Cyanoethylation of Some Alkanolamines

J A Bell and C Kenworthy

(Synthesis 1971, 650-652)

Summary

This paper describes the preparation of a series of alkanolamines $(HO \cdot R \cdot IH_2)$ bearing one or two cyanoethyl $(-C_2H_4CN)$ groups on the amino nitrogen. Choice of reaction conditions and certain structural features determine whether mono- or disubstitution occurs, and when both products are formed, the mixture may be conveniently analysed by non-aqueous titration. All products have been characterised as p-nitrobenzoyl derivatives.

Cyanoethylation of Some Alkanolamines

J.A. BELL and C. KENWORTHY

Explosives Research and Development Establishment, Ministry of Defence, Waltham Abbey, Essex, England

Compounds possessing labile hydrogen atoms may add to acrylonitrile, forming molecules containing a cyanoethyl group¹. Hydrogen donors may be amines, alcohols, or compounds in which hydrogen atoms are activated by electron-withdrawing groups.

Most amines add to acrylonitrile without the aid of a catalyst. Primary aliphatic amines react readily with acrylonitrile at low temperatures to give the 2-cyanoethyl derivative; at higher temperatures, the N,N-bis-[2-cyanoethyl] compound may be formed from some amines in the presence of excess acrylonitrile^{1,2}, but reaction is slow unless an acid catalyst is present^{3 4, 5}. Alcohols react with acrylonitrile in the presence of alkaline catalysts to form cyanoethyl ethers¹.

Hoffman and Jacobi⁶ have prepared some N-(2-cyanoethyl)-alkanolamines by adding the parent alkanolamine to cooled acrylonitrile. The only disubstituted alkanolamine previously reported is N,N-bis-[2-cyanoethyl]-ethanolamine², but reaction conditions were not specifed and no yield was quoted.

We have examined the reaction of various other alkanolamines with acrylonitrile under reflux or in an autoclave, and the mono- and bis-[2-cyanoethyl] derivatives obtained are described here (Table 1).

N,N-Bis-[2-cyanoethyl] derivatives were obtained from alkanolamines in which the amino group is attached to a methylene group. Introduction of alkyl groups onto it a-carbon atom progressively reduces the reactivity. i.e., compound 6 yields a mixture of mono- and bis-cyanoethyl derivatives, compounds 7, 8, and 9 give only mono-cya5trethyl derivatives. Compound 2, which contains a methyl group on the β -carbon atom, was less reactive than ethanolamire.

The N,N-bis-cyanoethyl derivatives obtained could also be prepared by heating the reactar... at 110 120 (bath temperature) in a stainless-steel autoclave (internal pressure, 1.7 2.4 atm) for 2 hr, but similar treatment did not effect

Communications

further cyanoethylation of compounds 6-9. Attempts to obtain the bis-cyanoethyl derivatives of compounds 6-9 by adding acetic acid to refluxing reaction mixtures were unsuccessful.

We also investigated the cyanoethylation of the isomeric butylamines in excess acrylonitrile (reflux, 16 hr). Products obtained had equivalent weights 132.9 (from n-), 128.6 (from i-), 130.3 (from sec-), and 128.3 (from t-butylamine), indicating that little if any bis-cyanoethylation had occurred (molecular weights of the mono- and bis-cyanoethyl derivatives are 126.2 and 179.3, respectively).

The greater reactivity of the unsubstituted alkanolamines is probably due to hydrogen bonding, enhancing the nucleophilicity of the tertiary nitrogen atom.

2

Melting points were determined using a Kofler micro hot stage and are not corrected. I.R. spectra were measured using a Perkinmodel 237 spectrophotometer.

Preparation of N-(2-Cyanoethyl)-alkanolamines (Table 1):

The alkanolamine (0.02 mol) was added dropwise to redistilled acrylonitrile (0.04 or 0.08 mol), the temperature being maintained below 5° by external cooling (TCE/CO2) as required. Subsequentreaction was conducted at 5-20° or under reflux. Reaction complete, polymerised acrylonitrile, if present, was removed by passing the mixture through a filter aid, then excess acrylonitrile was removed under reduced pressure using a rotary film evaporator to leave the crude products. Solid products were purified by recrystallisation; attempts to purify liquid products by distilfation resulted in decomposition.

The lower reactivity of the substituted alkanolamines is probably due to steric hindrance of this hydrogen bonding.

Attempts to purify the cyanoethylated alkanolamines by distillation under reduced pressure were unsuccessful. All the compounds examined behaved like N.N-bis-[2-cyanoethyl]-ethanolamine², decomposing into acrylonitrile and the starting alkanolamine.

Structures of the products obtained were confirmed by elemental and I R analyses, by equivalent-weight determination involving titration with perchloric acid in acetic acid, and by preparing 4-nitrobenzoyl derivatives. The presence of residual hydroxy groups in the cyanoethylated alkanolamines was established by the presence of the O-CO-band (v, 1635 cm ') in the I.R. spectra of their 4 nitrobenzoates, the presence of NH groups in the monocyanoethyl derivatives was shown by the N-CO-(v, 1725 cm⁻¹) a sourption of the 4-nitrobergoate. The absence of N-CO- bands in the I.R. spectra of the 4-nitrobenzoates of the bis-[2-cyanoethyl] compounds eliminated the possibility that the OH group had been cyanoethylated. Further confirmation was obtained from the failure to cyanoethylate propare-1,2-diol in excess boiling acrylonitrile.

The proportions of mono- and bis-[2-cyanoethyl]-alkanolamine and of non-basic materials in the products can be obtained by titrating with perchloric acid before and after acetylation of the sample⁷. On acetylation the monocyanoethyl derivative, being a secor lary amine, is acetylated and is insufficiently basic to utrate. A typical sample of N,N-bis-[2-cyanocthyl]-2,3-dihydroxypropylamine of apparent molecular weight 200.2 (197.2 required) was calculated to contain bis-[2-cyanoethyl] compound (97.7%), mono-cyanoethyl derivative (0.6%), and non-basic material (1.7%).

4-Nitrobenzoates were prepared conventionally, but only oils were obtained from N,N-bis-[2-cyanoethyl]-3-hydroxypropylamine and from 1,3-bis-[2-cyanoethylamino]-2-propanol, attempted preparation of 3,5-dinitrobenzoates of these compounds also gave oils. N-(2 Cyanoethyl)-N-(tris-{hydroxymethyl}-methyl)amine afforded only a tris-[4-nitrobenzoate], which contained no N-CO-absorption but a small NH peak in the LR spectrum, suggesting that the amine hydrogen had not reacted.

The reaction of N-(tris-[hydroxymethyl]-methyl)-amine (7), which was almost insoluble in acrylonitrile, was accomplished by using ethanol as solvent. No further cyanoethylation occurred when the monocyanoethyl derivative was dissolved in boiling acrylonitrile for 16 hr.

Preparation of 4-Nitrobenzoates

4-Nitrobenzoates (Table 1) were prepared by shaking a mixture of the cyanocthyl alkanolamine (0.01 mol) with 4-nitrobenzoyl chloride (0.02 mol per replaceable hydrogen atom) in pyridine (100 ml) for 16 hr. The mixture was then added to water (500 ml) and extracted with chloroform (3 × 100 ml). The combined extracts were washed successively with water (100 ml), aqueous sodium carbonate (2 x 100 ml), dilute hydrochloric acid (3×100 ml), and water (100 ml), then dried (MgSO₄) and evaporated under reduced pressure (60, 15 mm Hg.). The crude product was crystallised from aceton (charcoal), light petroleum (b.p. 60°-80°).

Many thanks are due to Mr. J. V. Griffiths, who performed some of the nonaqueous titrations, and to Miss M. K. Best, who performed the microanalyses.
