to the investigation of natural ice. -- NSV

ON THE GLACIATION OF SARYTAG RIVER BASIN.
 (Ob oledenenii basseina reki Sarytag; Text in Rus-
 sian). Izvestiia Vsesoiuznogo Geograficheskogo
 Obshchestva, 99(1):75-78, 1967. 4 refs.
 DLC, G23.R6

Widely developed glaciation is the characteristic feature of the Sarytag River basin which affects the drainage in different ways. This basin has the largest glaciation coefficient (relating the ice covered area to that of the whole basin) among the particular basins of the Zeravshan River (Altai Mts.). According to investigations in 1964 the glaciers in this area are separated, consisting predominantly of smaller forms filling cirques, the outcrops around them showing fresh traces of glacial scouring. Recent moraines are associated with some but the ancient end-moraines extend for 4 to 5 km beyond their ice margins indicating the scale of former glaciation. These eroded, smoothed, and forested moraines filter and clarify melt waters passing through them, control daily water discharge of the river and even the amount of yearly drainage. -- NSV

BELUKHA GLACIERS IN 1965. (Ledniki Belukhi v
 1965 godu; Text in Russian). Izvestiia Vsesoiuznogo
 Geograficheskogo Obshchestva, 99(1):70-75 incl.
 tables, diagr., 1967. 8 refs.
 DLC, G23.R6

Data obtained in periodic surveying of the Belukha Glaciers starting with the year 1895 indicated that the middle of the 19th century was a turning point in the Altai glacial regime manifest in an overall and still active reduction accompanied by deposition of end-moraines. Only the Gebler Glacier moraines could be dated accurately, but the morphological similarity of those associated with other glaciers left no doubt about their simultaneous origin. Against the background of general climatic conditions, the retreat of each Belukha Glacier depended on its size and the mode of occurrence. While the ice-covered area was decreasing the number of glaciers increased with progressive thawing due to the division of major bodies into separate units. -- NSV

CALCULATION OF CONDUCTIVITY OF PERMAFROST GROUND. (K voprosy rascheta provodimosti mnogoletnemerzlykh gruntov; Text in Russian). Elektrosviaz', No. 5:75-77 incl. graphs, May 1957. 1 ref.
 DLC, TK5101.A1E5

Apparent electrical conductivity of permanently frozen ground was determined by measuring the inductance between two single-wire lines and the resistivity in one wire-earth loop. The emf induced in a two-wire line was calculated from the data on apparent conductivity of the ground. The computation results were verified by measuring line emf by VK-7 voltmeters. Zones of current flow from single-track rails were studied by introducing current into the rail and measuring its variation and that of electrical potential along the track. The results indicate that due to high specific resistivity of the permafrost surface layers in the Extreme North the coefficient of current potential along rails is considerably lower compared to that of the middle latitudes. -- NSV

PERMAFROST ON SARY-DZHAZ HIGH ALTITUDE WATERSHEDS. (O mnogoletnemerzlykh gornykh porodakh na Sary-Dzhazskikh syrtakh; Text in Russian). Akad. Nauk Kirgizskoi SSR. Geogr. Obshch. Izv., Vyp. 6:77-83 incl. illus., map, 1966.
 DLC, AS581.F753

General conditions of occurrence and development of perennially frozen grounds in this region of Tien Shan are described and discussed concluding that the following circumstances favor a state of preservation: peculiar geographic position of the region, proximity of large glaciation centers, orographic closure, distant position from seas, surrounding Asiatic deserts, and high elevation above sea level. These factors create unusual heat-exchange between soil and atmosphere resulting in a sharply continental climate, intensive solar radiation, little cloudiness, low average yearly air temperatures with large daily and seasonal fluctuations. Various cryogenic phenomena originate as a result of ground deformation affected by repeated freezing-thawing and irregular cooling in the seasonally frozen layer. These formations depend on the composition, humidity, ice content, temperature, and freezing speed of the frozen layer, the structure of the upper zone of the perennially frozen ground, and the course of thermo-mechanical interaction between the latter. -- NSV

Three new distinguishing features of rock glaciers are added to the previously established ones for a better definition and identification of such bodies: 1) their slope; 2) percentage of the largest fragments oriented with their apparent length parallel to the slope, i.e. those forming an angle smaller than 45° with the maximum slope, and 3) percentage of largest fragments the length of which is more or less oriented in a plane vertical to the largest slope. According to that, rock glaciers will differ from

hillside waste by a smaller slope (7 to 24° compared to 27 to 40°) and strong prevalence of fragments oriented in the vertical plane. -- NSV

ROCK GLACIERS IN THE SWISS NATIONAL PARK OF ENGADINE. (Les coulées de blocs du Parc National Suisse D'Engadine; Text in French). Le Globe, Vol. 62:1-38 incl. illus., maps, 1923. DLC, G29.S5

The results of successive surveying of rock glaciers in the Sassa and Acqua Valleys during 1918, 1919, and 1920 are described in detail and discussed. Description includes surface forms, material composition, and the rates of movement. In Sassa the middle parts of the glaciers were moving with an average velocity of 1 m 35 cm per year, which movement was believed to be responsible for the surface features of these bodies. The lateral parts were advancing at different speeds averaging approximately 40 cm on the right and 85 cm per year on the left side. These rates were somewhat higher for the Acqua rock glaciers. It is concluded that the rock glaciers described originated on the terrain evacuated by the normal glaciers, by a slow sliding of the material forming the frontal moraine of the glaciers, and that their present movement is a continuation of the former advancement of this material with the difference that no new material is added. -- NSV

MEASUREMENT OF NATURAL PARTICULATE FALLOUT ONTO HIGH POLAR ICE SHEETS. PART II. ANTARCTIC AND GREENLAND CORES. Res. Rept. 139, Part II, U.S. Army Cold Regions Research and Engineering Laboratory, 40p. incl. graphs, diags., appendixes A-F, March 1967. 5 refs. CRREL files

Greenland and Antarctica ice samples were analyzed for size distribution of the particulate content. Samples are from Little America V, age 800 yr; Byrd Station, age 1340 yr; Byrd Station, age 450 yr; and Site 2, Greenland, age 220 yr. Particle concentration is lower in the younger Byrd samples than in the older ones. Concentration was seen to vary cyclically with depth. Annual accumulation deter-

mined by peak to peak measurement on the dust concentration profiles compares favorably with that determined by surface stratigraphy. The results indicate that winter snow is dirtier, mean particle size changes as a result of relatively discrete addition of well sorted fallout to the log-normal distribution, and that annual accumulation of dust was about 8 times higher in Greenland than in Antarctica at the times represented by the samples studied. A NEW SOLUTION OF THE BOUNDARY LAYER EQUATION AND ITS APPLICATIONS. Res. Rept. 217, U.S. Army Cold Regions Research and Engineering Laboratory, 29p. incl. tables, graphs, appendixes A-F, Aug. 1967. 7 refs. CRREL files

Solutions of the boundary layer equation for an unsteady flow have previously been obtained for only a few boundary conditions such as those which exist in suddenly accelerated or uniformly accelerating flows. In this paper a general solution using the method of successive approximations for an arbitrarily accelerating flow is presented. The solution, which is expressed in an integral form including the acceleration as a chosen function of time, is valid for both two-dimensional and axially symmetrical flows. An example is presented in which the variation of velocity outside of the boundary layer is a fourth degree polynomial in time multiplied by a function depending on shape of object. A STUDY OF HEXAGONAL AND CUBIC ICE AT LOW TEMPERATURES. Res. Rept. 231, U.S. Army Cold Regions Research and Engineering Laboratory, 21p. incl. illus., tables, graphs, July 1967. 19 refs. CRREL files

The formation of hexagonal and cubic forms of ice was studied by the use of a cold stage in an electron microscope within the temperature range of -190 to -170°C. Ice crystal specimens were made on cold substrates, i. e., a collodion film, gold foil, or copper grid on the specimen holder of the cold stage. The structural forms of the ice were detected with the electron microscope using the selected area electron diffraction method. The hexagonal form of ice formed on the cold substrates at temperatures

CRREL BIBLIOGRAPHY

from -90 to -100°C. At -100 to -130°C, both hexagonal and cubic forms of ice were detected. From -130 to -160°C only cubic ice was found. At temperatures below -170°C, minute crystals of cubic ice were detected. No transformation of the structural form of ice from hexagonal to cubic or from cubic to hexagonal occurred when the temperature of the specimens was varied in the range of -90 to -160°C. The minute crystals of cubic ice formed below -160°C were transformed into larger cubic ice crystals by heating them to a temperature between -130 and -150°C. The lattice constants of hexagonal and cubic ice, and the coefficient of thermal expansion of ice were calculated from the experimental results. (Author's abstract)

AN ANALYTICAL AND EXPERIMENTAL STUDY OF A MELTING PROBLEM WITH NATURAL CONVECTION. Res. Rept. 234, U.S. Army Cold Regions Research and Engineering Laboratory, 13p. Incl. table, graphs, July 1967. 4 refs.
CRREL files

The correlation by O'Toole and Silveston (1959) of natural convection heat transfer for fluids confined between two parallel horizontal plates has been extended to the case involving phase change. The new correlation, which is applicable for melting from below in a water-ice system, is described with special focus on theoretical considerations, estimation of heat flux, and the experimental and analytical results. In all experiments, bubble-free, homogeneous ice samples were prepared beforehand to assure reliable and reproducible results. In general, the results from theory and experiment are in close agreement. (Author's abstract)

MORPHOLOGICAL FEATURES OF THE GERKHOZHANSU RIVER VALLEY CHARACTERIZED BY ROCK-STREAM DANGER (CENTRAL CAUCASUS). (Morfologicheskie osobennosti doliny selcopasnoy r. Gerkhodzansu (Tsentral'nyi Kavkaz); Text in Russian). Vestnik Moskovskogo Univ., Ser. 5, Geograf. 2:137 incl. illus., 1967.
DLC, QC851.M27

An attempt was made to establish a set of local features characterizing river valleys in which sudden movements of rock trains can be expected, thus avoiding time-consuming detailed investigation of entire basins. The most typical features were rock ridges and rock terraces in such valleys; the first representing a haphazard piling-up of boulders ranging in size from 0.20 to 4 m, devoid of any filling

material, and extending along the river channel; the second were flat platforms built of smaller boulders and gravel with sandy filling. Both types of structures were traced upstream almost to the place of the rock-stream origin. They were not observed in the river valleys where rock streams were absent or where there was no danger of sudden movement. -- NSV

TRACES OF ROCK STREAM ACTIVITY IN THE UPPER COURSE OF THE KOLYMA RIVER. (Sledy defatelnosti seley v verkhov'fakh r. Kolymy; Text in Russian). Vestnik Moskovskogo Univ., Ser. 5, Geograf. 2:138-140 incl. illus., map, 1967. 5 refs.
DLC, QC851.M27

Rock-streams observed in the Khibiny Mts. and Sub-polar and Polar Urals differed in origin and material composition from those in Central Asia; they were studied in the upper course of the Kolyma River at mean elevation of 1400 m and typed as "water-rock streams". The area of their development was characterized by Alpan topography, bald steep slopes, glacial cirques, smooth almost vertical walls of river valleys, and the end-moraines left by ancient glaciers, which supplied most of the material for rock streams. Their movement was associated with seasonal snow melting when large masses of rock waste activated by streams with velocities reaching 4 m/sec were descending along smooth valleys devoid of any vegetation. Their deposits differed from those of solifluction processes by the coarseness of material and lack of the clay-silt fraction. Morphology and basic parameters of the valleys favorable for the development of water-rock streams are listed. -- NSV

DENDROLOGICAL METHOD OF DETERMINING TIME AND PERIODICITY OF ROCK STREAM MOVEMENT. (Dendrologicheskiy metod ustanovleniya vremeni i periodichnosti prokhozheniya selevykh potokov; Text in Russian). Vestnik Moskovskogo Univ., Ser. 5, Geograf. 2:140-142, 1967. 3 refs.
DLC, QC851.M27

This dendrochronological method consists of dating the events of catastrophic rock stream movements and the variations in environment in former periods by comparative study of growth rings in the stumps of sawn-off trees. For this purpose the trees are chosen in the areas of rock stream development and cut down according to a definite pattern after their orientation with respect to the channel of the stream

CRREL BIBLIOGRAPHY

is established. Observations made of their growth rings indicate the age of the tree; the year of its mechanical injury by passing rock streams; repetition of rock stream movements, and maximum daily amount of precipitation. Such studies in the region north of Baikal indicated that rock stream movements of maximum destructive force originated on certain ridges which had daily precipitation exceeding 40 mm, repeating periodically every 10 to 15 years. -- NSV

ABSORPTION OF SOLAR RADIATION BY THE ICE UNDER A POOL. (O pogloshchenii solnechnoi radiatsii l'dom pod snezhnitsel; Text in Russian). *Prob. Arktiki Antarktiki*, Vyp. 25:66-70 incl. tables, graph., diagr., 1967. 3 refs.
DLC, G575.L422

Solar radiation (q) penetrating a pool and absorbed by the ice beneath was mathematically analyzed using the q attenuation coefficients in sea water obtained by N. T. Chernigovskiy for clear water and by V. M. Klimovich for river water inflow, and assuming that the attenuation of short-wave radiation with depth follows the Bouguer-Lambert law. A formula is derived for calculating q absorbed by different layers of ice accounting for changes during melting. The results indicate that q depends very little on the pool depth if the water is clear, so that stages of ice destruction are more advanced in this case. In the river-water pools, melting of the ice surface proceeds more rapidly than in clear water, but the internal ice layers absorb less radiation and therefore, are much stronger. -- NSV

EQUILIBRIUM CONDITION OF POLAR ICE. (O ravnovesnom sostoyanii polarnykh l'dov; Text in Russian). *Prob. Arktiki Antarktiki*, Vyp. 25:77-83 incl. table, graph, diagr., 1967. 16 refs.
DLC, G575.L422

A state of equilibrium is reached by ice when the opposing effects of atmospheric cold and oceanic heat are balanced. This particular case for drifting polar ice can be used for evaluating the thickness that can be reached by growing ice, and the changes when the thickness exceeds or is below the balanced thickness. In problems involving polar ice and climate, the balanced thickness becomes a climatic characteristic of the corresponding geographical region. An attempt is made to calculate the state of polar ice equilibrium on the basis of theoretical postulates, and to evaluate the effect of different thermal factors determining the variation of its thickness in a balanced state. -- NSV

CONCERNING THE ACCURACY OF MEAN WATER TEMPERATURE VALUES IN THE ARCTIC BASIN. (O tochnosti srednikh znachenii temperatury vody v Arkticheskom basseine; Text in Russian). *Prob. Arktiki Antarktiki*, Vyp. 26:35-38 incl. table, 1967. 7 refs.
DLC, G575.L422

The accuracy of water temperature variation obtained on the basis of single measurements and by continuous serial observations is evaluated according to a statistical procedure described, concluding that a probability of 0.95 can be assumed in a single measurement of the Arctic basin temperature to give true value with an accuracy of ± 0.08 . Thus, the accuracy of isolines on the maps or cross-sections of temperature distribution with water depth is about ± 0.1 . Because the mean daily values of water temperature in this basin are stable in time, the observations carried out during 2 to 3 decades may be regarded as synchronous. Mean monthly values of water temperature may be obtained from two measurements per day during the period to be averaged; at that, the degree of approximation of the temperature and its mean quadratic deviation will be the same as in the case of more frequent observations. These conclusions do not extend to micropulsations, which require special observation. -- NSV

NOMOGRAMS FOR CALCULATING TURBULENT HEAT EXCHANGE AND HEAT LOSS BY EVAPORATION. (Nomogrammy dlya vychisleniya turbulentnogo teploobmena i zatrat tepla na isparenije; Text in Russian). Prob. Arktiki Antarktiki, Vyp. 26:39-44 incl. diags., 1967. 7 refs.
 DLC, G575.L422

Two nomograms are offered for direct reading of heat losses by turbulent heat exchange and evaporation. The plotting requires graphic solution of an equation in three unknowns, using the system of Cartesian coordinates and the A. R. Konstantinov formula for turbulent heat exchange curves. The coefficients in this formula were obtained by A. V. Smetannikova for the surfaces of arctic seas. Heat loss for evaporation is obtained from two graphs: for the open and ice-covered sea. The application of the nomograms is explained by a practical example. -- NSV

Movement of broken ice over water surfaces is mathematically analyzed and a numerical coefficient is introduced for a quantitative evaluation of this motion. It is assumed that the broken ice forms a continuous, locally isotropic cover which can be regarded as a layer of viscous compressible fluid the movement of which is characterized by the Reynolds number. This approach makes it possible to study different aspects of broken-ice movement on the sea surface, to evaluate its resistance to the motion of a vessel, and to model such processes according to the gravitational similarity laws. -- NSV

POISSON'S COEFFICIENT OF ICE UNDER STATIC LOAD. (Koeffitsient Puassona l'da pri staticheskoj nagruzke; Text in Russian). Prob. Arktiki Antarktiki, Vyp. 26:49-52 incl. table, diags., 1967. 6 refs.
 DLC, G575.L422

The Poisson's coefficient of ice subjected to deformation by tension without a preliminary pressure-treatment for strength was determined for three types of ice: granular, fresh-water structurally modified forms, and artificial sea ice with salinity 1%. Data on sample deformation was transmitted by highly sensitive inductive data units and registered on an oscillograph's tape. Smaller values of the coefficient were obtained for the samples under tension than for those under compression. In the structurally modified ice, near rupture, the coefficient greatly exceeded the maximum value possible in plastic materials. During the initial loading-stage the coefficient for the salt-water samples was similar to that of the fresh-water ice, differing only by the absence of a sudden jump near rupture. -- NSV

otkrytom more s pomoshch'iu sudovogo lokatora;
Text in Russian). Prob. Arktiki Antarktiki, Vyp.
26:104-107 incl. graphs, diagrs., 1967.
DLC, G575.L422

Special observations of ice drift in the open sea were carried out in 1964 to obtain additional information on the small scale variations of ice movement by serial photography of the ship's radar screen. The investigation procedure is described in detail and the results are presented graphically. Drift direction in the areas studied was plotted from the courses of three ice floes traced for 4 1/2 hours, their position being registered every 15 minutes. Distances traveled by the floes during that time varied from 90 to 350 m with the observation error amounting to ±40 m. The Lagrange space-time correlation function was obtained for drift velocity components; it showed periodical maxima in the correlative relation of ice-floe movement, indicating a disturbance shifting from ice floe to ice floe with a velocity about 6 m/sec., which was ascribed to wind since its direction and velocity coincided with those of the disturbance. -- NSV

otkosov kanalov; Text in Russian). Gidrotekhnika i
Melioratsiia, 5:63-66 incl. illus., table, 1967. 5
refs.
DLC, TC1.G53

Solifluction processes caused by frost heaving or excessive moisture absorption during freezing of the ground and the subsequent loss of slope strength at ground thawing were destroying the drainage channel near Ulan-Ude (Buryat SSR). The maximum movement consisted of alternating clay and sand layers that accumulated 45-53% of moisture at the time of mud-flow development, which usually started with liquifaction of clays followed by slumping of the over-lying sand beds. Intensity of this process strongly depended on the rate of temperature increase in warm season. During a protracted spring when the quantity of melting ice in the ground was about equal to that of water evaporation, these phenomena were absent. Different ways of preventing solifluction under the conditions described are mentioned, among them the replacement of frost-heaving ground by gravel or coarse sand along the channel slopes with simultaneous drainage of water which penetrates into the fill. -- NSV

6 refs.
DLC, GB651.L38

The relationship between the thickness of a frozen upper layer in swampy and non-swampy, normal ground is analyzed and used as a basis for estimating the freezing depth of an unexplored swamp from combined data on the gradual freezing of non-swampy soil and on meteorological conditions. This method was especially suitable for the West Siberia periods: fall and winter, during which the intensity of freezing varied in each type of ground due to differences in moisture content, thermal capacity, and in addition the thermal conductivity and thickness of the overlying snow cover. Formulas are derived for calculating freezing depth of a swamp during winter of average hydrometeorological conditions and tables are given for the depths of frozen layers in different swamp types. -- NSV

CAUSES OF SOLIFLUCTION IN THE GERKHOZHAN-SU RIVER BASIN. (Prichiny selevoi aktivnosti v basseĭne r. Gerkhozhan-Su; Text in Russian). Gosudarstvennyi Gidrologicheskiĭ Institut, Trudy, Vyp. 141:121-126 incl. tables, 1967. 4 refs.
 DLC, GB651.L38

This basin is characterized by periodic solifluction set off by strong rains or glacier melting. An attempt is made to correlate these two factors and evaluate the possibilities of forecasting such events, reaching the conclusion that by knowing the amount of winter precipitation and the June-July weather it is possible to calculate the probability of rain solifluction in the coming year. In the years of average hydrometeorological conditions solifluction can be started by a strong rain exceeding 50 mm. Solifluction caused by ice melting is expected in less rainy years, the March through August weather being most significant. Both rain and thaw waters saturate the moraines, preparing the later rock stream movement. Only by observing the rate of moraine saturation is it possible to obtain quantitative estimates of the coming events. -- NSV

 DLC, QC851.M27

The All-Union Scientific Research Institute of Hydrotechnical Sciences carried out experimental investigations to determine the water vapor distribution coefficient (D) for the following types of snow: fresh snow, density 0.13-0.15 g/cm³, settled snow, density 0.23-0.26 g/cm³, and old medium-grained snow, density 0.32-0.38 g/cm³. The results indicate a definite relationship between D and snow temperature (or density). D exceeded 3.5 to 4.5 times the coefficient of molecular diffusion in the temperature range of 0 to -1°C; D lowered considerably with drops in snow temperature; definite D value corresponded to every snow density. No essential difference in D was noticed for the snow density range 0.13-0.38 g/cm³ at temperatures below -12°C. Formulas are derived for describing the mass-transfer process in snow and calculating the variation of its density in time under the action of vapor sublimation. -- NSV

ICE CONTROL OF UNDERGROUND DRAINAGE. (Nalednoe regulirovaniye podzemnogo stoka; Text in Russian). Gosudarstvennyi Gidrologicheskiĭ Institut, Trudy, Vyp. 139:180-205 incl. tables, graphs, diagr., 1967. 22 refs.
 DLC, GB651.L38

The term "ice control" applies to the yearly redistribution of underground water drainage during warm seasons, the process consisting of two parts: water accumulation in the ground as ice, and its subsequent release by melting. Several methods of determining the amount of ice-bound water are discussed and an attempt is made to establish the regularities governing this process by theoretical and experimental means. Stationary observations along the Samokit River (Yakutia) provided data on the nature of ice distribution, the places of its maximum concentration, quantitative evaluation of the ice-bound water reserves, and physical regularities governing their growth and melting. A hydrograph of water discharge was plotted for the Samokit River basin in which the genetic components of underground drainage were separated and a preliminary evaluation of the ice control process in time and along the course of the river within the experimental basin was obtained. -- NSV

EVALUATING EXPLOITATION EFFECTIVENESS OF ICEBREAKERS. (Otĭenka ekspluatatsionnoi effektivnostiĭ lineĭnykh ledokolov; Text in Russian). Morskoi Flot, No. 9:13-14, 1967.
 DLC, VM4.M6

Formulas are derived for calculating the exploitation effectiveness of certain types of icebreakers working under especially difficult conditions in clearing the way for vessel convoys in very thick ice. It is believed that the usual formula relating yearly expenses to the conveying capacity of the vessel is inapplicable. The performance of such ice-breakers should be measured by the sum of the gross register holding capacities of all the vessels convoyed, multiplied by the distance sailed by the vessels behind the icebreaker, i. e., by gross ton-miles. -- NSV

GEOLOGY OF THE USA CRREL PERMAFROST TUNNEL, FAIRBANKS, ALASKA. Tech. Rept. 199, U. S. Army Cold Regions Research and Engineering Laboratory, 26p. incl. illus., tables, graphs, diagrs., maps, July 1967. 29 refs.
CRREL files

This study provides the pertinent regional and historical geology of the tunnel site and immediate surroundings as well as data on the index properties of the material through which the tunnel passes. The tunnel is in the center of the zone of discontinuous perennially frozen ground. The tunnel geology is discussed with emphasis on bedrock, gravels, silts, ground ice, and chemical gradient. A study of the stratigraphy of the section reveals a record of the past climatic history of the area, based on the structure and distribution of the ice wedges, chemical gradients, sedimentary structures, radiocarbon dates, and the lithology of the material exposed along the tunnel section and vertical ventilation shaft. Two recognizable unconformities appear in the section. The large size of the wedges suggests that depositional rates were fairly slow during the period of wedge development. It can also be concluded that within the last 30,000 yr a minimum of 30 ft of silt was deposited, most of which is of Wisconsin age. (Author's abstract)

CRYOGENIC SLOPE PROCESSES. (Kriogennye sklonovye protsessy; Text in Russian). Izd-vo "Nauka", 296p. incl. illus., tables, graphs, diagrs. 1965. Approx. 700 refs.
DLC, GB406.K3

This book deals with the study of slope processes originating and developing under the action of cryogenic conditions in the Arctic and Sub-arctic territories and in the high mountains of any latitude. An attempt is made to generalize all the material published on this subject in the USSR and abroad, to define the approach to its study, and to formulate the trends of future investigations. Recent concepts of the mechanism of cryogenic slope processes are summed up, the deposits and relief features formed by them are described, and the influence of different natural phenomena and their geographical distribution is discussed, with basic emphasis on solifluction as the most important and best studied cryogenic process. -- NSV

HOLOCENE MORAINES AND ROCK GLACIERS IN THE CENTRAL BEN OHAU RANGE, SOUTH CANTERBURY, NEW ZEALAND. J. Glaciol., 6(47):737-748 incl. illus., maps, June 1967. 19 refs.
DLC, GB2401.J68

Young moraines and rock glaciers in the central part of the Ben Ohau Range, about 42 km south of the highest peaks of the Southern Alps, are briefly described. A new formation, the Ben Ohau Formation, consisting of the Ferintosh, Jacks Stream and Dun Flunary Members, is proposed for moraines and rock glaciers believed to have been built since the climatic optimum by three minor glacial advances. Moraines, and outwash and fan gravels, deposited during a more extensive pre-climatic optimum advance which was contemporaneous with the Cockburn Glacial Phase (Cochrane) in North America are assigned to the Birch Hill Formation. The sequence of glacial advances recorded in the Ben Ohau Range is compared with that found in western North America. (Author's abstract)

THE DISCHARGE IN THE CLOSED RIVER WITH THE WHOLE FROZEN SURFACE. (Keppyō kasen no ryūryū; Text in Japanese with English abstract). Seppyo, 28(1):13-18 incl. illus., table, graphs, Jan. 1966.

DLC, Orientalia Div.

In the open channel, the water stage is connected closely to its discharge and the discharge is obtained by the observation of stage. But, almost every river in a cold climate such as Hokkaido freezes at the surface in winter. Therefore, the results of studies about the open channel can not be applied directly to the closed river with the whole frozen surface. The stage-discharge curve of the above mentioned closed river is obtained by the same method in the open channel. If the water stage of the closed ice-covered river is defined as the water level in the hole of ice drilled for measurement. But, it is indicated theoretically that the curve is not invariable and varies with the changes of the accumulated snow weight on the whole frozen surface and the other conditions. The lower limit level of the surface ice of river was introduced as the parameter of the discharge in the closed river with the whole frozen surface. It is the theoretical and suitable parameter and is not affected by the accumulated snow weight and the other conditions. The vertical distribution of the suspended material in the closed river with the whole frozen surface was explained by the constant apparent viscosity all over the depth. The total suspended material corresponds to the lower limit level of the surface ice of river. (Author's abstract)

Drag of bodies moving through snow with high speeds (15~40 m/sec) was studied. Shells (as high-speed moving bodies) were shot into a snow pile by an air gun, and output in a built-in acceleration meter was recorded on an oscillogram. The impulse acceleration of shells was measured when they hit the snow surface, and the relation between the drag and the speed of the shell was obtained by integrating the curve on the oscillogram. In the speed range studied, the drag of a body can be expressed as a sum of a term proportional to the square of the velocity and a constant term. (Authors' abstract)

SNOW PRESSURE ON POLES FOR PREVENTING AVALANCHE ON THE TADAMI-LINE. (Tadami-sen ni okeru nadare bōshikō ni kakaru setsuatsu; Text in Japanese with English abstract). Seppyo, 28(2):41-45 incl. illus., diagrs., graphs, Mar. 1966.

DLC, Orientalia Div.

The maximum depth of snow-cover in the Tadami region averages 3 m to 5 m. Before providing protection, to collect snow data poles 2 m or 3 m long were set up for preventing avalanches at glens and uniform slopes. Four simple snow manometers were fitted on the 2 m poles (B-type), and six simple snow manometers on the 3 m poles (A-type): 1) The total pressure on the poles was greater at glens than on uniform slopes. (about 10 tons). 2) A-type poles were almost deformed at glens. 3) The total pressure on B-type poles was about 10 tons at glen, and 5 tons to 8 tons at uniform slopes in A test section; 5 tons to 6 tons in B test section and 6 tons to 8 tons in C test section. 4) According to the data on B-type poles, bending moment is nearly equal to total pressure, 5 tons to 10 tons. 5) Avalanche poles taller than 2 m are found useless both technically and economically. TRANSITION OF CONDITION ON HILLSIDES TERRACED AGAINST AVALANCHES. (Nadare bōshi kaidan-kō shikōchi no keinen henka; Text in Japanese with English abstract). Seppyo, 28(3):55-64 incl. illus., tables, diagrs., May 1966.

DLC, Orientalia Div.

CRREL BIBLIOGRAPHY

The authors have been carrying out a survey about the transition of conditions on hillsides where the terracing works for ground avalanche prevention were executed before. This paper presents the results of investigation conducted during the period of 1963-1965 on the snowy area with maximum snow depth of 2-3 m in winter. The matters deduced from obtained data are as follows: 1) The terracing work shows a gradual decline of its function against avalanches in the course of breaking of executed terracing and soil accumulation on terraced steps. However, the function of terracing lasts effectually for 20-25 years in every place except the area susceptible to erosion such as a sandstone zone. 2) It is estimated that natural trees on the terraced hillsides generally begin to function against ground avalanches about 15 years after execution of the terracing. PREPARATION OF LOW DENSITY SULFUR FOAM. Tech. Rept. 206, U.S. Army Cold Regions Research and Engineering Laboratory, 18p. incl. illus., tables, graphs, Sept. 1967.
CRREL files

It has been demonstrated that it is possible to lower the density of rigid sulfur foam to as low as 10 lb/ft³ in continuous pressurized process equipment and as low as 6 lb/ft³ in laboratory glassware at atmospheric pressure. Based on past experience, each reduction of foam density becomes progressively more difficult to achieve. With further research the densities might be further reduced, lowering the unit volume cost of the material and improving the thermal conductivity of the foam. The attractive features of the foam include stress-strain characteristics which should allow use in a variety of structural applications; low thermal conductivity, making it a good thermal insulation material; low moisture absorption; low water vapor permeation; low cost; insensitivity to ambient temperature conditions but favored by low temperatures; and the capability of being produced at a remote field site. CALCULATING MAGNITUDE OF GROUND FREEZING AND HEAVING ACCOUNTING FOR WATER MIGRATION. (Raschet promerzaniya i velichiny pucheniya grunta s uchetom migratsii vlagi; Text in Russian). Akademiya Nauk SSSR, Sibirskoe Otdelenie, Institut Merzlotovedeniya. Moscow, Izd-vo "Nauka", p. 19-25 incl. graphs, 1965. 10 refs.
DLC, TA713.A4385

A simple and accurate method is offered for forecasting the degree of ground heaving. Formulas are derived for heat- and mass-exchange in freezing grounds assuming that for fine-grained soil the water migration under the action of temperature gradients and the heat-transfer of moisture moving toward the freezing front may be neglected. It is also assumed that water flow from the thawed zone toward the frost boundary is determined by the freezing of free water and partly of bound water at certain temperature. With these assumptions the variation of moisture content in the ground due to water migration from below does not depend on the position of the front, i.e. does not depend on time but only on the properties and state of the ground and the speed of its freezing. The advantage of this method over the systems of differential equations offered by G. A. Martynov and N. S. Ivanov for the description of the same processes, is that electronic computers are not required. -- NSV

DLC, TA713.A4385

A correct determination of freezing depth and the time when a freezing layer unites with the permanently frozen ground is required for calculating the depths of water-lines, foundations, water wells, and other structures. The popular way of obtaining these data is a time consuming operation in which the depth is determined for a series of short time-intervals until the moment of a complete union of the layer with permafrost; besides, the existing formulas account only approximately for the thermal resistivity of a snow cover. A very simple calculation procedure is offered in which the dynamics of snow cover and the variation of air temperature in the winter are accounted for when determining the maximum freezing depth of a layer at any time, including the time of reaching the permafrost level. -- NSV

METHODS OF DETERMINING THERMAL PROPERTIES OF ROCK IN WELLS. (K metodike opredeleniya teplovykh svoystv gornykh porod v skvazhinakh; Text in Russian). Akademiya Nauk SSSR, Sibirskoe Otdelenie, Institut Merzlotovedeniya. Moscow, Izd-vo "Nauka", p. 36-44, 1965. 16 refs.
DLC, TA713.A4385

The method of determining specific thermal capacities and the coefficients of thermal conductivity of rock walls in wells is still in the stage of development. The theoretical postulates and the structural peculiarities of the instruments to be used in wells for such measurements are discussed; they depend on two basic factors: the physical properties of fluid filling the well and those of the surface of the well wall. Analysis of possible combinations of these factors indicated that the methods may be divided into four basic groups: for the dry or fluid-filled wells with or without casing. These can be arranged into two groups: one based on the assumption that the thermal properties are thermo-isotropic and the phase transformations are absent; the other based on accounting for the transition of moisture in the rock pores and the dependence of thermo-physical coefficients on temperature. Only the first group methods are discussed. -- NSV

CRREL BIBLIOGRAPHY

The thickness of snow cover, h after a long snowless interval, expresses to a certain degree the summation of the following factors: snow density, ρ and the structure and texture of the snow, which change in time under the action of snow weight, wind, temperature, and the firnification processes. It is difficult to obtain one empirical relationship $\rho(h)$ for all geographic regions, thus, an attempt is made to calculate $\rho(h)$ for the specific conditions of Yakutia. The formulas derived describe the variation of snow thickness because of surface melting, disregarding its settling as a result of structural changes produced by peripheral melting of snow crystals after moistening. The settling starts at the very beginning of snow melting and lasts a short time. The formulas may be corrected for the structural changes by introducing the empirical corrective formula of P. P. Kuz'min. -- NSV

Electrical potential originating during gradual cooling of doubly distilled water, weak salt solutions, and clay suspensions was studied experimentally in relation to moisture migration in soil during freezing. The experimental procedure consisted in keeping the sample-filled flasks, insulated on all sides but the bottom, under definite minus temperature conditions and observing the variation of the magnitude and sign of potential in time. Curves relating these variations to the distance between the measuring electrode and the cooling surface, and to cooling time were plotted from the readings obtained. Interpretation of the results indicated that a change in water structure preceding its freezing was the cause of origin of electrical potential and that this effect on water migration in freezing soil is dependent on the concentrations of salts dissolved in the soil moisture, the mineralogical composition of colloidal particles suspended in the solution, and the composition of exchange cations on the surface of these particles. -- NSV

DLC, TA713.A4385

The magnitude of heat originating in the process of a reaction between natural rocks and solutions at different temperatures was studied experimentally by leaching fine-grained rocks, differing in mineralogical composition and contents of water-soluble salts and exchange bases, with 1N solutions of H_2SO_4 and HCl. The results indicated that thermal effects depend mostly on the properties of the reacting solution and chemical composition of rocks, also on temperature and duration of the reactions. Decrease of thermal effect is determined by the direction of reaction at positive and negative temperatures; temperature decrease increases the solution viscosity, decreases the translation movement of ions in the solution, and decreases the speed of ion removal from the dividing surface. -- NSV

The term "air-ice" cover is used for a layer of ice, supported above ground by short wooden or concrete pillars, which protects the ground against winter freezing. Such a cover is obtained by flooding the ground with a layer of water of certain thickness and letting it freeze down to 20-30 cm with subsequent evacuation of the remaining water. The air-ice cover is widely used in practice, the demensions usually being estimated intuitively. The author presents a method of calculating thermal conductivity coefficients of ice and air interlayers and a detailed discussion of the optimal dimensions of the cover and their calculation. -- NSV

DLC, TA713.A4385

It is shown that the heat losses of water and the starting period of a water line occurring in frozen ground cannot be accurately determined by using the well known Newton formula relating the quantity of heat-loss per unit time to the area of the pipe surface, water temperature, and that of the pipe wall, since the conditions of filling the same line at the same water temperature depends on the temperature of the surrounding ground. Formulas are derived for the heat exchange processes at the moment of water line filling when the temperature of pipe walls is minus, and which account for additional factors such as: the inside icing of the pipe and heat separation because of phase transformations of water, variation of heat-exchange conditions due to icing, and the replacement of cooled portions of water by the subsequent portions with a higher temperature. -- NSV

DLC, TA713.A4385

Different types of air-ice covers, consisting of ice layers separated by air are discussed and their thermal conductivities evaluated mathematically. It is recommended that layer thickness be held to a minimum, thus increasing the heat-protection effect of the covers, the depth of the water layer on the ground being the same. The surface ice-layer must be thick enough to withstand the weight of a man with an instrument and of snow cover while the underlying layers must be much thinner. The thickness of air layers is determined by the possibilities of maintaining water level to the least required depth while that of the underlying ice-layers is determined by the capability of withstanding their own weight. -- NSV

Merzlotovedeniĭa, Moscow, Izd-vo "Nauka", p. 122-
129 incl. tables, graphs, illus., 1965. 5 refs.
DLC, TA713.A4385

Recent permafrost processes in wave-built islands were studied in terms of the physical and geographical conditions of their origin and for sites of future emergence. Only the shelf zone of the Arctic Basin within the limits of the Kara, Laptev, and East Siberian Seas is considered. Four stages were distinguished in the formation process: 1) one-year cycle in which, prior to the island emergence, the sea bottom deposits freeze seasonally to the permafrost depth; 2) a three-year period characterized by the appearance and growth of an intermediate non-freezing layer in the bottom deposits due to intensive sediment accumulation; 3) next 2 years of steady rise of the permafrost level ending in a complete freezing of the intermediate layer; 4) steady upbuilding and final emergence of the island during which the freezing processes are intensified by sediment aggradation until the ice cover reaches the sea-bottom, producing constant lowering of temperature in the deposits. -- NSV

Izd-vo "Nauka", p. 111-121 incl. tables, diagrs.,
1965. 1 ref.

DLC, TA713.A4385

Geothermal conditions of permafrost ground under heated buildings were studied in an attempt to develop means of their control, and verify the standing norms of ground loading for structural design. The results indicated continuous lowering of ground temperature under ventilated cellars even when the thermal regime was disturbed by incorrect building techniques. This effect increased the carrying capacity of the ground and became progressively greater with the increase in the cellar space and in the height between the ground and the reinforced-concrete girders. Because of a continuous permafrost spread in this area and its rigid climatic conditions, resulting in increased carrying capacity of the ground under heated buildings, an increased load on the bearing ground was authorized and the erection of 7- and 8-story buildings was permitted. -- NSV

diagrs., illus., 1965. 4 refs.

DLC, TA713.A4385

The results obtained in the study of thermal effect of solar radiation and air temperature on the destruction of frozen unconsolidated Quaternary deposits containing ice layers and forming escarpments on Mostakh I. in the Laptev Sea indicate that the speed of erosion by thawing does not depend on slope. Snow drifts may slow down the thawing depth of a cliff surface by 35%, the yearly mean depth of thawing of the exposed surface being 4.3 cm/24 hrs, basically dependent on solar radiation and air temperature. These data may be approximately extended to the whole Yakutia sea-shore and the near-shore islands. Destruction speed of outcropping deposits not containing ice layers was dependent on their mechanical properties and varied in the same climate from none to that of exposed ice. -- NSV

 DLC, TA713.A4385

The Institute of Geocryology, Siberian Branch of the Academy of Sciences USSR conducted daily observations of temperature variation in natural snow cover near Yakutsk and generalized on the characteristic features of an undisturbed snow. It was concluded that rimed snow is continuously formed under the action of vapor sublimation at first in the lower, then in the middle layer of the cover, the processes of snow recrystallization being so strong that they are often reflected in temperature distribution producing an anomalously cold layer in the lower part of the snow cover. Climatic peculiarities of Yakutsk create a rapid growth of temperature gradient along the snow profile, especially in spring, so that the upward migration of vapor and its sublimation may be considerable. -- NSV

GLACIOLOGICAL OBSERVATIONS IN THE VICINITY OF GENERAL BERNARDO O'HIGGINS BASE, ANTARCTIC PENINSULA. (Observaciones glaciológicas en las cercanías de la Base General Bernardo O'Higgins, Península Antártica; Text in Spanish with summaries in English and German). Chile, Univ., Santiago, Escuela Geol., Comun., No. 8, 29p. incl. illus., table, graphs, diagr., maps, Sept. 1965. 21 refs.

DLC, Unbound periodical

The methods and results of observations on types of glaciers and their rates of movement and on the texture, density, and hardness of snow on the Trinity Peninsula are discussed. The permanent snow line seems to lie between 0 and 100 m above sea level. Ice streams originating in plateau glaciers move at a rate of about 3 m/mo.; those originating in highland glaciers move about 10 to 15 m/mo. The size of the grains of firn (1 to 5 mm) and the density of the firn of the uppermost 2 m of the firn bed (0.48 to 0.56) correspond to values for the oceanic Arctic and indicate a more rapid process of firnification than has been found in other areas of the Antarctic. Rammsonde measurements yielded a maximum hardness at 20 to 25 cm and an average increase of hardness with the square of the depth, down to about 2 m. (Author's abstract, modified)

ROCK-STREAM FLOODS IN THE REGIONS BEYOND POLAR CIRCLE. (Selevye pavydki v Zapol'nykh; Text in Russian). Meteorologiya i Gidrologiya, No. 12:31-32, 1957. 1 ref.
 DLC, QC851.M27

The phenomena described were observed in the Central Siberian Plateau where different cryogenic slope processes were widely developed and the channels of local streams contained large amounts of rock debris ranging in diameter up to 1 m. They occurred most frequently in early spring when the upper courses of streams were heavily dammed up by snow. The accumulated melt water broke the snow dams and entire ice-rock-water masses moved downslope at a velocity of 5 m/sec reaching the lower broad part of the valley and spreading over it like a flood. Such events were triggered off by definite meteorological conditions and were typical for slopes devoid of vegetation. -- NSV

ZONALITY OF THE STRENGTH OF THE SEASONALLY THAWING LAYER AND ITS MAPPING IN WESTERN AND SOUTHERN YAKUTIYA. Translation: Siberian Dept. Acad. Sci., USSR, Inst. Frozen Ground Res., Seasonal Thawing and Freezing of the Ground in the Northeast Territory of the USSR. Moscow, Izd-vo "Nauka", p. 14-20 incl. tables, maps, 1966. 5 refs.

CRREL files

The zones of seasonal thawing layers are mapped for Western and Southern Yakutia. In order to separate the territory into zones, data on the depth of thawing at various points are compared, but under conditions that are comparatively homogeneous - according to some limiting complex of criteria. In parts with contrasting conditions it is sufficient to compare data of a standard part to establish boundaries. To establish the practical significance of seasonal thawing it is necessary to combine the regionality of a territory according to geological-geomorphological criteria on special small-scale and medium-scale charts of seasonal thawing and divide it into zones according to the greatest depth of thawing under definite conditions. The first brings out specific types of areas and covering sediments represented in any region and the predominant seasonal thawing layer. The second essentially fixes the gradation of the thawing depth as an aid in economic exploitation of the territory.

SITE AND SOIL DIFFERENCES IN THE BROWN HILLS REGION OF THE DARWIN GLACIER, ANTARCTICA. N. Z. J. Sci., 10(2):563-577 incl. illus., tables, map, June 1967. 14 refs.
DLC, Q1.N525

Three soils typical of those formed in small, enclosed, glacially scoured basins in the Brown Hills region were studied. The soil-forming factors, parent material, regional climate, and age were considered to be the same for each of the soils; slope and aspect were the principal site variants, and these gave rise to considerable moisture variations. The soils can be arranged in a sequence, from a dry soil that contains only a little salt and shows little weathering of clay minerals, to a wet, very salty soil that contains clay minerals, which, by Antarctic standards, are considerably weathered and hydrated. SOME RESULTS OF FIELD OBSERVATIONS ON THE FROST PHENOMENON ON PEAT SOIL. J. Hydrol. (Amsterdam), 5:269-278 incl. diagr., table, 1967. 8 refs.
DLC, GB651.J6

Field observations on ground frost carried out during the winter period 1953-1954 on peat soil revealed e.g. the following: 1) The relative total water quantity in the frozen zone formed during a period of slow cooling (in percent by volume) is higher than that resulting when freezing takes place at a fast rate. 2) With increasing frost depth, the soil immediately under the frozen zone dried out to such extent that the minimum values of its moisture content were lower in the winter than in the summer. 3) The total quantity of water stored in the frozen zone either in frozen or in liquid condition (in percent by volume) increased continuously in the course of the winter with further increase in frost depth. 4) After the increase of frost depth had ceased, the moisture content of the soil layers under the frozen zone once more began to increase, already before the start of the thawing period. 5) The frost penetration was the deeper but the relative total water quantity of the frozen zone (in percent by volume) the lower, the lower the level at which the water was kept dammed in the open ditches surrounding the area. The free-board amounts subjected to comparison in this respect were 20, 35 and 60 cm. The observations show that the frost phenomenon both developed and acted on the moisture conditions in the soil investigated in a manner largely similar to that which it is known to follow on mineral soils.

PROBLEMS OF RELATION AND INTERACTION OF GROUND WATERS AND FROZEN ROCKS. (Voprosy vzaimosv'язi i vzaimodeistviia podzemnykh vod i merzlykh tolsheh gornykh porod; Text in Russian). Vestnik Moskovskogo Univ., Geologiya, No. 4:22-36 incl. map, diagr., 1967. 13 refs.
DLC, G1.M68

Physical interaction between frozen rocks and ground water, expressed in thermal and material exchange, is discussed. Ground waters change thermal conditions of rocks by starting convective heat flows in the process of their movement through the frozen zone. These heat flows combine with conductive heat currents originating in the rock layers characterized by periodical heat-cycles, and with the heat inflow from deeper zones in the crust. This way

CRREL BIBLIOGRAPHY

ground waters redistribute heat energy in the upper rock layers and determine the cryogenic structure of the epi- and syn-genetic frozen rocks. Perennial freezing of the lithosphere effects ground-water supply, its movement and drainage by creating mobile water-resistant layers which divide single hydrodynamic systems in the frozen rocks, temporarily interrupts the communication between separate localities, and changes the velocity and direction of water movement. All these factors are briefly discussed with an attempt to distinguish definite types of ground water in the perennially frozen regions and plot their areal distribution on a map. -- NSV

by a modified frost penetrometer. The direct reading penetrometer, which was found to be fast and accurate, was used as a check on the indirect methods. Moisture-block and thermistor resistances and penetrometer measurements were made at weekly intervals throughout the frost seasons of 1963-64 and 1964-65. It is concluded that of the three indirect methods tested only the resistance blocks gave a reliable estimate of frost depth. Blocks were easily installed in the stone-free soils, and the accuracy of the method was limited only by the vertical spacing of the blocks and the natural variation in ground freezing. The study was made in a moist soil. Whether change in resistance should be as good an indicator of frozen ground in dry soils was not determined. -- NSV

EFFECT OF FROST ACTION ON THE SIZE OF SOIL AGGREGATES. *Soil Science*, 104(4):268-271 incl. tables, Oct. 1967. 11 refs.
DLC, S590.S6

It has been suggested that freezing and thawing modify the physical condition of fine textured soils decreasing ultimate particle size and increasing erodibility; on the other hand, there were indications that frost action causes an increase in the size of aggregates, which results in a decrease in the erodibility of the surface soil. This paper reports the results of the field study and four laboratory tests undertaken to investigate the influence of frost and soil moisture content at the time of freezing on the size of aggregates in soils. The objects of study were Haverhill loam, Sceptre clay, Hatton fine sandy loam, and Chin loam soil. There was little effect of frost on the aggregate-size distribution in clay or fine sandy loam. However, frost action decreased the percentage of erodible particles in a loam soil. Freezing and thawing decreased the percentage of erodible particles in the clay, loam, and fine sandy loam soil at higher moisture levels. Essentially there was no difference in the water-stable aggregates because of freezing and thawing. -- NSV

PLASTIC PROPERTIES OF ICE (LAKE AND CONTINENTAL ICE OF THE MARGINAL ANTARCTIC ZONE TAKEN AS AN EXAMPLE). (Plasticheskie svoystva l'da (na primere ozernykh i materikovykh l'dov kraevoy zony Antarktity); Text in Russian). *Merzlotnye Issledovaniya*, Sbornik Statef, Vyp. 4: 397-419 incl. illus., tables, graphs, diagrs., 1964. 7 refs.
DLC, GB646.55.M44

This paper reports the results of the laboratory study undertaken to determine the viscosity coefficients of different types of ice samples obtained from the marginal zone of Antarctica, and to investigate the stress-deformation relationship for the ice samples, and its variation in time. An attempt was also made to establish quantitatively the effect of temperature of a sample on its plasticity and to determine the relationship between the viscosity coefficient and structure of different ices. Ice was tested according to the method based on bending of a small ice beam, described by B. A. Savel'ev in his book "Study of Mechanical and Physical Properties of Ice" (*Izuchenie Mekhanicheskikh i Fizicheskikh Svoystv L'da*, Izd-vo AN SSSR, M., 1957). Structural features of ice, optic orientation of its crystals, their form and sizes were established microscopically. Formulas are obtained which describe the effect of temperature and deformation speed on ice plasticity, and the effect of ice structure on its viscosity is illustrated by stereograms of ice crystal orientation in the samples studied. -- NSV

CORRELATION METHOD OF PROCESSING ICE DRIFT DATA. (Korrelatsionnyy metod obrabotki dannykh nabludeniy za d'reifom l'da; Text in Russian). Prob. Arktiki Antarktiki, Vyp. 21:56-59 incl. tables, diag., 1965. 6 refs.
 DLC, G575.L422

This article presents the continuation of an earlier investigation in which the basic methods of distinguishing the wind- and current-induced components of ice drift were analyzed and a procedure offered for obtaining mean values of wind coefficients for the both components as well as the velocity and direction of the "steady" current, independent of local wind conditions, by correlating the projections of the ice-drift and wind vectors on the coordinate axes. In that procedure the resulting wind vectors had to be preliminarily turned by an angle corresponding to the mean deviation of drift direction from that of the wind. A new way of calculating this angle is offered, which is similar to the K. Watanabe method only more simple and convenient for use with data obtained from the drifting and automatic radio-meteorological stations. -- NSV

APPEARANCE OF THERMOKARST AT THE BOTTOM OF THE LAPTEV SEA. (Poyavlenie termokarsta na dne moria Laptevykh; Text in Russian). Prob. Arktiki Antarktiki, Vyp. 23:26-32 incl. illus., diagrs., 1966, 8 refs.
DLC, G575.L422

The profiles of the Laptev Sea bottom recorded by echo sounders showed typical thermokarst structures, of presumably recent origin, occurring at different development stages in the forms of wedge-shaped vertical troughs, large tetragonal or polygonal depressions, and sink holes of varied sizes, depending on the shape of melting ground ice, the most frequent forms of which were veins and lenses. Similar ice forms were widely developed on the adjacent land in the area of the Lena River delta and on the Novosibirsk Islands. Submerged thermokarst was found mostly at the depths exceeding 15 m; it was gradually developing during short periods of positive water temperatures, locally increased by inflows of warm river waters. The general aspect of the sea-bottom relief was very similar to that of the adjacent land, in particular, the large polygonal depressions near the Novosibirsk Islands closely resembling in size and form the polygonal fracture pattern on the tundra surface. -- NSV

EXPERIMENT IN CALCULATING MOUNTAIN GLACIER THICKNESS BY THE BALANCE METHOD. (Opyt vychisleniia moshchnosti gornyykh lednikov metodom balansov; Text in Russian). Geograficheskii Sbornik, 17:18-30 incl. tables, diagrs., 1964, 7 refs.
DLC, G58.G34

A discussion is presented on the basic postulates of the balance method and different ways of its application in which three formulas are offered for determining glacier thickness when its form is approximated by a half-ellipse, parabola, and trapezoid. The calculation procedures for using these formulas are explained and illustrated by a practical example of determining the thickness of the Central Tuyuksu Glacier (Kirgizia), in which it is shown that

the first two formulas produce almost identical results, the calculation procedures being much simpler than that for the third formula. The advantages of the method described consist in using all the basic field measurements obtained in the study of a glacier in one summer period, and in determining in the course of computation the amount of glacier's runoff and its cross-profile areas which are needed for evaluating the dynamic and hydrological regime of the glacier. The accuracy of the balance method was sustained during the IGY (1960-61) when its results proved to be quite close to those of seismic and electrical sounding. -- NSV

CRYOTECTONICS AND ITS ROLE IN GLACIOLOGY AND GEOLOGY. (Kriotektonika i ee rol' v glatsiologii i geologii; Text in Russian). Geograficheskii Sbornik, 17:41-49 incl. maps, diagrs., 1964, 21 refs.
DLC, G58.G34

Cryotectonics is defined as a branch of structural glaciology which studies ice movements, the types of tectonic structures formed by ice and the dynamics of their development. Because in polar regions ice is regarded as rock, it is suggested that all the means of geological investigations be applied to the study of ice, including structural and topographic mapping. Such maps should show the lines of outcropping of seasonal ice layers, mode of occurrence, cleavage orientation, faults, thrust-

CRREL BIBLIOGRAPHY

faults, intrusive ice bodies, zones of structural non-conformance, and the boundaries of basic structurally different glaciological stages. Similar maps prepared by P. S. Voronov and J. H. Zumberg for Antarctica are discussed, and the M. G. Grosval'd technique of drawing glacier cross-sections and cryotectonic schemes of ice movement are explained. It is further suggested that it is necessary to collect all bibliographies on the subject, to develop a legend for cryotectonic maps, and to systematize the existing cryotectonic nomenclature on the basis of geological terminology.

BASIC REGULARITIES GOVERNING RECENT GLACIATION IN KIRGHIZ ALATAU. (Osnovnye zakonomernosti sovremennogo oledeneniya v Kirgizskom Alatau; Text in Russian). Geograficheskii Sbornik, 17:51-69 incl. tables, graphs, maps, diagrs., 1964. 28 refs.

DLC, G58.G34

Ten types of glaciers observed in this region are described, among them the rock glaciers widely developed in the Kirghiz Alatau. They usually originated in corries, descended along steep valleys, did not exhibit outcrops of buried ice, and in some cases were associated with the terminal moraines of present glaciers. Their structure is similar to that of buried glaciers, only the activity is greater and the shape narrower. Movement capability of rock glaciers has been proved but the presence of an ice core is considered problematic. A total of 89 rock glaciers covering a general area of 35.9 km² were registered, most of them located on the northern slope of the mountains. The region studied was subdivided into eight zones according to qualitative differences in recent glaciation, the various ways of preparing maps of glaciological zonation are discussed, and the distinguishing features of each zone are described separately.

DLC, G58.G34

A calculation procedure was developed for evaluating the glacial run-off in the total water yield of the Zeravshan River over a period of years. The amount of run-off is based on analysis of the Zeravshan hydrograph at the river's mountain egress, the snow-line oscillations, and the general energy balance of the glaciation zone. Yearly outflow of glacial waters is calculated by subtracting the amount of groundwater supply during the July-September period from the total water discharge during that time because the amount of maximum glacier melting occurs during that period. To obtain more accurate results when estimating mean glacial runoff over a period of years, only those years are considered during which the snow line was at its highest level. The snow gone before the July-September period and its part in the glacial runoff may be neglected.

SIZE OF RECENT GLACIATION IN KUNGEI-ALATAU. (Razmery sovremennogo oledeneniya Kungei-Alatau; Text in Russian). Geograficheskii Sbornik, 17:90-93 incl. tables, 1964. 18 refs.

DLC, G58.G34

General area of Kungei-Alatau covered by glaciers was determined by aerial photography to verify old estimates of the military topographic maps dated 1915, 1921, 1937 and 1958 according to which it amounted respectively to 150, 237, 90, and 130 km². The results indicated that the territory covered by the open glaciers and buried ice (18.7%) amounted to 523 ± 52 km², closely approaching that of the Kirghiz Alatau (520 km²) and slightly less than the Zaiflyskii Alatau (544 km²), the typical feature being the predominance of medium-size glaciers (1.13 km²). -- NSV

**BOL'SHAIA ALMATINKA GLACIERS OF THE
 ZIL'SKII ALATAU RANGE ACCORDING TO 37
 YEARS OF THEIR OBSERVATION.** (Bol'sheal-
 matinskie ledniki khrebtā Zailiyski Alatau za 37
 let nablūdeniĭ; Text in Russian). Geograficheskii
 Sbornik, 17:94-101 incl. table, graph, diagr.,
 1964. 8 refs.
 DLC, G58.G34

The distribution and structure of the major glaciers
 in the Bol'shaia Almatinka river basin are described
 in detail. Movement rates are estimated. Glacier
 ablation is discussed on the basis of studies made
 in 1960 and the data referring to glacial retreat are
 tabulated. According to new observations the slopes
 of terminal parts were periodically increasing dur-
 ing retreat and decreasing during advance, which
 appeared to be a typical feature of all the glaciers in
 the Zailiyski Alatau. The observation procedure
 used was recommended as a pattern for future
 similar work. -- NSV

**STUDY OF SNOW COVER AND UPPER ICE LAYERS
 IN THE DOMES OF FRANZ-JOSEF LAND.** (Izu-
 chenie snezhnogo pokrova i verkhnikh gorizontov
 l'da na kupolakh zemli Franĭsa-Iosifa; Text in Rus-
 sian). Geograficheskii Sbornik, 17:149-157 incl.
 illus., tables, map, 1964. 11 refs.
 DLC, G58.G34

Glaciological investigation of snow cover and ice
 domes was carried out on 9 islands of Franz Josef
 Land, the results showing snow depth variation
 from 2 cm to about 2 m depending on such under-
 lying surfaces as ice domes, ice-free land, lake-
 or sea-ice. In the case of ice-domes the depth of
 snow depended on the height of the dome above sea-
 level, prevailing wind direction, and the degree of
 dome convexity. Microscopic study of the upper ice
 in the domes revealed two layers: the uppermost
 layer with spongy texture, abundance of air-pores,
 and mineral inclusions; and a deeper light-blue
 layer of infiltrated ice containing vertically oriented
 series of air-bubbles marking the boundaries of the
 yearly ice layers. Average thickness of these
 layers ranged from 8 to 10 cm, ice density, 0.87 to
 0.89, and the size of individual ice-crystals, 1.5 to
 2 cm; the position of main crystal axes ranged from
 normal to parallel orientation with respect to ice
 layering. -- NSV

 gornogo oledeneniĭa; Text in Russian). Geografi-
 cheskii Sbornik, 17:102-140 incl. tables, graphs,
 diagrs., 1964. 87 refs.
 DLC, G58.G34

Selected world literature is reviewed and conclusions
 drawn regarding the existence of rhythmic patterns
 in glacial fluctuations as a function of crustal sur-
 face variation under the action of extra-terrestrial
 forces. A definite pattern was clearly indicated
 during the later Quaternary and related to the
 rhythmic advance and retreat of the position of the
 southern permafrost boundary, and other evidence.
 During this period unusually strong and protracted
 tide-forming forces were manifested and two phases
 in world glacier behavior were distinguishable, oc-
 curring in different geographic zones, that of a
 short, intensive transgression and a long-lasting,
 gradual regression. -- NSV

BUDGET ANALYSIS ON THE SEA EFFECT SNOW
OBSERVED ALONG THE JAPAN SEA COASTAL
AREA. J. Meteorol. Soc. Jap., Ser. II, 45(1):53-
63 incl. illus., diags., tables, February 1967.
19 refs.

DLC, Orientalia Div.

Based on the aerological observations of smaller scale networks which were set up in January of 1963, 1964 and 1965 in Hokuriku district, the Japan Sea coastal area of central Japan, the heat and moisture budgets were compared among these three years. The flux divergence of vapor assumes nearly the same values for three winters, whereas the amount of precipitation changes very much from year to year. Although the difference in the evaporation from the sea surface and that in the convective transfer are estimated to be of considerable amount, the precipitation is principally related to the net transport of condensed water either from or to the surrounding region. The vapor import in 6 hours is compared with 6 hour precipitation within the region. Better relation is found in the precipitation on the downstream side stations. It is shown that the sensible heat increment is nearly twice as much as the latent heat decrement if they are computed by mean flow flux divergence. This circumstance is observed well in the cloud layer regardless of the scale of network. The surplus of the heat energy must be transported by convective activity. It is suggested that, when heavier snowfall is observed, the convective activity is so predominant that more heat energy than that supplied from the sea surface is transported into the cloud layer. RELATION OF METEOR STREAM TO NATURAL
ICE NUCLEI AND PRECIPITATION. J. Meteorol.
Soc. Jap., Ser. II, 45(1):128-136 incl. illus., table,
diags., February 1967. 7 refs.

DLC, Orientalia Div.

In order to confirm the increase of natural ice nucleus count around the 28th day after a meteor shower, measurements of natural ice nuclei were made with an improved filter paper technique at sufficiently separated two or more sites. The measurements were made continuously for the two periods of more than ten days in May and November, 1962 and January-February, 1963. It was found that the concentration of ice nuclei increased at each site around the same day, that is, the 28th day after major meteor showers. Other increase by local

source was seldom found during the periods. From 1960 to 1964, the time variation of all the concentration of measured ice nuclei during the several days around the 28th day after a meteor shower was examined by a mixing cloud chamber or filter paper technique. Almost always the ice nuclei showed unusual increase during the 27th to 29th day after the meteor shower. From the statistical examination, it was recognized that the increment of precipitation amount occurs for the period of the ice nucleus increase following the major meteor shower. LATTICE PARAMETERS OF ICE I AT LOW TEMPERATURES. (Gitterparameter von eis I bei tiefen Temperaturen; Text in German with English abstract) Acta Crystallogr., 23(3):343-345 incl. illus., diags., diags., tables, September 1967. 11 refs.
DLC, QD901.I523

Lattice parameters of hexagonal ice have been determined in the temperature interval 15-200°K with a special X-ray powder camera allowing the application of the Straumanis method. Within this temperature interval any temperature can be adjusted with a relative accuracy of better than 1×10^{-2} . The relative error of the magnitude of both the parameters a and c is better than 1×10^{-4} . The expansion coefficients along the a and the c directions, calculated with these lattice parameters, agree very well with the results of dilatometric measurements. Earlier investigations are discussed. (Authors' abstract)

SURFACE TOPOGRAPHY OF ICE SHEETS. Nature, 215(5105):1029-1032 incl. graph, diagr., Sept. 1967. 17 refs.

DLC, Q1.N2

The hypothesis that the thickness of glacier is inversely proportional to the surface slope, provided conditions are uniform around the observation point, does not fit the observations in certain areas. The use of continuous radio echo sounding has provided information which makes a more detailed study of this problem practicable along a line of ice flow to the south of Camp Century in North Greenland. It was found that surface slopes can vary rapidly in response to changing longitudinal stresses caused by ice moving over undulations of the sub-glacial floor. A relationship between surface slopes and

CRREL BIBLIOGRAPHY

variations of stress along the line of flow is derived from elementary considerations. This relationship provides a satisfactory numerical explanation of observations when stress changes are averaged over a distance of the same order as the depth of ice. This article describes the basic concept which is used and shows how it works in practice. -- NSV

THERMAL PROPERTIES OF A PUMICE SOIL. *Soil Sci. Soc. Amer. Proc.* 31(4):454-459 incl. tables, diags., July-Aug. 1967. 10 refs.
DLC, S590,S64A13

Dacite pumice materials deposited by the eruption of Mount Mazama cover a land area for as much as 161 km (100 miles) north and east of Crater Lake, Oregon. Frequent night frosts occur in this region. Thermal properties of the pumice material were investigated to determine their affect on the occurrence of low temperatures in the area and thus gain a better understanding of the factors governing the distribution of lodgepole (*Pinus contorta* Dougl.) and ponderosa pine (*Pinus ponderosa* Laws). Thermal conductivities were determined experimentally with a line heat source and calculated theoretically. The thermal conductivities of dacite pumice were found to be very low, which may account for the frequent occurrence of night frost in this region. (Authors' abstract)

OCCURRENCE AND EFFECTS OF OPEN WATER IN McMURDO SOUND, ANTARCTICA, DURING WINTER AND EARLY SPRING. *Polar Rec.*, 13(87):775-778 incl. map, Sept. 1967. 15 refs.
DLC, G575,P6

Dispersal of fast ice from the eastern shore of McMurdo Sound is aided by a polynya that forms between Cape Royds and Cape Bird almost every boreal winter or spring. Recent observations support the suggestion that the ice edge coincides with a line of junction of 2 strong currents, sweeping respectively from Cape Bird and from the Ross Ice Shelf west of Ross I., and combining to flow southwest and west across the sound. Reports from 3 seasons between 1901 and 1916 and from 12 seasons between 1955 and 1966 show that open water appeared off Cape Royds in 6 of 10 Oct. observations, 7 of 11 Nov. observations, and 13 of 15 Dec. observations. The western side of the sound often retains fast ice until Jan. or Feb. and sometimes retains it from year to year. The presence of the polynya on the eastern shore makes it possible for colonies of Adelle penguins to exist at Capes Bird and Royds.

COMPARISON OF PERMAFROST CONDITIONS IN CANADA AND THE USSR. *Polar Rec.*, 13(87):741-751 incl. illus., diagr., Sept. 1967. 31 refs.
DLC, G575,P6

A comparison of permafrost conditions in Canada and the USSR indicates significant differences between the two countries. Although they lie at roughly the same latitude in the Northern Hemisphere, the permafrost region extends farther south in Siberia than in Canada. Ground temperatures at the depth of zero annual amplitude are similar in both countries but permafrost is much thicker in the USSR. At the boundary of the discontinuous and continuous zones, permafrost ranges in thickness from 60 to 100 m in Canada and 250 to 300 m in Siberia. The thickest known permafrost in Canada is about 500 m

CIREL BIBLIOGRAPHY

in contrast to 600 m in Siberia. A similar relationship between mean annual air temperatures and the distribution of permafrost exists in both countries, but summers are warmer and winters are colder in Siberia. Under similar conditions it is postulated that the active layer can be thicker in Siberia, although there are no comparative observations to validate this suggestion. Differences in snow fall, vegetation, and the history of continental glaciation between Canada and USSR are considered the most important factors causing variations in permafrost conditions. -- NSV

STRUCTURAL PECULIARITIES OF THE SEASONAL THAWING LAYER IN CENTRAL YAKUTIA. (Nekotorye osobennosti stroeniya sezonoprotalivayushchego sloya Tsentral'noy Yakutii; Text in Russian). Akad. Nauk SSSR, Sibirskoe Otd., Inst. Merzlotovedeniya, Sezonnoe Protalivanie i Promerzanie Gruntov na Territorii Severo-Vostoka SSSR. Izd-vo "Nauka", Moskva, 21-28 incl. graphs, diags., 1966. 6 refs.
DLC, GB648.55.S4

Basic structural features of seasonal freezing-thawing layers in Central Yakutia strongly depend on climate, lithological composition, and texture of surface deposits. Formation of such layers in loam in dry climate in the vegetation zones ranging from steppe to taiga is discussed. Their most persistent feature is the foliated texture which is preserved all through the layer due to the exceptional dryness of air, which in turn affects the cryogenic structure by determining the distribution of ice veinlets among soil flakes. Lenticular or netted cryogenic textures develop only in the uppermost soil layer in taiga which contain some humus and in which is concentrated the major part of fall precipitation. The frost action loosens the taiga soils during thawing causing an increase in the size of aggregates. -- NSV

THERMAL REGIME OF BOTTOM SEDIMENTS IN THE SHALLOW WATERS OF ARCTIC SEAS.
 (Teplovoi rezhim donnykh otlozhenii na melkovod'e arkticheskikh morei; Text in Russian). Akad. Nauk SSSR, Sibirskoe Otd., Inst. Merzlotovedeniia, Sezonnoe Protaiwanie i Promerzanie Gruntov na Territorii Severo-Vostoka SSSR. Izd-vo "Nauka", Moskva, p. 40-46 incl. tables, graphs, 1966.
 DLC, GB648,55,S4

This paper reports the investigation at Yana Bay, undertaken to determine thermal regime of bottom deposits and their freezing conditions in the shallow water areas at water-depths of 1.0 to 1.5 m, 1.5 to 2.5, 3 m, and more. In the first case, during winter, water frozen completely and the active layer of bottom sediment frozen to its union with permafrost; in the second case, the layer frozen only to a certain depth under the completely frozen water, while in the third case, the bottom deposits were never frozen above the depth of 4.5 m. Thermistor readings indicated that thawing of bottom sediment continued to the end of August and the maximum depth of 1.3 m; the maximum melting speed was 7.9 cm/24 hrs at the end of July with a gradual decrease to 1 cm/24 hrs. Mean temperature of the upper 10 cm of bottom sediments equalled that of water, but a sudden drop amounting to 1° for every 6 cm in the thawed layer and 1° for every 20 cm in the frozen layer was observed below the upper 10 cm of sediment. -- NEV

CALCULATION OF THAWING DEPTH WITH AN ACCOUNTING FOR EXTERNAL HEAT EXCHANGE.
 (Raschet glubiny protaivaniia s uchetom vneshnego teploobmena; Text in Russian). Akad. Nauk SSSR, Sibirskoe Otd., Inst. Merzlotovedeniia, Sezonnoe Protaiwanie i Promerzanie Gruntov na Territorii Severo-Vostoka SSSR. Izd-vo "Nauka", Moskva, p. 47-57 incl. tables, graph, 1966. 9 refs.
 DLC, GB648,55,S4

An approximate solution of the problem concerning the calculation of thawing-depth variation in time in the course of melting is presented, in which that part of the heat energy spent on evaporation and turbulent heat-exchange in air, and that penetrating the ground are accounted for. The temperature field of air and of frozen and thawed rocks is des-

cribed by a system of three differential equations of thermal conductivity for certain boundary conditions, assuming that the thermal field of air is quasi-stationary. This system is solved by the method of successive approximations developed by M. E. Shvetsov for the problems of boundary layer dynamics. Its advantage lies in the possibility of reducing the solution of a system of differential equations with moving boundary to the solution of a system of ordinary differential equations with respect to thawing-depth. -- NSV

Merzlotovedeniia, Sezonnoe Protaiwanie i Promerzanie Gruntov na Territorii Severo-Vostoka SSSR. Izd-vo "Nauka", Moskva, p. 58-76 incl. tables, graphs, 1966. 8 refs.
 DLC, GB648,55,S4

An attempt is made to increase the accuracy of certain approximate methods developed for the calculation of freezing- and thawing-depths of ground. Such methods are based on the solution of a system of thermal conductivity equations for the frozen and thawed zones without accounting for mass-exchange in the ground. It is believed, that more accurate results may be obtained in two ways: by calculating more precisely the boundary conditions determining heat exchange in the ground, and by developing convenient ways of accounting for water convection and migration in the ground during its freezing and thawing. Only the first way is analyzed in this article for the case of a horizontal terrain, and new equations for depth determination are obtained on the basis of this analysis. The use of these formulas is illustrated by practical examples. -- NSV

The possibility of forecasting minimum temperature

CRREL BIBLIOGRAPHY

(t_{min}) of the upper layer of perennially frozen ground for a period of years is discussed. The analysis is based on the relation of minimum annual air temperature to the sum of minus degree days per year and the snow thickness. The differential equations describing the basic laws of thermal conductivity are modified to account for the main factors on which t_{min} is dependent: 1) moisture content, thermal and physical properties of the layer down to the depth of zero amplitudes of annual temperature fluctuation, 2) the sum of minus degree days of air per year, and 3) mean thickness of snow per winter. This method was used in determining t_{min} for the experimental area of the Institute of Geocryology, Siberian Branch of the Academy of Sciences, USSR, at the depth of 2.75 m for the period 1954-1960. According to the theoretical and experimental curves the calculation error did not exceed 0.6°. -- NSV

ELECTRICAL PHENOMENON OCCURRING DURING FREEZING OF DILUTE AQUEOUS SOLUTIONS. J. Applied Phys., 38(11):4416-4420 incl. diagrs., illus., October 1967. 14 refs.
DLC, QC1.J83

The electrical effects occurring during freezing of dilute aqueous solutions have been studied using NH_4OH and NH_4Cl solutions. The freezing potentials depend on the concentration of the solution and the rate of growth of the solid phase. This effect is an impurity effect and does not appear in pure material. The phenomenon can be explained by a model in which the impurity rejected by the growing solid into the solution ionizes, one kind of ion being adsorbed on the solid surface at the interface and the other kind diffusing into the liquid. The impurity ion adsorbed on the surface moves with the surface and is not incorporated into the solid phase. This effect is confined to a narrow range of concentration of the solutions. THE EFFECT OF WATER IN A SEASONAL THAWING LAYER ON ITS THICKNESS AND TEMPERATURE REGIME. (Kharakter vlianiya nadmerzlotnykh vod na temperaturnyy rezhim i moshchnost' sloya sezonnogo ottaivaniya'; Text in Russian). M.G.U. Merzlotnye Issledovaniya, Vyp. 5:26-42 incl. tables, map, diagrs., 1966. 11 refs.
DLC, GB648.55.M44

Water moving in a seasonal thawing layer was studied in East Siberia in river valleys under different geomorphological and geocryological conditions. Several water zones were found in the thawing layer within the same water-bearing interval; they differed by the conditions of ground-water recharge, the time span of water existence in the zone, and the way the water affected the ground temperature. The size of such zones depended on quantity and distribution of atmospheric precipitation, and slope and freezing conditions of the ground. A scheme is offered for classifying the waters present in a thawed layer according to the rock type in which the waters circulate, their relation to the water-impervious frozen layer beneath, and their recharge conditions. The areal distribution of such waters can be mapped on the basis of this scheme. -- NSV

VARIATION OF THERMAL CONDUCTIVITY OF A MOIST GROUND BECAUSE OF PHASE TRANSITION OF WATER DURING FREEZING. (Izmenenie teploprovodnosti vlazhnykh gruntov za schet fazovykh perekhodov vody pri promerzani; Text in Russian). M.G.U. Merzlotnye Issledovaniya, Vyp. 5:92-99 incl. tables, graph, 1966. 9 refs.
DLC, GB648.55.M44

The relative variation (B) of the thermal conductivity coefficient (λ) of frozen and thawed soil samples ($B = \lambda_r / \lambda_{thwd}$) with respect to their composition, density, and moisture content was studied experimentally. The results indicated that B of an absolutely dry sample remained practically constant at plus and minus temperatures. It varied in moist soil on account of water freezing, the nature of this

CRREL BIBLIOGRAPHY

variation depending entirely on the moisture content of soil. For sandy and clayey soils containing 3-7% water, B of the frozen samples was lower than B of the thawed samples due to the disturbance of thermal contacts in the soil by the growing ice crystals. An increase in moisture increases the quantity of heat transmitted through ice crystals, so that at a certain degree of water saturation $B = 1$. This moisture content was 8 to 10% for sandy soils and approached the maximum molecular moisture content in very fine soils. Further increase in water saturation resulted in a linear increase of B. Formulas are given for calculating B for loam and sandy soils. -- NSV

EXPERIMENT IN GEOBOTANICAL MAPPING OF PERENNIALY FROZEN ROCK AREAS IN THE ALDAN REGION OF YAKUT ASSR. (Opyt geobotanicheskogo kartirovaniâ v raionakh razvitiâ mnogoletnemerzlykh gornykh porod na primere Aldanskogo raiona Yakutskoi Assr; Text in Russian). M. G. U. Merzlotnye Issledovaniâ, Vyp. 5:171-179 incl. table, 1966. 10 refs.
DLC, GB648.55.M44

Characteristic features of geobotanical mapping in permafrost regions are analyzed taking as an example the preparation of a small scale map for the Aldan region of South Yakutia, which shows the association of plant types with definite complexes of physical and geographical conditions. The map was prepared from aerial photography and land surveying data. Mapping units were differentiated on the basis of a combination of conditions determining the appearance of certain plant cover, relief, local climate, soil, moisture in the ground and the type of its seasonal freezing and thawing. -- NSV

ENERGIC INHOMOGENEITY OF WATER IN FINE GRAINED ROCKS. (Energeticheskaiâ neodnorodnost' vody sodержashchejsâ v tonkodispersnykh gornykh porodakh; Text in Russian). M. G. U. Merzlotnye Issledovaniâ, Vyp. 5:221-228 incl. table, 1966. 18 refs.
DLC, GB648.55.M44

Study of water phases in fine grained frozen rocks indicated the presence of two water types: one which crystallizes at freezing temperature, and another which remains fluid at the same temperature; both types are energetically inhomogeneous. This inhomogeneity is produced by the distortion of the molecular structure of water due to the surface activity of rock particles, which changes the forces governing the mobility and interaction between ad-

acent water molecules. The relationship between the fluid and solid water phases in a freezing rock, with respect to changing temperature, is analyzed and the facts sustaining energetic inhomogeneity of water are discussed. -- NSV

ON THE COEFFICIENT OF LATERAL DEFORMATION AND VOLUME DEFORMATIONS OF FROZEN SOILS DURING CREEP. (O koeffitsiente poperechnoi deformatsii i ob ob'emnykh deformatsiâkh merzlykh gruntov v professe polzuchesti; Text in Russian). M. G. U. Merzlotnye Issledovaniâ, Vyp. 4:229-240 incl. tables, graphs, 1966. 9 refs.
DLC, GB648.55.M44

The coefficient of lateral deformation (μ) of frozen loam and clay was determined according to the results of testing these soils for creep and strength under continuous loading under uniaxial compression (σ). Density and moisture contents of the soils were respectively 1.81 to 1.82 g/cm³ and 26% for loam and 2.06 to 2.08 g/cm³ and 20 to 24% for clay; testing was conducted at -5, -10 and -20°C and at different compressive forces, which were maintained constant for each individual sample. Lateral deformation was measured at the base and middle of a core sample. The results indicated that in the process of soil creep μ depended on σ , time, temperature, and the type of soils. These relations are illustrated graphically. -- NSV

GEOCHEMICAL SOIL PROCESSES IN FREEZING GROUND OF MONSOON LANDSCAPES. (Pochvenno-geokhimicheskie protsessy musonno-merzlotnykh landshaftov; Text in Russian). Pochvennyi Institut im. V. V. Dokuchaeva. 166p. incl. illus., tables, graphs, diagrs., Lzd-vo "Nauka", Moscow, 1967. 114 refs.
DLC, Slavic Div.

Soil formation processes characteristic of seasonally freezing ground in the areas of a monsoon-type climate are discussed in this monograph. New material is presented on the chemical composition of soils, vegetation, rocks, ground- and river-waters, and on this basis are determined the biological, hydrochemical, pedological, and geological cycles of chemical elements migration and accumulation. The processes governing redistribution of sesquioxides and silica are especially emphasized; the procedures of zoning and mapping soils on a geochemical basis are analyzed; and the measures for increasing soil fertility recommended. -- NSV

DLC, Slavic Div.

This book presents the characteristics of frozen formations in north Yenisey. Peculiarities of permafrost distribution, the temperature regime, thickness and cryogenic structure of perennially frozen rocks are established by analyzing natural conditions of this region. The procedure of mapping such areas is explained, and illustrated by a geocryological map (scale 1: 2,500,000) of the region described. History of permafrost development during the Quaternary Period and the genesis of cryogenic formations are stressed. -- NSV

gations, which also generalizes the former experience in applying airborne survey to geocryology and the related subjects, and which proposes the trends of their further development. -- NSV

 No. 1:43-45 incl. graph, 1966. 2 refs.
 DLC, QC851.M27

This paper reports the results of a 3-year testing (1962-65) of new materials on which ice does not form and which can be used in hydrotechnical practice. The study of the effect of meteorological, hydraulic, and hydrothermal factors of icing of different materials was a part of this investigation. Experiments were conducted under natural conditions in the channel of a hydroelectrical power plant. Metallic sheets covered by the iron, concrete, bitumen, and different polyethylene coatings were immersed and oriented parallel and perpendicular to cold stream flow. Temperature of water and air, the velocity and direction of wind, the moisture content of air and the stream velocity were observed. The results indicated that a complete icing of iron, concrete, and bitumen required 10 to 15, 15 to 20 and 20 to 25 minutes respectively; the polyethylene films were entirely free of ice. The use of polyethylene coating on slopes and bottoms of water channels, spillway grating, and the submerged parts of structures is recommended to prevent icing. -- NSV

This article reports the results of an attempt to forecast the dates of ice events (grease ice forma-

CORREL BIBLIOGRAPHY

tion, ice-bound state, ice break-up) on the rivers in the northern and central regions of the USSR from the atmospheric circulation data, without considering the effect of hydrological factors. A set of the coefficients from the Chebyshev polynomial expansion of a certain meteorological field was used in the evaluation of atmospheric circulation because this field characterized the prevailing stream in the troposphere and its contour. Charts were available for a long series of years. Equations were derived for forecasting different ice events in various regions 25 to 60 days in advance. The predictors - separate components of atmospheric circulation - used in these equations varied for different regions, but the same equation was used for areas occurring under approximately equal meteorological conditions.

ON THE PROCEDURE OF STUDYING RADIATION PROPERTIES OF AN ICE SHEET COVERING WATER BODIES ON LAND. (K metodike izuchenija radiatsionnykh svoystv ledianogo pokrova vod sushi; Text in Russian). *Meteorologiya i Gidrologiya*, No. 2:108-111 incl. illus., graphs., 1967. 7 refs.
DLC, QC851.M27

The penetrating capacity of solar radiation through ice was evaluated by the total and scattered radiation flux density measured by a pyranometer which was also capable of measuring radiation falling on a perpendicular surface; the radiation falling directly on the pyranometer's thermopile through a spherical glass hood and that passing through a water filter 1 cm thick was also measured. The degree of cloudiness, temperature, pressure, and moisture content of air were observed simultaneously. The results indicated that under a clear sky the scattering and absorption of solar radiation by the atmosphere increases the infrared part in the atmosphere while cloudiness filters out the infrared radiation. A growing scattered radiation component was increasing the penetration capacity of total radiation through water, snow, and ice. -- NSV

AN X-RAY DIFFRACTION STUDY OF SILVER IODIDE FROM AEROSOL GENERATORS AND A PRELIMINARY EXPERIMENT ON ICE-NUCLEATING ABILITY OF β -AgI AND γ -AgI. *J. Meteorol. Soc. Jap.*, Ser. II, 45(2):157-166 incl. diags., illus., table, April 1967. 8 refs.
DLC, Orientalia Div.

The crystal structure of silver iodide produced by an aerosol generator was studied with the aid of an X-ray diffractometer. The aerosols produced by the vaporization of a mixture of silver iodide and

potassium iodide consisted of the hexagonal silver iodide (β -AgI) and some complex, such as KAg_3I_4 . Little trace of potassium iodide was detected in the aerosols. The aerosols produced by the vaporization of an iodide ion-rich silver iodide sample consisted mainly of the hexagonal form. On the other hand, the aerosols produced from a sample with an excess of silver ion consisted mainly of the low-temperature cubic form of silver iodide (γ -AgI). The low-temperature cubic form of silver iodide was found to be more efficient in ice-nucleating than the hexagonal form. The different efficiency could be explained in terms of the misfit of the crystal against ice. (Authors' abstract)

SCATTER OF FREEZING POINTS EXPECTED FROM THE HOMOGENEOUS NUCLEATION. *J. Meteorol. Soc. Jap.*, Ser. II, 45(2):185-189 incl. tables, diagr., April 1967. 10 refs.
DLC, Orientalia Div.

Two theories related to the freezing problem are analyzed to determine the amount of scatter attributable to the nucleation mechanism. One is a stochastic approach to explain observed scatter of freezing points as proposed by Bigg, the other is a thermodynamic nucleation theory which treats the equilibrium between the supercooled water and the ice embryos in it. The purpose of this analysis is to find to what extent the scatter of freezing points can be expected, if the freezing process really has the nucleation mechanism as treated in the theories.

HYDRAULIC CALCULATION OF FLOW UNDER AN ICE COVER. (*Gidravlicheskiy raschet potoka pod ledianym pokrovom*; Text in Russian). *Meteorologiya i Gidrologiya*, No. 12:46-48 incl. graph, 1966. 1 ref.
DLC, QC851.M27

When calculating water flow in an ice-bound river the roughness of the ice surface which comes into contact with water has to be accounted for separately since it differs from the roughness of the river channel. The authors have conducted a series of experiments to determine the velocity profile of the stream under the ice and to evaluate the coefficients of ice and river-channel roughness: n_2 and n_1 respectively. A graph relating n_1/n_2 to the ratio of maximal and dynamic stream velocities was plotted in logarithmic coordinates and a general formula for the family of parallel lines on this graph was obtained and transformed into the final equation for n_2 .

CRYOGENIC PHENOMENA ON THE SEA SIDE OF THE YANA DELTA. (Kriogennye yavleniya u morskogo kraia del'ty Yany; Text in Russian). Yakutsk, Gosudarstvennyĭ Universitet, Uchenye Zapiski, Vyp. 16:77-83 incl. illus., diags., 1965. 3 refs. DLC, AS262.Y3A3

Cryogenic relief-forms appearing on the northern part of the Yana River delta were studied, with emphasis on frost-fracture structures, thermokarst, and frost heaving. Frost fractures formed on the periodically flooded areas were disappearing with the seasonal thawing of the upper layer of ground. Ground veins were observed on the surface of the marginal parts of the delta, and in a buried state in the floodplain deposits. They gradually disappeared and instead ice veins appeared toward the center of the delta. Frost fractures formed a polygonal pattern without ridges in the marginal parts of the delta, the ridges appearing temporarily during flood periods. The polygons with ridges were developed on the high flood plain where ice veins grew only laterally. -- NSV

CHARACTERISTIC FEATURES OF THE CAVING-IN OF SHORES OF THE KOLYMA RIVER AND ITS RIGHT TRIBUTARIES IN RELATION TO COMPOSITION AND STRUCTURE OF TERRACE CUSPS. (Nekotorye osobennosti obrusheniya beregov Kolymy i ee pravyykh pritokov v svyazi s sostavom i stroeniem terrasovykh ustupov; Text in Russian). Yakutsk, Gosudarstvennyĭ Universitet, Uchenye Zapiski, Vyp. 16:85-90 incl. illus., 1965. 3 refs. DLC, AS262.Y3A3

Destruction of river shores built of perennially frozen rocks was observed in the Kolyma River basin during the summer of 1963. The nature of the process was closely related to the lithological composition, structure, and ice content of the river bench deposits and to the distribution of ice lenses in the bench cliff. Melting of ice in looser sediments resulted in the development of a so-called thawing niche which grew gradually into the cliff undermining the above lying deposits. The same process of intensive ice melting in the terrace slope proceeded differently and led to various forms of slope sculpturing depending on the granular composition of the sediments, the nature of their bedding and the size of buried ice lenses. -- NSV

STRUCTURAL FEATURES WHICH PREDETERMINE THE FORMATION OF TROUGH ROCK-GLACIERS IN ZABAİKAL'IE. (Strukturnoe predopredelenie peremetykh zemlfanykh gletcherov v Zabaikal'e; Text in Russian). Geogr. Obshch. SSSR, Zapiski, Zabaikal'skiy Otd., Vyp. 22:142-144, 1963.
DLC, G23.G272

A short description is presented of the rock-glaciers developing in East Transbaikal in the local troughs characterized by steep slopes and a swampy bottom. Rock waste accumulates at the bottom of such a trough by talus creep and solifluction, its specific structural features being a complex alternation of sand and clay interlayers, ice lenses, and a strong water saturation. The rock glaciers several meters thick moved along the trough bottom under their own weight helped by water lubrication, with a velocity of several millimeters per year. The majority of rock-glaciers were associated with the mountain crests cut by faults or those exposing strongly fractured water-bearing rocks; however, this association was true only for East Transbaikal.

LIMITS TO NAVIGATION BY ICE IN PORT OF CHURCHILL. Proceed. of Amer. Soc. of Civil Eng. J. of Waterways and Harbors Division, 93(WW4):11-26 incl. map, tables, graphs, diags., Nov. 1967.
DLC, TC1A4

Icing conditions in two zones are discussed as affecting and limiting the navigation season: (1) Hudson Bay; Hudson Strait, eastern end; Hudson Strait, western end; and (2) Churchill Harbor. Mitigation of the ice conditions during freeze-up in Churchill Harbor could extend the shipping season not more than an average of 14 days. Extension of the season would also depend upon certain changes in the conditions of operation. These could be: improvement of aids to navigation with emphasis upon operations in northern waters; provision of escort service by ice breakers in Hudson Bay and Straits; more frequent aerial ice reconnaissance; and use of ice-strengthened ships specially adapted for northern navigation routes. The Churchill River responds to atmospheric cooling quickly, hence, ice production commences in the river before it does in the sea and owing to the surface current distribution makes the harbor untenable. Diversion of the river at Southern Indian Lake would greatly reduce the fresh water flow and cause ice to appear a few days earlier but the volume of ice should be substantially reduced. Local ice production within the harbor would not be affected. -- NSV

LONG-CHAIN ALCOHOL SUPPRESSION OF SNOW
EVAPORATION. Proc. Amer. Soc. Civil Engrs. J.
Hydraulics Div., 93(HY6):271-279 incl. illus.,
tables, Nov. 1967.
DLC, TC1.A39

Results obtained from studies of hexadecanol dis-
tribution on a melting snow surface using isotopes
and autoradiographs are given. In addition, investi-
gations of complimentary pan evaporation studies
describe the method of applying alcohols and give
the effects of a specific mixture of long-chain alco-
hols on snow evaporation. The combined results
indicate that long-chain alcohols can spread on a
melting snow surface. The rate of spread of hexa-
decanol to a concentration sufficient to form a com-
pressed film was less than 1 cm per hr. Under the
conditions of the study, 10% emulsion applications
of a hexadecanol-octadecanol mixture were far
superior to powder applications. An average reduc-
tion of 38.3% was obtained with this mixture in those
runs having evaporation reductions significant at the
5% level. Although still in the development stage,
the autoradiograph technique appears to have promise
for future studies of long-chain alcohol distribution
on snow surfaces. Longer duration and larger scale
studies are necessary to determine the practicality
of field applications. -- NSV

THE PHYSIOGRAPHY OF ARCTIC-CANADA. WITH
SPECIAL REFERENCE TO THE AREA SOUTH OF
PARRY CHANNEL. The Johns Hopkins Press,
Baltimore, Maryland, 336p. incl. illus., tables,
graphs, maps, diagrs., 1967. 713 refs.
DLC, GB132.N6B5

An examination of the physiography of arctic Canada
south of Parry Channel brings together in one work
information about the arctic landscape and its evolu-
tion accumulated during the last two decades. The
material is presented in 23 chapters which deal with
general features of the physical geography, climate,
distribution of glaciers, permafrost, soils, vegeta-
tion, the major episodes in landscape development,
the geomorphic processes in the present-day land-
scape, and the special elements in the landscape.
The field work forms the basis of this study, the
next most important source of information being air
photograph analysis and the work of other scientists.

Timms, Albert G.
PREPARING FOR COLD WEATHER CONCRETING.
Modern Concrete, p. 26-27, 30, 32-34, October
1967.
DLC, TA680.M6

Special precautions in making and protecting con-
crete to be placed in cold weather are pointed out.
Although no new developments in this field are
mentioned, certain refinements in the methods
used are discussed. Satisfactory structures can be
built if the concrete during subfreezing weather is
maintained at 65°F or higher from the time of placing
and for several days thereafter. During this time
satisfactory moisture conditions must be maintained.
The duration of protection required will vary with
conditions favorable to the continuing development
of strength; it will also vary with the strength needed
immediately after protection. The development of
tough transparent plastic sheets and improved heat-
ing devices has made it possible to place concrete
(except for pavements) economically all winter.

SOME THERMODYNAMIC RELATIONSHIPS FOR SOILS AT OR BELOW THE FREEZING POINT: II. EFFECTS OF TEMPERATURE AND PRESSURE ON UNFROZEN SOIL WATER. Res. Rept. 222, Pt. 2, U.S. Army Cold Regions Research and Engineering Laboratory, 9p. incl. table, graphs, July 1967. 8 refs.

CRREL files

Thermodynamic methods are presented for calculating, from the water adsorption isotherms, the change in unfrozen water content of a partially frozen soil with temperature at a constant pressure or with pressure at a constant temperature. Then, using pertinent experimental data for Na-Wyoming bentonite, the increase in unfrozen water caused by a confining pressure of 100 atm is obtained as a function of temperature. Such information is shown to be relevant to the mechanical properties of frozen soils under stress. (Authors' abstract)

Mock, Steven J.
ACCUMULATION PATTERNS ON THE GREENLAND ICE SHEET. Res. Rept. 233, U.S. Army Cold Regions Research and Engineering Laboratory, 15p. incl. table, maps, July 1967. 16 refs.
CRREL files

All available mean annual accumulation data on the Greenland ice sheet (excluding the Thule Peninsula) have been collected and analyzed using multiple regression techniques to develop equations capable of predicting mean annual accumulation. The analysis was carried out for north Greenland, south Greenland, and for the transition zone between the two major regions. The resulting equations show that mean annual accumulation can be predicted from the independent parameters, latitude, longitude, and elevation. The patterns of accumulation are shown in a series of isohyetal maps (contours of accumulation in terms of water). The major feature shown is a well defined asymmetry in accumulation; a pronounced east slope maximum in south Greenland and

an equally pronounced west slope maximum in north Greenland. Poleward of 69°N, isohyets decrease in elevation to the north. Mean annual accumulation ranges from > 90 gm/cm² in southeast Greenland to < 15 gm/cm² in northeast Greenland. A brief discussion of mass balance estimates of the Greenland ice sheet and of the relevance of this study to them is included. (Author's abstract)

THE ADSORPTION OF METHANOL VAPOR ON SILVER IODIDE. J. Phys. Chem., 71(11):3373-3377 incl. graphs, October 1967. 21 refs.
DLC, QD1.J95

The adsorption of methanol vapor on silver iodide was measured at 9.77, 19.79, and 30.02° over the pressure range 0.24-108 mm. The silver iodide was prepared by the reaction of silver and iodine in vacuo with subsequent liquid ammonia treatment. The adsorption isotherms do not fit into the Brunauer classification. The shape of the isotherms indicates the absence of three-dimensional clustering in the adsorbed phase. The dependence of the isosteric heats of adsorption upon surface coverage reveals the dual nature of the silver iodide surface. The surface is heteroenergetic with approximately 12% of the surface consisting of higher energy sites located patchwise over the surface. Selection of methanol vapor as the adsorbate eliminated three-dimensional clustering in the adsorbed phase due to hydrogen bonding, and thus characterization of the silver iodide surface was straightforward. (Authors' abstract)

CRYOGENIC SLOPE TERRACES. (Kriogennye sklonovye terrasy; Text in Russian). Gos. Kom. po Delam Stroitel'stva SSSR, Proizvod. i Nauch. - Issled. Inst. po Inzhenernym Izyskanifam v Stroitel'stve, Izd-vo, "Nauka", 94p. incl. illus., diagrs., Moscow, 1966. 87 refs.
DLC, GB591.V85

The term cryogenic slope terraces is used for the structures formed on mountain slopes by cryogenic processes, primarily by solifluction and frost weathering. A new hypothesis concerning their origin is offered, as well as a new interpretation of some of their structural and morphological characteristics. An attempt is made to develop a genetic classification of the cryogenic slope terraces, in which different development stages of the terraces and the processes responsible for their origin would be accounted for; this classification may serve as a basis for mapping these relief forms. -- NSV

CRREL BIBLIOGRAPHY

Definite plant communities which reflect the presence of perennially frozen ground at a shallow depth were studied in three regions of Siberia differing by their geographical locations and the type of vegetation. That is, the upper course of the Amur River, the middle course of the Vilyui River and the lower course of the Ob River. Although by their specific composition such plant associations sharply differed from the surrounding environment, they had the same characteristic features and general outlook in all three regions. Their most typical features were: an absolute absence of seedling growth; the presence of dwarfed birch and wild rosemary among bushes; large numbers of swamp plants; and very thick and widely developed peat moss of different varieties. -- NSV

DLC, GB648.55.M44

Pressureless moisture migration in dusty loam in a hydrologically closed system was studied experimentally in an attempt to explain a sudden decrease of moisture saturation immediately below the lower ground freezing boundary. The presence of this moisture depleted zone is explained from the standpoint of energetic inhomogeneity of water contained in fine grained rocks. The experimental results indicated that a continuous decrease in the moisture content of the thawed zone adjacent to the frozen part results in the strengthening of water binding, lowering of its energetic level, and a decrease in its capacity for migration. -- NSV

EVALUATING THICKNESSES OF NON-FROZEN WATER LAYERS IN FROZEN ROCKS. (Otsenka tolshchiny sloev nezamerzshel vody v merzlykh gornykh porodakh; Text in Russian). Moskov. Gosud. Univ., Merzlotnye Issledovaniia, Vyp. 6: 221-228 incl. tables, 1966. 13 refs.
DLC, GB648.55.M44

By author's definition, non-frozen water is that part which does not crystallize in freezing rocks at freezing temperatures but remains fluid and in a dynamic equilibrium with ice crystals. The water occurs in films enveloping rock particles, the film thickness, as determined by the nuclear magnetic resonance method, varying upwards from a monomolecular layer. Moscow State University, Department of Geocryology has developed a procedure for an approximate evaluation of the water-film thicknesses in fine-grained frozen rocks, in which the thickness values are obtained as an averaged result from the division of the volume of non-frozen water by the specific surface of the rock, the specific surface being determined by the method of nitrogen adsorption at low temperatures. -- NSV

of winter period observations which are related to channel discharge in terms of water-stage, river-bed frictional velocity, and formation and displacement of the river ice. Results indicate that the whole frozen ice is displaced vertically by changes in the water-stage and accumulated snow cover, the displacement being periodic across the river's width. The growth of the uppermost layer into snow jam is calculated by heat transfer coefficients varying with wind velocities and air temperature. The river-bed temperature affects the melting of the river ice to a much greater extent than the turbulent dissipation in the parallel flow between two flat planes. -- FMM

SUPPLEMENTARY NOTES ON THE ICE FORMATION AND THE STREAMFLOW UNDER ICE CONDITIONS IN THE RIVER. (Kasen no keppyo to kore ni tomonau suiri ni kansuru kenkyu (tsuho); Text in Japanese with English summary). The Civil Eng. Res. Inst., No. 42, p. 7-15 incl. tables, graphs, November 1966.
DLC, Orientalia Div.

Stresses on a river bank due to the vertical displacement of the surface ice in a river are obtained by assuming the surface ice to be an elastic plane. The stresses occurring when the surface ice covers the whole water surface in a river are presented. Ice formations are explained by using the heat transfer coefficient from the ice surface to the air. In the preceding paper (SIP 25799) the formula of the formation of the ice covered with the accumulated snow is presented. Generally speaking, the heat transfer coefficient consists of three factors, i. e., the turbulent flow of air over the surface, the evaporation of ice, and the heat radiation. The behavior of these factors in the case of ice formation in a river is explained. The temperature of a river bed is evaluated by measuring the melting velocity of the surface ice: $(6 \sim 10) \times 10^{-3} \text{ } ^\circ\text{C}$ is obtained as the temperature for the bed in the Ishikari river. Determining the position of the maximum velocity in a vertical direction under the whole frozen surface is very important, since the maximum position is related closely to the frictional velocity when the discharge is given. Data indicate that the distance from the lower limit level of the surface ice to the maximum position is smaller than the distance from the bed to it, and that the ratio of the two distances is 1.14 on an average. Akad. Nauk SSSR, Inst. Geografii, Teplovo i vodnyy rezhim snezhno-lednikovyykh tolshch, Izd-vo "Nauka", Moskva, p. 87-117 incl. tables, graphs, diagra., 1965. 20 refs.
 DLC, GB2405.A36

Two indirect methods are offered for determining the sum of atmospheric precipitation falling on glaciers: 1) according to daily snow measurements on an experimental area, and 2) from the data on the intensity and duration of snow storms. The results obtained by both methods were used in checking the accuracy of the precipitation gage readings, and establishing the regularities governing the fallout redistribution on glaciers. The possibility of using this procedure in mountains as well as on forestless plains increased its practical value; the established relationship between the summary snow transfer and its deposition on plane surfaces and in depressed areas during storm made it possible to calculate snow concentration in the wind shadow. It is concluded that, as a rule, the maximum distance of snow transfer in mountains is 100 m. -- NSV

HEAT EXCHANGE IN THE ICE OF THE FRANZ JOSEF LAND ICE-FEEDING DOMES. (Teploobmen vo l'du na kupolakh Zemli Franza-Iosifa s lednyym pitaniem; Text in Russian). Akad. Nauk SSSR, Inst. Geografii, Teplovo i vodnyy rezhim snezhno-lednikovyykh tolshch, Izd-vo "Nauka", Moskva, p. 75-80 incl. tables, diagra., 1965. 2 refs.
 DLC, GB2405.A36

Vertical distribution of ice temperature in glacial domes and its variation in time were studied to determine the thermal balance of ice covered by 80 cm of snow. The results indicated that thermal exchange between air and ice went through the snow cover, which in turn was reflecting air temperature oscillations. Monthly heat exchange in ice in the ice-nourished domes varied from 0.01 to 1.00 kcal/cm², the maximum heat released occurring in March and the maximum heat accumulation in July. In separate years the ice was losing more heat in the winter than obtaining it in the summer, or vice versa, but on the average, over a series of years the yearly heat balance was almost zero with a slight tendency toward a plus balance, despite the negative solar radiation balance on the domal surface. -- NSV

SNOW TRANSFER BY WIND ON THE NOVAYA ZEMLYA GLACIERS. (Perenos snega vetrom na Novozemel'skom lednikovom pokrove; Text in Russian). Akad. Nauk SSSR, Inst. Geografii, Teplovo i vodnyy rezhim snezhno-lednikovyykh tolshch, Izd-vo "Nauka", Moskva, p. 142-160 incl. tables, graphs, diagra., 1965. 20 refs.
 DLC, GB2405.A36

A mathematical procedure is offered for estimating the amount of snow transported by storms, its redistribution, and its value in the balance of a glacial cover by comparing the calculated values of snow drift to the precipitation measured. Comparison of the mean snow accumulation values and the precipitation on different areas made it possible to distinguish three zones within one glacier: 1) snow accumulation and partial drift, 2) snow inflow and redistribution, and 3) the area of predominant snow drift increasing down the slope. The mathematical operations are illustrated by the practical example of studying the amounts of precipitation, snow drift and its accumulation along the longitudinal profile of the Shokal'skiy glacier. -- NSV

STABILITY OF CONCRETE AND REINFORCED CONCRETE AT MINUS TEMPERATURE. (Stoikost betona i zhelezobetona pri otritsatel'noy temperature; Text in Russian). Gosstroystroy SSSR, Nauchno-Issled. Inst. po betonu i zhelezobetonu, Izd-vo Literaturny po stroitel'stvu, Moskva, 132p. incl. illus., tables, graphs, diagrs., 1967. 139 refs. DLC, Slavic Div.
- The resistance of concrete and reinforced concrete to different freezing temperatures are discussed as well as the frost-stability and deformation of concrete structures in the cold regions where temperature may drop to -60°C. Durability of the reinforced concrete structures under these conditions is estimated from the testing and observation data and the analysis of previously published information. Destructive processes originating during freezing from the unbalance between the deformation of concrete and steel are analyzed and different ways of increasing the durability of reinforced concrete under the extreme cold conditions are recommended.

ELECTRIFICATION ACCOMPANYING THE BURSTING OF BUBBLES IN WATER AND DILUTE AQUEOUS SOLUTIONS. Trans. Faraday Soc. 63(537):2234-2245 incl. diagrs., Sept. 1967. 11 refs. DLC, TK1.F25
- The electric charges carried on the drops ejected from air bubbles bursting at the surface of water and aqueous solutions have been measured in relation to the bubble size and the concentration of the solution. Drops ejected from pure water and solutions of concentration less than about 10^{-4} M carry

CRREL BIBLIOGRAPHY

a negative charge, the magnitude of which decreases rapidly with increasing concentration and becomes vanishingly small at concentrations greater than about 10^{-4} M. For more concentrated solutions the drops carry a small positive charge. The negative charging of the drops is explained quantitatively by a thin film of water rising from the inner surface of the bubble cavity to form a small jet that breaks up to produce the drops, their charge resulting from the rupture of the electrical double layer at the air/water interface. The depth of the diffuse double layer is less in solutions of higher concentration and this accounts for the smaller charges on the drops. The positive charging of the drops at high concentrations is attributed to the separation of charge during the break-up of an initially uncharged varicose jet, when water containing an excess of positive ions is forced into the swelling regions that form the drops from the constricting necks between them. DEVELOPMENT OF WINTER SERVICE FOR LONG-DISTANCE HIGHWAYS IN WEST GERMANY FROM 1956 TO 1966. (Die Entwicklung des Winterdienstes auf den Bundesfernstrassen von 1956 bis 1966; Text in German). Strassen-und Tiefbau, 21(2):67-84 incl. illus., tables, diagrs., February 1967. 19 refs. DLC, TE3,S758

Since 1956 the West German state administrations have been reporting costs and operations to the Federal Department of Transportation in the form of standardized data, covering cost of sanding and salting, operation and maintenance of equipment, outlay for snow protection, salaries, and operation of federal and rented vehicles. This article is essentially an administrative report based on these data for the ten winters 1956-1966, but it also touches on problems of engineering interest, such as the use of salt, rather than sand, to prevent skidding, the possible damage caused by salt to various road surface materials, corrosion due to salt and protection against it, heating of roads, etc. A graph is presented, showing the amount of reduction of the skid coefficient on an icy road as a function of speed and the amount of salt used. As shown in another graph, the use of salt has almost entirely replaced sanding in the last years of the report period. In addition to being more effective, salting has also been found to be less expensive, despite the higher unit cost, because of a reduction in operational cost, due to the much smaller amount of material needed. -- GTT

STUDIES OF HEAT INSULATING LAYERS IN ROAD FOUNDATIONS. (Untersuchungen an Wärmedämmschichten im Strassenbau; Text in German). Strassen-und Tiefbau, 21(5):332-340 incl. illus., tables, graphs, diagrs., May 1967. 8 refs. DLC, TE3,S758

An experimental test of heat insulating effectiveness of a 2.6 cm layer of styropor, a foam material developed at the German Federal Institute of Roads (Bundesanstalt für Strassenwesen) is described. The test installation is a 6 x 12 m area under a cooling device, half of the area being used with the insulating material and the other for control. The styropor layer was placed 50 cm deep under several layers of road material, and vertical styropor plates were inserted at the edges, to a depth of 1.2 m to prevent cooling by horizontal conduction. Temperatures were taken at several depths. Surface temperature was regulated in such a way as to duplicate typical climatic conditions for specific areas in Germany. The results are presented in graphs. The material was found to be adequate, in the thickness tested, for several areas in Germany, but not those where severe winter conditions normally occur. The test also shows that side panels of insulating material should be inserted to a depth of 1.5 m. Other tests, involving plastic properties of foam materials, effects of moisture, etc., are described in general terms. The use of an analog computer in evaluating experiments and deriving empirical formulas is discussed. -- GTT

PIPING FLEXIBILITY STUDY WITH--SLIDING
SUPPORT FRICTION AND CRYOGENIC BOWING.
Heating, Piping Air Conditioning, 39(11):93-100
incl. illus., diagrs., November 1967.
DLC, TH7201.H45

In this design study of cryogenic industrial piping the problems are outlined and the methods of analysis given as follows: 1) Axisymmetric thick shell computer program--pressure, temperature, and discontinuities (where discontinuity stresses are to be investigated); 2) MEC-21 piping flexibility computer program--weight, thermal displacement, and restraint loads; 3) Detailed analysis--support concentrations and guide clearance, bowing effects, and recycle stability vs buckling. In the results, 5 cases of weight and cold shock were of interest. One, a simple case of thermal contraction (weightless) known as the free thermal case, provides reference displacements for a comparison with other cases. Three of the cases consider an empty pipe that is subsequently filled with either liquid hydrogen or nitrogen. A detailed study was also made for bowing combinations. Subsequent articles are to treat piping pressures and discontinuities, stress intensification at supports, cryogenic bowing, and interference with thermal displacement. -- FMM

COMBINED GEOPHYSICAL STUDIES IN THE WEST
ICE SHELF. (Kompleksnye geofizicheskie issledovanifa na zapadnom shel'fovom lednike; Text in Russian). Sovet. Antarkt. Eksped., Trudy, Vol. 48: 79-96 incl. illus., tables, graphs, diagrs., 1967. 11 refs.
DLC, G860.S63

Seismic, gravity, and magnetic studies were conducted on the West Ice Shelf to determine ice thickness, the structure of the upper part of the snow-firn cover, and the underlying topography, and to study the magnetic and gravity fields of this region. According to seismic reflections the glacier cross-section consisted of three layers: upper, middle and lower, with the following wave velocities and densities: 1) 2200-2400 m/sec. and 0.4-0.5 g/cm³; 2) 3000-3300 m/sec. and 0.6-0.7 g/cm³; and 3) 3700-3850 m/sec. and 0.8 g/cm³; the total thickness of the snow-firn cover varied from 20 to 40 m.

GEOTHERMAL METHOD OF STUDYING FROZEN
ROCKS. (Geotermicheskiy metod issledovanifa tolsheh merzlykh porod; Text in Russian). Akad. Nauk SSSR, Izd-vo "Nauka", Moskva, 155p. 1966. 70 refs.
DLC, GB642.R4

This monograph presents the geothermal method developed by the author for studying frozen rocks in a stationary and non-stationary state. The presentation is based on the analysis of factual data obtained in geothermal investigation of different permafrost regions. The geothermal field in the upper layers of the lithosphere is the object of study; in the permafrost regions it is characterized by phase transformations of water at corresponding temperatures, therefore, in such regions it is a thermodynamic field in which temperature is just one of the parameters determining the field. The analytical discussion is presented in three parts: 1) analysis of the non-stationary state of frozen rocks and their temperature fields; 2) investigation of the stationary state of frozen rocks and their temperature fields, and 3) thermodynamic factors affecting the geothermal field and the technique of geothermal field investigation. -- NSV

RESULTS OF SEISMIC AND GRAVITY SURVEY IN
QUEEN MAUD LAND. (Rezultaty seismogravimetri-cheskikh issledovanif na zemle korolevy Mod; Text in Russian). Sovet. Antarkt. Eksped., Trudy, Vol. 48:105-127 incl. illus., tables, graphs, diagrs., 1967. 12 refs.
DLC, G860.S63

Four groups of reflections were distinguished on the seismograms obtained in this area: T₁ - related to the snow-firn thickness and the upper ice zones; T₂ - waves reflected from the ice-water boundary; T₃ - reflections from the water-ocean bottom boundary, and T₄ - waves proceeding from the ice-rock boundary. According to the records the seismoglaciological cross-section consisted of four layers in the floating part of the glacier and of three layers where the glacier rested on solid ground. The upper part of the cross-section was represented by snow-firn layers merging gradually into ice; in these layers the density of material and wave velocities were increasing with depth. Separate more dense interlayers in the snow-firn zone related to the seasonal snow accumulations, did not affect the general pattern of the velocity increase with depth.

STRUCTURE OF SNOW-FIRN COVER IN THE LAZAREV STATION AREA. (Stroenie snezhno-firnovoy tolshchi v raŭone stantsii Lazarev; Text in Russian). Sovet. Antarkt. Eksped., Trudy, Vol. 48: 145-151 incl. illus., tables, graphs, 1967. 6 refs. DLC, G860,S63

Snow cover structure and the variation in its yearly layering were studied in a 35-m deep hole located in the station area. Climatic conditions of the past summer seasons were reconstructed to a certain degree from the results obtained. The upper 80 cm of the snow-firn cross section contained granular snow with a density of 0.38 - 0.44 g/cm³ and the grain size range 0.2 - 0.44 mm. It was overlying a series of firn and ice layers differing in thickness and structure. Alternating layers of coarse and fine firn with grain sizes and densities ranging correspondingly from 0.8 to 2.8 mm and from 0.40 to 0.53 g/cm³ prevailed to the depth of 5.0 m, the layer thickness varying from 10 to 20 cm. Ice was encountered mostly in the coarse firn in the form of vertical bodies, thin interlayers, lenses and nodules. Firn layers in the depth interval 5.0 - 6.3 m contained solid ice layers 15 - 20 cm thick with grain sizes up to 2.8 mm and an average density of 0.50 g/cm³. Below the 6.3 m mark and down to 10.8 m the firn structure was very similar to that in the upper cross section. The lower part of the snow cover contained little ice, consisting of homogeneous firn layers up to 60 cm thick. -- NSV

STRENGTH OF ANTARCTIC SEA ICE. (Prochnostnye kharakteristiki morskogo Antarkticheskogo l'da; Text in Russian). Sovet. Antarkt. Eksped., Trudy, Vol. 48:190-193 incl. tables, graphs, 1967. 4 refs. DLC, G860,S63

This paper reports the results of testing Antarctic sea ice for shearing and compressive strength and the resistance to impact. The results indicate that the lower layers of an ice sample have the greatest shearing strength when the sample temperature equals that of the ice cover under natural conditions; several days later, when the ice sample has acquired the temperature of air its middle layers had the greatest shearing strength, as well as the strongest resistance to compression. Ice resistance to impact was affected only by temperature variation in the upper and lower ice layers, while that of the middle layers had practically no effect. Deviations of calculated values of the Young and shear moduli of ice at different levels from their mean values were insignificant. -- NSV

This paper reports the results of an investigation of the composition and physical properties of marly soils located in the seasonally thawing zone of the Vorkuta region, undertaken to establish the causes of their thixotropy. The results indicated that at a definite water-solids ratio in the Vorkuta marls, the dust particles do not settle but remain "suspended" in the thin fraction of soil, distributed uniformly over the whole volume. Therefore, no sediment separation into different fractions takes place, but a single loose-network structure prevails in the whole volume of soil, the closed cells of which retain considerable amounts of free water. This is how the so called coagulation structure of soil is formed which is characterized by a great mobility due to the presence of fine water films separating soil particles. -- NSV

This is a report of a supervising engineer employed on a section of the Dal'nevostochnaya Doroga (Far-East Railroad Line) characterized by frequent development of naled; this type of icing usually occurs in the places where water-bearing formations are tapped or have an exit to the surface. Different ways of coping with naled are discussed and illustrated by practical examples. Drainage proved to give the best results as long as the drain was not installed far below the water exit to the surface, in which case the drain worked satisfactorily but the amount of icing was not reduced. Among the preventive measures mentioned are different protective screens, fences, earth dams, and modern techniques of operating "heated" drainage ditches; warmed channels, inserted air layers and others. -- NSV

CONTROLLING ICING ON RAILROADS AND HIGHWAYS IN THE KRASNOLARSK REGION. (Bor'ba s naledfami na dorogakh Krasnoġarskogo kraġa; Text in Russian). Kom, po zem. pol. Bor'ba s naledfami na zheleznykh i avtomobil'nykh dorogakh. "Transport", Moskva, Vyp. 7:17-23, 1966.

DLC, Slavic Div.

The reliability and effectiveness of several permanent and temporary means of icing control are described and evaluated. Regularities governing the formation of local icing on railroad tracks, highways, and bridges are analyzed for the regions with and without perennially frozen ground, and different geological and hydrological conditions. The way icing affects the underlying ground, and the behavior of various types of naled during thawing periods are also analyzed. Observations indicated that thicknesses of naleds produced by water seepage from the ground increase until a stable heat exchange is established between the air and the underground stream, with subsequent melting of the ice at the bottom due to the warming effect of the naled. This ground warming effect of icing combined with the similar effect of ground water is believed to be responsible for the lowering of the permafrost level beneath road bridges and for their deformation.

FILTRATION DIKES IN THE AREAS OF NALED DEVELOPMENT. (Fil'truġshchie nasypi na nalednykh uchastkakh; Text in Russian). Kom, po zem. pol. Bor'ba s naledfami na zheleznykh i avtomobil'nykh dorogakh. "Transport", Moskva, Vyp. 7:46-51 incl, diagrs., 1966. 5 refs.

DLC, Slavic Div.

The rationality of building water filtration dikes in cold regions is discussed, and their structure analyzed from two standpoints: their effect on the natural regime of the surface and ground waters and on the formation of naled, and the through-put capacity of a filtration dike in the case of its icing. It is concluded that filtration dikes do not disturb the natural regime of ground waters, they do not contribute to the formation of naled, and therefore may be built in permafrost regions. Through-put of a dike may be increased if needed by installing drainage pipe systems. -- NSV

near the seaward edge of the Ross Ice Shelf between

CRREL BIBLIOGRAPHY

Ross and White Is.; ice thicknesses at the drill sites were calculated to be 33, 48, and 94 m, respectively. The rate of melting at the bottom of the shelf was 1 m/yr at two drill sites. The vertical density gradient in each of the holes is larger than that observed at Little America Station, and the density increases abruptly by about 0.1 g/cm³ at the top of a brine-soaked layer estimated to be less than 6 m thick in each hole. Temperature profiles can be explained on the assumption that the brine moves horizontally through the shelf from the seaward edge to the interior and supplies heat to the shelf by convection and by liberation of latent heat during freezing. The observed brine level in the holes is about 20% lower than the hydrostatic level. (Auth., mod.)

Miers, a warm freshwater lake, are discussed. The presence of rock debris on the floating lake ice has led to the formation of dirt cones and melt pools. Fossil levels of these pools show that the annual ablation is 15 to 20 cm. Despite a mean annual air temperature of -20°C, the bottom waters of the lake are at +5°C. This is shown to be a natural example of solar heat storage, and the observed temperature profile is satisfactorily accounted for. Chemical evidence suggests that the lake has been filled by fresh water containing K, Na, Cl, and O₂, and that it is now stagnant below the 4°C depth. In the lower zone, Ca, Mg, CO₂, and SiO₂ diffuse upward from the lake bed. Their release may be caused by anaerobic biological activity. (Author's abstract, modified)

SOILS OF TAYLOR DRY VALLEY, VICTORIA LAND, ANTARCTICA, WITH NOTES ON SOILS FROM OTHER LOCALITIES IN VICTORIA LAND. N.Z.J. Geol. Geophys., 10(2):498-539 incl. illus., table, diagrs., maps, May 1967. 55 refs. DLC, QE1.N55

A map and descriptions of the soils of Taylor Valley are presented. Soils from Hallett Station, Ross I., and other areas near McMurdo Sound are described and compared with those of Taylor Valley. The role of the soil-forming factors and the nature of the soil-forming processes in Victoria Land are discussed. Soils on slightly elevated gentle slopes on moraine or similar parent material may be regarded as zonal soils. They are virtually lithochromic, coarse textured, structureless, and without humic horizons. Two groups are recognized: (1) soils in arid Taylor Valley, which have a surface or sub-surface layer slightly to moderately cemented with calcium carbonate or gypsum and are underlain at depths of about 12 in. by frozen ground; and (2) soils outside Taylor Valley, in areas where more moisture is available, probably from more frequent summer snowfalls, and soluble materials are distributed throughout the soils and do not form surface crusts. Soils with much moisture and those rich in organic matter are classed as intrazonal. (Author's abstract, modified)

ICE-CORED MORAINES AND ICE DIAPIRS, LAKE MIERS, VICTORIA LAND, ANTARCTICA, N.Z.J. Geol. Geophys., 10(2):599-623 incl. illus., diagrs., map, May 1967. 25 refs. DLC, QE1.N55

Lake Miers is covered by a thick ice sheet which is domed over most of its area and thrust into sharp debris-covered ridges around its margin. Except in summer, the shore ice is frozen to the lake bed. The margin of the floating ice raft is thrust over the fast shore ice to form pressure ridges. The debris cover resulting from upward migration of infrozen gravels causes locally increased insolation. Because the cover is thin, heat is conducted to the underlying ice, and ablation is increased. These moraines are young and active. Ice domes in the center of the lake are related to the ridges and are caused not only by the same compressive forces as the ridges, but also by upwelling of the ice in diapirs. The arching process is dynamic and self-perpetuating. When continued for several years, it becomes diapiric. (Authors' abstract, modified)

SELF-DIFFUSION IN ICE MONOCRYSTALS, Res. Rept. 232, U. S. Army Cold Regions Research and Engineering Laboratory, 45p. incl. tables, graphs, diagrs., illus., Oct. 1967. 53 refs. CRREL files

The self-diffusion of tritium, parallel and perpendicular to the optical axis of naturally occurring and artificially grown ice monocrystals, were studied between -2.5 and -35.9°C. The artificial ice monocrystals were grown using a zone-melting technique.

CRREL BIBLIOGRAPHY

Activated samples were stored for several weeks, then sectioned by microtome and analyzed in a liquid scintillation counter to obtain the self-diffusion coefficients. The plane source solution of Fick's second law was used in treating the data. The diffusion coefficients were found to be identical for both types of ice. A slight anisotropy was found due to the geometry of the crystal; however, the activation energy was found to be 0.62 eV for all cases. Based on the experimental data, it is concluded that the diffusion takes place by a vacancy mechanism and that entire H₂O molecules are diffusing, i. e., molecular diffusion occurs. Theoretical calculations using the atomic diffusion theory and Zener's theory for D₀ are in excellent agreement with the experimentally determined diffusion coefficient. (Author's abstract)

THE MECHANICAL PROPERTIES OF SEA ICE. Cold Regions Science and Engineering II-C3, U. S. Army Cold Regions Research and Engineering Laboratory, 94p. incl. illus., tables, graphs, diags., Sept. 1967. 199 refs.
CRREL files

This review discusses the state of thinking of each of the main national groups investigating sea ice and gives an overall appraisal of the field as a whole. Emphasis is placed on (1) the physical basis for interpreting sea ice strength (phase relations, air volume, and structural considerations), (2) theoretical considerations (strength models, air bubbles and salt reinforcement, and interrelations between growth conditions and strength), (3) experimental results (tensile, flexural, shear, and compressive strength, elastic modulus, shear modulus and Poisson's ratio, time dependent effects, and creep), and (4) plate characteristics. The paper includes a review of problems in sea ice investigations, relates the chemical, crystallographic, mechanical, and physical aspects involved, and concludes by showing how to utilize this knowledge to solve practical problems. RESULTS OF THE WORK OF THE TRANSCAUCASIAN SNOW-GLACIER COMMISSION AT THE TRANSCAUCASIAN HYDROMETEOROLOGICAL INSTITUTE DURING 1960-1965. (Rezultaty rabot Zakavkazskoi snego-lednikovoï komissii pri Zakavkazskoi snego-lednikovoï komissii za 1960-1965 gg; Text in Russian). Zakavk. Nauchno-Issled. Gldromet. Inst., Trudy, Vyp. 20: 5-7, 1966.

DLC, Slavic Div.

The Commission, organized in Dec. 1959, consists of 17 representatives of 14 organizations of the Caucasian republics engaged in investigations of snow cover, avalanches, and glaciers. The principal task of the Commission is the unified study and coordinated planning and intensification of theoretical investigations designed to improve the hydrometeorological servicing of the national economy. During the past 5 yrs 3 conferences (Baku, 1960; Tiflis, 1962; and Erevan, 1965) were held with the participation of from 120 to 130 representatives of scientific and other interested agencies. This paper describes the work of these conferences, the systematic glaciological investigation on 17 glaciers (as compared with 3 in 1960), and refers to a number of published monographs, scientific papers, and reference books. The authors call attention to a number of shortcomings, including the lack of observations on the elements of the heat balance at the Krestovyy Pereval Snow-Avalanche Station and at the Kozbegi High Mountain Station. Presents results of a study of the structure of natural hailstones conducted in the summers of 1962-1964 on the South-Georgian upland (elev. 2200/m) by the Samarskaia Expedition. The hailstones were studied in the field without freezing. After recording the shapes and sizes and photographing the hailstones their central parts (0.4-0.8 mm thick) were cut out and examined in reflected, through, and polarized light; they were also photographed with a mirror camera with different filters. Hailstones of 47 hail storms averaging 10-15 mm with a maximum of 32 mm were studied. After each storm several hundred hailstones were examined and up to 100 of various sizes were photographed. Several photographs (with mm scales) of hailstones with large air inclusion are shown and discussed. On the basis of the obtained information an attempt was made to explain the mechanization of formation of some types of ice on hailstones. The authors believe that the ice deposited on the hailstones is formed from super-cooled cloud droplets under conditions of wet and dry growth. (Meteorol. & Geostrophys. Abstracts)

Inst., Trudy, Vyp. 20:57-64 incl. diagrs., tables, 1966. Ref.
 DLC, Slavic Div.

During the 1962-63 winter, which was extremely severe with heavy snows in all of the Northern Hemisphere including the Caucasus, the Inst. of Geog., Acad. of Sc. of the U. S. S. R. continued observations on the southern slope of Elbrus at the ice base (elev. 3750 m) which included daily measurements of depth and density of snow on a special plot and blizzard measurements. In 1961-62 when the depth of snow was ≈ 2 m, sufficient accuracy was attained by correcting for settling only in the surface layers of freshly fallen snow. However, in case of winters with exceptionally heavy snowfalls it is necessary to take into account settling in the entire depth. The method used in determining and applying the correction to the 1962-63 records is described. Results of measurements are tabulated and shown in graphs which include mass curves of snow accumulation on a firn field in the 1958-59, 1961-62, 1962-63 winters. Following are some of the conclusions from the analysis of the presented data. In exceptionally snowy winters snow accumulation on a glacier can be 2.0-2.5 times the average. There are fewer ground blizzards in snowy winters (400 against the usual 600-800 hrs) and the removal of snow is reduced from the usual 20-30% to 7-8%. In snowy winters snow accumulation is much more uniform than usual. (Meteorol. & Geostrophys. Abstracts)

DETERMINATION OF THE COEFFICIENT OF WATER VAPOR DIFFUSION IN SNOW. (K voprosu opredeleniia velichiny koeffitsienta diffuzii vodianogo para v snegu; Text in Russian). Zakavk. Nauchno-Issled. Gidromet. Inst., Trudy, Vyp. 20:75-78 incl. tables, 1966. Ref.
 DLC, Slavic Div.

The results obtained by Yosida (1955), Pavlov (1962), and Vin-Chao Yen (1963) are discussed. According to Yosida's and Pavlov's results the coefficient does not depend on snow density. In 1958-60 the author conducted experiments without considering density and structure of snow. Since 1964 an attempt has been made to determine the effect of structure. The experiments which are still continuing are conducted in the laboratory and in the field in the Elbrus area

and on Krestovy Pereval. The coefficient D is computed as in the cited investigations. This paper describes the experimental procedure. Although insufficient for final conclusions the preliminary results presented in tables indicate that, other conditions being equal, the diffusion is greater in snow with a coarse grain than with a fine grain structure. EFFECT OF HEIGHT OF THE SNOW COVER ON NATURAL REGULATION OF RIVER RUNOFF IN EASTERN GEORGIA. (Vliianie vysoty snezhnogo pokrova na estestvennuu zaregulirovannost' stoka rek Vostochnoi Gruzii; Text in Russian). Zakavk. Nauchno-Issled. Gidromet. Inst., Trudy, Vyp. 20:101-109 incl. diagrs., table, 1966. Refs.
 DLC, Slavic Div.

The coefficient of natural streamflow regulation (φ) first proposed by Sokolovskii (1952) is the ratio of the area up to mean discharge on the hydrograph to its entire area. For the rivers of eastern Georgia φ varies from 0.41 to 0.85, it ranges from 0.60 to 0.72 for most of them. Plotted data show that φ increases with the average elevation of the catchments. Another set of graphs shows that φ increases with the snow cover, but a further analysis indicates that this holds only for the long term mean and for an entire river basin. A still further study of the relationship for individual years for river basins in different physiographic regions showed that the Spring flow and its ratio to the annual flow Q_{spr}/Q_{ann} increases. With an increase in this ratio, φ decreases. The overall final conclusion is that φ increases with an increase in the long term average depth of snow on an entire river basin and that for individual years and for some specific elevation φ decreases with the depth of snow. ARTIFICIAL TRIGGERING OF AVALANCHES.
(Voprosy iskusstvennogo obrusheniia snezhnykh lavin; Text in Russian). Zakavk. Nauchno-Issled. Gidromet. Inst., Trudy, Vyp. 20:139-155 incl. diagrs., tables, 1966. Refs.
DLC, Slavic Div.

Existing methods, including artillery and mortar shelling, small rockets, and hand grenades are discussed briefly. Reliable methods of forecasting the time of onset of avalanche danger, on which artificial triggering must be based, are a meteorological problem which is not discussed. This paper deals with the engineering aspects--the conversion of the explosion energy into forces that affect the equilibrium of the snow cover on a slope. A nomogram (Bababuev and Sulakvelidze, 1953) for determining the maximum equilibrium depth of snow is shown. The forces acting on the snow released by explosions in the air, and at the ground surface under the snow are analyzed and various formulas are derived. It is concluded that the problem of explosions in the air has as yet not been worked out. The action of explosions under the snow can be considered as supplemental inertia forces applied to the snow. The developed theoretical basis of triggering makes it possible also to determine the required explosive charge and to compute the resistance coefficient when shelling falls to produce an avalanche. DLC, QC851.T52

A method is presented for graphical and analytical solutions of problems in the stability of snow on a slope governed and not governed by Coulomb's law.

The solution is extended to the case of a snow layer containing gravitational water. Practical recommendations are given for the determination of points of origin of avalanches in a known snow situation. Proposed also are methods of reverse computations of the strength parameters of snow and a method of constructing a characteristic strength curve of snow from measured cohesion and temporary resistance to rupture. Three nomograms for computing stability of the snow cover are shown. (Meteorol. & Geostrophys. Abstracts)

COMBATING AVALANCHES BY PREVENTION OF SNOW ACCUMULATION IN AVALANCHE BASINS.
(Bor'ba so snezhnymi lavinami preduprezhdeniem snegonakopleniia v lavinosborakh; Text in Russian). Zakavk. Nauchno-Issled. Gidromet. Inst., Trudy, Vyp. 20:166-177 incl. diagrs., tables, 1966. Refs.
DLC, QC851.T52

The means of combating avalanches are grouped into: 1) measures to prevent accumulation of snow in avalanche basins, 2) structures to hold the snow cover on the slope, 3) protection against moving avalanches, and 4) artificial triggering. This paper deals with the 1st of these groups which in effect reduces to combating transfer of snow by blizzards. The only Soviet paper on this subject (Goff and Otten, 1938) and the experience in Switzerland and Austria are referred to. In this paper, the author applies the theory developed in combating drifts on railroads to the avalanche problem. The protection of the Kufbyshev Railroad at kilometer 1727 from avalanches is used as a concrete example to illustrate the procedure. The occurrence of ground blizzard winds and the accumulation of snow in various directions are shown in tables and in a graph. Values used in the construction of the duration curve of the volume of blizzard (drifted) snow are tabulated. The probability volume (400 m³/running meter) to be provided for in the design is obtained from the curve. The type of snow fences to be used are obtained from a list of structures and plantings taken from the Instructions of the Ministry of Transport, U. S. S. R. (1958). (Meteorol. & Geostrophys. CRRREL BIBLIOGRAPHY

For a quantitative evaluation of avalanche feedings, the author utilized data on the amount of snow moved by avalanches from slopes onto valley floors; tabulated results show that in most cases it constitutes about 10% of the maximum snow accumulation. Calculations show that for small glaciers, with ratios of their areas to those of their catchments of 0.15 to 0.65, the amount of avalanche feeding can constitute 15-65%. Values for valley- and small glaciers with snow cover due to avalanches ranging from 0.3 to 30% are tabulated. Reported cases of snow field 50, 60 and 100 m deep formed by avalanches in the U. S. S. R. are discussed; the melting of the 100 m field took several years. Following are some of the conclusions. Avalanches together with snow drifting cause concentrations of snow on mountain glaciers. Supplementary feeding by avalanches ranges from a few to 200% of the maximum snow accumulation. Glaciers with avalanche feeding are most common in Central Asia. In individual cases ablation of glaciers occurs by avalanches from their surfaces. (Meteorol. & Geostrophys. Abstracts)

DLC, QC221.A53

Results are reported of an experimental study of sound velocity variation in ice samples occurring under hydrostatic pressure ranging from 0 to 500 at. It was noticed that with increasing pressure the mass density of ice increased from 0.9 g/cm³ at p = 0 to 1.0 g/cm³ at p = 500 at. A considerable variation of sound velocity in the ice measured in different directions at p = 0 is explained by the anisotropy of ice structure and air inclusions. At high pressures the anisotropy effect disappeared and the sound velocity became equal in the longitudinal and transverse directions. The increase in pressure also caused a slight increase in the velocity of sound. The results obtained make it possible to account for the variation of sound velocity in the body of a glacier and to measure more accurately its thickness. -- NSV

Geocryological conditions in the water-divide areas of the Udokan Ridge sharply differ in the thickness of the frozen zone, temperature, and the composition and physical properties of rocks from those in the valleys. The frozen zone thicknesses under the water-divides exceeded 900 m, while under the river valleys they amounted only to 100-120 m and were characterized by tubular isolated taliks. Deep rock freezing in the water-divide areas was caused by a low mean annual temperature of the surface, a considerable heat-conductivity of rocks (especially of silicified sandstones), a small inflow of the interstitial heat (0,030 kcal/m² hr) and an insignificant effect of ground waters below the freezing zone on the temperature of perennially frozen strata. -- NSV

The perennially frozen rocks of this basin were

studied and subsequently mapped according to the "landscape method" based on distinguishing cryolithological varieties of ground in the seasonally freezing-thawing zone. Typical localities were distinguished in which the intensity and course of cryogenic processes were similar. This distinction was based on the composition and origin of the deposit, the hypsometric position of the area, and the nature of its vegetation. For each area the thickness of the seasonally thawing zone was determined as well as temperature variation in the ground, its moisture content, and thermophysical characteristics. To determine the relationships among these factors the process of ground thawing was calculated according to the V. T. Balobaev formula; the theoretical results closely correlated with field data. -- NSV

DYNAMICS OF SNOW STORMS AND ROAD PROTECTION FROM SNOW DRIFT. (Dinamika sniježnih zapuha i zaštita saobraćajnica; Text in Croatian). Ceste i Mostovi, 14, No. 1-6:214-231 incl. illus., map, tables, graphs, diagrs., Jan. -June 1966. 10 refs. DLC, TE4.C4

More than 90% of snow accumulates on the roads by snow drift. During a storm the effective zone of snow movement usually does not exceed 2 km; the

CRREL BIBLIOGRAPHY

length of this distance depends on wind direction and topography. Formulas are derived for calculating wind velocity variation at small altitudes and in different geographical areas. No general law governing snow movement could be obtained since it is affected by many factors some of which are topography, type of vegetation near the road, and the road profile. Different countermeasures designed to protect roads from blowing snow are discussed with the conclusion that movable wooden fences consisting of a wooden frame supporting straw-thatching are most convenient and economical for road protection from snow. Such fences are manufactured in Finland and Denmark, last 3 to 4 seasons, and can be rolled up for easy transportation. -- NSV

STRENGTH OF SHIPS NAVIGATING IN ICE. (Prochnost' sudov plavalushchikh vo l'dakh; Text in Russian). Leningrad, Izd-vo "Sudostroenie", 223p. incl. illus., tables, graphs, diagrs., 1967. 53 refs.
 DLC, Slavic Div.

The theory of ship building is presented with emphasis on the calculation of structural frames and their strength in different vessel types navigating in ice covered seas. Methods are discussed for determining ice pressure on ship frames in relation to different navigational conditions, as well as the strength of ice. A classification of sea ice is proposed, and the nature of ice-cover deformation and its physical and mechanical properties are discussed. -- NSV

 DLC, QE575.A43

This paper reports experimental results obtained in artificial intensification of ice and snow melting by black body dusting, with the conclusion that:

1) Spraying of 50-100 g/m² coal dust over glaciers increases ice melting by 20-45% in July and August despite a high natural pollution of the glacier surfaces. 2) Maximum effect is obtained during first few days with subsequent gradual leveling of ice-melting intensity due to washing away of coal dust by melt waters. 3) Glacier ablation can be considerably prolonged by coal-dusting the snow cover on the glaciers during spring months. 4) Reliable data on the effectiveness of the black body dusting methods may be obtained only if the experimentation continues through the whole ablation period of a glacier. -- NSV

ON THE METHODS OF MEASURING PENETRATION OF RADIATION INTO SNOW, FIRN, AND ICE (REVIEW OF LITERATURE). (O metodakh izmereniya proniknoveniya radiatsii v sneg, firn i led (obzor literatury); Text in Russian). Akad. Nauk SSSR, Inst. geogr., Mater. glatsiol. issled. Khronika, obsuzhdeniya, No. 11:167-176 incl. table, 1965. 62 refs.
 DLC, QE575.A43

Because of relative transparency of snow, firn and ice, the penetrating solar energy creates an illumination inside the snow and ice layers. The spectral composition of this internal radiation and the radiation balance inside snow and ice are discussed. The methods of studying and measuring the penetration of solar radiation into snow, firn, river and sea ice are analyzed with the conclusion that special small-size and highly sensitive measuring instruments are needed which would not overly shade the inflowing radiation. An international standard should be worked out for such instruments to make possible the comparison of their readings. -- NSV

Considerable progress is reported in the studies of the electrical and acoustical properties of sea ice. The first stage of the former program (in the 20 to 50 x 10⁶ Hz range) is now essentially completed and was reported at the Low Temperature Conference in Japan. Some difficulty was encountered in interpreting the acoustical measurements but averaging techniques now under development are starting to give consistent and interesting results. The study of ice drift in the Gulf of St. Lawrence has shown that historical records lack the necessary precision to develop relations which could lead to improvements in ice forecasting techniques, and experimental observations on ice drift in the Gulf are proposed. Short reports are included on the other experimental programs of the Project. Progress is good on the energy exchange and crystal growth studies, but little has been accomplished on the very low temperature experiments on single ice crystals. (Author's abstract)

EXPERIMENTAL AND FIELD STUDIES OF PRECIPITATION PARTICLES FORMED BY THE FREEZING OF SUPERCOOLED WATER. Quart. J. Roy. Meteorol. Soc., 93(398):455-473 incl. illus., graphs, tables, Oct. 1967. 33 refs.
DLC, QC851.R8

Drops which freeze in isolation or by accretion on an ice particle are found to be single or polycrystalline depending on the drop supercooling and the particle temperature. Subsequent growth from the vapour depends on the number and orientation of these crystals. The airflow around the particle, characterized by the Reynolds Number, Re , is important in the initial accretion process. The particle falls steadily for small Re , but oscillates and eventually tumbles as Re approaches 500. The deformation of accreted

drops depends both on the dendrite freezing velocity and on the drop impact kinetic energy. Viscous dissipation becomes important as the deformation exceeds 10. The heat economy of a freezing accreted drop is dominated by a collecting particle which is large compared with the drop. Symmetrical freezing only occurs for surface temperature approaching 0°C, or when the drop accretes on a narrow spike. Drops accreting on particles growing spongily may interact first with a liquid layer and produce splash droplets. Opacity is related to bubble size. Opaque ice forms when the particle is growing spongily or dry, with transparent ice forming when the growth is just wet. Just spongy growth at low temperatures is associated with small crystals and opaque ice. (Authors' abstract, modified)

AN EXPERIMENTAL INVESTIGATION OF THE SELECTIVE ION-CAPTURE THEORY OF CLOUD ELECTRIFICATION. Quart. J. Roy. Meteorol. Soc., 93(398):474-482 incl., graphs, diagr., Oct. 1967. 10 refs.
DLC, QC851.R8

Measurements made of the charges acquired by water drops and smooth ice spheres suspended in electric fields and exposed to streams of positive ions only, negative ions only, and ions of both signs present in equal and unequal concentrations were found to be in excellent quantitative agreement with the equations of Whipple and Chalmers. Electrical masking was probably responsible for the slightly increased charging obtained when the experiments were repeated with ice spheres of irregular surface structure. The charges acquired by drops falling through ion streams in electric fields are explicable in terms of the Wilson process. (Authors' abstract)

GLACIER RESURGENCE AT THE ATLANTIC/SUB-BOREAL TRANSITION. Quart. J. Roy. Meteorol. Soc., 93(398):528-534 incl. table, Oct. 1967. 24 refs.
DLC, QC851.R8

Some mountain glaciers in both the Northern and Southern Hemispheres advanced in late Atlantic and early sub-Boreal time, between about 5,200 and 4,600 radiocarbon years ago, and several in the Southern Hemisphere reached their greatest post-glacial extents. This suggests that the cool phase was as severe as at the start of the sub-Atlantic (ca. 2,800 radiocarbon years ago), but many botanists believe that the fluctuation was weak.

CHREL BIBLIOGRAPHY

Much botanical evidence indicates that the cool phase was followed by renewed warmth and divided the Hypsithermal Interval into two parts of unequal length. (Author's abstract)

THE LOBE STRUCTURE OF GIANT HAILSTONES. Quart. J. Roy. Meteorol. Soc., 92(391):1-14 incl. illus., graphs, Jan. 1966. 10 refs. DISCUSSION. Ibid. 93(398):556-559, Oct. 1967.
DLC, QC851.R8

Photographs of thin sections through five giant hailstones are presented to portray their bubble and crystal structures. These are interpreted to show that the hailstones grew as three-dimensional arrays of more or less completely frozen lobes, sometimes but not always separated by regions of spongy ice characterized by radial lines of bubbles. Some lobes contained regularly spaced hyperfine growth layers consisting of series of concentric bubble fronts a few hundred microns apart. These layers are interpreted as being due to fluctuations in growth rate associated with the tumbling of the hailstones. The growing surfaces of the lobes were strongly convex outward. This caused successive growth layers to become convoluted or scalloped. When the surface of a whole hailstone was viewed it sometimes created the false impression that the stone was an aggregate of much smaller hailstones. The presence of surface knobs associated with the lobes significantly enhances the efficiency of heat loss from the hailstone surface. Such an effect is important in that it reduces the proportion of unfrozen water incorporated within a rapidly growing hailstone. There is even some evidence that a giant 8 cm diameter hailstone can grow in this way without becoming appreciably spongy. (Author's abstract)

TRANSVAAL HAILSTONES. Quart. J. Roy. Meteorol. Soc., 92(391):382-391 incl. illus., graphs, table, Jan. 1966. 12 refs. DISCUSSION. Ibid. 93(398):560-561, Oct. 1967.
DLC, QC851.R8

Characteristics of a large number of hailstones which have fallen in the Pretoria-Johannesburg area in the past five years have been summarized under the following headings: size distributions, shapes, growth centers, layers and internal structures. Most hailstorms did not produce large hailstones. Only 4 per cent of over 5,000 hail reports were of stones exceeding 3 cm diameter. With increases in size of the largest hailstones, broader size spectra tended to occur and the modal size of hailstones reported as being most common increased. Spheroidal shapes were encountered more often than others in practically all size groups but their relative frequency diminished with size. A high proportion of the hailstones had opaque growth centers. An investigation of layering revealed that many hailstones have more changes of opacity than of crystal structure. Two, three and four crystal layers were often found in medium, large and extra-large stones. A simple up-and-down trajectory can account for the structure of many stones. Slushy ice may form on large hailstones but it is not an essential growth stage. (Authors' abstract)

SNOWDRIFT CONTROL THROUGH HIGHWAY DESIGN. Public Roads, 34(11):227-234 incl. illus., Dec. 1967. 15 refs.
DLC, TE23.P86

In areas that are subject to large and frequent snowfalls, drifting snow on highways presents a serious maintenance problem. The author discusses the research that has been accomplished in this field and presents recommendations for dealing with the problem of snowdrift control. In many areas of the country, particularly the northern States, the maintenance costs of highways during the snow season can be reduced considerably if the problem of drifting snow is considered when a highway is in the design stages. Research shows that when topographic conditions are favorable the sweep of the wind can be

CRREL BIBLIOGRAPHY

used to control the accumulation of snowdrift on highways. In areas where blowing snow is a problem, information on prevailing winds and drifting should be considered in the selection of a highway location. The profile and cross sectional design can also provide snow control by taking advantage of the wind and should be considered when a highway is initially planned. Appurtenances such as curbs, guardrails, fences, signs, etc., must also enter consideration for snow control because they are obstacles to the free movement of the wind and therefore contribute to the formation of drifts. By generally streamlining the area surrounding the highway, drifting is minimized, the esthetic qualities are enhanced, and the operational safety is increased. (Author's abstract)

PROBLEMS OF BUILDING FOUNDATIONS ON SENSITIVE NORWEGIAN CLAYS. (Problemes de foundation dans les argiles sensibles de Norvege; Text in French). Norges Geotekniske Institutt, Nr. 87, 10p. incl. illus., graphs, diagrs., Oslo 1966. 7 refs. (Reprinted from Sols Soils, 3(11): 11-20, Paris, Dec. 1964.
DLC, TA710.A1078

Fluidity and high instability of Norwegian clays are related to the isostatic uplift of Norway after the melting of glaciers, which resulted in the elevation of marine clays above sea level and caused the replacement of salt water in clay pores by fresh water, thus reducing the yield point of the clays and their capacity to adsorb water. Several examples of building on such clays are discussed. When erecting a six-story building on the clays, especially when the bedrock occurs at a considerable depth, the foundation pit is excavated in small sections and each excavated section is immediately filled with concrete and the fill; this way the amount of settling is less than 2.5 cm. -- NSV

"PERMAFROST" IN THE ZHELEZNOVODSK REGION. ("Vechnaya merzlota" v raione Zheleznovodsk; Text in Russian). Priroda, 8:115, 1967.
DLC, Q4.P8

The presence of a "permanently frozen" area on the Razvalka Mountain near Zheleznovodsk, Caucasus, at elevation 720 m is briefly discussed. Underground currents of cold air sustain a zero temperature of soils near the surface; ice interlayers are found at a 3 cm depth. Plants typical of northern regions grow in this area, sharply differing from the surrounding

vegetation of a southern type. Pending further investigations, it is suggested that the localized permafrost could have been caused by CO₂ accumulation in a solid state in a sealed cave during a very long period, and its subsequent release to the surface through fractures which have developed much later in the cave walls. -- NSV

CAN THE TANKS PASS THROUGH FROM HERE OR THERE? (Pääseekö se... pääseekö tästä... tuosta; Text in Finnish). Hakku Pioneerien Lehti 3:15-21 incl. illus., 1967.
DLC, Unbound periodical

The ability of a tank to traverse country terrain under different winter conditions is analyzed, and formulas are offered for calculating the strength of ice on the ice-bound lakes and its capacity of supporting a moving tank. A snow blanket or a thin layer of frozen snow does not noticeably affect the motion of a tank, but it obliterates obstacles such as large stones, hollows, non-frozen soft spots in the terrain; therefore, the route of a tank under such conditions should be checked in advance. A tank can move independently of the snow-depth in a smooth field of snow, up to 1 to 2 m deep, if the air temperature is above 0°C. According to calculations, the ice cover on a lake must be about 60 cm thick to support tanks moving at 20 m intervals from one another. Blizzards can make tank movement entirely impossible due to poor visibility. The use of "infrared-devices" during the short dark winter days depends completely on the weather conditions. -- NSV

FORMATION AND PROGNOSTICATION OF GLACIAL MUDFLOWS. (O formirovani i prognozirovani glatsial'nykh selen; Text in Russian). Akad. Nauk SSSR. Inst. geogr., Mater. glatsiol. issled. Khronika, obsuzhdeniia, No. 12:144-149 incl. illus., diagrs., 1966. 5 refs.
DLC, QE575.A43

In high-mountain regions mudflows originate in the glacial-nival altitude belts in which high humidity is combined with an abundance of loose soil. Two types of mud flow are distinguished in the Central Caucasus: glacial - associated with glacier melting, and dependent on the snow and ice regime, and the mud flows produced by torrential rains which are of a smaller size and occur less frequently than the first type. The investigation indicated predominance of the glacial mud flows in river valley slopes. It is believed that soil absorbs most of the water accumulating at the top of glaciers during melting periods thus preparing suitable conditions for mud flows, while occasional hard rains, with their much smaller water volumes, may start the flows. A method is offered for calculating the degree of mud flow danger at different stages of the glacial ablation periods.

STUDYING SNOW STRUCTURE. (Izuchenie struktury snega; Text in Russian). Akad. Nauk SSSR. Inst. geogr., Mater. glatsiol. issled. Khronika, obsuzhdeniia, No. 12:149-152 incl. illus., graphs, 1966.
DLC, QE575.A43

Snow structure was studied in the Botanical Garden of the Moscow State University during the winters 1961-62 and 1963-64. The results indicated that the development of snow crystals depended on the form and size of fresh snow flakes falling during the whole period of snow recrystallization. The stellate crystals predominating in atmospheric precipitation changed within two weeks into rime crystals when the temperature gradient was large. Rime is very sensitive to temperature variation in air and the

snow, which is reflected in the multiple variation of crystal sizes in the upper part of a rime layer. The snow recrystallization processes proceed differently on different underlying surfaces: larger crystals with weaker bonds grow on ice surfaces compared to those growing on a grass-covered ground. -- NSV

SOIL AND MICRORELIEF OF THE VORKUTA TUNDRA. (Pochivennyi pokrov i elementy mikrorel'efa Vorkutskoi tundry; Text in Russian). *Vsesoiuz. Geogr. Obshch., Komi Filial, Izvestiya*, T. 2, 1(11):55-63 incl. diagrs., 1967. 8 refs.
 DLC, G23.G2625

The tundra described, located between 67° - 67°4' of

north lat. and 63° - 65° of east. long., is characterized by gently rolling topography and dusty-loam soils ranging in thickness from 0.5 to 5 m; they cover solid permafrost at least 100 m thick with mean annual temperature of -1.5°C. Frost heaving hummocks and spots were the most typical cryogenic features of the southern part of this area, the northern part having a hillocky-sink-hole relief; however, the landscape elements of both types were encountered in some areas. Both microrelief types are described in detail and their origin discussed with the conclusion that they were formed under different conditions and followed different development cycles. Soils of both landscapes have an almost identical lower part of the profile differing only by the thickness of the uppermost layer. Cryogenic migration of moisture and dissolved substances toward freezing surface and weak permeability of the thixotropic zone prevented intensive exchange of substances between the upper and lower part of the soil profiles. -- NSV

THE NATURE OF BOUND WATER AND PHASE TRANSITIONS OF WATER INTO ICE IN FINE GRAINED ROCKS. (Priroda svyazannoĭ vody i fazovye perekhody vody v led v tonkodypersnykh gornyykh porodakh; Text in Russian). Kom. po zem. pol. Bor'ba s puchunami na zheleznykh i avtomobil'nykh dorogakh., p. 131-138, 1965. 15 refs.
DLC, TE210.R84

The physical nature of pressureless moisture migration and the separation of ice in fine grained freezing rocks are discussed analytically from the standpoint of molecular structure of water and the conditions of its crystallization. It is concluded that strong frost effect on clays and shales compared to the very slight deformation of coarser rocks is explained by the pressureless moisture inflow into the freezing zone due to the difference in water contents between the frozen and non-frozen layers, which depends in a definite way on the distortion of molecular structure of water in fine grained rocks due to their greater specific surface. -- NSV

STRENGTH OF THAWING GROUND. (Prochnost' ottaivaiushchikh gruntov; Text in Russian). Kom. po zem. pol. Bor'ba s puchunami na zheleznykh i avtomobil'nykh dorogakh., p. 178-183 incl. table, graph, 1965.
DLC, TE210.R84

The process by which a frozen soil recovers its strength after thawing was studied in relation to building roads on excessively moisture-saturated ground. The results indicated that the strength of soil decreases during its thawing on account of moisture accumulation in winter, and due to structural changes produced by freezing. At constant density and moisture content the strength of ground is minimal during its transition from a frozen to a thawed state; after thawing it increases with time,

reaching the values higher than those before freezing. After repeated freezings the drop in the strength of the soil samples studied was smaller than that after the first freezing; this is believed to explain multiple deformations on roads during the first few years after their construction. -- NSV

MEASURING STRUCTURAL CHANGES IN GROUND BY THE METHOD OF SEEPING RADIOACTIVELY LABELED SOLUTION. (Izmerenie strukturnykh kharakteristik gruntov metodom fil'tratsii radioaktivnogo indikatora; Text in Russian). Kom. po zem. pol. Bor'ba s puchunami na zheleznykh i avtomobil'nykh dorogakh., p. 183-188 incl. table, graphs, diagr., 1965. 10 refs.
DLC, TE210.R84

Changes in the pore structure of sands and turfs influenced by freeze-thaw cycles were studied by saturating their samples with a solution labeled by radioactive substances--a method developed by M. P. Volarovich and N. V. Churaev and described in the monograph "Studying the properties of turf and the processes proceeding in it with the aid of radioactive isotopes" (Issledovanie svoystv torfa i protekaĭushchikh v nem professoov pri pomoshchi radioaktivnykh isotopov. M., Izd-vo AN SSSR, 1960). The experimental procedure is briefly discussed and the formulas used in calculating pore-diameters, the coefficient of pore-channel curvature, and the specific surface of the samples, on the basis of the experimental results, are presented. The most convenient labeling isotopes were sulfur-35 for sand, sandy marl, turf and organic ooze, and tritium (H^3) for clay and marl. -- NSV

An electrical device designed for measuring linear deformations of ground and especially suited for operation under the rigid climatic conditions of Siberia and the Extreme North is described in detail and illustrated diagrammatically. It consists of an electrical indicator and a series of metallic rings installed into the ground in a bore-hole. It is used in determining the magnitude of frost heaving

CRREL BIBLIOGRAPHY

in separate layers of earth, sagging of the perennially frozen ground due to its thawing, the amount of settling caused by natural compaction of earth, and the approximate freezing depth of the ground. The procedure of working with this instrument may be combined with the study of thermal regime of the ground by installing thermometers in the bore-hole and observing them in the periods between the measurement of ground deformation. This device may have extensive applications in scientific research laboratories and major organizations dealing with highway and foundation design. -- NSV

HISTORY OF THE STUDY OF PERENNIALY FROZEN ROCKS AND CRYOGENIC PHENOMENA IN PRIBAIKAL'E AND ZABAIKAL'E. (Istoriia issledovaniia mnogoletnemerzlykh gornyykh porod i kriogennykh iavlenii na territorii Pribaikal'ia i Zabaikal'ia; Text in Russian). Akad. Nauk SSSR, Sibirskoe Otd. Inst. Merzlotovedeniia, Geokriologicheskie usloviia Zabaikal'ia i Pribaikal'ia, p. 5-50 incl. maps, 1967. 287 refs.
DLC, Slavic Div.

A review is presented of the literature on perennially frozen rocks in the Pribaikal'e and Zabaikal'e territories published during the last century, with the conclusion that this subject received little attention prior to 1960; starting with this year the Moscow State University and the Institute of Geocryology, Acad. of Sci. USSR conducted extensive studies in the south of this region and a narrow strip along the Trans-Siberia railroad. The following areas have not been investigated: Stanovoï, Patomsk and Olekminsk plateaus and the Delün-Uransk, Severo-Muïsk, Barguzinsk, Kafsk and Malkhanskii ridges. Geocryological maps (scale 1:30,000,000) show schematically approximate geocryological conditions in these regions. -- NSV

GEOCRYOLOGICAL CONDITIONS OF PRIBAIKAL'E. (Geokriologicheskie usloviia Pribaikal'ia; Text in Russian). Akad. Nauk SSSR, Sibirskoe Otd. Inst. Merzlotovedeniia, Geokriologicheskie usloviia Zabaikal'ia i Pribaikal'ia, p. 51-70 incl. illus., tables, map, diagr., 1967. 28 refs.
DLC, Slavic Div.

A discussion is presented on the hydrological and geothermal processes taking place in freezing, frozen, and thawing rocks, the phenomena related to them, their manifestations in the folded mountain regions, and the regularities governing their dis-

tribution and intensity. The territory studied represents an intricate combination of different geocryological conditions: continuously distributed perennially frozen rocks in high mountains, large masses of isolated permafrost cut by through-taliks along the course of ascending ground waters in the zones of tectonic disturbance, and a double-layer structure of thick frozen zones. The processes responsible for frost heaving, solifluction, and naleds are discussed in relation to building and road maintenance. -- NSV

PERENNIALY FROZEN ROCKS OF TUNKA TROUGH. (Mnogoletnemerzlye porody Tunkinskoï vpadiny; Text in Russian). Akad. Nauk SSSR, Sibirskoe Otd. Inst. Merzlotovedeniia, Geokriologicheskie usloviia Zabaikal'ia i Pribaikal'ia, p. 78-90 incl. map, graphs, 1967. 24 refs.
DLC, Slavic Div.

Widespread opinion concerning the presence of 750-1100 m. thick perennially frozen rocks in the Tunka Trough was disproved by the results of thermal studies and modeling of the hydrological conditions of the territory. Apparently in the lake-swamp area (the central part) of the trough permafrost thickness amounts to 100 m, while on the high post-glacial terraces it varies from a few meters to 250 m depending on the local position of the basalt

CRREL BIBLIOGRAPHY

Intrusion. A through-taliks functions under the Irkutsk River channel becoming gradually limited by permafrost in the lateral directions. It is believed that perennially frozen rocks are entirely absent in the Badar sands area characterized only by seasonal freezing to a 4-5 m depth. -- NSV

ivers (Lena, Karenga, Upper Angara). In the North Zabaikal'e permafrost is continuous, its taliks also being restricted to major rivers and lakes. Through-taliks were observed in the intermontane basins as well as in the tectonically disturbed zones and in the places where ground waters ascend from below the permafrost cutting through the frozen formations. -- NSV

DLC, Slavic Div.

Zabaikal'e is characterized by exceedingly variable cryological condition due to its geographic position at the border of permafrost regions. The regularities governing permafrost distribution in the South Zabaikal'e were studied with the conclusion that locally, permafrost is associated with lower relief, the variations in its development in mountainous areas also depending on the steepness and exposure of mountain slopes. On the regional scale, there was a gradual variation of thickness and absolute temperature of the perennially frozen ground from west to east, the thickest series with the lowest temperature were associated with the elevated strongly dissected areas; temperature increased with the decrease in the degree of topographic dissection the highest temperature being observed in wide weakly dissected basins. A table is presented which shows the relation among permafrost thickness, topography, lithology, and vegetation. -- NSV

This short report presents data available on a widely developed zone of fracturing in the igneous rocks located immediately beneath the bottom of perennially frozen formations, which represents a natural water reservoir. Its origin is partially explained by multiple freezing and thawing of rocks due to the fluctuation of climatic conditions. -- NSV

DLC, Slavic Div.

The factors affecting the electric charge acquired by an ice sphere moving through natural snowfall have been investigated experimentally. When graupel particles were in the air the sphere always received a positive charge. If graupel was not present the sign of the charge appeared to be related to the direction of the atmospheric electric field. When the field was directed downwards the ice sphere received negative charge, and when the field was directed upwards the sphere received positive charge. The results are explained in terms of the direct transfer to the ice sphere of some of the net charge on the ice particles in the air making a glancing contact with the ice sphere. The charges that an ice sphere received by this mechanism appeared to be much larger than any charges that might have been generated by asymmetrical rubbing between the ice particles in the air and the surface of the ice sphere. (Author's abstract)

Conditions of frozen rock development in these territories and the associated phenomena are briefly described and discussed, with the conclusion that perennially frozen strata, the upper surface of which joins the seasonally freezing layer, are developed in Pribaikal'e in separated areas 200 to 800 m long with taliks located under the deep never freezing

THE NUMBER FLUX OF SNOW CRYSTALS AT THE GROUND. Monthly Review, 95(12):921-924 incl. illus., graphs, table, Dec. 1967. 2 refs.
DLC, QC983.A2

Many measurements of the snowfall rate R and the average mass per crystal \bar{m} have provided values of R/\bar{m} , the number of snow crystals reaching unit area of the surface per unit time. A typical number is 1 per cm^2 per sec. Over a whole season's data, the flux is proportional to the snowfall rate. Specifically, two-thirds of the measurements lie within a factor two of a locus R/\bar{m} ($\text{cm}^{-2} \text{sec}^{-1}$) = $1.5 R^{1.0}$ where R is in millimeters of water per hour. Thus the principal contribution to any increase in the snowfall rate is the formation of new crystals, rather than the growth of existing ones. (Author's abstract)

OBSERVED CONFIGURATION AND COMPUTED ROUGHNESS OF THE UNDERSIDE OF RIVER ICE, ST. CROIX RIVER, WISCONSIN. U.S. Geol. Survey, Prof. Paper 550-B:B192-B198 incl. illus., table, 1966. 11 refs.
DLC, QE75.P9

Ripple- and dune-like features on the underside of the cover of river ice on the St. Croix River, Wis., change with time and closely resemble ripples and dunes found on alluvial streambeds. In 12 observations the wavelength and amplitude of the "ice-dunes" averaged about 0.65 foot and 0.07 foot, respectively. In all dune profiles the steeper slopes were on the downstream sides of the features. No suspended sediment or frazil (slush) ice was present in the flow. It is suggested that the features may owe their origin to fluid turbulence. The Manning roughness coefficient, calculated for the underside of the ice by a new method which uses the results of discharge measurements through the ice and supporting field data, is related to the observed characteristics of the underside of the ice. (Author's abstract)

THE UNDERSIDE OF RIVER ICE, ST. CROIX RIVER, WISCONSIN. U.S. Geol. Survey, Prof. Paper 550-B:C195-C199 incl. table, diagr., 1967. 2 refs.
DLC, QE75.P9

Ripplelike and dunelike features have been found

during a second winter on the underside of the ice cover on the St. Croix River, Wis. Profiles of the features and measurements of ablation and accretion show that the features began to form when the underside of the ice was accreting, and continued their development during ablation. The Belokon-Sabaneev formula, $n_T = (2n^{3/2} - n_B^{3/2})^{2/3}$, satisfactorily shows the relationship between the roughness coefficients for the ice, the bed, and the total channel. Calculations of the roughness coefficients for the underside of the ice, n_T , range from 0.0039 to 0.0142, except for one calculation which indicates no retardation of the flow by the ice cover. This anomaly is believed to be caused by an incorrect estimate of the effective size of the roughness projections of the bed. Caution is therefore given that the computed (published) values of the ice-roughness parameters are slightly smaller than actual. (Author's abstract)

ANALYTICAL APPROACHES TO COMPUTATION OF DISCHARGE OF AN ICE-COVERED STREAM. U.S. Geol. Survey, Prof. Paper 550-B:C200-C207 incl. tables, graphs, 1967. 3 refs.
DLC, QE75.P9

Two analytical methods for computing winter discharge of an ice-covered stream have recently been developed from observations on the St. Croix River, Wis. One method is based on pipe-flow equations, and the other method on an analogy with methods used to compute open-water discharge for streams affected by backwater. Accuracy of computed discharge in the first method is within ± 19 percent of measured discharge, whereas the second method gives results within ± 9 percent. Relationships in both methods are developed with data either recorded or measured in the field. After the relationships have been developed for a particular stream-gaging station, only recorded data (water-surface stage at both ends of a reach) are needed to compute discharge. ICE FILAMENTS GROWN IN A GRADIENT OF
VAPOUR PRESSURE. J. Meteorol. Soc. Jap.,
Ser. II, 45(4):315-325 incl. illus., table, diagrs.,
Aug. 1967. 3 refs.
DLC, Orientalia Div.

It has been observed that when ice crystals are nucleated on fine threads in a low-pressure diffusion chamber, they grow preferentially upward and sublimate downward leaving, between crystals and threads, thin filaments and sheets of ice. The features and growth process of these structures are presently studied. Filaments and edges of sheets have a typical shape, formed by a nearly periodical series of "beads" and "necks". During growth, new beads appear at the base of the filaments, while all the structure looks as if it were rising up against the vapour flux. The phenomenon is explained by considering an alternate process of condensation upward and evaporation downward of the ice surface, due to the uni-directional vapour flux. It is shown that the vapour density in the region where filaments form is near to equilibrium, and the typical shape of "beads" and "necks" is related to the compensating effect of the different equilibrium vapour pressure at their surfaces, due to their different curvature. The interpretation of the present phenomenon may be applied to explain the formation of ice filaments observed in more general conditions. (Authors' abstract)

Grounds of different lithological composition are classified according to their ability to separate during freezing into partially dehydrated mineral aggregates and ice, into those subject to strong and medium frost heaving, and those remaining undeformed under normal freezing conditions. The first class includes sandy loam and loam with a large dust fraction, the second, clays, loams, dusty sands, and the third, pure sand and gravel. The second class grounds are widely developed in Siberia, however, the intensity of cryogenic processes in them depends on the degree of pre-winter moisture saturation and local hydrological conditions. In Siberia maximum frost heaving was observed in mountainous taiga and the forest-steppe regions with rolling topography.

Artificial ground freezing is a valuable aid, and at times may be the only means possible, for excavation. The soil becomes stabilized to give shear strength for a retaining structure and a water stop. Design includes strength and deformation of a viscoelastic material in a structure, and of heat flow in a material in which water changes to ice causing radical changes in thermal parameters. Examples show how the rheological parameters of strain, temperature, stress and time for typical soils are related. Techniques and design data are given for the structural design of a cylindrical cofferdam. Thermal parameters and techniques, with assumptions and consequent equations for design, are provided with examples of two typical soils, straight and curved walls, for computing time of freezing, temperatures, energy and refrigeration-load from which cost estimates may be made for a particular job. Construction practices are discussed, with special attention to the hazards of the ground freezing technique. (Author's abstract)

ON MICROFLORA AND FAUNA ASSOCIATED WITH THE ANTARCTIC FAST ICE. (O mikroflore i faune, svřzannoř s Antarktičeskim pripařnym l'dom; Text in Russian). Zoologičeskij Zh. V. 46, Vyp. 10:1585-1592 incl. graph, diagr., 1967. 20 refs.
 DLC, QL1.Z747

The biological community associated with Antarctic fast ice was studied during the austral summer of 1965-66. Data on microalgae was very similar to that obtained by J. S. Bunt and E. J. F. Wood (1963); about 50 species of diatoms were discovered in the core samples of ice from the Alashev Bay (Enderby Land), their maximum quantities (37 million cells) living in the lower layers of loose ice. Two faunal assemblages depended on ice as a pasture and a shelter: 1) those inhabiting, or at least temporarily inhabiting, the lower layer of loose ice and 2) the organisms which do not enter the ice but are trophically related to the ice-inhabiting assemblage. Microflora affects the amount of light penetrating through the ice cover; instrument measurements show that during spring the amount of light penetrating the sub-ice waters is greatly decreased due to intensive growth of the diatoms. At the end of December, when the algae are returned to the waters by thawing ice, the water illumination increases about 100 times. -- NSV

This book is based on the results of a research program initiated by NIIZhelezobeton in which the authors participated, and on the generalization of the formerly published domestic and foreign experience in this field. It describes the principal characteristics of all presently employed methods of defrosting building materials and the basic data necessary for selecting, designing, and using different means of loosening materials such as sand, gravel, limestone, clay, and coal frozen during their transportation by train. Different vibrating mechanisms, milling devices, and steam and gas heaters designed for use directly in railroad vans and warehouses are described and their use and maintenance explained. -- NSV

DLC, TC1.A39

The ice and snow cover of the Chena River was dusted with coal dust and fly ash in the spring of 1966 to increase the absorption of solar energy and hasten melting. Because of a near-record snowfall during the winter of 1965-1966, a good deal of concern was felt for the flood damage which would result if an ice jam were to form at the mouth of the Chena River just downstream from Fairbanks. It was hoped that dusting would increase the absorption of the solar radiation to sufficiently weaken and melt the ice to prevent a jam. Theoretically, dusting could increase the radiation absorbed at breakup time in Fairbanks enough to melt and additional 2 cm of ice per day. Measurements of melting rates made in the dusted and clean sections of the river and observations of the river during breakup showed that dusting apparently had a significant beneficial effect. Because of its specific nature and lack of control, this experiment cannot be considered conclusive. (Authors' abstract)

diagrs., tables, 1966.

DLC, Slavic Div.

This is a continuation of research on physical properties of snow and on avalanches in the area of Tatra Mountains. The snow conditions were very favorable to the conducting of research, and the number of fallen avalanches was very high. The land measurements were made from March 20 to 24, 1962, i. e., in a period corresponding to the maximum of snow masses and characteristic for the flow of thaw waters. These measurements deal with depth of snow cover and reservoirs as investigated with a cone sonde. In places important from the point of view of occurrence of avalanches, this year the number fell from 158 on 112 paths. The elaborate study is illustrated with 26 photographs and 4 charts, showing the location of measuring posts, depth of snow cover, reservoirs in snow and the paths of falling avalanches.  diagrs., tables, 1966.
 DLC, Slavic Div.

Snow research in Hala Gąsienicowa was conducted in a small field in the lower part of the valley, below the meteorological station. The present research program embraced, besides those conducted in the past years, measurements of physical properties of snow, also the investigations in the layer of air above the snow cover at the 5, 50 and 100 cm height. Since the data from the level 0.5 m and 1.0 m differed little, the data for the level 1 m are omitted. A new feature begun in 1962 deals with the morphology of snow crystals and grains. In this work there are presented 16 most interesting photographs, each classified according to the international scheme and to the classification proposed by Nakaya. (Author's abstract)

DEVELOPMENT OF SNOW DENSITY OF KASPROWY WIERCH IN THE WINTER 1959/1960. (Kształowanie się gęstości śniegu na Kasprowym Wierchu w 1959/1960 roku; Text in Polish). Prace, Państwowy Instytut Hydrologiczno-Meteorologiczny, No. 87:59-64 incl. diagrs., tables, 1966. Refs.
 DLC, Slavic Div.

Results of the measurements of snow density in Kasprowy Wierch during the winter 1959/1960 are summarized. The analysis of the formation of snow density on slopes obtained with 4 main methods is based on 250 measurements. A great differentiation of snow density on several slopes, in the period of a relatively stabilized snow cover is shown. Average snow densities for winter 1959/1960 were S-0.36, E-0.35, W-0.33, and N-0.27 g/cm³. This distribution of snow density in summit parts of Tatra Mountains depends mainly on the daily course and on the intensity of insolation. (Author's abstract)

ICE ACCRETION ON ELECTRIC WIRES IN POLAND.
 (Oblodzenie przewodów w Polsce; Text in Polish). Prace, Państwowy Instytut Hydrologiczno-Meteorologiczny, No. 87:65-79 incl. diagrs., tables, Refs.
 DLC, Slavic Div.

On the basis of the observations of ice accretion on electric wires in 1956-1961 it was stated that the average number of days with ice accretion of wires was 12.3; almost 70% of cases of ice accretion occurred in Dec., Jan. and Feb. Soft rime occurred most frequently (about 43%), then glaze (about 33%), hard rime (about 13%), and snow pellets (about 12%). Soft and hard rime occurred most frequently in Jan. and Feb., glaze in Dec., snow pellets in late autumn and early spring. In plains weight values of ice accretion reached 160 g, in mountains, 580 g per running meter of wire. Ice accretion in Poland does not pose a serious threat to communication and power lines. CHEMICAL MEANS FOR PREVENTION OF ACCUMULATION OF ICE, SNOW, AND SLUSH ON RUNWAYS. Monsanto Research Corporation (Federal Aviation Agency) SRD Report No. 65-13, 28p. incl. illus., tables, maps, appendixes A-I, March 1965.
 DDC, AD615420

The objective of this contract was to develop a mixture capable of melting snow, ice, and slush at temperatures as low as -10°F. This mixture was to be of reasonable cost, be noncorrosive to aircraft and not cause deterioration of runway pavements. Nine primary deicers were tested and many mixtures of them were subjected to primary and secondary screening. These mixtures were then combined with potential corrosion inhibitors and the inhibitors needed was determined. The application rate to produce melting at -10°F was quite nominal (2 oz/ft²), and the compositions had at most slight spalling effect on concrete. The prime candidate for runway deicing has the following composition: Tripotassium phosphate 75% - formamide 25%. While the cost of these materials exceeds that of calcium chloride, the combination does not cause the extent of corrosion obtained with calcium chloride. A second combination proved outstanding for preventive corrosion of steel not under the potentially high stress of landing gear. Suitable for road usage was calcium chloride to which was added 1% by weight of Emulsifier STH. This composition retained all its ice-melting qualities with marked corrosion control. Because of the outstanding ice-melting and corrosion-controlled properties of the recommended runway deicer, and its superiority in these qualities to now available compositions, it should be field tested. Since 1952-1953 the Arctic and Antarctic Scientific
Research Institut has been running a program of
placing radio beacons and automatic meteorological
stations on the polar ice to the north of Russia. This
note gives a report of the progress of this work. The
movement of the beacons and stations has been
followed to determine the movement of the ice mass,
and in consequence the currents in the underlying
water. The automatic meteorological stations relay
data on temperature, pressure, wind speed and
direction. Statistics are given of the number of
stations (274 separate units) set up during 1953-
1955. A plot is given of their initial positions, and
data on the number of stations lost in the different
months of the year are illustrated graphically.
Some plots of drifts show the main current directions
in the Laptev Sea. (Authors' abstract)

THEORETICAL STUDY OF THE ICE ACCRETION
PROCESS. Quart. J. Roy. Meteorol. Soc., 93(396):
195-213 incl. diagrs., tables, April 1967. Refs.
DLC, QC851.R8

Calculations made of the freezing and subsequent
cooling times of a thin water film on the surface of
a ventilated sphere initially at a uniform tempera-
ture show that both the freezing and cooling pro-
cesses are dominated by the sphere temperature.
Except at sphere temperatures within a few degrees
of 0°C, the freezing time of the water film is short
compared with the total time taken to remove the
latent heat of fusion by the forced convection process.
Values of the freezing and subsequent cooling times
of the water film are presented for various values of
the ambient temperature, sphere radius, and film
thickness. The liquid water concentrations required
to maintain a sphere at a steady temperature have
been computed and found to compare well with those
given by the simple heat balance relation for a
spherical hailstone. Thus, the simple heat balance
relations are useful for predicting values for the
mean temperatures of an accreting surface in a
steady state situation. (Authors' abstract)

STUDY OF THIXOTROPIC PROPERTIES OF
CLAYEY SOIL IN THE OSPO VALLEY (TRIESTE).
(Misura delle proprietà tixotropiche di terreni
argillosi della valle dell'Ospo (Trieste); Text in
Italian). Geotecnica, Milano, 13(1-2):16-21 incl.
illus., map, graphs, diagrs., 1966. 3 refs.
DLC, Slavic Div.

A brief geological history of this region is given
and a geological profile across the valley is pre-
sented. The ancient channel of the valley was
filled with plastic blue marine silty clays over-
lying clayey sands and limestone breccia. Shear
strength variation of this clay was determined as
a function of time elapsed since the exertion of a
dynamic action on the clay, by measuring the force
required for pulling out cylindrical concrete model
piles driven into a remoulded sample. Series of
pulling tests were performed by means of a sensi-
tive beam scale at certain time intervals up to 27
days after driving the piles into the soil. The in-
struments used are described and curves of thixo-
tropic strengthening of the clays are presented.

AMINO ACIDS AS ICE NUCLEATORS, *J. Atmos. Sci.*, 24(3):274-277 incl. diagrs., tables, May 1967. Refs.
DLC, QC851.A283

The authors' recent studies on phenols and benzoic acids suggest that the ability of solid organic compounds to nucleate freezing of supercooled water may be predicted, at least in a limited number of cases, from purely thermodynamic considerations. A report that pure, optically active amino acids nucleate freezing at temperatures different from their inactive forms suggests that a quantitative study of the differences might be revealing. It was found that differences in nucleation temperature were related in a linear manner to differences in heat of solution of active and racemic forms. Tyrosine is an exception to the above behavior. It is suggested that nucleation on one of the forms may occur at the phenolic group. (Authors' abstract)

DISTRIBUTION OF SNOW COVER ON SMALL CATCHMENT BASINS OF A SEMIARID ZONE IN WESTERN KAZAKHSTAN. (O raspredelenii snezhnogo pokrova na malykh vodosborakh polupustynnoi zony Zapadnogo Kazakhstana; Text in Russian). Alma-Ata, Kazakhstan, Nauchno-Issledovatel'skiy Gidrometeorologicheskiy Institut, Trudy, No. 25:141-165 incl. diagrs., tables, 1966. Refs.
DLC, QC851.A277A1

Using as an example the small catchment basins of the western Kazakhstan runoff stations situated in the semi-arid zone, the author investigated the characteristics of the distribution of snow supplies in relation to the terrain. A detailed snow survey carried out on a meadow showed that a reduction in the number of snow surveys to 3-4 practically did not lower the accuracy of the snow reserves. The proportion of snow reserves in ravines and thalweg for years differing in snow transport amounted to 9-28% of the total for the catchment basins. Snow reserves determined from snow surveys in the channels of meadows by measuring heights and densities of snow at those points have in most cases large deviations which may amount to 200-300% of the snow reserves obtained by a detailed survey. The coefficient of variation of snow reserves depends directly upon the magnitude of the snow reserves, snow transport, and dissection of the terrain of the catchment basin. A verification of P. P. Kuz'min's approximate formula, applied to this region, showed a fully satisfactory relationship between data obtained with approximate and computational formulas; the mean deviation for different catchment basins was 6-10% and the maximum deviation 10-26%. TEMPERATURE OF HAILSTONES, *J. Atmos. Sci.*, 24(3):293-297 incl. diagrs., May 1967. Refs.
DLC, QC851.A283

A rigorous study was made of the temperature profile in spherical and homogeneous hailstones falling through clear air. It is found that a stone 1 cm in radius is liable to be a dozen degrees Celsius colder than the ambient air. For larger stones, the temperature difference becomes greater. The cooling effect of hail on the air is relatively small, if hail-size distributions of the sort commonly observed at the ground are considered. When a stone (1.1 cm in radius) falls through cloud, its heat capacity delays the commencement of wet growth by as much as 2 km. On the other hand, when hail grows in surroundings of high liquid water content, the heat capacity term of even the largest hail in the heat balance equation is quite unimportant. Such growth normally leads to mixtures of water and ice. (Authors' abstract)

RELATION BETWEEN FREEZING TEMPERATURE
OF SUPERCOOLED WATERDROPS AND COOLING
RATE. Bulgarska Akademiia na Naukite, Sofia,
Doklady, 19(12):1139-1142 incl. diags., 1966.
Refs.
DLC, Q59.B93

An investigation to determine whether the cooling rate and the freezing temperature of water are related. It was found that the mean deviations for the different cooling rates are very small and vary between +0.16°C and -0.15°C in an irregular way. It is assumed that with more experimental data available, the small discrepancies in temperature will tend to zero. (Authors' abstract)

can be induced by simple causes such as workers walking in foundation pits, or any crumpling of clay in the pit. In explaining the nature of thixotropy to construction workers, the following information is also given for dealing with such soils: 1) Concrete shall be placed in the foundation excavation immediately after its digging is finished to avoid clay swelling and rupture of its structural bonds. Pockets between the excavation walls and the basement must be filled immediately with pulverized clay. 2) Experiments indicated that a thin inter-layer of sand (grain size 0.25 mm), poured over the clayey ground "like a sandy rain" (rather than thrown-in separate larger portions) before placing the coarser fill - has prevented thixotropic phenomena. The thickness of this layer is determined experimentally. -- NSV

WATER TEMPERATURES IN A SHALLOW LAKE DURING ICE FORMATION, GROWTH AND DECAY. Res. Rept. 213, U. S. Army Cold Regions Research and Engineering Laboratory, 24p. incl. illus., diags., graphs, map, Dec. 1967.
CRREL files

Continuous water temperature measurements were made in a shallow lake in upper Michigan prior to and during ice formation, and during ice growth and decay. Several full circulations or "overturns" at 4°C were observed during autumn and the temperature throughout the lake just prior to complete freeze-over reduced to a minimum of +0.2°C. After a permanent ice cover had formed, the water beneath the ice began to warm up. Within a 25-day period during December the water temperature near the bottom of the lake increased from +0.3°C to 3.0°C. Quantitative analysis of this heat gain showed that it came principally from the energy stored during the summer in the underlying soils. Evaluation of the effect of solar radiation demonstrated that the sun during December contributed very little heat to the water because of the absorption qualities of the cover of snow and bubbly ice. During the ice thaw period in April a unique reduction in temperature was recorded throughout the main mass of water. Since the lake is thermally stratified, it was assumed that this cooling could only result from mechanical action in the water. This phenomenon probably takes place as the surface water from melting snow around the area flows into the lake and causes overturning. (Author's abstract)

AN IN SITU GAS EXTRACTION SYSTEM FOR RADIOCARBON DATING GLACIER ICE. Res. Rept. 236, U. S. Army Cold Regions Research and Engineering Laboratory, 4p, incl. illus., table, Oct. 1967. 5 refs.

CRREL files

In March 1966 at the Tuto ice tunnel, Greenland, a team from USA CRREL and the University of Bern tested a new down-borehole device which would allow gas to be extracted from within shallow or deep boreholes. The tunnel ice was unfractured and its temperature was constant at -10°C . A location where, in 1964, C-14 age dates had been obtained was used as a check point for the down-borehole tests. Comparative samples show good agreement and indicate a mean value of 5120 years B. P. for the age of ice at this location. The simplicity of the down-borehole gas extraction system enables application of the carbon dating method to any natural, undisturbed glacier ice mass which can be sampled by boring. The gas extraction apparatus and field experiments are described. (Authors' abstract)

SNOW AND ICE PROPERTIES AS RELATED TO ROADS AND RUNWAYS IN ANTARCTICA. Tech. Rept. 176, U. S. Army Cold Regions Research and Engineering Laboratory, 40p., incl. illus., diagrs., graphs, tables, Oct. 1967. 51 refs.

CRREL files

Dynamic tests were performed to determine the Young's modulus of sea ice, derived from longitudinal wave velocities measured with a sonoscope. Static tests consisted of standard ring tensile strength and simple beam or flexural strength tests. The strength data were plotted on a base of the brine volume for each test. The test results indicate that the annual sea ice at McMurdo Sound is capable of supporting cargo type aircraft. Snow runways capable of supporting a C-130 aircraft on wheels and providing marginal support to a C-121 can be constructed either with the Peter plow or with the pulvimixer. However, the runway would be reliable only during comparatively low temperatures ($< -15^{\circ}\text{C}$). Peter snow miller processing and bulldozer compaction methods appear to be feasible for effective depth processing and compaction of high strength snow pavements. The criteria for support of various types of aircraft on a snow runway are presented. (Authors' abstract)

CALCULATING CARRYING CAPACITY OF ICE COVER ACCOUNTING FOR ITS INHOMOGENEITY WITH THICKNESS. (Raschet nesushchei sposobnosti ledianogo pokrova s uchetom neodnorodnosti ego po tolshchine; Text in Russian). Izvestiia Vyssh. Ucheb. Zavedeni, Stroitel'stvo i Arkhitektura, No. 2:3-8 incl. tables, 1966. 2 refs.
DLC, TH4.R8

Ice cover may consist of several layers with different ice structure; because in nature these layers occur under different temperature conditions, the mechanical properties of ice vary with its thickness according to very complicated laws. A method is offered for calculating carrying capacity of an inhomogeneous ice cover taking into consideration the variations of its mechanical properties with thickness. A theoretical analysis is presented of the temperature effect on stress distribution along the thickness of a structurally homogeneous ice cover. It is established that at usual temperatures of ice the temperature factor may vary the maximum value of stress by 5 to 10%. A problem is solved of stress distribution along the thickness of a two-layer ice cover; it is shown that the presence of the upper layer of turbid ice may affect the carrying capacity of ice cover, especially when the greatest tensile stress is developing in the upper surface of ice.

RESULTS OF CLIMATOLOGIC INVESTIGATIONS WITH RELATION TO MAPPING THE USSR TERRITORY ACCORDING TO ICING INTENSITY. (Rezultaty klimatologicheskikh razrabotok primentel'no k gololednomu raionirovaniu territorii SSSR; Text in Russian). Leningrad, Glavnaia Geofizicheskaiia Observatoriia, Trudy, Prikladnaia klimatologiia, Vyp. 200:16-32 incl. tables, graphs, 1966. 15 refs. DLC, QC801.L46

Separate problems related to subdivision of the USSR territory according to the intensity of icing processes are discussed in connection with an attempt to improve the existing procedure of calculating ice load on electrical wires and tall buildings, used in engineering design. Formulas are presented which were derived by the Leningrad Main Geophysical Observatory for calculating the norm of glaze thickness according to weight of ice deposit per unit length of wire. Further improvements and simplification of procedures by nomograms were developed in the All-Union Scientific Research Institute of Power Engineering. The concept "norm of glaze thickness" was introduced especially for this type of mapping, defined as the thickness of the wall of ice accumulated on a wire, calculated according to given formula reduced to the height of wire suspension (maximum 12 m) and wire thickness (10 mm). The use and limitations of the statistical tables and graphs presented are explained. Problems related to icing of wires and structures exceeding 50-100 m in height are not discussed. -- NSV

SYSTEMATIC PACKING FROM THE STANDPOINT OF THE PRIMITIVE CELL. Res. Rept. 201, U.S. Army Cold Regions Research and Engineering Laboratory. 29p. incl. tables, graphs, Dec. 1967. 25 refs. CRREL files

The systematic packing of uniform spheres is generalized by describing the primitive rhombohedral cell which characterizes the arrangement between layers. Volume and porosity are found to depend on only two angular parameters, α and β :

$$V = 8R^3 \frac{\sin \alpha \sin \beta}{\pi}$$

$$n = 1 - \frac{\pi}{8 \sin \alpha \sin \beta}$$

β is the angle between rows in a layer, and α is the altitude angle between members of adjacent layers. An azimuth angle γ determines the position of the plane in which α is measured but does not enter into the porosity calculation. Four critical stacking arrangements are described, the porosities of which may be written as functions of the single parameter β . The stable packings studied by Graton and Fraser (1935) are special cases of the critical positions. Typically unstable packings lie between these positions. Tables and graphs are presented which give the porosity of the primitive cell, as a function of α and β , over the entire range from open to close packing for every possible layer configuration. ELECTRICAL CONDUCTION IN ICE. Res. Rept. 198, U.S. Army Cold Regions Research and Engineering Laboratory, 59p. incl. tables, graphs, diagrs., appendix, Sept. 1967. 21 refs. CRREL files

In an attempt to resolve the conflict existing in the literature as to dc electrical conductivity of ice, an extensive series of measurements has been made. Since surface conduction is a possible cause of some of the confusion, both bulk and surface conductivity have been measured at dc and audio-frequencies. Evidence was found for significant surface conductivity when slight contamination was present. In order to explain these results quantitatively, it is necessary to postulate a surface conduction region whose thickness varies with temperature. Extrinsic bulk conductivity due to trace impurities has been found to play an important part also and probably accounts for some of the disagreement in the literature. Using ice of the highest purity, both measurements show that, for a fresh sample, the dc conductivity is nearly independent of temperature down to temperatures at which the high frequency ac and dc conductivities are about equal. The results suggest that the high frequency conductivity is limited by 2 processes in parallel and that the dc conductivity is limited by the same 2 processes in series. (Authors' abstract)

LIGHT SCATTERING IN GLACIER ICE. (Zur Lichtstreuung im Gletschereis; Text in German). Arch. Meteorologie, Geophys. Bioklimatologie, Ser. B, 15(1/2):175-185 incl. diags., tables, 1967. Refs.
 DLC, QC851.A732

Extinction in glacier ice has been evaluated by a special set of equations which especially take into consideration the influence of a directed light flux. For the numerical calculations the dispersion function for air bubbles enclosed in the ice has been evaluated according to the laws of geometrical optics. As a result dependence of the albedo on the zenith-angle of the oriented light flux, dependence of the ratio between light from above and from below, and the extinction coefficient of the light fluxes in a boundary layer on the depth below the glacier surface are obtained. (Meteorol. & Geoastr., Abstract)

Recent investigations of the phenomena and the countermeasures include discussions on the special measuring instruments, calculation procedures, and the forecast of mudflows and avalanches. Three types of protection from avalanches are distinguished: 1) engineering structures preventing avalanche movement (protective walls, stone and earth dams, artificial obstacles in the path of an avalanche), and those designed to stop or divert an avalanche; 2) engineering structures preventing the movement of snow-masses and the formation of an avalanche: slope terraces, wooden and metallic fences, stone and concrete walls, moats, forest strips; and 3) prevention of catastrophes by employing signs in the danger area, light signals, traffic regulation, rescue-squad organization, and different ways of destroying snow accumulations on slopes, mainly by blasting. The formula of Khristianovich-Gongadze derived for obtaining the impact force of an avalanche was checked under natural conditions and gave greatly exaggerated results. -- NSV

CONCERNING ONE CHARACTERISTIC FEATURE OF SLOPE PROCESSES. (Ob odnoi osobennosti sklonovykh protsessov; Text in Russian). Moskovskii Universitet, Vestnik, Ser. 5. Geografiia, No. 3: 94-95, 1967.
 DLC, G1.M68

The hypothesis concerning "vertical projection" of heavy particles during water erosion of slopes, according to which they maintain their position in plan regardless of the erosion intensity, was studied in a model simulating wash-out of sandy slopes with the inclination angles varying from 0 to 20°. The sand contained separate pieces of quartz weighing 50 to 55 g; "rain" intensity varied from 0.5 to 1.8 mm/min. Slow-motion films of this process indicated imperceptible movement of the heavy pieces down the slope, the displacement distance being proportional to the thickness of the removed sand layer and the slope angle. Empirical formulas obtained for calculating this distance (L) at different slope angles are presented; they indicate that the weight of the particles and the degree of their superficial roughness have little effect on L. -- NSV

 DLC, GB641.V88

The relationship between permafrost thickness, its areal distribution, and recent tectonic movements was studied in rock outcrops and in the process of exploratory drilling. It is believed that the amplitude of tectonic movements, approximate age, changes in the direction of movements and structural inheritance may be determined from studying facies changes of perennially frozen rocks. Such an analysis accounts for permafrost development in space and time, and combines the interpretation of data on the permafrost topography, climatic, geological, geographical, and geomorphological conditions of territory development. A group of factors entirely dependent on tectonic influence are discussed for plicated and mass movements, and the use of the analytical procedure offered is illustrated by the practical example of studying the Bol'shaya Zemlia tundra. -- NSV

DLC, QC801.L46

Ice forming ability of metaldehyde and phloroglucinol aerosols obtained by thermal dispersion (sublimation in a flux of hot air) was studied experimentally in view of determining temperature relationships of ice nucleation during seeding of supercooled fogs. The curves relating the amount of icing nuclei produced to the temperature of supercooled fog are presented. They indicate that the ice forming ability of the aerosols obtained by the procedure described is quite comparable to that of AgI fumes. A great advantage of both substances is their higher temperature threshold of ice nucleation than that of AgI and their stability toward ultraviolet radiation. -- NSV

DLC, G1.M68

The effect of soil freezing in winter on the intensity of its erosion during thaw was studied experimentally on light and heavy loam samples. Freezing-thawing of the absolutely dry, air-dry, and the maximum hygroscopic saturation samples did not affect initial resistance to erosion; the same was true for the samples containing 50% of total moisture-saturation, but the strength of those with 75% saturation was lowered and the effect became stronger with the increase in the initial water content and the number of freezing-thawing cycles. This was explained by increased growth of ice veinlets in soils, which weaken and disrupt cohesion between soil particles. The process studied had a greater effect on the heavy loam than on the light loam. -- NSV

PHLOROGLUCINOL AS A CRYSTALLIZER OF WATER DROPS IN SUPERCOOLED FOG AND CLOUDS. (Floriglutsin-kristallizator kapel' vody pereokhlazhdenogo tumana i oblachnosti; Text in Russian). Leningrad, Glavnaya Geofizicheskaya Observatoriya, Trudy, Vyp. 186:10-17 incl. tables, 1966. 1 ref.
DLC, QC801.L46

First results obtained in the laboratory and field investigations of the phloroglucinol seeding of supercooled clouds and fog in 1949-51 are reported. Effectiveness of the phloroglucinol sublimation products at -10°C temperature of the fog has exceeded that of solid CO₂ and was increasing with the increase in blow off, indicating that particle coagulation in phloroglucinol may be considerable and that it can lower the effectiveness of this agent, which also depends on the moisture content and other characteristics of the supercooled fog. The effect of ice, light, and the time length of particle existence on the stability of the phloroglucinol sublimation products was also studied. Field experiments with this substance produced weaker effects than those with CO₂, in particular no optic phenomena (like halo) were visible; this was explained by the use of insufficient quantities of the seeding agent. -- NSV

cheskaya Observatoriya, Trudy, Vyp. 186:18-25 incl.
tables, graphs, 1966. 11 refs.
DLC, QC801.L46

Laboratory investigations of the effect of surface-
active-substances (SAS) on ice nucleators have
shown that 1% concentration of SAS added to the
seeding agents lowers their freezing temperature
by 4 to 7°C, so that the threshold temperature for
the crystallization of a supercooled fog is lowered
by 3 to 8°C. The yield of ice nuclei during the
atomization of AgI, PbI₂ and C₆H₃(OH)₃ in the fog
chamber depended on the SAS concentration in the
solutions; an increase in SAS concentration from
10⁻⁷ to 10^{-1%} resulted in the decrease of ice crys-
tals from 2 x 10¹² to 5 x 10¹⁰g⁻¹; this relation was
more pertinent for the colloidal solution of AgI than
for the true solutions of PbI₂ and C₆H₃(OH)₃. In
the supercooled fog droplets of the atomized ice
nucleators froze rapidly with the separation of SAS
particles, which in turn served as additional icing
nuclei. Calculations have shown that the number of
drops of the atomized solutions was twice smaller
than that of ice crystals. -- NSV

wind velocity, at the same time its value for a point-
source of icing nuclei was smaller than that for a
plane-source. Depending on cloud density, the
crystallization zone either increased in time to a
complete disappearance of the cloud layer, or at-
tained its maximum with subsequent decrease in
size on account of moisture drops penetrating into
it. Usually, the size of the zone crystallized by
one pyro-cartridge amounted to 20-30 km² in one
hour. The time of the appearance of a clearance in
the solid layer of a supercooled cloud depended on
cloud density and wind velocity within it; the empir-
ical formula for this relationship is presented.

ORIENTED CRYSTALLIZATION (EPITAXIS) ON
ISOMORPHOUS CONDENSATION NUCLEI.
(Orientirovannaya kristallizatsiya (epitaksiya) na
izomorfnnykh sadrakh kondensatsii; Text in Russian).
Leningrad, Glav. Geofiz. Observ., Trudy, 186:120-
125 incl. diags, 1966. Refs.
DLC, QC801.L46

The conditions of oriented growth of crystals on a
surface in the absence or in the presence of adsorp-
tion of admixtures are examined. The most general
expressions for the criterion of epitaxis in the
presence of adsorption are given by the formulas:

$$\Delta \theta_{\text{min}} = \left\{ \left(\frac{2\sigma}{C_{11} + C_{12}} \right) \left(1 - \frac{2W}{\psi} \right) \left[1 - 3 \frac{n^2}{n_3^2} \left(\frac{\psi' - W}{\psi - 2W} \right) + 2 \frac{n^2}{n_3^2} \right] \right\}^{1/2} \left(1 + \frac{\psi' - \psi + W - \sigma}{4TS} \right)^{-1/2}$$

and

$$\Delta \theta_{\text{min}} = \left\{ \left(\frac{2\sigma}{C_{11} + C_{12}} \right) \left(1 - \frac{2W}{\psi} \right) \left[1 - \frac{n^2}{n_3^2} \left(\frac{\psi' - W}{\psi - 2W} \right) \right] \right\}^{1/2} \left(1 + \frac{\psi' - \psi + W - \sigma}{4TS} \right)^{-1/2}$$

In the case of W = 0 (i. e., in the absence of adsorp-
tion) these formulas are transformed into the ex-
pression for $\Delta \theta_{\text{min}}$ given by the formulas:

$$\Delta \theta_{\text{min}} = \left[\left(\frac{2\sigma}{C_{11} + C_{12}} \right) \left(1 - 3 \frac{n^2}{n_3^2} \frac{\psi'}{\psi} + 2 \frac{n^2}{n_3^2} \right) \right]^{1/2} \left(1 + \frac{\psi' - \psi - \sigma}{4TS} \right)^{-1/2}$$

and

$$\Delta \theta_{\text{min}} = \left[\left(\frac{2\sigma}{C_{11} + C_{12}} \right) \left(1 - \frac{n^2}{n_3^2} \frac{\psi'}{\psi} \right) \right]^{1/2} \left(1 + \frac{\psi' - \psi - \sigma}{4TS} \right)^{-1/2}$$

In the case of n = n₃ and n = 0 these are the expres-
sions obtained:

$$\Delta \theta_{\text{min}} = \left[\left(\frac{2\sigma}{C_{11} + C_{12}} \right) \left(1 - \frac{\psi'}{\psi} \right) \right]^{1/2} \left(1 + \frac{\psi' - \psi - \sigma}{4TS} \right)^{-1/2}$$

and

$$\Delta \theta_{\text{min}} = \left(\frac{2\sigma}{C_{11} + C_{12}} \right)^{1/2} \left(1 + \frac{\psi' - \psi - \sigma}{4TS} \right)^{-1/2}$$

ON THE CONDITIONS OF SNOW, GRAUPEL, AND HAIL GROWTH IN CLOUDS. (Ob usloviakh rosta snega, krupy i grada v oblakakh; Text in Russian). Leningrad, Glavnaia Geofizicheskaiia Observatoriia, Trudy, Vyp. 186:136-144 incl. graphs, 1966. 10 refs.
DLC, QC801.L46

A mathematical analysis deals with the transition zones between the formation of flat snow crystals, graupel, and hail, taking the equality of the coagulation and sublimation velocities of the growth of an ice particle as a criterion for the transition, and disregarding the coagulation of ice crystals with each other, which results in the formation of snow flakes. Certain characteristic elements of clouds are discussed which favor the growth of ice particles by coagulation and the formation of dense and loose ice layers on their surface, depending on temperature and the quantity of moisture received by the ice particle. Curves relating the sizes of graupel to the water content of supercooled clouds, and those showing the variation of water content in a cloud with altitude are presented. -- NSV

DLC, Slavic Div.

Boundary conditions for calculating the velocity of ice movement in glaciers occurring in a state of plane stress-strain are discussed, as well as the theory of determining boundary conditions from experimental data, illustrated by an example of its application to the longitudinal profile of the Fedchenko Glacier. Since it is practically impossible to measure stress and strain rate at the bottom of a mountain glacier, the boundary conditions are given only on its free upper surface. As far as this is an open surface, the boundary conditions sufficient for solving the problems of ice movement must include the values of the unknown functions and their derivatives in a nontangential direction (the Cauchy problem). Therefore, it is necessary to know stress deviators and strain rates on the glacier surface as well as the gradients of their variation along a direction other than that which is tangential to the glacier surface (for example, in the vertical direction); the article shows how to determine these values. -- NSV

DLC, Slavic Div.

This is a short report on the results of coal-dusting of the Barkrak Glacier of the Pskemskii Mountain Range in August 1962. Coal dust was spread in quantities of 5 to 10 g/m² and in a few cases 25 and 50 g/m². The best effect was produced by the dust fraction 0.1 to 0.4 mm. It is believed that fine fractions cover snow and ice more evenly and

CRREL BIBLIOGRAPHY

densely, thus increasing their melting rates. Small doses of the dust had an effect on clean surfaces and practically no effect on the naturally polluted snow and ice, in which cases the doses had to be increased to 25 or 50 g/m². The evaluated amount of heat expenditure for evaporation, which lowers thawing intensity of the blackened surface, was approximately 60-70 cal/cm² per day. The reduction of surface reflected radiation decreased rapidly due to washing away of dust by melt waters. The snow surface was more affected by this treatment than the ice, since the melt water of the snow penetrates into the cover displacing the coal particles not deeper than 5 cm downward, decreasing the amount of heat spent for evaporation. -- NSV

MECHANISM OF FROST ACTION ON CONCRETE. DETERMINING ITS FROST-RESISTANCE THRESHOLD. (Mécanisme de l'action du gel sur les bétons. Détermination des seuils de gélivité; Text in French). C.R. Acad. Sc. Paris, Serie D., Vol. 263:929-932, Oct. 1966. 4 refs.
DLC, Q46.A14

Frost-resistance threshold was established for concrete during the study of the regularities governing volume decrease of cement during its hydration. The behavior of freezing concretes is explained in terms of their composition as well as temperature. It is shown that dehydration of concrete during freezing is related to the hydrostatic pressure, originating when water in the concrete turns to ice. Under such conditions concrete will be destroyed if the volume of this ice exceeds certain limits. The following cases are discussed theoretically: 1) water inflow into the cement mixture from outside; 2) no such water inflow; and, 3) a part of the water which enters the mixer is separated. Frost-resistance threshold is calculated according to formulas derived. -- NSV

ON THE POSITION OF PERMAFROST BENEATH SMALL STREAMS. (O polozenii vechnoi merzloty pod malymi vodotokami; Text in Russian). Materialy VIII Vsesoyuz. Mezhdudev. Soveshch. po Geokriologii (merzlotovedeniū), Vyp. 2:185-195 incl. graphs, diags., Yakutsk, 1966.
DLC, GB641.V88

A short review of the existing conflicting opinions on the subject is followed by a mathematical analysis of the position of the top of perennially frozen rocks (Tpf) beneath small permanent and intermittent streams under different geological conditions. The calculations were based on the investigation results obtained from 50 small streams; the following equation was solved for all stream cross-sections: $k_1 = h_1^{CP} / h_0^{CP}$; where k_1 is the coefficient of comparison characterizing Tpf variation at typical points of the stream; h_1^{CP} , h_0^{CP} is the mean depth of Tpf occurrence, correspondingly, at the typical points within and outside the stream channel. It was assumed that permafrost preserves its initial position at $K_1 = 1$; its top is raised at $k_1 < 1$ and lowered at $k_1 > 1$. Two formulas were derived for calculating Tpf position: $h_{p1} = h_0(1.55h_{b1} + 1)$ for permanent shallow streams with broad channels and for intermittent streams, and $h_{p1} = h_0(0.028t_b^2 + h_{b1}^2 + 1.35)$ for both types of streams with well defined channels; here: t_b - water temperature, h_b - water depth, h_p , h_0 are correspondingly, depths to Tpf beneath and beyond the stream channel. -- NSV

THERMAL BALANCE AT THE SURFACE OF HIGH MOUNTAIN GLACIERS IN SUMMER. (Teplovoy balans poverkhnosti vysokogornyykh lednikov v letniy period; Text in Russian). Akad. Nauk SSSR, Inst. Geografii, "Nauka", Moscow, 149p. incl. tables, graphs, diagrs., 1966. 75 refs.
DLC, QE576.V57

Field investigation data on which this work is based were obtained during the International Geophysical Year and the following years (1958-1962) on the El'brus Mountain and other areas of the Central Caucasus. The basic topic of this monograph is the analysis of thermal balance at glacier surfaces and a quantitative evaluation of the role of its separate components in the glacier ablation. No single answer is given to the controversial problem of what is more important for the ablation -- solar radiation or heat inflow from air, because the data obtained by different investigators were modified by different factors such as geographical position of the glaciers, the type of weather prevailing during the observation period, and the method of calculating the characteristics of vertical turbulent exchange. On El'brus the solar radiation was mainly responsible for snow and ice melting, the maximum registered ablation values falling on cloudless days.

CLIMATE OF SOVIET ARCTIC REGIONS (RADIATION REGIME). (Klimat Sovetskoy Arktiki (radiatsionnyy rezhim); Text in Russian). Leningrad, Arkt. Antarkt. Nauch.-Issled. Inst., 155p. incl. illus., maps, tables, graphs, diagrs., 1965. 134 refs.
DLC, QC911.C52

The results of many years of actinometric observations carried out at the polar and drifting stations as well as during marine expeditions and flights over the territory are generalized and systematized in this monograph. Basic elements of radiation are analyzed and the methods of calculating separate components of radiation balance are discussed analytically with an attempt to increase their accuracy. The regularities governing geographic distribution of these components in the Arctic regions have been detected. Schematic maps of monthly values of global and absorbed radiation, radiation balance, and natural illumination are presented, as well as the tables of the observation data analyzed. -- NSV

REFLECTION OF HIGH TIDE WAVES FROM ICE EDGE. (K voprosu ob otrazhenii prilivnykh voln ot kromki l'dov; Text in Russian). Leningrad, Arkt. Antarkt. Inst., Trudy, Vol. 269:57-63 incl. tables, diagrs., 1966. 3 refs.
DLC, G600.L4

Reflection takes place when waves approach fast ice from clear water and vice-versa, when the waves emerge from beneath the ice into the clear water area; this is caused by the difference in water depths under the ice and in the clear area, by the elastic resistance of ice to vertical water oscillations, and by ice friction. Frictional reflection depends mostly on the absolute water depth and wave periods. A mathematical discussion is presented of a simple problem: frictional reflection of a free plane tidal wave in an infinite channel partially covered by ice. It is assumed that ice does not move in the horizontal direction and that it does not resist the vertical water oscillations. The last condition was added to separate frictional reflection from other types. Formulas are derived for the relations among the intensities of reflected, transient, and incident waves, the velocities of wave propagation, and the coefficients of wave attenuations in clear water and beneath ice. -- NSV

RELATION BETWEEN TURBULENT HEAT EXCHANGE AND EVAPORATION IN THE KARA SEA DURING SUMMER-FALL SEASON. (Sootnoshenie mezhdyy turbulentnyy teploobmenom i ispareniem v Karskom more v letne-osenniyy period; Text in Russian). Leningrad, Arkt. Antarkt. Inst., Trudy, Vol. 269:67-70 incl. table, graph, diagrs., 1966. 2 refs.
DLC, G600.L4

Relation between turbulent heat exchange (P) and evaporation (LE) in the Kara Sea was calculated for the period July-October according to the Konstantinov and Sverdrup formulas:

$$P = \frac{0.130v(T_a - T)}{\ln \frac{x_v}{x_0} \ln \frac{x_r}{x_0} \left(1 - 0.5 \frac{\ln \frac{2M}{x}}{\ln \frac{2M}{x_0}} \right)}$$

CRREL BIBLIOGRAPHY

where P is heat flow in turbulent exchange; v is wind velocity at the level z_T ; T_B and T is temperature of water and air respectively; z_T is the level of temperature measurement; z_0 is the coefficient of sea roughness.

$$LE = \frac{0.0089(E-e)v}{0.0872 \lg \frac{z_T+z_0}{z_0} \lg \frac{z_0+z_0}{z_0} \cdot \Delta z v}$$

where LE is heat flow on account of evaporation; (E - e) is moisture deficit; z_0 is the height of air moisture measurement; z is thickness of the laminary layer. The results indicate that when the difference between the air and water temperature is negative P is two times larger than LE; at a small positive difference (1.5°C) heat loss on account of evaporation is twice as large in turbulent exchange; P and LE are approximately equal when temperature difference varies from 3 to 4°C. -- NSV

FORMATION OF PRECIPITATION AND MODIFICATION OF HAIL PROCESSES. (Obrazovanie osadkov i vozdeistvie na gradovye protsessy; Text in English). Translated from Russian by Israel Program for Scientific Translations, Jerusalem, 208p. incl. illus., tables, graphs, diagrs., 1967. Refs.
 DLC, QC925.S9

Results of theoretical and experimental investigations into the formation of precipitation in the form of showers from convective clouds and new concepts of the mechanism of hail formation are presented in this work. Methods are described for the detection of hail centers by radar and for the determination of the size of hailstones in convective clouds. The method is explained for modifying hail processes, developed in 1960-1962 and used in 1963 for protecting agricultural crops from hail damage. The organization of these operations and their results are also described. (Authors' abstract)

COMPARISON OF MEASURED AND THEORETICAL SNOWPACK TEMPERATURES. J. Hydrol. (Amsterdam), 5(1):1-20 incl. diagrs., graphs, March 1967. 5 refs.
 DLC, G3651.J6

A theoretical and experimental study has been made of the heat exchange at the surface of a snowpack, the purpose of this study being to construct a mathematical model from which it will be possible to calculate rates of snowmelt from meteorological data. Theoretical solutions of the heat flow equation were found for constant and sinusoidally varying surface temperature profiles for both a homogeneous and nonhomogeneous snowpack. In the nonhomogeneous snowpack an exponential type of variation for density and conductivity was assumed. These theoretical results were compared with the results obtained in field measurements of snow temperatures. A description of the apparatus developed for this work is given. It is shown that the theoretical model appears to be good for temperatures below freezing. However, modification of the snowpack during melting of the snow requires additional experimental measurement of these modifications, and corresponding

CRREL BIBLIOGRAPHY

modification of the mathematical model. This study is related to a flood forecasting study previously made for the Fraser River system in British Columbia. (Author's abstract)

Weller, G.
HEAT-ENERGY TRANSFER THROUGH A FOUR-LAYER SYSTEM: AIR, SNOW, SEA ICE, SEA WATER. *J. Geophys. Res.*, 73(4):1209-1220 incl. tables, graph, diagr., Feb. 15, 1968. 13 refs.
DLC, QC811.J6

The heat-energy transfer through a four-layer system of air, snow, sea ice, and sea water is determined numerically, and the optical, thermal, and composition properties of the solid layer are discussed. The annual sea ice investigated was close to the Australian National Antarctic Research Expedition station of Mawson. The observation was made over a period of five months from the middle of June to the middle of November 1965. Net long-wave radiation losses through the surface of the sea ice are high to balance a large heat flux from the water below. The disappearance of the snow cover over the ice in summer results in a drop of the albedo from 75 to 37%. Idealized curvature characteristics of measured wind and temperature profiles are used over the sea ice to compute the eddy heat flux. The aerodynamic roughness parameter z_0 is computed to have a mean value of 0.013 cm. The latent heat flux at the upper boundary and eddy heat flux at the lower boundary are treated as remainder terms in the energy balance equation. Advection of heat by water currents is considered, and error estimates of the heat budget components are discussed. The heat exchange between the sea ice and the atmosphere is compared with the heat exchange between an ice-free ocean surface and the atmosphere and is found to be an order of magnitude smaller. NATURAL DESALINATION AND EQUILIBRIUM SALINITY PROFILE OF PERENNIAL SEA ICE. *J. Geophys. Res.*, 73(4):1251-1257 incl. table, graphs, Feb. 15, 1968. 15 refs.
DLC, QC811.J6

Owing to the great local and temporal scatter of ice salinity, the shape of its steady-state profile in ice of equilibrium thickness is only approximately known. Hence the purpose of theorizing on the way in which it establishes itself is to suggest pertinent experiments rather than to explain physical causes. Four mechanisms of salt migration are discussed: (1) 'Brine pocket diffusion,' as explained by W. G.

Whitman; it is too slow to be of significance here. (2) 'Gravity drainage,' as observed in the laboratory by W. D. Kingery and W. H. Goodnow. It is unlikely to occur in natural, thick floating ice. Their basic concept may, however, be applicable in a modified form as a 'flushing' mechanism. (3) 'Flushing' or washing-out, a quantitative calculation that assumes the replacement of brine by meltwater from the surface to be a function of ice salinity and maximum temperature, leads to a steady-state salinity profile similar to that suggested by observations. (4) 'Brine expulsion,' as a result of temperature changes and the separation of liquid and gaseous inclusions during the cooling cycle is also treated numerically and results, as does (3), in a steady-state salinity profile resembling of observations. VARIATION IN VOLUME OF FROZEN FINE-GRAINED SOILS DUE TO PHASE TRANSITION OF WATER AT TEMPERATURE FLUCTUATIONS. (Ob'emnye izmeneniia merzlykh dispersnykh gruntov v sviazi s fazovymi perekhodami vody pri temperaturnykh kolebaniiax; Text in Russian). *Materialy VIII Vsesoiuz. mezhdovedomstvennogo soveshchaniia po geokriologii (merzlotovedeniia)*, Vyp. 5: 11-21 incl. illus., tables, graphs, Yakutsk, 1966.
DLC, GB641.V88

Fine-grained frozen soil represents a complicated 4-component system consisting of mineral skeleton, cementing ice, non-frozen water, and water vapors; theoretically, the volume of this system must increase with temperature drop and decrease with its rise. Entirely opposite results were obtained during experimentation with various soils at different minus temperature intervals. The results indicated the variation of soil expansion and contraction within broad limits, depending on its grain sizes, moisture content, temperature, mineralogical composition, and the type and quantity of the water-soluble salts. Coagulation of colloidal and mineral soil particles and partial dehydration proceeded parallel to water freezing, decreasing soil volume until the total moisture in the soil was frozen. Temperature increase was accompanied by ice melting, hydration of colloidal aggregates, their peptization, and consequent increase in soil volume. Absolute increment in volume continued for several days after the sample temperature reached that of the surrounding medium, due to complex structural transformation, the appearance of internal stresses, and their relaxation in time. -- NSV

 DLC, GB641.V88

A thawing bearing soil represents a heterogeneous medium consisting of a thawed zone overlying a frozen one, both being heterogeneous horizontally, and a temperature variation with depth. This anisotropy affects the distribution of stresses along the thickness and bottom of a foundation, i. e. its settling. This article concerns only the structure of a thawing bearing soil along the vertical and the stress distribution in the same direction, which were studied in a model under the guidance of N. A. Tsytoich. The results obtained are presented graphically, the curves relating variation of the porosity coefficient of the thawing soil to the thawing depth, and showing the course of soil deformation under different loads. The results indicated that cyclic freezing-thawing lowers the capacity of soil to swell by moisture absorption. At any time, soil porosity increases with depth, determining its mechanical properties, i. e., the variation of the mechanical properties of a thawing soil is proportional to that of its porosity, which is especially typical of fines (clay, loam, marl).

 DLC, GB641.V88

A mathematical analysis is presented of ice strength variation under the action of repeated loading which increases in time and rapidly reaches the limiting values, but which has so short a duration that the rheological factors related to the action (creep, stress relaxation), though affecting the ice strength, are not readily apparent. In addition, ice strength was tested experimentally in view of disagreements in published data on the effect of loading speed on the ice strength limits. Although the testing procedure involved rapidly increasing intermittent loading, it was of a static rather than percussion nature. Both theoretical and experimental results indicated lowering of the ice strength limit with an increasing load rate. -- NSV

DETERMINING CARRYING CAPACITY OF WINTER HIGHWAYS BUILT OF SNOW AND ICE. (K voprosu opredeleniia nesushchei sposobnosti snezhnolednykh konstruktsii avtozimmikov; Text in Russian). Materialy VIII Vsesoiuz. mezhdovedomstvennogo soveshchaniia po geokriologii (merzlotovedeniui), Vyp. 5:80-92 incl. table, graphs, diagrs., Yakutsk, 1966. 10 refs.
 DLC, GB641.V88

Winter highways (called "avtozimmik") built of ice and snow in the Soviet Union usually have one of the following types of structure: a) a layer of packed ice or snow resting on a frozen ground foundation, or b) a frozen ground foundation covered by a layer of packed snow topped by a snow-ice plate. Deep tracks and bumps are more readily formed in type (a) while (b) is characterized by cracks and ruts. Two mathematical procedures are presented for calculating the carrying capacity of snow and ice pavements of both types of winter highways for motor-vehicles of different weight. Formulas are derived for stress distribution with depth in a homogeneous snow layer and in the snow-ice layer, and for the settling of the snow-ice mass under load. Comparison of the theoretical data obtained to the field measurements showed good correlation.

Materialy VIII Vsesoiuz. mezhdovedomstvennogo soveshchaniia po geokriologii (merzlotovedeniĭ), Vyp. 5:160-168 incl. table, diags., Yakutsk, 1966. 1 ref.
DLC, GB641.V88

In the areas of deep seasonal ground freezing, light buildings are erected on special columnar foundations equipped with an "anchor" plate, placed below the freezing depth, and designed to resist the pull-out stresses of the frost heaving ground. It is assumed that the forces keeping such foundations in place exceed the weight of the ground overlying the anchor plate. The normal forces acting along the upper surface of the plate counteract the tangential forces of frost heaving thus stabilizing the foundation. Experimental testing of this technique in models and on experimental grounds with seasonal freezing depth of 3 m, indicated great stability of the foundations and the dependence of their performance on the size of the plate overhang and the strength of normal pressures acting on the upper surface of the plate during frost heaving. -- NSV

DLC, Q115.S686

This paper reports the results of an expedition undertaken to measure the thickness of shore ice and of the snow covering it over a distance of 35 km from the shore, with simultaneous measurement of wind force and direction at different distances from the shore. A snow-ice-cover profile was plotted from the data obtained; it indicates a clearly defined zone of wind calm with its center about 10 km from the shore. Maximum snow accumulation and minimum ice thickness were observed in this zone; the latter is explained by the insulating properties of snow and retarded ice formation. It is believed that thinning of the ice sheet under this zone indicates a constant rather than random nature of maximum snow accumulation at that distance from the shore. -- NSV

THE PURPOSE OF GLACIER MAPPING. Can. J. Earth Sci., 3(6):743-746, Nov. 1966.
 DLC, QE1.C17

As an introduction to the Symposium on Glacier Mapping and for the purpose of providing a basis for further discussion, the requirements in various types of glacier maps are differentiated. Most maps of glaciers are not made specifically for glaciologists but as part of a general geographical survey program. It is very important that glaciologists define their most urgent requirements, remembering that glaciers normally cover a fairly small percentage of a total area to be mapped. Standardized symbols would be good; standardized content might be better. The glaciological content has to be adapted to the scale of the map and to the needs of specialized research. CARTOGRAPHIC REPRESENTATION AND SYMBOLIZATION IN GLACIER MAPPING. Can. J. Earth Sci., 3(6):761-769 incl. tables, Nov. 1966. 17 refs.
 DLC, QE1.C17

In glacier cartography, as in all mapping, questions of convention and standardization have long plagued cartographers. National and international efforts at standardization have generally failed. To assess the styles, techniques, and status of glacier representation, several hundred maps of glaciers and related features were examined and evaluated. As a result it is suggested that there is room for innovation and that greater attention be devoted to the following problems: (1) color symbolization, (2) perception of symbols and color by map users, (3) inclusion of more symbolic information on medium-scale maps, and (4) effects of automated cartography on representation techniques. GLACIER MAPPING IN GREENLAND. Can. J. Earth Sci., 3(6):771-774 incl. illus., Nov. 1966.
 DLC, QE1.C17

The history and problems of mapping in Greenland are briefly reviewed, with particular reference to the Indlandsis (the Ice Cap) and the glaciers. The author calls for greater collaboration between the glaciologist and the topographer, and cautions against placing too great reliance on the present maps for calculations of the volume of the Indlandsis. Techniques now being developed will lead to a much more accurate assessment of volume. Finally, the regime of an ice-dammed lake in southwest Greenland is discussed on the basis of photogrammetric data and as an example of how such data can be used to explain glaciological phenomena. SOME FUNDAMENTAL CONSIDERATIONS ON GLACIER MAPPING. Can. J. Earth Sci., 3(6):747-759 incl. illus., tables, diagrs., map, Nov. 1966. 24 refs.
 DLC, QE1.C17

Five glacier maps at scales of 1:5,000 and 1:10,000 were produced by the Photogrammetric Research Section of the National Research Council and the Axel Helberg Island Expedition of McGill University for use in glaciological research in the Canadian Arctic. After general comments on the need for and scope of glacier mapping, the authors discuss in some detail the main problems encountered. It is maintained that glacier maps belong to the class of 'special maps' and that the specifications for them should be set by the glaciologists. Accuracy requirements, choice of mapping scale and contour interval, delineation of various glacier units, extent of detail plotting, etc. are critically reviewed. The 1:10,000 map of the entire White Glacier catchment area, accompanying this paper, is an example of a map which serves various glaciological purposes, primarily calculations of mass change. To facilitate future glacier mapping, the authors suggest that clear definitions of glaciological terms such as 'active glacier' or 'glacierized area' should be established and that their cartographical presentation should be further standardized. APPLICATIONS OF PHOTOGRAMMETRY TO SURVEYS OF GLACIERS IN CANADA AND ALASKA. Can. J. Earth Sci., 3(6):783-798 incl. illus., graphs, maps, tables, Nov. 1966. 18 refs.
DLC, QE1.C17

The paper emphasizes that the choice of a proper procedure is essential for efficient glacier surveying. Terrestrial versus aerial photogrammetry and the use of electronic surveying procedures versus triangulation have been tested in surveys on the Athabasca and Saskatchewan glaciers, and on glaciers in northern Ellesmere Island, southeastern Alaska, and the Yukon Territory. The Otto Fiord glacier survey in northern Ellesmere I. demonstrates that no ground control is needed for volumetric glacier studies. Accurate maps needed for other studies depend on the establishment of control. Control can most efficiently be determined by tellurometer and phototheodolite with helicopter support, as shown in Alaskan glacier surveys. For large glaciers photography provides a good means of extending control from tellurometer traverse stations, as demonstrated in the Mount Kennedy survey. Simple one-color maps are an economical means of preserving survey results for future glaciological evaluation. (Author's abstract)

SOME PROBLEMS OF GLACIER MAPPING EXPERIENCED WITH THE 1:10,000 MAP OF THE ALETSCHE GLACIER. Can. J. Earth Sci., 3(6): 799-809 incl. illus., diags., table, Nov. 1966. 6 refs.
DLC, QE1.C17

The difficulties of the aerial survey of the Aletsch Glacier lay in establishing ground control in the high mountains and locally on the moving glacier surface, and in plotting featureless névés on the autograph. The major problem in plotting proved to be the delineation of the margins of active glaciers

where marginal zones were thickly covered with debris or fresh snow, or where it was necessary to define the boundary between the active glacier and stagnant ice. The distinction between active and stagnant ice is based on movement and nourishment, that is, on characteristics not directly visible in the air photographs, and the boundary is too often a matter of personal judgment. The authors hold that this boundary would be better omitted on an accurate map of the type discussed, while the glacierized area should be represented only in so far as ice is clearly indicated by surface features. A further provisional boundary might be given to indicate suspected buried ice. The paper emphasizes the importance of favorable glacier conditions when the control photographs are taken, to facilitate the mapping and interpretation of glaciological features. (Authors' abstract)

Meyer, Mark F.
SOME GLACIOLOGICAL INTERPRETATIONS OF REMAPPING PROGRAMS ON SOUTH CASCADE, NISQUALLY, AND KLAUWATTI GLACIERS, WASHINGTON. Can. J. Earth Sci., 3(6):811-818 incl. illus., diags., maps, Nov. 1966. 6 refs.
DLC, QE1.C17

Remapping programs on glaciers are undertaken to determine changes in ice thickness and volume, which supposedly reflect glacier response to changing climate. However, thickness changes, derived photogrammetrically, cannot be used to determine ablation or other specific mass budget quantities, or response characteristics, without concurrent measurements made on the glacier surface. The varied nature of the difficulty is illustrated by the following example: (1) data from South Cascade Glacier demonstrate that the rate of change of thickness is the vectorial combination of emergence velocity, specific net budget rate, and (in the accumulation area only) a compaction velocity; (2) limitations on the use of photogrammetric data to detect and interpret kinematic waves are illustrated by results from Nisqually Glacier; (3) changes in two lobes of Klawatti Glacier show that climatic changes cannot be extrapolated from single-glacier maps because of meso-scale meteorological complications. (Author's abstract)

MAPPING GLACIER TERMINI IN SOUTHERN ALASKA, 1931-1964. Can. J. Earth Sci., 3(6): 819-825, Nov. 1966. 16 refs.
DLC, QE1.C17

A program to map changes in the positions of glacier

CRREL BIBLIOGRAPHY

termini in the coastal mountains of southern Alaska was initiated by the author in 1931, and since 1941 has been sponsored by the American Geographical Society. Wherever possible, stations previously used for surveys or photography were reoccupied, including a few established as early as the 1880's. After nine field trips, 50 triangulation networks have been established to cover 76 different termini of large and small glaciers, of which 26 are tidal. Photographs were taken from the principal stations to record changes in the topography and vegetation cover. The principal glaciers of Glacier Bay in southeastern Alaska and of Prince William Sound in southcentral Alaska have been surveyed five times. The surveys, supported by the photographic record, have documented pronounced advances of 8 termini and appreciable recession of 37; the remaining glaciers have either oscillated or remained virtually unchanged. The reason for the program, the instrumentation and procedures, and the field problems encountered are discussed, and recommendations are made for the future. (Author's abstract)

EXPERIENCE IN GLACIOLOGICAL MAPPING OF ICE SHEETS AND MOUNTAIN GLACIERS. Can. J. Earth Sci., 3(6):841-847, Nov. 1966, 22 refs.
 DLC, QE1.C17

As a result of the I. G. Y. -I. G. C. programs, the whole complex of glacier processes has received particular attention in the USSR. This has led to the development and perfection of cartographic methods in the study of glaciers. Three main lines in glacier mapping are being followed in the USSR in the preparation of (a) general geographical maps of glacierized areas, (b) special glaciological maps, and (c) glacier atlases. The characteristics of the various types of maps are described, and details are given on their preparation and on the representation used for natural features and glacier processes. New applications of cartographic methods to glaciological investigations are indicated. (Authors' abstract)

SOME NOTES ON GLACIER MAPPING AND ICE MOVEMENT. Can. J. Earth Sci., 3(6):863-876 incl. illus., diagrs., Nov. 1966. 19 refs.
 DLC, QE1.C17

Since the time of Agassiz, 1840, the Unteraar Glacier has maintained its role as a focus of glaciological research for mapping, seismic sounding, glacier movement, and hydrology. Variations of the velocity of the Unteraar Glacier with ice thickness and time are presented and discussed. The new map of the Aletsch Glacier at the scale of 1:10,000 enables the author to demonstrate the extent to which detailed mapping of the surface features of a glacier facilitates the study of surface velocity. PHOTOGRAMMETRIC MEASUREMENTS OF THE ICE WASTAGE AND MORPHOLOGICAL CHANGES NEAR THE CASEMENT GLACIER, ALASKA. Can. J. Earth Sci., 3(6):827-840 incl. illus., tables, maps, diagrs., Nov. 1966. 7 refs.
 DLC, QE1.C17

Two sets of maps were compiled for the Casement Glacier and its outwash area from aerial photography taken in 1948 and 1963 and plotted on a Wild B-8 aviograph. The major problems resulted from lack of measured ground control; they were overcome by stereotriangulation for planimetric control and by the use of the extensive bodies of water to provide both model levelling and a height datum. An analysis of the accuracy of the results is made. Comparison of the two sets of maps reveals extensive ice wastage, with a maximum retreat of the ice front of 1.5 km. Large masses of stagnant ice have been detached from the glacier and covered by fluvio-glacial deposits. The development of landforms in these deposits resulting from the wastage of the buried ice is discussed. (Authors' abstract)

Østrem, Gunnar
SURFACE COLORING OF GLACIERS FOR AIR PHOTOGRAPHY. Can. J. Earth Sci., 3(6):877-880 incl. illus., map, Nov. 1966. 4 refs.
 DLC, QE1.C17

To make glacier mapping possible in white firn areas where stereo-effect is difficult to obtain, a large number of surface markers were placed on the glacier before air photographs were taken. Experiments proved that 3- to 5-kg powdered dye (yellow or brown ochre, or lamp black), packed in

CRREL BIBLIOGRAPHY

paper bags, made excellent surface markers when thrown from between 50- and 100-m elevation above the glacier surface. Color circles, applied by hand, also proved to be a good means for identifying ablation stakes, etc., in the firn area. An example of a map is given where the construction of contour lines was based upon the easily determinable dye markers that were clearly visible on vertical photographs taken from 7,300-m altitude. INTERNATIONAL EXPERIMENTS IN GLACIER SOUNDING, 1963 AND 1964. Can. J. Earth Sci., 3(6):887-892 incl. illus., graph, Nov. 1966. 6 refs.
 DLC, QE1.C17

In 1963 and 1964, under the sponsorship of the United States Army, specialists in ice sounding from various countries assembled at Camp TUTO, Greenland, to evaluate the latest sounding techniques. These international experiments showed that British and American radio-sounding systems gave results of comparable accuracy to those obtained by seismic sounding. In the two seasons bottom profiles of the ice cap were obtained along traverses totalling about 640 km. Ice thicknesses up to 2,000 m were measured as fast as the support vehicles could travel across the ice cap. (Author's abstract)

Robin, G. de Q.
MAPPING THE ANTARCTIC ICE SHEET BY SATELLITE ALTIMETRY. Can. J. Earth Sci., 3(6):893-901 incl. illus., table, Nov. 1966. 7 refs.
 DLC, QE1.C17

It is proposed that a radio altimeter be installed in a satellite to measure its height above the surface. It should work at a frequency of the order of 10^4 Mc/s and measure heights to an accuracy as close as practicable to ± 5 m. Heights above the ocean would be extrapolated to calculate satellite heights above sea level while over the Antarctic continent, and the difference between this calculated height and the measured height would give the surface elevation. Geometrical sounding errors and systematic errors may cause errors up to 50 m on relatively flat ice sheets, but incremental errors over 10 km should be of the order of 10 m. The systematic coverage of the Antarctic continent by a few weeks' observations from a satellite should make a detailed contour map practicable. The system would not be satisfactory for the peripheral areas where many slopes exceed 1:200 and are less regular than elsewhere, but these areas are being surveyed by conventional methods. THE GLACIOLOGICAL MAPS OF MEIGHEN ISLAND, N.W.T. Can. J. Earth Sci., 3(6):903-908, Nov. 1966. 5 refs.
 DLC, QE1.C17

The small ice cap on Meighen Island has been studied since 1959 by scientists working with the Polar Continental Shelf Project, Department of Mines and Technical Surveys, Ottawa. The Surveys and Mapping Branch of the same Department has produced a glaciological map of the ice cap, at the scale of 1:25,000, from special photography taken from a height of 2,280 m in 1960, and a 1:50,000 map of the whole island, showing features of glaciological interest, from standard mapping photography taken from a height of 9,150 m in 1959. The control, photography, and compilation methods used in producing these maps are discussed, and an account is given of the special features shown on them. (Author's abstract)

TEST OF CONTOUR ACCURACY ON A PHOTO-
GRAMMETRIC MAP OF ATHABASCA GLACIER.
Can. J. Earth Sci., 3(6):909-915 incl. map, Nov.
1966. 7 refs.
DLC, QE1.C17

An independent survey of the positions and elevations of 59 surface markers set in the lower part of Athabasca Glacier permits assessment of the accuracy of contours on a large-scale map of the glacier. The root mean square difference between the elevation at each marker as determined from the survey and from the map was 49 cm. This is an upper limit to the standard error of the contours. It is less than three times the theoretical error and about 15% of the contour interval. (Author's abstract)

A REEXAMINATION OF HOMOGENEOUS NUCLEATION THEORY: THERMODYNAMIC ASPECTS.
J. Atmos. Sci., 25(1):47-53 incl. diagrs., Jan. 1968. 9 refs.
DLC, QC851.A283

This paper presents a thermodynamic discussion of homogeneous nucleation. Some serious misconceptions are exposed concerning the proper thermodynamic energy representation that is required for the nucleation problem. The thermodynamic definition of surface tension is found, and the conditions for unstable equilibrium between a liquid drop and its vapor-air environment are developed. A derivation of Kelvin's equation is presented, and the free energy barrier that a cluster of molecules must surmount in order to become a growing drop is discussed. The conventional approach to this problem is compared with our treatment. (Author's abstract)

SNOW COVER AND THE CALCULATION OF SNOW FRESHETS IN THE FOREST-STEPPE AND STEPPE ZONES. (Snezhnyĭ pokrov i raschet snegovykh pavodkov v lesostepnoi i stepnoi zonakh; Text in Russian). Akad. Nauk SSSR, Inst. Geografii, 128p. incl. illus., tables, maps, graphs, diagrs., "Nauka", Moscow, 1966. 94 refs.
DLC, GB2507.G7

This monograph presents the results obtained in the study of snow cover in the Don Basin in relation to the development of a new analytic method of snow freshet calculation and forecasting. The plotting of the snow-water reserve maps, the improvement of this method, and the justification of the basic parameters used in it, are emphasized. A large volume of the observation data obtained by the author and other investigators is generalized and new analytical and empirical relationships are being related to the formation of snow cover and snow freshets. The importance of this work lies also in its practical aspect: the mathematical operations discussed may be used in hydrological calculations, forecasting, and mapping of snow covers in open terrains.

THE INFLUENCE OF ENVIRONMENTAL PARAMETERS ON THE FREEZING AND FRAGMENTATION OF SUSPENDED WATER DROPS. J. Atmos. Sci., 25(1):82-96 incl. illus., diagrs., tables, Jan. 1968. 20 refs.
DLC, QC851.A283

CRREL BIBLIOGRAPHY

The fragmentation of freezing water droplets in natural clouds has been postulated by several workers, and this phenomenon has been observed in numerous laboratory investigations. However, the profound effect that environmental conditions can have on fragmentation has not been fully appreciated. In the first part of this paper the factors that might affect the freezing behavior and fragmentation of a water drop are discussed, and, where possible, are analyzed in detail. In the second part of the paper results are presented of laboratory experiments on the freezing of suspended water drops 1 mm in diameter. Drops nucleated in air under equilibrium conditions were never observed to shatter and only one drop in ten ejected an ice splinter. The shattering and large splinter counts from suspended drops nucleated in air which have been reported by other workers are attributed to the contamination of the drops by carbon dioxide and nucleation under non-equilibrium conditions. Drops frozen in hydrogen shattered frequently if the temperature was lower than -9°C . Drops frozen in helium at -10 to -12°C shattered on occasions. In a mixture of air and carbon dioxide the shattering behavior was very dependent on the concentration of carbon dioxide. Large numbers of ice splinters were detected only if a drop shattered. (Authors' abstract)

Parungo, Farn P. and Janet Wood
 FREEZING OF AQUEOUS SOLUTIONS OF MACRO-
 MOLECULES. *J. Atmos. Sci.*, 25(1):154-155,
 Jan. 1968. 9 refs.
 DLC, QC851.A283

To confirm ice nucleation on surfaces the freezing of a group of solids and nucleation temperatures of water droplets on corresponding solids was investigated. Macromolecular species which did and did not show line broadening of water protons were selected. The following compounds were used: agar, gelatin, citrus pectin, polyvinyl pyrrolidone, starch, methoxycellulose, ovalbumin, porcine pepsin, bovine albumen, polyvinol alcohol, ribonucleic acid and deoxyribonucleic acid. No important change in freezing point was observed for any solution of any concentration. There is no obvious relationship to effects previously reported from NMR data, to the viscosity of the solutions or any obvious parameter. It thus appears that the water immobilized in the structure of some macromolecules is not held in an ice-like lattice, whatever the NMR spectrum may look like. None of the macromolecular species tested is particularly active as a nucleating agent, whether in solution or as a solid. -- FMM
