FOREWORD

This report represents the results of the efforts expended in performance of Contract F33615-69-C-1121, "Development of Stability and Control Prediction Methods for Stoppable Rotor Aircraft." The work was performed by Bell Helicopter Company under Project No. 8219. It was sponsored by the Air Force Flight Dynamics Laboratory, Air Force Systems Command, from December 1968 through February 1970. Mr. Charles L. Livingston was the Bell Helicopter Company Project Engineer. Mr. Robert Nicholson was the Air Force Project Engineer.

This final report is presented in four volumes. The first describes the mathematical model and the methods used to calculate stability characteristics. They are of sufficient complexity that a digital computer is necessary for the solution of the equations. The second volume presents the results of sample computations and discusses input and output formats and good user techniques. The third volume describes the computer program while the fourth volume contains Appendices which are computer generated documentation of the program.

The author gratefully acknowledges the assistance of Messrs. B. L. Blankenship and Tyce McLarty of the Bell Helicopter Company Aeromechanics Group and Mr. C. L. Livingston of the Stability and Control Group in the development of the mathematical model.

This technical report has been reviewed and is approved.

ABSTRACT

This report describes a mathematical model of rotorcraft that may be used to determine characteristics of performance, stability, response, and rotor blade loads. The complexity of the equations used requires the use of a digital computer for efficient solution. This four volume report describes the computer program in detail and illustrates the method of computing rotorcraft characteristics by specific example.

This volume contains aids for the computer programmer. The first and second volumes contain a discussion of the mathematical model and detailed instructions for the users of the program. The fourth volume contains computer generated documentation of the program.

The programming aids are divided into two groups: background material for the programmer just starting to work on this computer program and the detailed explanation of the computer generated documentation which is necessary for any programmer to work effectively on this program.

SECTION I

INTRODUCTION

The purpose of this manual is to provide the information required to modify the computer program. The assumption is made that the reader of this volume will have first read Volumes I and II. No effort was made to make this volume self-contained because efficient and effective programming of ASAJ01 requires knowing how to use the program and knowing something of the engineering and analysis involved, as well as a knowledge of FORTRAN programming techniques.

The information in this volume is of two types, general and specific. The general information is discursive, providing background and perspective. The detailed information is that which any programmer must have at hand when making additions or modifications and when debugging these additions or modifications.

SECTION II
GENERAL PROGRAMMING AIDS

A. MACRO FLOW CHARTS

The flow charts in Figures 1 through 4 describe the functional structure of the program without regard to flow by subroutine. Figure 1 shows the total program structure and is a composite of Figures 1 through 10 in Volume II. Figure 2 provides some detail of the trim process in Figure 1. Figures 3 and 4 similarly amplify the stability analysis and maneuver functions, respectively, in Figure 1. Information which is normally presented in more detailed flow charts is, for the most part, provided in Table I and Appendices A through E, Volume IV. This table and these appendices also contain vital information which is not found in detailed flow charts.

B. FORTRAN SUBROUTINES

The FORTRAN subroutines contained in ASAJ01 are listed in alphabetical order, except for the main program, C81, which is first. A few remarks are made for each subroutine which indicates its general purpose or use in the general structure of the program. Great detail of explanation is not attempted here since it would be redundant. In the case of multiple entry subroutines, the names of all the entries will be given in the order that they occur in the subroutine. The first entry has the same name as the control section which appears in Table I.

1. C81. This routine is the main program of ASAJ01. This subprogram reads the control cards which direct the flow of the whole problem. The path is selected and calls initiated to begin working the problem. Upon return, possible errors are checked for and appropriate action is taken. If an error is detected, an error message may be printed out. Then the program either terminates execution or starts the next problem, with the severity of the error determining which.

2. AJACOB. This subroutine handles computation of quantities which depend upon variables which are changed in either subroutine TRIM or subroutine STAB, which are used in the calculation of partial derivatives. These quantities are then calculated and used then in the computation of forces and moments.

3. ANAL. Output of this subroutine consists of forces and moments from each surface or mechanism which produces either a force or a moment and the total summation of forces and moments. In the subroutine itself are calculated the forces and moments

of the wing, elevator, fin; and fuselage as well as jet thrust. The first subroutine in the rotor analysis is called and returns the rotor forces and moments.

4. CATS. The inputs to this subroutine are two sets of Euler angles and a direction number for each set. The output is a set of Euler angles which are related to the two sets input. The two sets input are the Euler angles connecting three different coordinate systems X, Y, and Z with set one connecting coordinate systems X and Y and set two connecting coordinate systems Y and Z. The output set of Euler angles connect coordinate systems X and Z. It is possible by manipulation of the direction numbers in the input and the order in which they are input to get the output set of Euler angles to be in either direction desired.

5. CLCD. The inputs to this subroutine are the angle of attack and Mach number, as well as the aerodynamic description of any airfoil. The output is the coefficient of lift and the coefficient of drag.

6. COMSOL. This subroutine solves systems of linear equations in complex variables.

7. CON1. The function of this subroutine is to take the input control group and initialize and calculate quantities which are then used in the computation of the settings of the swash-plate from the control position.

8. CON2. This subroutine has a similar function to CON1 but is more specialized. The quantities which are initialized in this subroutine are confined to control phasing and secondary linking of the controls.

9. CURVET. This subroutine analyzes the time history of selected variables during a maneuver. This analysis is accomplished by a least squares curve fit followed by comparison of both the amplitude and phase angle of different variables. Then one variable is expressed as a linear function of two others.

10. C81L. The function of this subroutine is the transfer to a disk of maneuver time history data which has been stored on a tape or the transfer to a tape of maneuver time history data which has been stored on a disk.

11. DAMPER. This is the variable damper for TRIM. The purpose of this is to gradually dampen out oscillations of the trim iterations. This is accomplished by checking the errors generated in TRIM against an upper limit and, whenever all errors are less than this limit, reducing both the partial

derivative increment and the maximum amount which one of the TRIM variables can change in one iteration.

12. DAT. This is a block data subroutine which contains the alphameric data for subroutine PARA and the alphameric data for subroutines PLOT and CURVET.

13. DAT1. This is a second block data subroutine which contains primarily C_L and C_D tables for the rotors. Other secondary data tables are included but they are of minor importance.

14. DET. In this subroutine is calculated the value of the determinant during the extraction of eigenvalues for a stability analysis.

15. DISK. This prints out the gust velocity distribution over the rotor disk during a maneuver. No printout is made if the velocity is uniform over all of the rotor disk or if none of the velocities are greater than .5 ft/sec.

16. DOGS. The inputs to this subroutine are two vectors. The output is the cross product.

17. DOROT. This subroutine is the one which performs the integration out the blade and around the azimuth during the rotor analysis. During a maneuver this integration around the azimuth is simply a summation of the quantities produced for each blade. During trim it is, however, a true integration quasi-statically around the entire azimuth.

18. ELEC. This subroutine calculates time constants, damping factors, and gains during a stability analysis.

19. GUST. This subroutine is entered only during a maneuver in which a gust is being generated. It calculates the distance of each part of the rotorcraft from the start of the gust and then calculates from that distance the magnitude of the gust velocity at each point on the ship.

20. INIT. Output is the sole function of this subroutine. It prints out the full page of the maneuver time history data. It also writes out on disk the same variables.

21. INRO. The function of this subroutine is the initialization and calculation of problem constants from the rotor inputs only.

22. ITRIM. Included in this subroutine is the iteration loop of the trim section of the program. The function here is to iterate to a stable-flight condition.

23. ITROT. This subroutine initializes variables for subroutine DOROT and, when specified by the input parameters, activates the iteration loops to balance the rotor flapping moments.
24. IVAR. This subroutine handles the initialization of the maneuver inputs for subroutine VARI.
25. JACOBI. As the name of this subroutine implies, its function is to calculate the Jacobian for use in the Newton-Raphson iteration method in TRIM or for calculating the displacement derivatives for use in the stability analysis.
26. LAMODE. This subroutine calculates the characteristic coefficient matrix for the lateral mode of the stability analysis.
27. LMODE. This subroutine calculates the characteristic coefficient matrix for the longitudinal mode of the stability analysis.
28. MANU. This subroutine controls the time variant maneuver segment. It handles the integration of the differential equations and the calling of the other subroutines necessary to a maneuver.
29. MATRIX. The function of this subroutine is to calculate the transformation matrix from a set of input Euler angles and return the proper matrix to either subroutine CATS or subroutine RATS.
30. MICE. This subroutine is a two dimensional version of subroutine RATS which rotates a vector with two components through an angle.
31. MNEM. The function of this subroutine is to calculate problem constants from input data and to initialize for a problem.
32. MODE. This subroutine controls the section for calculating the response of a rotorcraft to a given control input during the stability analysis.
33. NDSLOT. The input to this subroutine is the dimensionalized characteristic coefficient matrix in the stability analysis. The output is the nondimensional characteristic coefficient matrix.
34. NOPSIO, NOPSII. The inputs to this subroutine are the number of azimuth stations for use in the rotor analysis. The

outputs are quantities which are a function of the number of azimuth stations.

35. OFFTRM. The outputs of this subroutine are the values to which the forces and moments on the fuselage and the rotors must be driven in order to achieve a trim condition in either a push-over, a pull-up, or a banked turn.

36. PARA. This subroutine is for output only. It prints the trim parameter summary which comes at the end of the trim.

37. PCG. As the name implies this subroutine is the prop-rotor collective governor.

38. PDZ1, PDZ. The inputs of this subroutine are a trim partial derivative matrix, that is the Jacobian, and the type of helicopter or rotorcraft being flown. This subroutine then changes the partial derivative matrix to conditions which are known to hold. Essentially, this is a crude attempt to filter numerical "noise" in the matrix.

39. P PLOT. This is the printer plot routine which produces plots of time histories of the variables calculated during a maneuver.

40. RATI. Inputs to this subroutine are the corrections to the trim variables and the maximum allowable correction. The subroutine then checks to see that no correction applied exceeds the maximum and makes proper dimensional adjustments to the corrections and then makes the corrections.

41. RATS. Inputs to this subroutine are the three components of a vector in one coordinate system and three Euler angles and a direction number of the Euler angles. The output is the three components of a vector in the other coordinate system.

42. READIN. As the name implies this subroutine reads in the input data for a problem.

43. ROOA, ROOB. This subroutine is used in the determination of the eigenvalues of the characteristic coefficient matrix in the stability analysis section of the program.

44. ROTAN. This subroutine may be considered to be the outer section of the rotor analysis.

45. SETE. This subroutine saves values of the forces and moments calculated at the end of trim or at the start of the stability analysis section for later use in comparison and in calculation of derivatives.

46. SLTE. In the part of the stability analysis concerned with the response of the rotorcraft to a step input from one of the controls, this subroutine puts the derivative with respect to the appropriate control in the proper position in the characteristic coefficient matrix.
47. SLTT. After the roots to the characteristic coefficient matrix have been calculated as a result of a modification by SLTE, this subroutine then restores the characteristic coefficient matrix to its original form.
48. SOLVE. This subroutine solves systems of linear equations by Gaussian elimination.
49. SRT. This subroutine might be considered as the driver for the finding of the roots of the characteristic coefficient matrix in the stability analysis section.
50. STAB. This subroutine is the primary subroutine in the stability analysis section and it generates or it does the calling for such quantities as the Jacobian, the rate derivatives, and the subroutines which then do the lateral and longitudinal modes analysis.
51. START. The function of this subroutine is to change units of the input arrays and set them equal to mnemonics.
52. SWAS1, SWAS. This subroutine performs the function of linking the control to the swashplates with the appropriate linkage factors and phase factors.
53. TABINT. As the name implies, this subroutine does a table interpolation for C_L or C_D in the rotor analysis.
54. TILT1, TILT, HSAF, TFFA. This subroutine handles CG shift for several different manners of shifting CG. The primary function is in a mast tilt maneuver. It provides not only for CG shift but also for changes in control phasing as a function of the mast tilt angle. Secondary entries handle CG shift with folding of a rotor either when it is being folded aft after being tilted forward and stopped or being folded horizontally after a stop.
55. TINIT. This subroutine should be considered as a subsidiary of subroutine MNEM.
56. TRIM. As the name implies, this subroutine is the primary one of the section of the program for finding the stable flight condition.

57. TURN. This subroutine handles a banked turn. Secondly, it handles push-overs or pull-ups. It does so by checking input data, picking up proper inputs, and doing the appropriate initialization to get started finding a stable flight condition.

58. VARI. Produced by this subroutine are the effects of the disturbances during a time variant maneuver. The inputs to this subroutine are the user supplied forcing functions and the results produced from those are the output of this subroutine.

59. VIND. This subroutine calculates the induced velocity of a rotor.

60. WAG1, WAG. A study of aerodynamics as started by Wagner and Küssner and developed by Buettiker for helicopter applications are handled in this subroutine.

61. WRFM. This is an output subroutine which writes out the rotor force and moment summary in shaft reference and the fuselage reference force and moment summary.

62. WROT1, WROT. This is another output subroutine which produces the heading for the printout of the input data, the trim page, and the printer plots.

63. WRVP1, WRVP. This is still another output subroutine which produces the printouts of the partial derivative matrices calculated and the independent variables used in the calculation of those derivatives.

64. YFIX. This subroutine takes the aerodynamic inputs, initializes and changes the dimensions on them and calculates constants for subroutine CLCD.

C. ASSEMBLY LANGUAGE SUBPROGRAMS

Besides the usual group of software routines furnished by the computer manufacturer and used by numerous programs, ASAJ01 uses three locally written general purpose subprograms. Since they are even more hardware dependent than the FORTRAN subroutines, they are included here only to give a brief description of how they are used by ASAJ01.

The first subroutine, ABDUMP, produces a dump and an abnormal termination of job when it is called. This routine is called by subroutine C81 only.

Subroutine DATE has three entries. They are DATE, SETIME, and TIMEX. The first entry, DATE, returns, as an argument in the calling sequence, the current date; that is, the date on

which the call is executed, in eight characters of alpha. The second entry SETIME has an input only. This initializes a timer for later use by the third entry TIMEX which has three arguments in the calling sequence. The first argument is the amount of time used since the beginning of the job step. The second argument is the amount of time that has elapsed since the last call to TIMEX. The third entry in the calling sequence has as its value the time left; that is, the number which was input at entry SETIME minus the first argument in TIMEX.

Function DOTX is the third subprogram. It is basically a vector dot product. The first input argument is the first element of the first vector. The second argument is the spacing between consecutive elements of the first argument which are to be used in the dot product. The third argument is the first element of the second vector to be used in the dot product. The fourth argument is the spacing between elements of the third argument. The fifth argument is how many elements are in the dot product. The effect of the second and fourth arguments is to make the routine general enough that tensors of any order may be used as the first and third arguments. The major purpose of the function is to accomplish double precision accumulation of products of single precision vectors in minimum time.

SECTION III

DETAILED PROGRAMMING AIDS

A. CONTROL SECTION CROSS-REFERENCE

The information contained in Table I is necessary and sufficient for the construction of the overlay scheme for ASAJ01. The first column contains the names of the subroutines in alphabetical order, except for the main program, C81, which is first. The second column, length, contains the size, in bytes in hexadecimal number base, of the compiled or assembled subprogram. The FORTRAN subroutines were compiled on the O/S 360 FORTRAN IV (H) Compiler with OPT=2. The third column contains several operations and the fourth column, in the same and following lines, if any, contains the names of the subroutines associated with that operation. Subroutine SLTE is a good example. The calling chain which contains SLTE is: C81 calls STAB, STAB calls LAMODE or LMODE, LAMODE or LMODE calls MODE, MODE calls SLTE, SLTE calls SRT, and SRT calls DET or ROOA. With this sequence of calls in mind, the operation "Called By" refers to MODE; "Calls" refers to SRT; "IS Used By" refers to C81, LAMODE, LMODE, and STAB; "Uses" refers to DET and ROOA.

It should be noted that, for subroutine AJACOB, there is the peculiarity that subroutine ITRIM appears for both "Called By," and "Is Used By." This means that subroutine AJACOB is called by ITRIM which also calls JACOBI which then calls AJACOB.

B. DEFINITION OF VARIABLES IN COMMON

Appendix A, which is a dictionary of the variables in common, is for use in conjunction with Appendices B through F. In the format given, the variables are first sorted by length, one-letter variables first, two-letter next and so on. Within a group of equal length, the variables are then sorted into alphabetical order. Since it is possible to have a number in a variable name, numbers follow the letter Z.

Note that in some places the variable definition begins with a number in parentheses or a group of numbers separated by commas, all within parentheses. This means that the variable is an array and its size is given. Any array that has a subscript with a maximum value of "2" is a rotor variable. The variable with the subscript one, for example B(1), refers to the first rotor, and the variable with the subscript two, for example B(2), refers to the second rotor.

Sometimes, one of these variables, which is dimensioned two, is defined by two more variables. Again, B is a good example. Variables are usually easily recognizable in the cases where one variable is defined in terms of another. It is always easy to check if some set of letters or a word is a variable by referring to the proper place in Appendix A. Local variables are not defined because it is assumed that a local variable may have its meaning deduced from how its value is calculated.

C. CROSS-REFERENCE OF VARIABLES IN COMMON

ASAJ01 is a program with a large number of subroutines and a large number of variables. The nature and order of the computations in this program are, in general, such that they prevent ready modularization below the level exhibited in Figure 1. These characteristics of ASAJ01 make cross-referencing of its variables necessary. The contents of Appendices B through E are designed to supplement a compiler which has a cross-reference option. Such a compiler provides the necessary information about the location of the usage of variables within a subroutine, while the appendices provide analogous inter-subroutine information. Appendix B is a digest of information extracted from the compiler.

Appearing at the top of each page of Appendix B are column headings of subroutine names. Immediately below the subroutine names and in the left column appear the names of the labeled Commons. Next are all of the variables arranged by the same scheme used in Appendix A. The Common which contains that variable is in the next to the last column on the right and a sequence number is given in the right column. An "X" in the middle of a line denotes that the variable whose name appears in the left column on that line is used in that subroutine. Variables which are in a subroutine only because the Common that they are in is in the subroutine are not noted. Only those variables which are used in the subroutine are entered in the tables.

As an example of reading and using Appendix B, find the line for the variable AP in the left column. Across on that line is an "X" under the column headed by "MNEM." This means that the variable AP is used in an equation or calling sequence in subroutine MNEM. Similarly noted is the usage of AP in subroutines ANAL and INIT. The next to last column on the right contains the name of the labeled common, MANAL, which contains AP. The line for MANAL indicates that AP is available for use in subroutine START but not available in subroutine READIN. Since this latter information is easily accessible in the compiler cross-reference, no particular effort was made to develop a cross-reference to enhance it.

Note that some variables are preceded by an asterisk. An example is B. Referring to Appendix A, the variable B is defined as two other variables, BM and BTR. In Appendix B, entries are made for both BM and BTR in all the subroutines for which there are entries for B.

This means that in the subroutines which have an entry for B, the variables BM and BTR are replaced in the Common by B.

The most common uses of Appendix B are checking the usage of a variable during program modification and debugging.

Appendix C is a list of variables and Commons appearing in a subroutine. The subroutine name heads the list, followed by the names of the labeled Commons appearing in this subroutine, followed by the names of the variables used in the same order as they appear in the left column of Appendix B. The subroutines are listed in order of appearance in the page headings of Appendix B reading from left to right. After the subroutine listings come similar listings for each of the Commons. That is a Common name followed by the names of the variables which are in that Common. Again the order is the same as in the left column of Appendix B. The order given here is not necessarily the same as the order that the variables appear in the FORTRAN listing in Appendix F.

One page of Appendix C is derived from Appendix B by selecting a column, printing the subroutine name, heading that column, and then searching down the column for an "X." When an "X" is encountered on some line, print the variable name that is on that line in the left column.

Appendix C is primarily used to check the contents of Appendix B with the compiler and thus assure the accuracy of Appendix B.

Appendix D is Appendix B grouped by Common and is used to decide whether to put a Common in a subroutine or to put the needed variables in the calling sequence. This decision is made after considering the number of variables needed, the frequency of changing the Common and thus recompiling the subroutine.

Appendix E is derived from Appendix D by combining subroutines into sections. The column headings of Appendix E are the names of the subroutines which control their section. The first section, C81, contains only subroutine C81. The second section, START, contains subroutines START through VIND (reading across the headings of Appendix D) and TILT and IVAR; section ROTAN contains subroutines VIND through DOROT; section ANAL contains subroutines ANAL through SWAS; section

MANU contains subroutines MANU through WRFM; section STAB contains subroutines WRFM through WRVP; section TRIM contains subroutines JACOBI through IVAR; section PLOT contains subroutines PLOT through CURVET.

Appendix E is used to group the variables for the labeled Commons.

D. FORTRAN LISTING

The FORTRAN subroutines are listed in Appendix F in alphabetical order except for the main program, C81, which is first.

11. SUPPLEMENTARY NOTES		12. SPONSORING MILITARY ACTIVITY Air Force Flight Dynamics Laboratory Wright-Patterson AFB, Ohio 45433
13. ABSTRACT This report describes a mathematical model of rotorcraft that may be used to determine characteristics of performance, stability, response, and rotor blade loads. The complexity of the equations used requires the use of a digital computer for efficient solution. This four volume report describes the computer program in detail and illustrates the method of computing rotorcraft characteristics by specific example. This volume contains aids for the computer programmer. The first and second volumes contain a discussion of the mathematical model and detailed instructions for the users of the program. The fourth volume contains computer generated documentation of the program. The programming aids are divided into two groups: background material for the programmer just starting to work on this computer program and the detailed explanation of the computer generated documentation which is necessary for any programmer to work effectively on this program.
