ABSTRACT :

€

Serological confirmation using DIFCO commercial antigens, was not obtained in every case of leptospirosis even when the organism was isolated from the blood of the patient. One of the possible reasons could have been that the infecting strains in Ceylon were different from those used in the preparation of the DIFCO antigens. Therefore investigations were undertaken to establish the scrotypes prevalent and the vectors for them in Ceylon. The methods adopted were i. human and animal tissues and body fluids were cultured direct; ii-tissues from some animals were passaged through hamsters ; iii. surface waters from suspected endemic areas were passaged through hamsters; i i iv. serological studies of blood of both humans and inimals. Leptospira belonging to the following sero-groups were isolated and vectors for them established; L. javanica . icterohaemorrhagiae; L.grippotyphosa; L. hebdomadia; .. pomona; and L.autumnalis. The vectors are rodents and dogs. Though large numbers of J. canicola were isolated from patients, no vectors have been established for this . Sera of cattle (30.0 %) and swine (22.1 %) were found to be seropositive for leptospira. Whe same cattle sera, except for two (2) were seconegative for brucella. These findings are proof that leptospirosis is more widespread among the dairy animals in Ceylon than hitherto recomised and the cause of abortion in the beef herds in our state farms should therefore be more alligently investigated. The isolation of a large number of Le sutumnalis and the following hitherto unknown new serotypes, viz: L.icterohaemorrhagiae gem; L.autumnalis lanka; L. grippotyphosa ratnapura; L. hebdomadis isvaweera; L. altumalis alice and L. j. vanica ceylonica: the first five only in the Ratnapura district is an indication of a possible sylvan reservoir which needs further investigation in addition to the wildlife of the rest of the island.

Introduction

C.

C:

Analysis of the indoor morbidity statistics . in government hospitals in Ceylon reveals that amongst the largest groups of morbidity, Pyrexias of Unknown-Origin ranks second to the big group of bowel diseases. The role of leptospirosis in the group of P.U.O. has not been evaluated. Awareness to this disease in Ceylon was created in 1959 (I). Since then Maretic,Z: Arunainayagam,P: Mityananda,K: Wickremasinghe,R.L. and Ratnatunge, P.C.C., 1962 (2): Nityananda, K. 1962 (3): Rajasuriya, K: Munasinghe, D.R.: Vitarane, U.T.: Wijesinghe C.P.de S.: Ratnaike, U.T. and Peiris, O.A. 1964 (4): Wallooppillai, N.J.: Markhus, H.K.N.I. and Mityananda, K. 1966 (5): Nityananda, K. 1967 (6) and Silva, W.A.S.: Kendis, N. N. P. and Nityananda, K. (unpublished) by their studies have shown that leptospirosis is widely prevalent in this country. Yet the epidemiology of this disease has not been investigated, with the result that the public health importance of it is not appreciated. This is reflected very much in the attitude of most public health and veterinary personnel, who refuse to believe that leptospirosis may be prevalent amongst the liveatock of this country to a significant degree as to adversely affect the agricultural economy. Tjalma, R.A. and Galton, M.M. in 1965 (7) while discussing the current concepts regarding the public health significance of this disease observed, the phenomenal apparent spread and establishment of episootic leptospirosis among livestock has served to create an enormous reservoir and potential source of human infection. In 1954 (7), the United States Department of Aggriculture estimated an annual loss to their aggricultural economy of over IOO million dollars due to leptospirosis.

Dr. A.Bandaranayake, the Deputy Director, Animal Production and Health, in Ceylon states, the incidence of abortion among the livestock in this country is about 5-IO % and this is normal in dairying, the cause according to him is brucellosis (personal communication). Reinhard in I952 (8) stated that when abortion is the principal sign it may be necessary to obtain laboratory assistance to distiguish leptospirosis from brucellosis, vibriosis or physiological and toxic causes;

Since each leptospiral scrotype is believed to have a primary host, it is essential to know the association between the scrotypes and their animal hosts in Ceylon before the epidemiology of leptospirosis in this country could be fully understood. This pape? describes the work that was conducted to study the vectors and the probable infecting strains of leptospira present in Ceylon.

History of Leptospirosis in Ceylon

The available earliest evidence in record of weil's Disease having been diagnosed in Ceylon, is in 1953 (9). As the knowledge of the disease increased and with the availability of improved laboratoty facilities more cases were diagnosed, confirmed in the laboratory and reported. The majority of the cases were from Ratnapura in the Sabaragamuwa Province, then Ragama, Colombo and Kalutura in the Western Province, Matara in the Southern Province, to a lesser degree from Kandy and katale in the Central and Anuradhapura in the North Central Province. These reports varied from time to time and place to place depending on the clinician working in thatplace. In 1959 (3) the first leptospira L.ioterohaemorrhagiae was isolated from the blood of a patient in Colombo and soon after from the kidney of a sewer rat trapped in the vicinity of that patient's home. Since then upto 19 leptospiral serotypes belonging to 7 serogroups have been isolated and incriminated as the causative agent of leptospirosis in man and/or animals.in Ceylon.

L.autumpalis, the elusive and confounding agent of Fort-bragg fever, is described by some workers out side Ceylon as apparently rare as a human pathogen. In Ceylon however, 56 leptospiral isolates obtained from humans in Ratnapura have been identified and 26 (46.4%) of these belong to the L.autumpalis serogroup.

Source of Infection

For many years rats, dogs and pigs were believed to be the primary animal carriers of leptospira. Today as a result of extensive studies the host range (IO) has broadened to such an extent that no living agent, both demestic and wild, can safely be excluded. In addition to animals water too has long been recognised as an important vehicle by which pathogenic leptospira are disseminated and infection transferred from animal carriers to human beings. Three classical examples of water being the source of infection are, the outbreak of Fort-bragg fever in 1942 (II) and those described by Schaeffer in 1951 (I2) and Bordjoski in 1952 (I3).

A few such episodes have been investigated by the author in Ceylon too. In 1964 (5) some members of a gang of labourers dredging a canal at Wattala were taken ill with leptospirosis. In 1967 at Panadure a party of volunteers composed of civilian and police personnel worked ankle to knee deep to reclaim marshy land, as part of a Shramadana-Campaign (community-

welfare). Out of these, I2 (37.5%) were subsequently taken ill with leptospirosis. Further the majority of the patients investigated at the Ratnapura hospital stated that bathing in the river Kalugangs or panning for gens along the jungle streams as the probable source of their infection.

Materials and Methods

a. liaterials

C·

C

Rodents were trapped alive wherever possible, brought to the leptospirosis laboratory at the Medical Research Institute, anaesthetised and opened up under strict aseptic conditions, Blood was obtained from the heart and kidney plugs taken with sterilo pasteur pipettes. Heart blood and kidneys from cattle and swine were taken at the time of their slaughter in the mmicipal slaughter house in Colombo. Heart blood and kidneys from stray dogs were taken soon after these animals were gassed at the municipal dog pound.

mals were gassed at the municipal dog pound. The rodents investigated were; Rattus norvegious (R.n.) - the sewer rat: Gunomys gracilis (G.g.)-Ceylon mole rat, also known as the paddy field rat: Rattus rattus rufuscens (R.r.r.) - Ceylon flat-country house rat: R.r.kandyanus (R.r.k.) - Ceylon hill-country house rat: Bandicoota malabarica (B.m.) - bendicoot and Suncus caeruleus giganteus (S.c.g.) - the shrew, which is a member of the carnivores family.

b. Methods

i. Kidney tissues of all animals were inoculated direct into Fletcher's semi-solid medium, and/or ground up, suspended in sterile normal saline and passaged through hamsters.

ii. Blood was examined for evidence of leptospiral agglutining from, (a) rat pound workers who are of occupational risk: (b) daily river bathers at Ratnapura which is a suspected endemic area and, (c) cattle, dogs and pigs.

ili. Surface waters from suspected endemic areas (Ratnapura and Ragama) were passaged through hamsters. These hamsters which were inoculated, i? they died between the 6th and 14th day after inoculation, were opened up and their liver tissue inoculated into Fletcher's semi-solid medium. No leptospira were isolated from these waters.

Findings

a. <u>Isolations</u>. Kidney tissues from a total of I6II animals were processed. These included, 592 rodents of 5 species, 3 shrews, 359 cattle, 351 ()gs, 293 swine, 5 rock-squirrel, 2 red-mongoose, 2 grey-mongosse, I mongoose, I hare, I civet cat, and I field rat. The number of leptospira isolated is shown in table I.

b. Serological survey

E)

Sera were examined for the presence of leptospiral agglutining by the microscopic agglutination (agglutination lysis) test employing live cultures belonging to 21 scrotypes, as antigens. Agglutination reaction at a titre of 1:100 or more was considered significant. The employment of multiple screening antigens revealed a significantly high prevalence of seroreactors.

i. <u>Rat pound workers (rat catchers)</u>. The Colombo Municipal Council maintains a regular anti-plague campaign in which a permanent labour force distributes or lays rat cages in the city's sewers, surface drains and house gardens, collect these cages the following morning with the trapped live rodents, transport them in wans by the central rat depot and destroy

6,

them. Most of the Celon nole rate, sewer'rate, shrews and bandicoots from which there have been a high percentage of leptospire isolations by the author, were supplied alive from this campaign. These labourers walk bare-footed and work with their unprotected hands. They therefore are liable to injury and subsequent contamination directly with the urine of these rodents during collection and transport or ind rectly from the polluted floor boards of the vans. Therefore one would expect a reasonable percentage of seropositivity among these labourers. The sera from 26 of these labourers who had been engaged in this work over several years were examined and all were seronegative. These findings are similar to those of Dr. J.C.Broom (15) and Dr. Jan W.Wolf (15), who investigated inhabitants of rat infested dumps. Both found that though the rats in those areas were carriers of leptospira, none of the human beings living there showed evidence of infection.

ii. <u>Random samples</u> Blood was examined from persons residing in Ratnapura bassar area, who bathe regularly in the Kaluganga river. Of the 70 sera tested for leptospira agglutining I9 (27.1%) were seropositive.

Ċ

iii. <u>Cattle</u> Though no leptospira has been isolated from the kidneys of cattle and swine, there is strong serological evidence that both these are carriers of leptospira in Ceylon.

Out of 359 cattle sere examined IOS (30.0%) were positive for leptospire agglutinins (Table 4). If so small a sample can yelld so many positives the problem on a national basis must be one of tremendous proportions. The majority of the seropositives were against <u>L.wolffi</u>. All the cattle sere investigated for leptospirosis wire also tested for brucellosis and only 2 specimens out of the 359 (0.5%) were positive. Therefore the cause of abortion in the cattle in Ceylon requires a more diligent investigation.

iv. Swine Of the 293 swine sera examined 65 (22.13) were seropositive (Table 5). The majority of the positive reactors were against <u>L.pomona</u> and <u>L.canicola</u>. Apparently leptospirosis in swine is more widespread in this country than hitherto recognised. Though serum samples P-209 and P-212 were positive in very high titres, 1:25600, it was unfortunate that no leptospira were isolated from the kidneys of these two animals.

Table 7. Results of serviying of isolates and serology from 3 dogs: D-16, D-19 & D-32.

The leptospira isolated from the

kidney of dog -16 has been identified as <u>L.hebdomadis</u> whereas the serum from the same animal is negative against the homologus antigen, but positive against <u>L.canicola</u>, <u>L.autumralis</u> and <u>L.Fort bragg</u> antigens. Further the leptospirae isolates from the kidneys of dog-29 and 32 have been identified as <u>L.javanica</u> and <u>L.pomona</u> respectively, but the sera from these animals are seronegative against the full range of antigens belonging to the 21 serotypes including the homologus.

Discussion

Cr

Leptospirosis is associated with a broad animal host spectrum and is transmitted from the animal carriers to other animals and man. In the investigation of possible reservoirs among wild and domestic animals, serological investigation alone may provide useful clues; at the same time they may provide an erroneous or misleading index of infectivity rates, since some seronegative animals may be carriers. This limitation is very clearly shown in table 7: Dogs -29 and 32. The total absence of antibodies in carriers as in these dogs, though cannot be satisfactorily explained, has been met with. Mrs. Sulser from the leptospirosis unit of the National Communicable Diseases Centre in Atlanta states, 'we once had a laboratory dog that had no antibodies but we isolated leptospira from the urine of this dog for once a month for as

II

long as one year after disease' (personal communication).

Almost all homes in Ceylon are rat infested, either with R.r.rufuscens or R.r.kandyanus. From the findings of this study it is evident that the above two species of rattus are not vectors for leptospira in Ceylon; a finding of great relief indeed. The demonstration of <u>L.pomona</u> infection in the dog prompts the potential role of the dog in the infectious cycle of human and animal leptospirosis. In addition to <u>L.canicola</u>, <u>L.icterohaemorrhagiae</u> and <u>L.pom-Opa</u>, dogs can be infected and can serve as a potential source of infection with numerous other serotypes. These include <u>L.hebdomadis</u>, <u>L.javanica</u> (Table 2); <u>L.australis</u>, <u>L.autumnalis</u>, <u>L.bataviae</u>, <u>L.medimensis</u> and <u>L.byos</u> 1957 (16).

While L.icterohaemorrhagize, L.javanica, L.cenicola, L.autumnalis, L.hebdomadis, L.grippotyphose, L.pomona and L.wolffi appear to be the primary serotypes involved in human and domestic animal infection in Ceylon, the detection of new serotypes hitherto unknown; vis: L.ictero. gem.(17), L.jav. ceylonice, L.grippo, ratnapura (18), L.hebdo. javaweera (18), L.autum, alice (18) and L.autum.lanka (19), emphasises the need for public health, medical and veterinary laboratories to maintain a greater awareness to this disease. Further studyof the new feral mamals will be necessary to determine the prevalence of infection in other parts of the island and to determine their role in the epidemiology of this disease.

Summary

€

The evidence established so far shows that in Ceylon, rodents, dogs, cattle and swine are carriers of leptospira. The infecting strains are L.ictérohaemorrhagiae, L.canicola, L.grippotyphosa, L.hebdomadis, L.javanica, L.autumalis, L.pomona and L.wolffi.

Acknowledgements

The author is indebted to Mrs. Catherine R. Sulser and Mr. Harvey of the leptospirosis laboratory, M.C.D.C. Atlanta, for reporting on the specimens; the medical and public health staff of the health department, Drs. Subramaniam and Cooke of the Colombo Municipality for helping to collect the specimens. He also thanks Mr. Jinapala the technician without whose assistance this study could not have been attempted. Finally the author thanks the United States Army Research and Development Group (Far East) for their encouragement and aid which made this study possible.
