OBJECT OF TEST

The object of this test is to determine the free air output of a Dapco Air Compressor, model number SK 375 at 10#/ , in² back pressure increments, ranging from 10#/in² to a pressure where the volumetric efficiency approaches zero.

METHOD

The air compressor was a two stage, air cooled type. It was manufactured by Dapco Products, Inc., Defiance, Ohio. It was belt driven by a Wisconsin gasoline engine. The engine model was AK, size 2 7/8 x 2 3/4, serial number >39706, specification number 16864-3. The namufacturer's rating is 2.9 horsepower at 2200 RPMs.

The unit ran 14 hours with no load at various speeds to break it in. When the motor was first run, the speed was kept at a minimum.

Under load, an attempt was made to keep the revolutions per minute as close to 2250 as possible.

The compressor was fitted with 150 feet of 5/16 inch I.D. oxygen hose, terminating with a 1/4 inch throttling globe valve. After the throttling valve, the piping was increased to 3/4 inch. At this point, about 3 feet of 3/4 inch I.D. rubber tubing was connected to an air meter discharging into the atmosphere. Just prior to the meter, a pressure tap was inserted in the line. The load from this was connected to a water manometer. The meter used was a type generally used in household installations. It was manufactured by the American Meter Company, Albany, New York. The calibration was in liters and the correction factor was 0.984.

A test gauge was located just prior to the throttling valve and another one at the compressor. The back pressure was controlled by the throttling valve at the distal end of the hose.

The compressor was run under load for a period of about one hour in the course of these tests. Discharge volumes were measured by observing the flow in one minute. The intake air temperature was about 40°F. The safety valve on the air compressor was set at $115\#/in^2$. This was later set higher when tests were begun at $110\#/in^2$, back pressure. The unit was located outdoors where the temperature was about 40°F. All measurements were made indoors where the temperature was about 70°F. No air volume tank was used. The RPMs were measured by an instantaneous reading tachometer.

DISCUSSION OF RESULTS

The performance of this compressor with respect to its ability to deliver free air at high back pressures was satisfactory. It delivered 122 liters at $10\#/in^2$ back pressure and 95.5 liters at $110\#/in^2$ back pressure. This is a loss of but 21.5%. None of the volumes are corrected for standard temperature and pressure since the tests were of a preliminary nature. The meter correction factor of 0.984 and the pressure in centimeters of water above atmospheric at the adit side of the meter were also ignored, since their effect was small. The latter value at its maximum was only 5 centimeters.

Attention is invited to the high friction loss at low back pressures. This is as anticipated, since friction loss in pipes increases with velocity. The pressure gauge at the compressor was rather difficult to read because of its vibration.

The revolutions per minute had a plus or minus error of about 10. They too, were difficult to read due to the vibration of the compressor. An attempt was made to keep the RPMs at 2250. This was not possible at higher back pressures. There was a tendency of the unit to wander with regard to RPMs for no apparent reason. The effect was minimized by checks before each test when equilibrium conditions were established.

The heating of the compressor did not appear to be excessive. This was determined merely by touch. No attempt was made to evaluate this characteristic by positive tests. It is to be noted that the intake and ambient temperatures were about 40°F. This is a lower temperature than usually encountered in diving operations. The temperature of the air after throttling was not taken.

The compressor failed to produce a proportional volume of air when the back pressure was increased to $120 \#/in^2$. All possible external causes were investigated such is obstructions, kinks in the hose, etc., without results. The compressor was then disassembled. The diaphragm of the high pressure side was found to be ruptured. The break occured about 1/4 inch from the outside of the diaphragm at the point where the under side of it touches the housing. Substantial wear was evident at this diameter throughout the diaphragm. The low pressure diaphragm was also inspected. There was also substantial wear at the same relative part of the diaphragm. It appeared as if it were in imminent danger of failure.

No other failures or shortcomings were evident in the compressor engine.

-2-

CONCLUSIONS

The volume of free air produced at back pressures up to $110\#/in^2$ is satisfactory. The volume drop from 10 to $110\#/in^2$ is but 21.5%.

The inadequacy of the diaphragms was indicated in the above tests. When the short period of operation is considered, (14 hours idling, 1 hour under load), this factor is all the more prominent. Moreover, the low ambient operating temperature placed the compressor in more favorable conditions than would be normally expected with regard to its heating.

The above results would point to a failure of material, faulty design, or a combination of both. Until these shortcomings are eliminated, this air compressor should not be considered for diving operations. DATE : 22 January 1948
