FORWORD

Although the problem of ablative and evaporative cooling in the interior ballistics had been considered before, the mechanism of the cooling is not clearly understood. In order to optimize the cooling effectiveness a thorough theoretical and experimental study must be made.

This report summarizes the effort in the period from January 1970 to April 1971 to study the cooling mechanism in the interior ballistics. The basic aim is to explore a better prediction of film cooling convective coefficient for a simplified model which however retains the basic characteristics of the interior ballistics problem.

The experimental study was carried out at Rock Island Arsenal by personnel from Science and Technology Laboratory of the Rock Island Arsenal. This part includes design and modification of cooling projectile, conversion and interpretation of experimental data. The theoretical study deals with the solution of gas dynamics and heat transfer in a unsteady incompressible, two-phase flow with non-isothermal wall. Heat transfer convective coefficients are predicted or correlated with the experimental results.

one of the main consistence and interest and the consistence and the consistence of the c

#### I INTRODUCTION

It is well known that the present firing arms are limited for their continuous firing capability due to the thermal expansion or cook-off from the excessive heating in firing. For example, Cohn [1] and Corner [2] show that a heat input of 1,000 Btu/ft sec. is possible. Many approaches have been attempted to remove this large amount of heat transfer such as the change of configuration, different propellant, change in firing frequency, and liquid cooling. Without changing the existing design, one of the most promising methods of cooling is to coat an ablative and evaporative material on the interior wall by the projectile as it passes through. The thermal resistance of the so generated vapor may seal off the heat transfer from the combusted gas to the wall . It was shown by Cohn [1] and Adams and et al [3] that even smearing with silicone oil or coating with teflon or beeswax on a projectile does have some cooling effect. However the exact mechanism of the insulation is not clearly understood. The present theoretical and experimental research is motivated to study the cooling mechanism and to optimize the effectiveness of such cooling devices.

The experimental study used an XM140 Aircraft Automatic Gun as the model to analyze the cooling effectiveness of the cooling projectile which contains water as coolant and to obtain the boundary conditions that are needed in the theoretical analysis. The theoretical study analyzes the gas dynamics of the propellant gas to the barrel occurring behind the projectile.

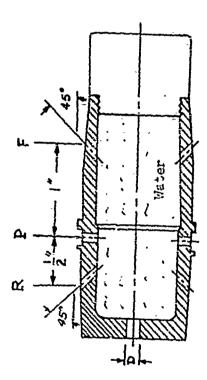

Convective heat transfer coefficient which is important in heat transfer calculation was derived for unsteady compressible flow with and without liquid cooling in a barrel.

#### II CONCLUSIONS

Before details of experimentation and theoretical analysis are reported, important conclusions are first presented in this section for readers who are interested in the present results and the application of the solutions obtained. It is concluded that:

- Solid material coated on the projectile is not an effective coolant because of the low melting rate in a time interval of two to three milliseconds. Therefore, liquid is adapted as the coolant.
- 2. Water as a coolant is proved to be excellent, since it is inert, nontoxic in both liquid and vapor phase, more transparent than silicone oil in vapor phase. Antifreezer may be added to water to lower the freezing point in use.
- 3. Proper geometry of the modified projectile that contains coolant is essential for an effective and uniform cooling. Of the eight modified configurations (see Fig II-1) tested, the No. 2 type gave a distinctively effective and uniform cooling. These modifications are based on the analysis given in Appendix IIA. We conclude that injection of coolant through side copper band and the front portion of a projectile gives a better, even distribution of coolant than other combinations.
- 4. Experimenting with water as the coolant in the No. 2 type modified projectile the peak temperature on the interior wall is reduced by as much as 40% in comparison with the standard round based on the single shot experiment as shown in Fig II-2. Cooling is particularly effective near the muzzle end.
- 5. The analysis of the gas dynamics of the propellant gas behind the projectile and the heat transfer through the propellant and the coolant to the wall may be divided into three regions core flow, gas boundary layer flow and liquid layer flow.

- 6. Gas and liquid boundary layers are found to be small compared with the diameter of the barrel. The thickness of the layer is about one hundredth of the diameter.
- 7. The gas core solution is solved provided that

  the pressure response at the breech and the projectile position as a

  function of time are known. The result gives the following dependent

  variables in dimensionless form (deviation given in Chapter V).

Pressure:

$$P(3,t) = P_{b}(t) - 0.5928 \frac{3}{2} (3 - \frac{3}{2}(0)) / (2 \frac{3}{2}(t))$$
 (2-1)

Density:

$$P(t) = 0.5928/3p(t)$$
 (2-2)

Temperature:

$$\theta(3,t) = \left[ \frac{P_b(t)}{\delta P} / c. s = \frac{2\delta}{2} - \left[ \frac{3}{2} - \frac{3}{2} \frac{1}{2} (c) \right] / (2 \frac{3}{2} \frac{1}{2} (c)) \right]$$
 (2-3)

Gas yelocity:

$$W(3-t) = \frac{3}{3}p^{3}/3p^{(t)}$$
 (2-4)

Heat generation;

$$\begin{cases} u_{ie} = \left( \left( \frac{1}{2} \frac{3}{4} \right) + \frac{1}{2} \frac{1}{4} \right) - \left( \frac{3}{2} \frac{3}{2} \frac{3}{2} \frac{3}{2} \frac{3}{2} \right) / \frac{3}{2} \frac$$

The analysis shows that the pressure distribution can be predicted to a

15% accuracy at any location behind the projectile. Fig II-3 shows the comparison between theory and experiment. The above solutions are also programmed in Appendix IIB for general input of projectile position versus time and breech pressure functions. The above analysis should be used 0.15 milliseconds after the firing, since the solution is inaccurate during the strong propellant reaction.

8. The gas boundary layer flow without liquid cooling is first solved to understand the heat transfer mechanism. The solution is obtained through similarity transform. The analysis deals with an unsteady compressible laminar flow with heat generation and non-isothermal wall. For the wall temperature of the type (see Chapter V, Eq (5-13))

$$\Theta_{\omega} = \frac{\pm^{1.65}}{f_{1}(c)} \left[ P_{b} - c.54 \pm^{-3.25} (3^{2} - 3^{2}_{p}(c)) \right]$$
 (2-6)

the local Nusselt number which is function of time and position is

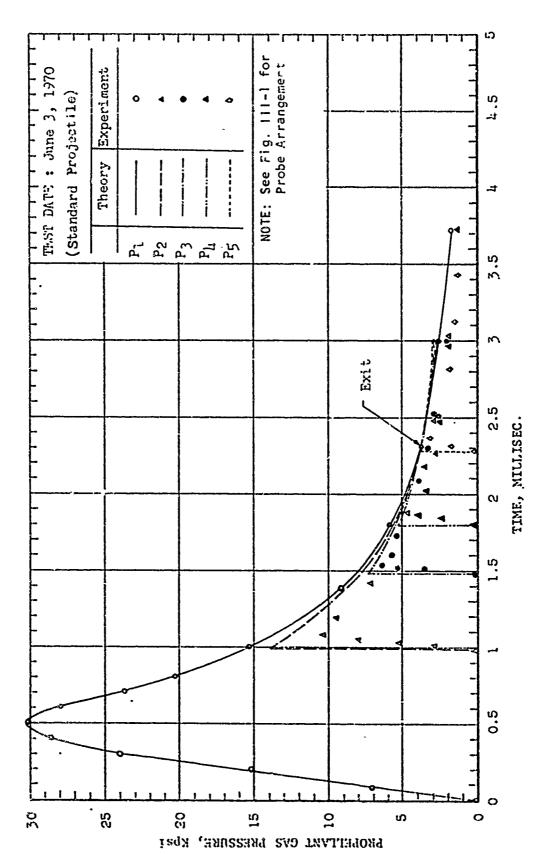

$$N_{ii} = \frac{h(3.4)L}{K} = R_{e}^{c.5} \left( \frac{-f_{i}(0)}{f_{i}^{2}(0)} \right) t^{0.325} \left[ \dot{p}_{b}(t) - c.54t^{-3.25} (3^{2} - 3^{2}(0)) \right]$$
(2-7)

For the XM140 Model or the like  $f_1(o) = 3.2, f_1(o) = -0.12$ . It should be noted that Newton's cooling law is defined here as

$$g = h Tr \left( \frac{\beta + u}{h_r f + \nu} \right)$$
 (2-8)

where 
$$Tx = \frac{u^2}{R}$$

and that the time and location in Eqs (2-6) and (2-7) must be behind the projectile or  $z < z_p(t)$ . For other type of interior ballistics  $-f_1'(c)/f_1^2(c)$ 

Mg. II-3. Pressure and Time Correlation

ANTHORITY OF ANTHO

and the sections of the contract of the contra

in the equation (2-7) may be taken as a constant to be determined from experimental data. The limitation of the formula (2-7) is that the non-isothermal wall temperature must be given by Eq. (2-6) which may only approximately represent the actual response in experiment. Nevertheless it is recommended over the use of steady incompressible laminar formula. Examples of using Eq. (2-7) can be found in Chapter VI.

9. The heat transfer from the propellant to the wall through a liquid layer is solved approximately in Chapter VII. The Nusselt number which is also function of time and distance along the axial direction is given as

$$N_{u} = \frac{h(\lambda,t)L}{k_{p}} = R_{e}^{c,r} \frac{1}{y_{h}} \left[ \theta_{h} - \theta_{hw} - \frac{\partial \theta_{hw}}{\partial t} \frac{\theta_{h}}{z} \delta^{2} y_{h}^{2} \right]$$
 (2-9)

where y_i is the liquid film thickness. A method of calculating y_i is given in Chapter VII section 1. Because there is not enough information about the existence of a liquid film behind the projectile and about the percentage of liquid in the modified projectile that may get behind the projectile the solution thus obtained from Eq. (2-9) can only be taken as preliminary one. Further study is needed to verify many assumptions which are not theoretical, but are experimental and yet to be established. An alternative heat transfer formula is also derived in Chapter VII section 3 based on the response of the solid wall of the barrel.

10. In general with cooling liquid there is about 30% of reduction in heat flux from the propellant gas to the wall for the modified projectile of No. 2 (see Fig II-1). The mechanism of cooling effect mainly comes from the absorption of heat by the liquid and therefore the reduction of temperature gradient near the wall.

#### III EXPERIMENTAL STUDIES

### III-1 Projectile Modification

In the design of the modified projectiles for experiment, considerations were made to provide an even distribution of coolant on the interior wall and a good lubrication effect for the motion of projectile. Then several single shot experiments were conducted to determine the best coolant exit locations and hole diameters among the proposed modified models. The hole diameters are calculated from a theoretical analysis under the criterion that the coolanc is completely squeezed out by the time when the projectile leaves the muzzle end. In the analysis the effective pressure to squeeze the coolant out of the projectile is assumed to be one half of the bore pressure at that given instant. (See Appendix II A)

A capsule containing water is inserted into the hollow space of the projectile as shown in Fig. II-1 for an initial test. One hole at the bottom and four to eight holes evenly spaced around the projectile are drilled. As the projectile is fired the pressure on the base of the projectile will squeeze the water out of the projectile through the holes around the projectile. The water then is coated to the inner wall of the barrel. The precise dimensions for machining are shown in Fig. II-1.

Approximately 17 grams of water were sealed in the projectile by a polyethylene capsule, a rubber bag, and a polyethylene tape respectively. The experimental results show that the modified projectiles NO. 2, gave the best result with uniform cooling and lower wall temperature (40% reduction in the maximum wall temperature from that of the standard round. See Comparison of Figs. II-2) It was established that the front holes and peripheral has located between the copper band gave the best result.

Therefore No. 2 is adapted for experiments of continuous firing. The

data obtained for single shot experiment are the measurements of the interior and exterior wall temperature, and the pressure response in five locations of the gun barrel. All experiments were performed at the Rook Island Arsenal by personnel of the Science and Technology Laboratory. The data are included in Appendixes III A,B, and C.

#### III-2 Instrumentation

The Instrumentation of the experiment was also set up by

personnel of Science and Technology Laboratory at Rock Island Arsenal.

The model used for the experiment was XM140 barrel. Five pressure probes,

four interior wall temperature probes and six external thermocouples were

used to record data. Kistler pizo-electric high pressure transducers were used for

pressure measurements. The platinum -platinum 10% rhodium Mo-Re surface

temperature probes were used to measure internal wall temperature. Both

probes have a response time of microseconds which is sufficiently accurate

for a test interval of 2 to 3 milliseconds. The external temperatures were

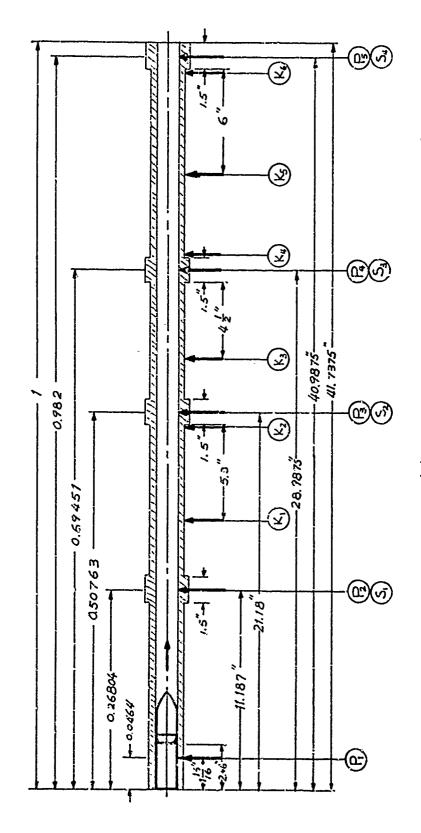

measured by chromel-Alumel thermocouples welded on the outer barrel surface. The

arrangement of probe locations is shown in Fig. III-1.

#### III-3 Kesults and Discussion

#### III-31 Recommended Model

Eight proposed modifications of the projectile shown in Fig. II-1 were tested on a single shot basis in the first two experiments and compared with the standard round. Each modified projectile contains G.039 lbm (17.6 grams) of water. All eight modified projectiles exhibited substantial cooling effect in the first experiment. In particular, the peak internal surface temperature can be reduced as much as 40% from the standard projectile. This can be seen from figures in Appendix III, where internal surface temperatures are designated by S₁, S₂, and S₃. Among the

(3) The values on the upper side of the barrel are dimensionless.

eight experiments of modified projectiles the first three rounds #1, #2, and #3 (specified in Fig. II-1) are judged to provide satisfactory results. For test projectiles #4 through #8 data obtained in a short time after the firing are satisfactory. However, because of the separation of the aluminum cap from the projectile at approximately 1 millisecond after firing, data thus obtained are insufficient to indicate the effectiveness of the modifi-Nevertheless, these data provide a relative comparison among the projectiles #4 through #8. Based on the results of projectiles #1, #2, and #2 gives the best cooling effect through out the barrel. This modification shows that a better, uniform coating of liquid on the surface of the barrel can be achieved by squeezing liquid out from the front portion and between the copper rings of the projectile as shown in the Fig II-1 by P and F. Since the cap of projectile separated from the projectile for #5 (which has the same configuration as #2 except a larger diameter at the bottom of the projectile denoted D in Fig. II-1) this series of the test did not allow us to compare the effectiveness of projectiles \$2 and \$5. Therefore, the type \$2 is recommended III-32 Temperature Response

From Fig. II-2 we see that with liquid cooling the peak internal wall temperatures are greatly reduced. This may attribute to the liquid sealing effect that prevents the hot propellant gas from contacting the wall. It should be noted that with a pressure higher than the critical pressure of water in the barrel the evaporation effect of liquid is almost negligible. Only when the projectile has left the muzzle can evaporation be a cooling ffect. Note also that at a given instant, say 2.3 millisecond, Fig. II-2 gives a high temperature for a larger distance from the breech. This can be explained from the fact that a larger projectile velocity near the

muzzle end contributes to a larger friction heating and hence a larger temperature response.

Referring to Appendix IIIA, on external wall temperature we observed that imperature response at  $K_5$  appears to be the highest one. This is because the barrel thickness at  $K_5$  position is the thinest over the entire length of the barrel. We note also that temperature response at  $K_1$  is high although the thickness of  $K_1$  is thick. However this may be explained by the fact the core temperature inside the  $K_1$  position is hottest of the core temperatures.

## III-33 Pressure Response:

In the case of liquid cooling the peak pressure of P₁, at the breech, was cut down about 5 kpsi, compared with a standard round, while the response at other positions remain the same. This can be seen from the pressure curves of PROOF ROUND NO. 3 and PROJECTILE NO. 2 tested on June 3, 1970, Appendix III A. This is due to a pressure release to fill up the hollow space inside the modified projectile at the early stage. However, this does not seem to slow down the exit velocity. It can be seen from the following fact:

For standard projectile (without cooling PROOF ROUND NO.3) the projectile velocity at the exit,  $W_p$ , is, based on the core solution

and for modified projectile (modified Projectile No. 2) its velocity in ft/millisec. is based on experimental data,

$$\hat{W}_p = \frac{dZ_p}{dt} = 1.87696 = -0.55565\bar{t}^2 + 0.05672\bar{t}^3$$

at the exit of the barrel  $\tilde{t} = 2.38$  millisec.

$$W_D = 2079$$
 ft/sec.

The above evidence indicates that the exit velocity of the modified projectile even though

there is a drop in peak pressure. This indicates that the liquid squeezed from the lateral and front sides of the projectile on the wall of the barrel does serve as a lubricant and reduces the friction force between the wall and the projectile. This reduction in drag force provides a higher acceleration near the muzzle end for the modified projectile.

III-34 Continuous Firing

Twenty rounds of the modified projectile number 2 were tested in an experiment of continuous firing. However only ten rounds were fired when a malfunction of test gun occurred. The result of the experiment was given in Fig. III-2 III-3, III-4, and III-5. Where Fig. III-2 gives the location of temperature probes and Fig. III-3 gives the internal wall temperature measurement at 2.37" from the muzzle end without cooling. Figs. III-4 and III-5 are external wall temperature measurements with and without cooling respectively. It should be noted that there were twenty rounds of standard projectile fired during the experiment which does not allow a direct comparison with the data of modified projectiles where only ten mounds were fired. Nevertheless, we observed that with and without cooling the external temperature increases linearly with time after the first five rounds. Although based on the single shot experiment the heat transfer behind the projectile can be reduced by liquid cooling, the combined total cooling effect under continuous firing needs further investigation before conclusions can be reached.

#### IY FORMULATION OF THEORETICAL ANALYSIS

#### IV-1 General Consideration

Consider that projectiles are continuously fired with a certain frequency. The analysis of the gas dynamics behind the projectile is then basically a viscous, compressible periodic flow with heat transfer. Although the analysis of gas flow without liquid cooling is not contained in the original proposal it is included here because with some modification the solution can be extended to the flow with liquid cooling.

The mathematical analysis consists of two essential parts. They are the gas core flow where the viscosity and conductivity are not important and the boundary layer flow where the viscosity and conductivity plays the major role. This division is based on the order of magnitude analysis of an unsteady viscous flow in the following. From the characteristic of the viscous diffusion of an unsteady flow it is known (for example see Chapter V of Reference (4)) that thickness of the velocity boundary layer,  $\frac{\Gamma_0}{2}$ , at a given time under an accelerated flow is the characteristic length, t, the characteristic time, and , v, the kinematic viscosity of the propellant gas. Also it is known (for example see Chapter XII, p. 270 Effect of Prandtl Number of Ref. (4)) that the temperature boundary layer is of same order as the velocity layer if the Prandtl number of the fluid is of the order of magnitude one. Consider that for the present problem £ is the radius of the barrel, 0.6 inches and t, the duration of the projectile in the barrel, 2 milliseconds. Then the maximum boundary layer thickness is only one hundredth of the radius. Therefore 99% of the gas flow near the center of the barrel is not affected by the viscosity and the condictivity of the fluid. Hence a core analysis may be performed independently of barrel wall conditions. When the core solution is obtained the boundary

layer solution can be solved. Also when the cooling liquid film is included, the analysis in the boundary layer becomes a rather complicated two-phase flow. Fig. IV-1 illustrates the division of the analysis in the following sections.

#### IV-2 Assumptions

According to the general physical understanding, the following assumptions are made.

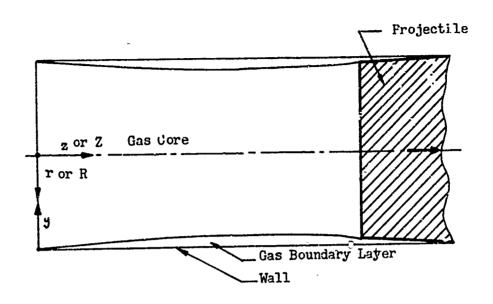

- (1) The flow is not too far away from the laminar flow and the Navier-Stokes Equations can be used for the present analysis.
- (2) The gravitational force is negligible.
- (3) The flow is axially symmetric (i.e.,  $\frac{\partial}{\partial \phi} = 0$ ) and there is no circumferential velocity component (i.e., V = 0).
- (4) The liquid layer is incompressible, and the gas is compressible.
- (5) The flow is periodic in time.
- (6) The wall is smooth but non-isothermal.
- (7) Transport properties are constant.

#### IV-3 Governing Equations

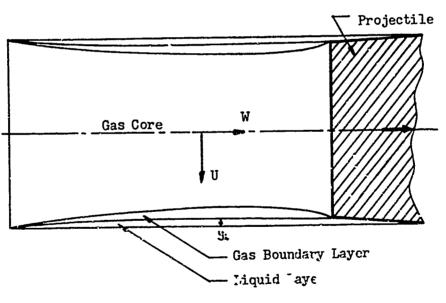

It will be convenient to take the cylindrical coordinate system with axis being the center line of the barrel. Let (U,V,W,) be the velocity components in the direction of  $(R,\phi,Z)$  respectively. Then U,W,T,P are functions of  $(\bar{t},R,Z)$  (see Fig. IV-1). For the gas stream(without subscript):

(A) Continuity equation

$$\frac{\partial \bar{e}}{\partial \bar{t}} + \frac{1}{R} \frac{\partial}{\partial R} (\bar{e}RU) + \frac{\partial}{\partial \bar{z}} (\bar{e}W) = 0$$
 (4-1)

(a) Flow without cooling

(b) Flow with cooling

Fig. IV-1. Schematic Drawing of Flow Fields

(B) Momentum equations

I

R-direction,

$$\overline{\rho}\left(\frac{\partial U}{\partial \overline{\xi}} + U\frac{\partial U}{\partial R} + W\frac{\partial U}{\partial Z}\right) = -\frac{\partial P}{\partial R} + \mu\left[\overline{\nabla}U + \frac{1}{3}\frac{\partial}{\partial R}(\overline{\nabla}\cdot\underline{\xi}) - \frac{U}{R^2}\right] (14-2)$$

where p is the viscosity of the gas, and

$$\frac{?}{P} = \frac{1}{R} \frac{\partial}{\partial R} (RU) + \frac{\partial W}{\partial Z}$$

$$\nabla^{2} = \frac{1}{R} \frac{\partial}{\partial R} (R\partial_{R}) + \frac{\partial^{2}}{\partial Z^{2}}$$

$$\nabla^{3} = \frac{1}{R} \frac{\partial}{\partial R} (R\partial_{R}) + \frac{\partial^{2}}{\partial Z^{2}}$$

Z-direction,

$$\overline{\rho} \left( \frac{\partial \overline{w}}{\partial \overline{t}} + \overline{u} \frac{\partial R}{\partial w} + \overline{u} \frac{\partial S}{\partial w} \right) = -\frac{\partial R}{\partial w} + \overline{u} \left( \overline{\nabla}^2 w + \frac{1}{3} \frac{\partial}{\partial \overline{z}} (\overline{\nabla} \cdot \underline{S}) \right)$$
(4-3)

(C) Energy equation

$$\overline{\varrho} \operatorname{cr} \left( \frac{\partial \overline{t}}{\partial \overline{t}} + \overline{U} \frac{\partial \overline{t}}{\partial R} + \overline{W} \frac{\partial \overline{t}}{\partial Z} \right) = \frac{k}{R} \frac{\partial}{\partial R} R \frac{\partial \overline{t}}{\partial R} + k \frac{\partial^2 \overline{t}}{\partial Z^2} + \frac{\partial \overline{t}}{\partial R} + \overline{U} \frac{\partial \overline{t}}{\partial R} + U \frac{\partial \overline{t}}{\partial R} + W \frac{\partial \overline{t}}{\partial R} + W$$

where

$$\overline{\underline{\phi}} = 2\left[\left(\frac{\partial U}{\partial R}\right)^2 + \left(\frac{U}{R}\right)^2 + \left(\frac{\partial W}{\partial R}\right)^2\right] + \left(\frac{\partial U}{\partial R} + \frac{\partial W}{\partial R}\right)^2 - \frac{2}{3}\left(\frac{1}{R}\frac{\partial}{\partial R}(RU) + \frac{\partial W}{\partial R}\right)^2 \quad (4-5)$$

 ${\bf k}$  is the thermal conductivity of the gas,  ${\bf Q}_{\hat{\bf h}}$  is the heat generation due to combustion.

(D) Equation of state

$$\hat{\Gamma} = \vec{\rho} \vec{R} TC_{\epsilon}$$
 (4-6)

where  $C_{\rm c}$  is a correction factor depending on the range of pressure under consideration. For a pressure below 37 kpsi  $C_{\rm c}$  is 0.726 approximately.

For the liquid layer (with subscript  $\ell$ ):

(A) Continuity equation

$$\frac{1}{R}\frac{\partial}{\partial R}(RU_k) + \frac{\partial}{\partial z}W_k = 0$$
 (4-7)

(B) Momentum equations

K-direction,

$$\overline{f}_{i}\left(\frac{\partial U_{i}}{\partial E} + \overline{f}_{i}\frac{\partial U_{i}}{\partial R} + \overline{W}_{i}\frac{\partial U_{i}}{\partial R}\right) = -\frac{\partial P}{\partial R} + \underline{W}\left[\frac{1}{R}\frac{\partial R}{\partial R}R\frac{\partial U_{i}}{\partial R}\right] + \frac{\partial \overline{U}_{i}}{\partial R} - 2\frac{\overline{U}_{i}}{R}\right]$$

$$(11-8)$$

where  $\bar{\rho}_{\underline{\ell}}$  and  $\mu_{\underline{\ell}}$  are density and viscosity of the liquid layer respectively. Z-direction,

$$\frac{\partial \tilde{W}_{1}}{\partial \xi} + \tilde{U}_{1} \frac{\partial \tilde{W}_{2}}{\partial R} + \tilde{W}_{1} \frac{\partial \tilde{W}_{2}}{\partial Z} = -\frac{\partial \tilde{L}_{1}}{\partial Z} + \mathcal{U}_{1} \left[ \frac{1}{R} \frac{\partial}{\partial R} R \frac{\partial \tilde{W}_{2}}{\partial R} + \frac{\partial^{2} \tilde{W}_{1}}{\partial Z^{2}} \right]$$
(4-9)

(C) Energy equation

$$\overline{R}_{C}(R)\left(\frac{\partial L}{\partial E} + \overline{U}_{1}\frac{\partial L}{\partial R} + \overline{V}_{2}\frac{\partial L}{\partial S}\right) = K_{1}\left(\frac{1}{16}\frac{\partial R}{\partial E}\left(R\frac{\partial L}{\partial R}\right) + \frac{\partial^{2}L}{\partial S^{2}}\right)$$
(h-10)

 $T_{\ell}$  and  $k_{\ell}$  are temperature and thermal conductivity respectively. Here we have nine unknowns (i.e., liquid  $U_{\ell}$ ,  $W_{\ell}$ ,  $P_{\ell}$ ,  $T_{\ell}$ , and gas U,W,P,  $T,\bar{\rho}$ ) with nine equations.

## IV-4 Boundary and matching conditions

(1) Boundary Conditons

At wall 
$$(R = R_0)$$
  
 $\forall e(\bar{t}, R_0, \bar{t}) = 0$  (1-11)

$$T_{\underline{t}}: T_{\underline{t},\infty}(\underline{x},\overline{e}) \tag{14-12}$$

きころしり At breech

$$\mathbf{U} = \mathbf{c} \tag{4-13}$$

At the projectile at any instance  $Z = Z_p(t)$ 

$$P = P_{c} (\tilde{\epsilon} R, Z_{p}(\epsilon))$$

$$W = W_{c} (\tilde{\epsilon}, R, Z_{p}(\epsilon))$$
(4-14)

- (2) Matching conditions (the subscript i denoting the gas-liquid interface)
  - (A) Kinematic condition

The continuity of velocity components

$$U_{k_{k}} = U_{k} \qquad (h-15)$$

(B) Dynamic condition

The continuity of normal stress
$$P_{1} = \frac{2M_{1}}{\sqrt{2R}} \left(\frac{\partial U_{1}}{\partial R}\right) = P_{1} + 2M_{2} \left(\frac{\partial U_{1}}{\partial R}\right). \tag{3-16}$$

$$M_{\mu}\left(\frac{\partial W_{\lambda}}{\partial R} + \frac{\partial U_{\lambda}}{\partial Z}\right)_{\lambda} = M\left(\frac{\partial W}{\partial R} + \frac{\partial U}{\partial Z}\right)_{\lambda} \tag{4-17}$$

WE WEST AND THE PROPERTY OF TH

## (C) Thermodynamic conditions

The conservation of energy

$$\Delta h + k_{\ell} \left( \frac{\partial T_{\ell}}{\partial R} \right)_{\Lambda} = K \left( \frac{\partial T}{\partial R} \right)_{\Lambda}$$
 (4-18)

The continuity of temperature

$$T_{2} = T_{A} \tag{14-19}$$

where  $\Delta h$  is the heat of evaporation. However  $\Delta h$  is negligible for the operating pressure near or above the critical pressure of the fluid. For water the critical pressure is 3.21 kpsi.

#### IV-5 Nondimensionalization

We make the above variables dimensionless by letting

$$u_{p} = \frac{U_{1}}{U_{r}} \quad W_{1} = \frac{W_{2}}{U_{r}} \quad p_{1} = \frac{P_{k}}{P_{1}U_{r}^{2}} \quad 0_{2} = \frac{T_{1}}{T_{r}} \quad 2 = \frac{Q_{k}L}{P_{1}G_{1}T_{1}U_{r}}$$

$$u = \frac{U}{U_{r}} \quad w = \frac{W}{U_{r}} \quad p_{2} = \frac{P}{P_{1}U_{r}^{2}} \quad 0 = \frac{T}{T_{r}} \quad q_{2} = \frac{3L^{2}}{U_{1}^{2}} \quad (i_{1}-20)$$

$$v = \frac{R}{U_{2}} \quad 3 = \frac{Z}{L} \quad t = \frac{E}{L} \quad p_{2} = \frac{P}{P_{2}}$$

$$where \quad \overline{U}_{2}, \quad \rho_{r}, \quad L, \quad t_{r}, \quad T_{r}, \quad are \ dimensional \ characteristic \ quantities$$

defined as follows with typical values in the parentheses.

L -= characteristic length of the barrel (3.478 ft)

U_ =projectile velocity at exit. (2130.8 ft/sec)

$$t_r$$
 =characteristic time  $\frac{L}{v_r}$  (1.6322 millisec.)

 $\rho_r$  = density of the propellant gas right behind the projectile at the exit (5.504  $lb_m/ft^3$ )

$$T_r = \text{characteristic temperature} \frac{U_r^2}{R}$$
 (2173.9 °R)

D = diameter of the barrel (1.2 inch)

$$P = \text{characteristic pressure } \rho_r U_r^2 \text{ (5.388 kpsi)}$$

 $M_0$  = mclecular weight of the propellant gas (23.805)

$$\vec{R}$$
 = Gas constant  $(\frac{3545.33}{M_{\odot}} = 64.9142 \frac{\text{ftlbf}}{1b_{m}})$ 

 $\Delta h = 1$ atent heat

with known transport properties

$$\mu = 2.8 \times 10^{-5} \frac{m}{\text{ftsec}}$$
 (see TABLE IVA)

$$\eta = 1.243$$
 $\mu_{\ell} = 0.071 \times 10^{-3}$ 
Ib in ftsec

$$K_g = 0.35 \text{ Btu/hr.ft}^{\circ} R$$
 (500°F)

$$c_{p} = 0.435 \text{ Btu/1b}^{\circ} R$$
 (gas)

$$c_y = 0.35 \text{ Btu/lb}^{\circ} R$$
 (gas)

Define the dimensionless parameter:

Reynolds number 
$$R_e = \frac{U_r \rho_r L}{\mu}$$

Prandtl number 
$$P_r = \frac{c_p \mu}{K}$$
,  $P_{r\ell} = \frac{c_p \ell^{\mu} \ell}{K_{\ell}}$ .  
Eckert number  $E = \frac{U_r^2}{c_p T_r} = \frac{1-1}{1}$ ,  $E_{\ell} = \frac{U_r^2}{c_p \ell^T r}$ 

We have then the governing equations, in dimensionless form as

- (1) For the gas stream
  - (A) Continuity equation

$$\frac{\partial P}{\partial t} + \frac{1}{r} \frac{\partial}{\partial r} (P r u) + \frac{\partial}{\partial z} (P w) = 0 \qquad (4-21)$$

(B) Momentum equations

$$\ell\left[\frac{\partial f}{\partial t} + H\frac{\partial f}{\partial t} + m\frac{\partial f}{\partial t}\right] = -\frac{\partial f}{\partial t} + \frac{1}{Ke}\left[\nabla^2 H - \frac{H}{t^2} + \frac{1}{3}\frac{\partial}{\partial t}(\nabla^2 f)\right](1-22)$$

$$P\left[\frac{\partial \omega}{\partial t} + u \frac{\partial w}{\partial t} + w \frac{\partial w}{\partial s}\right] = -\frac{\partial h}{\partial s} + \frac{1}{R_e} \left[\nabla^2 w + \frac{1}{2} \frac{\partial}{\partial s} \left(\nabla \cdot \frac{v}{s}\right)\right] (h-23)$$

where

$$\Delta = \frac{1}{\sqrt{5}} \left( \lambda \frac{5}{5} \lambda \right) + \frac{5}{5} \frac{3}{5}$$

$$\Delta = \frac{1}{\sqrt{5}} \frac{5}{5} \left( \lambda n \right) + \frac{5}{5} \frac{3}{5}$$

R-direction

$$\frac{P_{1}}{P_{1}}\left(\frac{\partial u_{1}}{\partial t} + u_{2}\frac{\partial u_{1}}{\partial r} + u_{3}\frac{\partial u_{1}}{\partial s}\right) = -\frac{\partial P_{2}}{\partial r} + \frac{1}{R_{2}}\frac{u_{1}}{u_{1}}\left[\nabla^{2}u_{2} - 2\frac{u_{1}}{r^{2}}\right]$$
(4-27)

Z-direction

$$\frac{\Re\left(\frac{\partial w_{k}}{\partial t} + u_{1}\frac{\partial w_{k}}{\partial r} + w_{2}\frac{\partial w_{k}}{\partial z}\right) = -\frac{\partial k_{k}}{\partial z} \cdot \frac{1}{\Re e} \frac{u_{1}}{u_{1}} \left[\nabla^{2} w_{2}\right]$$
 (4-28)

(C) Energy Equation

$$\left(\frac{\partial G_{P}}{\partial t} + U_{P} \frac{\partial G_{P}}{\partial x} + W_{P} \frac{\partial G_{P}}{\partial y}\right) = \frac{1}{P_{P} R_{e}} \frac{\rho_{P} M_{P}}{\rho_{e} M_{P}} \left[ \nabla^{2} G_{P} \right] \qquad (4-29)$$

(3) Boundary and matching conditions

At wall 
$$(r = r_0)$$

$$W_i = W_i = c$$

$$Q_i = Q_{iw}(t, i)$$

$$(1i-30)$$

At breech (z = 0)

$$p = p(t, r, 0)$$

$$w = 0$$
(4-31)

. .

 $\theta = \theta(t,r,^{\circ})$ 

At projectile 
$$(z = z_p)$$
  
 $p = P_p(c,r, x_p)$   
 $w = w_p(c,r,z_p)$   
 $u = 0$  (4-32)  
 $\theta = \theta_p$ 

At interface

$$u_{l.i} = u_{i}, w_{l.i} = w_{i}$$
 (4-33)

$$\left(\frac{b_{k}+\frac{\lambda u_{k}}{\lambda r}\frac{\partial u_{k}}{\partial r}\right)_{k}=\left(\frac{b_{k}+\frac{\lambda u_{k}}{k e}\frac{\partial u_{k}}{\partial r}\right)_{k}.$$
(4-34)

$$\frac{m}{n^3} \left( \frac{5\lambda}{9m^3} + \frac{53}{9n^3} \right)^2 = \left( \frac{5\lambda}{9m} + \frac{93}{9n} \right)^2$$

$$\frac{K}{K^{2}} \left( \frac{\partial A}{\partial \theta^{2}} \right)^{V} = \left( \frac{\partial A}{\partial \theta^{2}} \right)^{V}. \tag{17-35}$$

Obviously the above problem is difficult to solve. However with the division of flow region given in IV-1 we may proceed to solve the problem in the following sections.

#### V-1 Core Problem

From the general consideration in Section IV-1 we found that the boundary layer thickness is very small compared with the diameter of the barrel. The propellant gas flow near the center of the tarrel can be solved by neglecting the boundary layer. Accordingly, the analysis becomes that of one-dimensional unsteady compressible flow with the governing equations as follows:

$$\frac{\partial \ell}{\partial t} + \frac{\partial}{\partial s} (\ell \omega) = 0 \tag{5.1}$$

$$\left(\frac{\partial \omega}{\partial t} + \omega \frac{\partial \omega}{\partial s}\right) = -\frac{\partial P}{\partial s} \tag{5-2}$$

$$\ell\left(\frac{\partial \theta}{\partial t} + \omega \frac{\partial \theta}{\partial \delta}\right) = E\left(\frac{\partial P}{\partial t} + \omega \frac{\partial \rho}{\partial \delta}\right) + \ell_{core}$$
 (5-3)

$$\beta = C_{c} \rho = 0.726 \rho \theta \tag{5-4}$$

where  $\rho$ , w,p and  $\theta$  are unknown core density, velocity, pressure, and temperature. q is the heat generation of the propellant gas.

The above governing equations are solved with the following boundary and initial conditions

at 
$$z = z_p(0)$$
  $w = 0$   $p = \beta_b(t)$  (breech pressure)

(5-5)

at  $z = z_p(t)$   $w = w_p = \frac{dz_p}{dt}$ 

where  $z_p(t)$  is the projectile position at the given instant. For the present case  $z_p(0) = 0.04642$ .

At  $z_p$  = 0.268 (where data is available)  $\rho$  = 2.21 (5-6) where  $\rho$  is determined in Appendix VA.

the form the second of the second of the second second second second second second second second second second

at 
$$t = 0$$
  $w = 0$  (5-7)

The projectile position as function of time is obtained from the experiment through the method of least squares as (standard round)

$$z_p = 0.04642 + 0.92578 t^2 - 0.11475 t^3 - 0.00919t^4$$
 (5-8)

Thus we have the projectile velocity

$$w_p = \frac{dz_p}{dt} = 1.85156 - 0.34425t^2 - 0.03676t^3$$
 (5-9)

Equations (5-8) (5-9) are plotted in Fig. V-1 and Fig V-2.

### V-2 Method of Solution

We assume that the density is a function of time only. This assumption leads to a sufficient condition of Lagrange's assumption which has been shown by Heiney (5) to be an adequate one for the interior ballistic problem. Under this assumption the pressure and temperature are still functions of the position, z, and time, t. From Eq. (5-1) we have

$$\frac{\partial w}{\partial z} = -\frac{1}{\rho} \frac{\partial \rho}{\partial t}$$
,  $\rho = \rho(t)$ 

Integrating with respect to z

$$w = -\frac{1}{0} \frac{dc}{dt} z + f_p(t)$$

Noting that at z = 0, w = 0, to that  $f_n(t) = 0$ , and that at  $z = z_p$ ,  $w = w_p$ , we have

$$w = \frac{w}{z_p} z \tag{5-10}$$

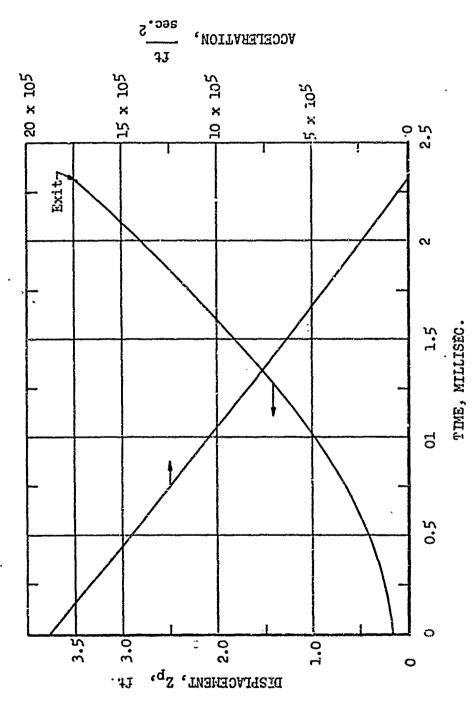

$$\frac{dz_{p}}{dt} = \frac{1}{\rho} \frac{d\rho}{dt}$$
 (5-10a)

Integrating Eq (5-10a) with respect to t

$$\rho(t) = \frac{C'}{z_{D}}$$

where C' is integration constant and is determined as C' = 0.5928 by using the condition in Eq (5-6).

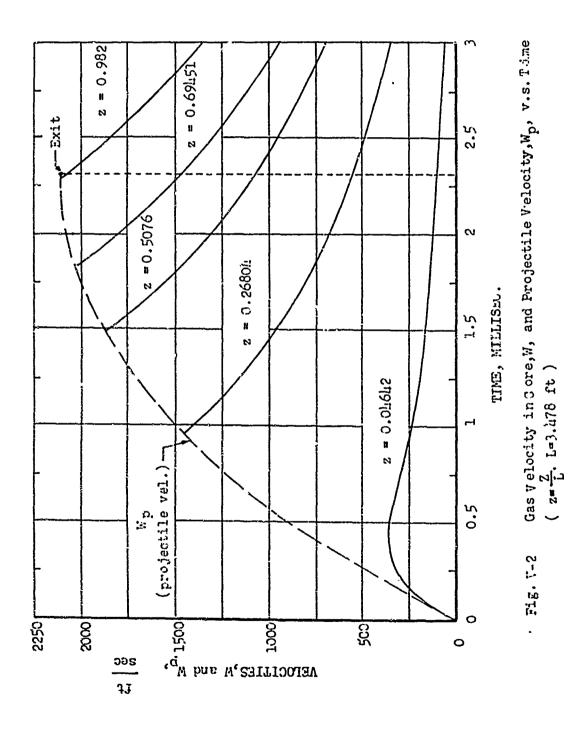

AND THE PROPERTY OF THE PROPER

THE ROLL WAS ASSESSED TO THE WAS ASSESSED TO THE WAS ASSESSED TO THE WAS ASSESSED. THE WAS ASSESSED TO THE WAS ASSESSED TO THE WAS ASSESSED TO THE WAS ASSESSED.

3. V.1 Projectile Displacement and Acceleration v.s. Time

The sufficient of the sufficie

The second of the second secon

Then

$$\rho(t) = \frac{0.5928}{z_{p}(t)}$$
 (5-11)

To find the pressure distribution we substitute Eqs. (5-10a) and (5-11) into

(5-2) and integrate to obtain
$$P(z,t) = P_b(t) - \frac{C'(z^2 - z^2)(0)}{z^2}$$

$$P(z,t) = P_b(t) - \frac{(5-12)}{z^2}$$

after satisfying the boundary condition (5-5). The temperature profile follows readily by substituting (5-10a)(5-11), and (5-12) into Eq. (5-4).

That is

$$\theta = \left[\frac{p_b z_p}{0.5928} - \frac{\dot{z}_p (z^2 - z_p^2(c))}{2 z_p}\right] \frac{i}{0.726}$$
 (5-13)

From energy equation (5-3) we obtained the heat generation of the propellant

88

$$q = \frac{c'(z^{2}-z_{p}^{2}(o))}{2z_{p}^{2}} \left(\frac{\ddot{z}_{p}}{\gamma} + \frac{\dot{z}_{p}\dot{z}_{p}^{*}}{z_{p}}\right) + \left(\frac{p_{b}\dot{z}_{p}}{z_{p}} + \frac{\dot{p}_{b}}{\gamma}\right) - \frac{\dot{z}_{p}\dot{z}_{p}^{*}}{z_{p}^{3}\gamma} z_{p}^{2}(o) c'$$
(5-14)

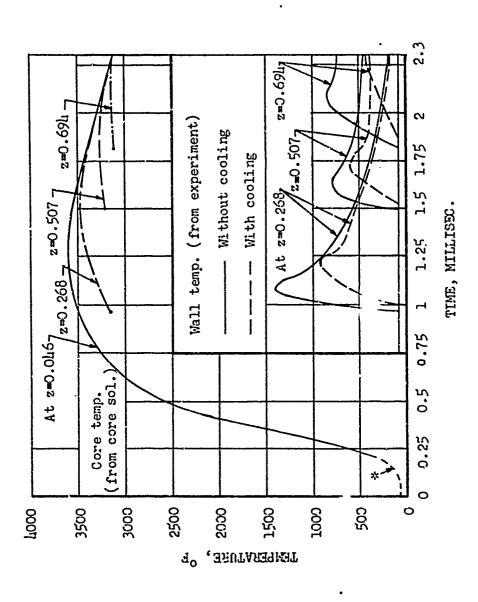

where the dot denotes the differentiation with respect to time (i.e.,

 $\frac{d(\ )}{dt}$  = ()). Therefore we have solved the core solution of the interior ballistic problem in terms of the projectile motion,  $z_p(t)$ , breech pressure,  $p_b(t)$ , for IMR propellant. The solution is computerized in Appendix  $\overline{p}_b$ . The propellant gas velocity, w, behind the projectile, the temperature,  $T = QT_r$ , the density,  $\rho$ , pressure, p, and heat generation q are all plotted in figures V-2 V-3, V-4, II-3, and V-5.

## V-3 Result and Discussion

Although many works on core solution of the interior ballistics are available such as Spurk (6), Heiney (5) Love and Pidduck (7), Vottis (8), and Carriere [9] the present solution has an advantage that the burning rate of

Ţ

not assumed, instead, they are all absorbed in he specified boundary conditions of projectile motion and the breech pressure. Both boundary conditions come directly from experimental measurements. Hence the error due to assumptions of burning rate and friction effects are eliminated. Also the present solution has an advantage of simplicity in analytical form over the solution obtained from theory of characteristics.

In the theory of characteristics the solution must be obtained from series of numerical evaluation of characteristics. Furthermore when heat generation is included in the gas flow the characteristic ablution can become very complicated. Therefore the present solution although less versatile is more desirable for prediction of convective heat themselves through the gas boundary layer.

In Fig. V-2 we plot both projectile velocity and fluid velocity behind the projectile. The dashed line is the experimental data obtained in Fig. V-1 while the solid lines show the theoretical gas velocity. It is interesting, to note that the gas velocity near the breech end first increases and then decreases, but at a larger distance the gas velocity decreases monotonically with time.

Fig. V-3 shows the predicted core temperature and measured wall temperature with and without cooling. The difference in the core temperature and wall temperature at a given time drives the heat flux from the core to the barrel. We note that at any given time the core temperature behind the projectile always decreases from the breech to the muzzle end. However the wall temperature at a given time with and without cooling increases from the breech to the muzzle end. More will be discussed in Chapter VI when boundary

layer analysis is given. Fig. V-4 gives the density variation with respect to time. The dashed at the small time was computed from the core solution. However in this period because propellant combustion is strong it is felt that the core solution should not be taken too seriously for its validity. Fig. V-5 is the plot of heat generation in the core. It is obvious that generation is the largest near the breech end. About 80 percent of total heat generation is confined in the ten percent of the barrel length near the breech.

With the core solution obtained the heat transfer and gas dynamics of boundary layer flow behind the projectile may be analyzed.

#### VI BOUNDARY LAYER SOLUTION WITHOUT COOLING

VI-1 Governing Equation and Similarity Transform

As already discussed in Chapter IV there are two flow regions in the barrel. One is the core stream in the central portion of the barrel and the other is the boundary layer near the wall. This boundary layer flow will be analyzed here. According to the boundary layer theory (see Ref. (4)) the pressure in the boundary layer is still that of core adultion. The other dependent variables such as density, temperature, velocity, and neat generation must now be a function of an additional variable r which does not appear in the core analysis. The core solution how becomes the outer boundary condition of the boundary layer while the wall condition is the other condition of the flow. Only when this flow is solved can the heat transfer between the propellant gas and the barrel be predicted. This problem is much more complicated to analyze in comparison with steady boundary layer flow because there are three independent variables r, t,z and both outer and wall condition are non isothermal and unsteady.

In dealing with this complicated problem, we note that Reynolds number in the flow is Re =  $\frac{p_r U_r L}{\mu} = 1.45 \times 10^9$  (or, in the conventional definitions Re =  $\frac{p_r U_r R_o}{\mu} = 2.9 \times 10^7$ ) which is very large. Consequently, the boundary layer thickness, in order of  $\frac{1}{\sqrt{Re}}$ , is very small. Therefore, for the boundary layer flow we shall define the new variables

 $y = \sqrt{Re} (r_0 - r)$ , distance from the internal wall of the barrel, and

Lu =  $\sqrt{Re}$  u, velocity in y-direction (6-1) to stretch the small quantities  $(r_0 - r)$  and u so that each term in the governing equations in these new variables is of order of unity. Upon neglecting the terms of small order we reduced the Eqs. (4-21) through (4-24) in terms of new variables, y and u, of gas boundary layer as

Continuity Equation

$$\frac{\partial \rho}{\partial t} + \frac{\partial}{\partial y} u \rho + \frac{\partial}{\partial z} \rho w = 0$$
 (6-2).

Momentum Equations

In y - direction

$$-\frac{\partial P}{\partial y} = 0 \tag{6-3}$$

In z - direction

$$\rho \left( \frac{\partial w}{\partial t} + u \frac{\partial w}{\partial y} + w \frac{\partial w}{\partial z} \right) = -\frac{\partial p}{\partial z} + \frac{\partial^2 w}{\partial y^2}$$
 (6-4)

Energy Equation.

$$\rho(\frac{\partial\theta}{\partial t} + \frac{\partial\theta}{\partial y} + w\frac{\partial\theta}{\partial z}) = \frac{1}{p_{r_{g}}} \frac{\partial^{2}\theta}{\partial y^{2}} + E(\frac{\partial p}{\partial t} + u\frac{\partial p}{\partial y} + w\frac{\partial p}{\partial z})$$

$$+ \dot{E} \left(\frac{\partial w}{\partial y}\right)^2 + q_{B,I,.} \tag{6-5}$$

Equation of State

$$p = \rho \theta \ 0.726$$
 (see Eq. (5-12) for p) (6-6)

Considering the solution form obtained in the core solution we see that the independent variable z can be separated out in the boundary layer flow by setting

$$w(t,y,z) = H(t,y)z$$
  $(t,y)z$  (6-7)

Furthermore, the heat generation  $q_{B.L.}$  in Eq. (6 5) is assumed to possess the similar form of  $q_{core}$  in Eq. (5-3), that is

the similar form of 
$$q_{core}$$
 in Eq. (5-3), that is
$$q_{B.L.} = \rho(\frac{\partial \theta}{\partial t} + w \frac{\partial \theta}{\partial z}) - E(\frac{\partial p}{\partial t} + w \frac{\partial p}{\partial z}) \qquad (6-8)$$

And it is noted that the Eckert number

$$E = \frac{v_r^2}{c_p T_r} = \frac{\gamma - 1}{\gamma} \approx 0.195$$

in the present case. The term  $E(\frac{\partial \omega}{\partial y})^2$  is thus negligible compared with other terms in Eq. (6-5) which are of order of unity.

officeries and the control of the interior of the control of the c

Substituting Eqs. (6-6), (6-7), and (6-8) in to Eqs. (6-2) to (6-5) we have the resulting governing equations

$$\frac{\partial \rho}{\partial r} + \frac{\partial \gamma}{\partial r} = \frac{\partial \gamma}{\partial r} + \rho H = 0$$
 (6-9)

$$\rho\left(\frac{\partial H}{\partial t} + u \frac{\partial H}{\partial y} + H^2\right) = c^{\frac{z}{2}} + \frac{\partial^2 H}{\partial y^2}$$
(6-10)

$$-P_{r_g} = \frac{u}{\partial y} = \frac{2}{\rho^2} \left(\frac{\partial \rho}{\partial y}\right)^2 - \frac{1}{\rho} = \frac{\partial^2 \rho}{\partial y^2}$$
 (6-11)

These unsteady compressible boundary layer equations are solved with initial and boundary conditions to be described in VI-2. The method of similarity transformation will be used to solve the above problems. The method of similarity transformation can be divided into two kinds, i.e., via separation of variables and one-parameter group theory. The excellent references for the latter method can be found in the books by Hansen (10) and Ames (11) and the paper by Morgan (12).

From the present experimental result we found that  $\frac{z_p}{z_p^2}$  in equation (6-10) could be approximated by a form of  $\frac{z_p}{z_p^2} = mt^n$  as shown in Fig. vi-1, where both m and n are constants. This makes it possible to apply one-parameter group theory of similarity transform to reduce our partial differential equations into a set of ordinary differential equations which can be solved numerically. In order to satisfy the invariant requirement of the method we have to choose the similarity variables as follows

$$\eta = t^{-A}y$$

$$\rho = \xi^{1-2A} + (\eta) \qquad u = \xi^{A-1} + (\eta) \qquad (6-12)$$

$$H = \xi^{-1}f_3(\eta)$$

where

E and n are new variables in another group

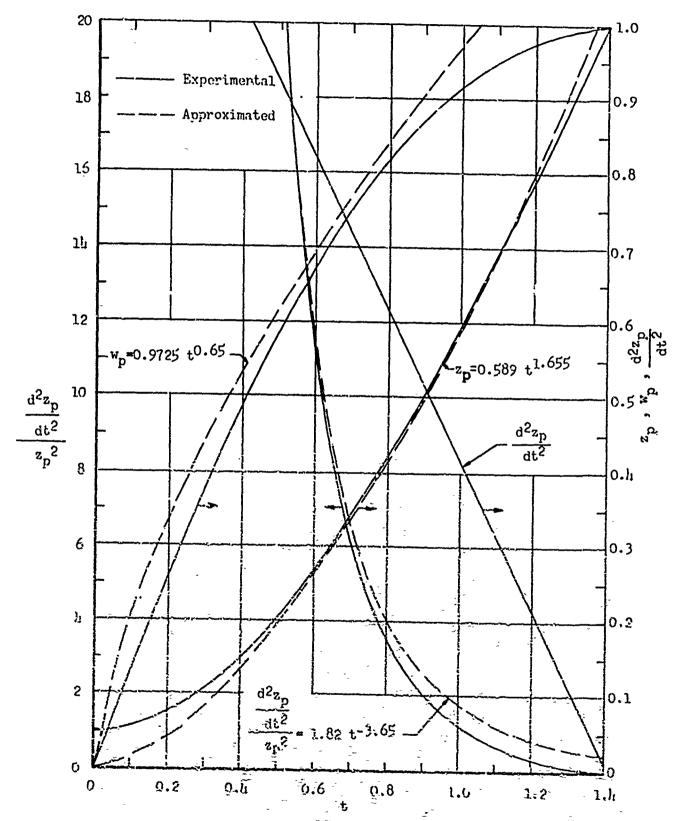

Fig. 91-1 Comparis on of Experimental and Approximated Values for Sugndary Layer Amilysis

 $A = -\frac{n+1}{2}$ , n is the index of mtⁿ

 $f_1$ ,  $f_2$ , and  $f_3$  are arbitrary functions of  $\eta$ .

Substituting Eq. (6-12) into Eqs (6-9), (6-10), and (6-11) we have a set of oridinary differential equations

$$(f_2 + \frac{n+1}{2} \eta) f'_1 + f_1 f'_2 + (f_3 + n+2) f_1 = 0$$
 (6-13)

$$(f_1f_2 + \frac{n+1}{2} nf_1) f_3' + (f_3-1)f_1f_3 - f_3'' = mc''$$
 (6-14)

$$2f_1^{-2} f_1^{'2} + P_r f_2 f_1' - f_1^{-1} f_1'' = 0$$
 (6-15)

where the primes denote the differentiation with respect to  $\eta$ . The detailed derivation is presented in Appendix VIA. From Fig VI-1 we see that

$$\frac{d^2z_p}{dt^2}/z_p^2 = mt^n$$
 can be approximated by 1.82t^{-3.65}, i.e., m = 1.82, n =-3.65.

These values give A = 1.325. The above differential equations then can be rewritten for XM140 model as

$$(f_2 - 1.325 \eta) f_1' + f_1 f_2' + (f_3 - 1.65) f_1 = 0$$
 (6-13a)

$$(f_1f_2 - 1.325 \eta f_1)f_3' + (f_3 - 1) f_1f_3 - f_3'' = 1.08$$
 (6-14a)

$$2 f_1^{-2} f_1^{2} + P_{\pi_0} f_2 f_1^{2} - f_1^{4} f_1^{4} = 0$$
 (6-15a)

VI-2 Initial and Boundary Conditions

It is seen that five conditions that combined initial and boundary conditions are needed to solve the problem.

At the wall, y = 0, or  $\eta = 0$ , the density related function can be approximated from the experimental data(see Appendix VI B) as  $f_1(x) = 3.2$ 

and the no-slip and impermeable condition give

$$(6-16)$$

$$f_2(0) = 0$$
 for  $u = 0$ 

$$f_3(0) = 0 \qquad \text{for } w = 0$$

m, no gradients in y direction can exist, From the core stream, thus

$$f_1^*(\infty) = 0$$
 for  $\frac{\partial \rho}{\partial y} = 0$ 

$$(6-17)$$
 $f_3^*(\infty) = 0$  for  $\frac{\partial w}{\partial y} = 0$ 

#### VI-3 Method of Solutions

The IBM 360 CSMP(Continuing System Modeling Program) computer language was employed to provide the numerical solutions. As CSMP program handles initial value problem, only condition (6-16) at n=0 can be used. Therefore, we must guess the values of  $f_1'(0)$  and  $f_3'(0)$  such that  $f_1'(\infty) = 0$ and  $f_3'(\infty) = 0$  at  $\eta \to \infty$ . After several attempts were made we found that  $f_1^*(o) = -0.12$  and  $f_3^*(o) = 2.024$  provided us satisfactory results. The computerized print-plots are presented in table and figures in Appendix VIC.

We examine the convergence of solutions in the following manner. From Eq (6-7) we have  $p = t^{1-2A} f_1(\eta) = t^{-1.65} f_1(\eta)$ . Now as  $\eta \to \infty$  the density in the boundary layer,  $\rho$ , should approach  $\ell$  core =  $\frac{C'}{z}$ , where C' = 0.5928 and  $z_p = 0.589t^{1.65}$  approximated from Fig. IV-1. Thus

$$\rho(t,\infty)=t^{-1.65}$$
  $f_1(\infty)=\frac{0.5928}{0.589}$   $t^{-1.65}=t^{-1.65}$ 

that is,  $f_1(\infty) = 1$  at  $\eta \to \infty$ . This condition is satisfied by the numerical solution as shown in the first figure in Appendix VIC.

From Eq. (6-13a), as  $\eta \to \infty$ ,  $f_1^* \to 0$ ,  $f_2^* \to 0$ , then  $f_3 = 1.65$ . From the computerized print-plots it is seen that  $f_2$  converges to -2.426 where  $f_2' \rightarrow 0$  satisfying  $\frac{\partial \rho}{\partial y} = 0$ , and  $f_3$  converges to 1.65, as n goes larger.

Finally, Eqs. (6-12) and (6-7) can be rewritten as

SAMINA SOLAS SIMPLEASE WAS A CONTRACT SOLAS SAME THE WATER OF

$$\eta = t^{-1.325} \gamma$$
 (6-18)

$$\rho = t^{-1.65} f_1(n)$$
 (6-19)

$$u = t^{0.325} f_2(n)$$
 (6-20)

$$w = Hz = t^{-1}\dot{x}_3(n) z$$
 (6-21)

With these expressions and the table in Appendix VIC we are able to evaluate the values of  $\rho$ , u, and w for any given value of  $\eta$ .

Now we examine the validity of our prior boundary layer approximation, in which we assume the boundary layer is thin compared with barrel diameter. To evaluate the maximum boundary layer thickness that occurs at the maximum time t=1.409 dimensionless, (the time the projectile exits) we observe from  $F_3$  plot in Appendix VIC that the velocity approaches the core solution  $f_3 \rightarrow 1.65$  at  $\eta \rightarrow 4$ . That is in y dimensionless coordinate

$$y = t^{1.325} \eta = (1.409)^{1.325} 4 = 6.3$$

The boundary layer thickness is estimated to be

$$(r_0-r) = \frac{y}{\sqrt{Re}} = \frac{6.3}{\sqrt{1.45 \times 10^9}} = 1.66 \times 10^{-4}$$

$$\gamma_0 = \frac{R_0}{L} = \frac{0.6}{42} = 1.43 \times 10^{-2}$$

thus

$$\frac{(r_0-r)}{r_0} = \frac{1.66 \times 10^{-4}}{1.43 \times 10^{-2}} = \frac{1}{86}$$

It is readily seen that the ratio of boundary layer thickness to the barrel radius is  $\frac{1}{86}$  which is about one percent of the barrel radius. Therefore, we conclude that our prior boundary layer approximation is valid.

## VI-4 Heat Transfer

Now we should consider heat flux from the gas to the cold wall and the heat transfer coefficient in the temperature field.

in in in its states and the contract of the co

From the equation of state and the expressions for p and p in Eqs(5-12) and (6-19), respectively, we obtain

and (6-19), respectively, we obtain 
$$\theta = \frac{p}{0.726\rho} = t^{1.65} \frac{t_1^{-1}}{0.726} \{p_b - 1.08t^{-3.65} - \frac{z^2 - z_p^2(0)}{2}\}$$
 (6-22)

Here we should remark that the boundary condition  $f_1(0) = 3.2$  in Eq(6-16) was approximated one. For the detailed evaluation is referred to Appendix VIB. In this approximation we did not take into account of the short time interval in which the temperature changed from room temperature to the approximated mean value,  $750^{\circ}$ F. Therefore, the temperature profile obtained from Eq. (6-22) and heat transfer formulas must exclude that short time interval.

Under the above restriction the local heat transfer is given by Fourier's law

$$q = -k \frac{\partial T}{\partial R} \Big|_{R = R_0}$$
 (6-23)

Recall that

7

......

$$y = \sqrt{Re} \left( \frac{R_0}{L} - \frac{R}{L} \right) = \sqrt{Re} \left( \gamma_0 - \gamma_0 \right)$$

Pefining Nu =  $\frac{qL}{k Tr} = \frac{hL}{k}$ , Nusselt number, from the modified Newton's cooling law q = hTr we obtain the dimensionless form of Eq.(6-23) as,

$$Nu = \sqrt{Re} \frac{\partial \theta}{\partial y} \bigg|_{y=0}$$
 (6-24)

The expression for  $\frac{\partial \theta}{\partial y}\Big|_{y=0}$  can be derived from Eq. (6-22). Upon substituting we obtain

$$N_{H} = -\sqrt{Re} \frac{f_{1}^{(6)} + \frac{0.325}{(3-3)(6)}}{f_{1}^{(6)} + 0.726} \left[ f_{1}^{(6)} - 1.68 + \frac{-3.65}{2} (\frac{3-3}{2})^{(6)} \right]$$
 (6-25)

where  $f_1^*(o) = -0.12$ ,  $f_1(o) = 3.2$  are obtained previously from similarity solution. Thus we have for laminar unsteady compressible flow in a pipe with a standard projectile the local heat transfer coefficient as

$$N_{N} = \frac{hL}{K} = 0.01614 \sqrt{Re} + \frac{0.325}{(P_{b}(e) - 1.68 + \frac{3.65}{2} \frac{3^{2} - 3^{2}(0)}{2})}{(6-26)}$$

Since the last term in the equation (6-26) usually is small compared with  $\mathbf{p}_{\mathbf{b}}$  term for approximate evaluation the Nusselt number may be taken as

$$N_{\rm H} = 0.01614 \, [Re] + {\rm C.325} P_{\rm b}(t)$$
 (6-27)

where

$$p_b = dimensionless breech pressure = \frac{P_b}{\rho_r v_r^2}$$

 $\mathbf{U}_{\mathbf{r}}$  = the exit velocity

 $\rho_{\rm r}$  = the reference density right behind the projectile at the exit.

$$Re = \frac{U_{rL}}{v}$$

#### VI-5 Discussion

From the  $f_2$  print-plot in Appendix VIC we note that  $f_2(F_2)$  in computer program notation) keeps increasing till a value of  $f_1 = 1.4$  is reached. Then it starts decreasing and finally converges to a value of  $f_2 = -2.426$ . As the vertical component of gas velocity  $g_1$  relates to  $g_2$  by Eq(6-20) this means that there are two flows coming together from the wall and the core, respectively, and then joining at a region where  $g_1 = 1.4$ . We note that the true value of the velocity  $g_2$  is very small since  $g_1$  relates to  $g_2$  in which Re generally is very large. Therefore, the radial velocity  $g_2$  does not affect significantly the one dimensional core flow outside the boundary layer.

In the following an example and a comparison of the present result with incompressible steady state flat plate boundary layer solution may illustrate the procedure for calculation. Consider the heat transfer calculation with present formula at the time t = 1.2 (i.e.  $\bar{t} = 1.9586$  milliseconds) and the position z = 0.5076 (i.e. Z = 1.7655 ft from breech) we have for the standard projectile in XM 140 model

$$R_r = 5.504$$
  $\frac{16m_{H^3}}{4t^3}$   $W_r = 2.30.8 \frac{ft}{sec.}$ 
 $L = 3.478$  ft  $M = 2.8 \times 10^{-5} \frac{16m}{ft sec.}$ 
 $R_r = 0.962$  (at t=1.2)  $R_r = 5.04 \cdot kpsi$ 
 $R_r = 2174$   $R_r = 3p(0) = 0.0464$ 
 $R_r = \frac{9.7 \text{ Gr} L}{M} = 1.4567 \times 10^9$   $R_r = 0.04 \frac{84M}{hr \text{ ft}^2}$ 

Thus from Eq. (6-26) we have

$$N_u = \frac{hL}{k} = 5.82 \times 10^3$$

the heat flux is then

$$q = hTr = 403$$
 Btu/ft²sec.

Although there is no similarity for the physical phenomenon between the present solution and steady laminar flow. If however the laminar solution is applied instantaneously at a local position some comparison may be made. We thus now assume that at the time t = 1.2 and position z = 0.5076 the steady incompressible flow solution (see p. 285 of Ref. 4) applies the above example. That is

$$N_{H_3} = \frac{h_3}{K} = 0.332. \left(\frac{\text{UZPr}}{M}\right)^{0.5} \left(N_{Pr}\right)^{0.1333}$$
 (6-28)

where

U = 1375 ft/sec (from core solution)

$$Z = 0.5076 \times L$$

N_{pr} = grandtl number = 0.75

Thus

$$N_{\text{M}_2} = \frac{h_2}{k} = 0.7237 \times 10^4$$

heat transfer is

$$q = h(T_{core} - T_{wall}) =$$

= 
$$\frac{0.7237 \times 10^4 \times k}{0.5076 L}$$
 (3250 - 520) = 1340  $\frac{Btu}{ft^2 sec}$ 

The above comparison shows the steady state heat transfer over estimates heat transfer at t = 1.2 and z = 0.507. Therefore the steady flow formula is not applicable to the present problem.

In the anlysis of liquid cooling effect many difficulties and uncertainties appear. For example, it is not known in what manner the cooling liquid is squeezed out from the modified projectile; how much of the liquid will get behind the projectile; and that whether or not the liquid will stay in a film layer. Also the extent of the influence of grooves on the cooling effect is not known. However an attempt is made to obtain some solutions even they are solved under crude assumptions. Therefore, the analysis herein should be viewed as preliminary result and further improvement certainly is necessary.

## VII-1 Determination of Liquid Film Thickness

In the following analysis we shall assume for lack of experimental evidence that the liquid squeezed out from the projectile will form a film behind the projectile. Then the total amount of the liquid behind the projectile,  $M_{\tilde{\chi}}$  ( $\tilde{t}$ ), from the breech to the projectile at any given time  $\tilde{t}$  is

$$M_{\lambda}(\tilde{t}) = \tilde{P}_{\ell} \pi D_{0} \int_{0}^{\tilde{z}_{\ell}} (R_{c} - R_{\lambda}) d\tilde{z}$$
 (7-1)

where Z = axial length

 $\bar{\rho}_{\varrho}$  = liquid density = const.

 $D_0 = inside diameter of the barrel$ 

 $R_{a}-R_{a}$  = thickness of liquid film on the wall

R, = radius of interface

Eq. (7-1) can be written in dimensionless form as

$$m_{\ell}(t) = \frac{M_{\ell}(t)}{\ell_r L^3} = \ell_{\ell} \pi d_c \int_{t}^{3p} (r_0 - r_a) ds$$
 (7-2)

$$e^{\frac{R_0}{2}} = \frac{R_0}{r_0} = \frac{R_0}{L} \qquad r_0 = \frac{R_0}{L}$$

$$d_0 = \frac{D_0}{L} \qquad \delta = \frac{Z}{L} \qquad \delta p = \frac{\overline{A}}{L^2}$$

Although the exact amount of liquid,  $m_{\chi}(t)$ , at a given time is not known a crude estimate of  $m_{\chi}(t)$  is given in Appendix VIIA from which we have

$$m_{1}(t) = \left( \frac{1}{2} \alpha \right) \sqrt{\frac{b(t')}{c^{2}}} dt' \qquad t \leq 1.407 \qquad (7-2a)$$

where p(t') is the pressure at the base of the projectile.

The liquid layer thickness  $(r_0-r_1)$  may be approximated by a polynomial form.

$$r_0 - r_{-} = f_0(+) \left[ a_0 + a_1 + a_2 + a_2 \right]$$
 (7-3)

where  $f_a(t) = function of t, and$ 

. and a are constants to be determined as follows.

At the breech, z = 0,  $(r_0 - r_1) = 0$ , so that  $a_0 = 0$ . Eq. (7-3) becomes

$$r_0-r_i = f_a(t) \left( a, 3 + a, 3^2 \right)$$
 (7-4)

Substituting Eq (7-4) into Eq(7-2) and integrating we obtain

$$m_{\ell}(t) = \ell_{\ell} \pi d_{0} f_{0} \left[ \frac{a_{1}}{2} 3_{p}^{2} + \frac{a_{2}}{3} 3_{p}^{2} \right]$$
 (7-5)

At the position immediately behind the projectile,  $z = z_p$ ,  $r_0 - r_1 = h_1(t)$ .

Where  $h_1(t)$  is the liquid thickness at the base of the projectile and is derived in Appendix VIIA. From Eq. (7-4) we have

Then  $a_1$  and  $a_2$  are determined from Eqs (7-5) and (7-6) as

$$\alpha_{l} = \frac{h_{a'}}{f_{a} \delta p} - \delta p \left[ \frac{3 h_{a'}}{f_{a} \delta p} - \frac{6 m_{e}(\epsilon)}{\ell_{e} \pi d_{o} t_{a} \delta p} \right]$$

$$\alpha_{2} = \frac{3 h_{a'}}{f_{a} \delta p} - \frac{6 m_{e}(\epsilon)}{\ell_{e} \pi d_{o} t_{a} \delta p}$$
(7-7)

Substituting Eq. (7-7) into Eq (7-4) and noting that  $y_i = \sqrt{Re} (y_0 - y_i)$  we have

Once  $m_{\ell}$  (Eq.7-2a),  $h_{i}$  (Eq.7-6), and  $z_{p}$  (Eq.5-8) are calculated the liquid film thickness,  $y_{i}$ , at a given time and a given position along z-axis can be evaluated from Eq.(7-8).

A alternative simple estimation of liquid film thickness is also presented as follows:

water filled in the projectile,  $M_o = 0.039 \text{ lb}_m$ . water density,  $\rho_{\ell} = 62.4 \text{ lbm/ft}^3$ 

diameter of the barrel,  $D_0 = 1.2$  inches

length of the barrel, L = 3.478 ft

Consider that all water is completely squeezed out and uniformly coated on the wall of the barrel during the time interval,  $t=0\sim 2.3$  m.s. Then the liquid film thickness,  $R_{\rm c}-R_{\rm i}$ , is

$$R_0 - R_{\lambda} = \frac{M}{P_0 \pi b_0 L} = \frac{0.039}{62.4. \pi \frac{1.2}{12} 3.478} = 5.725 \times 10^{-4} \text{ft}$$

The ratio of Ro-Ri to barrel radius Ro is

$$\frac{R_0 - R_1'}{R_0} = 0.01145$$

which is one percent of the barrel radius.

## VII-2 Two-Fhase Gas and Liquid Layer Flow

There are three zones in the flow, free stream (core solution) around the barrel center, liquid layer near the wall, and gas boundary layer in between. Among these regions the core solution is already obtained previously.

# VII-21 Gas Boundary Layers with Liquid Cooling

The liquid layer from the above estimation is very thin and the flow velocity in it is small compared with that in gas layer. Therefore, the existance of the liquid layer does not affect the gas velocity boundary layer presented in Chapter VI. For the gas temperature layer, since the cooler liquid film presents near the wall, it needs some modification. We thus assume that the mass flux ou in the y direction remains that of the gas boundary layer without cooling.

Substituting 
$$\theta = \frac{p}{p}$$
 into Eq. (6-11) we have the energy equation 
$$e^{\frac{2\theta}{2\eta}} = \frac{1}{R_3} \frac{2\theta}{2\eta^2}$$
 (7-9)

Making the substitution for  $\rho$  and u from Eq. (6-12) and setting  $f_4 = f_1 f_2$ . Here  $f_4$  can be approximated by the following

$$f_4 = 7 \eta - 5.225 \eta^2 + 1.1923 \eta^3 - 0.2894 \eta^4 \qquad (\gamma = \frac{4}{4}) \qquad (7-10)$$

we have 
$$t^{-A} f_4 \frac{\partial \theta}{\partial y} = \frac{1}{P_{\pi_g}} \frac{\partial^2 \theta}{\partial y^2}$$
, A = 1.325  
Diving by  $\frac{\partial \theta}{\partial y}$ , it becomes

$$t^{-A}f_{4} = \frac{1}{Pr_{1}} \frac{\frac{\partial b}{\partial y}}{\frac{\partial y}{\partial y}} = \frac{1}{Pr} \frac{\partial}{\partial y} \ln(\frac{\partial \phi}{\partial y})$$

Integrating once

$$\ln \frac{\partial \theta}{\partial y} = P_{r_3} t^{-A} \int_{y}^{y} f_+ dy + \overline{f}(+, \delta)$$

or

$$\frac{\partial \theta}{\partial y} = e^{\Pr_{y} + \Lambda} \int_{0}^{x} f_{x} dy + \tilde{f}(x, y)$$
 (7-11)

where  $\bar{f}(t,z)$  is a function of t and z.

Integrating Eq (7.11) once more

As  $y \rightarrow \infty$ ,  $\theta = \theta_{core} = f$ , where  $\theta_{core}$  is given in Eq. (5-13)

Then the temperature distirbution across the gas thermal boundary layer is

$$\theta = \theta_{core} - e^{\frac{1}{2}(4.3)} \int_{0}^{\infty} e^{\frac{1}{2}r^{2}} e^{\frac{1}{2}r^{2}} \int_{0}^{\infty} \frac{1}{r^{2}} dy$$
(7-12)

with  $\theta = \theta_{gi}$  at  $y = y_i$  we have

$$e^{\frac{1}{2}(t-\frac{1}{2})} = \frac{\theta_{012} - \theta_{12}}{\int_{0.1}^{\infty} e^{\beta_{1}} t^{-\Lambda} \int_{0.1}^{0} f_{01} dy}$$

$$\frac{1}{2} \int_{0.1}^{\infty} e^{\beta_{1}} t^{-\Lambda} \int_{0.1}^{0.1} f_{01} dy$$

$$\frac{1}{2} \int_{0.1}^{\infty} e^{\beta_{1}} t^{-\Lambda} \int_{0.1}^{0.1} f_{01} dy$$

$$\frac{1}{2} \int_{0.1}^{\infty} e^{\beta_{1}} t^{-\Lambda} \int_{0.1}^{0.1} f_{01} dy$$

The interface temperature will be determined by Eq (7-37) later. Here  $y_i(t.z)$  is the position of the interface, given in Eq. (7-8).

VII-22 Liquid Velocity Field

Since the velocities  $U_{\ell}$  and  $W_{\ell}$  in liquid layer are small, we consider viscosity and pressure terms only. The governing equation is, therefore, from Fq. (4-27)in y coordinate variable

$$\frac{\partial P}{\partial y} = \frac{\mu_1}{\mu_1} \frac{\partial w_1}{\partial y^2} \tag{7-14}$$

Integrating with respect to y

$$\frac{\partial w_{i}}{\partial y} = \frac{\mu}{\mu_{i}} \frac{\partial b}{\partial y} y + g_{i}(y) \tag{7-15}$$

At the gas-liquid interface the shear force should be matched, i.e.

$$\frac{\partial w_{\ell}}{\partial y} = \frac{\lambda}{\lambda_{R}} \frac{\partial w}{\partial y}$$
(7-16)

Then g₁(z) is determined as

Integrating Eq. (7-15) once more

T

$$W_{k} = \frac{24}{44} \left[ \frac{2p}{03} \frac{3^{2}}{2} + \frac{200}{03} \right] + \frac{2p}{03} \frac{3}{2} \frac{3}{4} \frac{3}{1} + \frac{3}{1} (3)$$
 (7-17)

It is readily seen that  $g_2(z) = 0$  for y = 0,  $w_1 = 0$ . As the liquid layer is very thin we may approximate

$$\frac{\partial w_{i}}{\partial y_{i}} \simeq \frac{\partial w_{i}}{\partial y_{i}} = 0$$
 (7-18)

which is obtained Chapter VI.

Since Eq. (6-7) gives w = z H(t,y), we have

$$\frac{\partial w}{\partial y}\Big|_{x} = \frac{\partial H}{\partial y}\Big|_{z} = \frac{\partial$$

where we have substituted  $H = t^{-1}f_3$  and  $f_3'(0) = 2.024$ .

Upon substituting Eq. (7-19) back to Eq. (7-17) and noting that

$$\frac{\partial E}{\partial y} = -1.08 \pm \frac{-3.65}{3} \tag{7-20}$$

from the core solution we obtain a final form for  $\mathbf{w}_{\mathbf{k}}$  in liquid layer

$$W_{1} = \frac{41}{\mu_{1}} \left[ -1.08 \pm 3 \frac{4^{2}}{2} + 1.08 \pm 34, 4 + 2.024 \right] \pm \frac{-2.325}{4} \left[ (7-21) \right]$$

yll-23 Liquid Temperature Field

With the yelocity profile known we may approximately solve the liquid energy equation by assuming that the dissipation is negligible.

We have the enrgy equation as

$$\frac{\partial \theta_{1}}{\partial t} + W_{2} \frac{\partial \theta_{2}}{\partial y} = \frac{1}{Q} \frac{\partial^{2} \theta_{2}}{\partial y^{2}}$$
 (7-22)

where 
$$\frac{1}{Q} = \frac{\rho_r \mu_g}{\rho_g \mu_r p_{rg}}$$
 (7-23)

Since the equation is still complicated we solve it by an approximation method in which the temperature profile is assumed in view of Eq. (5-13) as

$$\Theta_{k} = C_{o}(\cdot, 4.5) + C_{i}(t, 5)$$

where co and co are to be determined with known conditions.

We know that at z = 0,  $\theta_{\ell} = \theta(z = 0)$  because there will be no liquid cooling or gas boundary layer. Thus we have  $C_0(t,y) = \theta(z=0)$ .

Eq. (7-24) becomés

$$\Theta_{k} = \frac{\partial}{\partial t} \left( 2^{2} \epsilon_{i} \pm \right) + C_{i} \pm \epsilon_{i} \pm \left( 2^{2} \right) + C_{i} \pm \epsilon_{i} \pm \left( 2^{2} \right)$$
 (7-25)

If  $c_1(t,y)$  is further approximated by

$$C_1(t, y) = a_1(t) + A_1(t) y + A_2(t) y^2$$
 (7-26)

Now at y = 0,  $\theta_0 = \theta_{0u}$  we have

$$\theta_{k} \omega = \theta_{\text{tere}} (3 \cdot \epsilon, \pm) + \alpha_{\epsilon} (\pm) 3^{2} \qquad (7-27)$$

at y = yi, 0 = 0 gi we have

Also from the governing equation (7-22) evaluated at y = 0 we have

$$\frac{\partial \mathcal{L}_{ab}}{\partial t} = \frac{1}{Q} \frac{\partial \mathcal{L}_{ab}}{\partial y^2} \tag{7-29}$$

Substitute Eq. (7-26) into the right side of Eq. (7-29) we get

$$Q_{2}(E) = \frac{\partial Q_{2} \omega}{\partial E} \frac{Q_{2}}{Z}$$
 (7-30)

Eq. (7-28) with Eq (7-30) gives

$$\alpha_{1}(x_{1}) = \frac{\theta_{2} - \theta_{2}\omega}{3i \cdot 3^{2}} - \frac{\partial \theta_{2}\omega}{\partial t} \frac{Q}{2} \cdot \psi_{2}$$
 (7-31)

We therefore obtain the approximated temperature distribution in the liquid layer as

If  $\theta_{\rm gl}$ , the interface temperature, is known heat transfer can be easily calculated from Eq. (7-32) as

$$z = -k_2 \frac{\partial T_1}{\partial R}\Big|_{R=R_0} = \frac{k_2 T_2}{L} \frac{\partial \theta_1}{\partial y}\Big|_{R=R_0}$$
 (7-33)

When the heat transfer coefficient is defined as

$$q = hTr (7-3h)$$

then the local Nusselt number is

where Q and  $y_i$  are given by Eq. (7-23) and (7-8) respectively. To derive the interface temperature,  $\theta_{gi}$ , theoretically we must match the liquid

temperature profile with the gas profile. To do this we use the matching condition of heat flux at interface  $y \approx y_4$ . That is

$$\frac{\partial \theta}{\partial y}\Big|_{A} = \frac{K_1}{K} \frac{\partial \theta_2}{\partial y}\Big|_{A}$$
 (7-36)

Substitute Eqs. (7-11) and (7-13) for the left hand side of Eq. (7-36) and Eq. (7-32) evaluated at interface for the right hand side of Eq. (7-30) we have

$$Q_{3} = \frac{\theta_{cora} + \frac{K_{1}}{K} \frac{1}{3} (\theta_{kw} - \frac{\partial \theta_{sw}}{\partial t} \frac{\Omega}{2} 3^{2} y_{s}^{2}) \int_{y_{1}}^{c_{0}} e^{P_{1} t} \frac{-1.32x}{4y} dy}{4y} (7-37)$$

It is suggested that this equation should be evaluated in the further study. VII-3 Discussion

First it should be remarked that the solution obtained is an approximated one. Further improvement and study is certainly needed. However some conclusion based on the present result may be drawn. Let us consider a calculation of heat transfer with liquid cooling by Eq. (7-35) for XM140 Model at t = 1.2 and z = 0.507.

$$N_{u} = \frac{hL}{K_{z}} = \sqrt{Re} \frac{1}{4i} \left[ \theta_{yi} - \theta_{zu} - \frac{\partial \theta_{zw}}{\partial t} \cdot g^{2} y_{i} \frac{\partial}{\partial z} \right]$$
 (7-35)

Here  $\dot{y}_1$  is the dimensionless liquid thickness. To estimate this thickness we assume that three quarters of liquid in the projectile may reach behind the projectile and is uniformly coated on the barrel surface. Thus from Eq. (7-8)

 $(c_{gi} - \theta_{gw})$  in Eq. (7-35) is the dimensionless temperature difference between the gas liquid interface and the wall. To estimate this we assume that the gas-liquid interface temperature is approximately equal to that of the wall temperature of the standard round without cooling. From Fig II-2 we find that at z = 0.507 (i.e., where  $s_2$  probe is located) at t = 1.2 (i.e., 1.9586 milliseconds) the temperature difference is

$$\theta_{1} - \theta_{2w} = \frac{T_{1} - T_{2w}}{T_{V}} = \frac{500^{\circ} F - 420^{\circ} F}{2174^{\circ} R} = 0.0368$$

For  $\frac{\partial \theta_{lw}}{\partial t}$ , the time rate change of the wall temperature, we have from Fig II-2 at the same time and position as

$$\frac{\partial \theta_{z\dot{w}}}{\partial t} = \frac{\Delta T_{z\dot{w}}}{\Delta \bar{t}} \frac{tr}{Tr} = \frac{-120}{0.5} \frac{1.6322}{2.174} = -0.032$$

Q from Eq. (7-23) gives

Note that Reynolds number and the reference quantities are the same as given in Chapter TV. Now we may calculate the local Nusselt number from Eq. (7-35) as

$$N_u = \frac{hL}{K_0} = 4.63 \times 10^2$$

To calculate heat transfer we have from the definition of modified Newton's Law

Recall that we had q = 403 Bt:  2  sec for without cooling. This means that there is approximately 30% in reduction of heat transfer to the wall at t = 1.2 and z = 0.507 When modified projectile was used. Although the above calculation gives approximately the right order of reduction in heat transfer it is felt that there are many assumptions involved that may not be easily verified.

An alternative short way to estimate the heat flux and its coefficient is presented as follows. From the experiment we learned that the heat flow does not reach the external wall of the barrel at  $\bar{t}=2.3$  m.s. after the projectile was fired. We may, therefore, assume that within this time interval the heat transfer may be represented by the heat flow to a semi-infinite solid body exposed to a time-dependent temperature on the surface as  $\bar{t}>0$ , See Fig  $\bar{V}I-1$  The internal barrel surface is simulated as the surface of the semi-infinite body. Then at a given a tion of z we have the following governing equation on solid wall side, in dimensional

$$\frac{\partial(T-T_c)}{\partial \overline{+}} = \frac{1}{2} \frac{\partial^2(T-T_c)}{\partial x^2}$$
 (7-38)

where

T = temperature profile in the solid wall

 $T_o = \text{room temperature at } t = 0$ 

t = time variable

 $Y_S$  = distance from the surface pointing to the solid wall  $\alpha$  = the thermal diffusitivity of the solid.

Let

$$\vec{T} = T - T_0$$

$$\vec{t}' = \vec{t} - t_p$$
(7-39.)

where

t_p = the correspondent time where the projectile is located, in the barrel after the firing

We have Eq. (7-38)

$$\frac{\partial \overline{T}}{\partial \xi'} = d \frac{\partial \overline{T}}{\partial Y_s}$$
 (7-40)

with the initial condition

at 
$$t \le t_p$$
 and  $0 \le Y_s < \infty$   
 $\overline{t}' = 0$  and  $\overline{T} = T_o$ ,  $\overline{T} = 0$  (7-41)

and boundary conditions

at 
$$t > t_p$$
 or  $\bar{t}' > o$   
 $Y_s = 0$   $T = T_w(\bar{t}', z)$ ,  $\bar{T} = T_w - T_o = \bar{T}_w$ 

$$Y_s \rightarrow \infty \quad \bar{T} = 0$$
(7-)₁?)

The solution for  $\tilde{T}$  is readily obtained from the book by Carslaw and Jaeger (13) p.62.

$$\overline{\tau} = \frac{Y_s}{2\sqrt{\pi d}} \int_{0}^{\overline{\xi'}} \frac{\overline{T_u}(\lambda, \overline{z}) e^{-\frac{Y_s^2}{4d(\overline{\xi'} - \lambda)}}}{(\overline{\xi'} - \lambda)^{3/2}} d\lambda \qquad (7-43)$$

and

$$\frac{\partial \overline{T}}{\partial Y_{2}}|_{0} = \frac{1}{2\sqrt{\pi d}} \int_{0}^{\overline{T}} \frac{\overline{T_{w}}(\lambda, z)}{(\overline{x}' - \lambda)^{3/2}} d\lambda$$
 (7-44)

where  $\lambda$  is a dummy variable. The internal surface temperature  $\overline{T}_W(\lambda,Z)$  is a function of time and position along Z-axis and can be approximated from experimental data. Once  $\overline{T}_W$  is known the integration in Eq.(7.44) can be performed. However, the irregularity of the present experimental curves, Fig VII-1, did not allow us to provide an appropriate equation for  $\overline{T}_W$  at the time when this report was written. A further effort is certainly needed to investigate the Eq.(7.44). Then the local heat flux to the solid wall is

$$\delta = -K_s \frac{\partial \overline{T}}{\partial Y_c} = |K \frac{\partial \overline{T}}{\partial Y}|_{o}$$
 (7-45)

where

 $-Y_8 = Y =$ distance from the surface pointing to the gas flow From Newton's cooling law we have

With Eq. (7-45) we have

$$\Re(\overline{T}_{core} - \overline{T}_{m}) = k_{s} \frac{\partial \overline{T}}{\partial \gamma} \Big|_{o}$$
 (7-47)

Then the heat coefficient is

$$h = \frac{k_s \frac{\partial \overline{T}}{\partial Y}|_{o}}{(\overline{T}_{cerg} - \overline{T}_{W})}$$
 (7-48)

Substituting for  $\frac{\partial \overline{T}}{\partial Y} \Big|_{O}$  from Eq. (3-36) we obtain

$$h = \frac{k_s}{(\overline{t}_{ore} - \overline{t_w})} = \frac{1}{2i\pi d} \int_0^{\overline{t}'} \frac{\overline{t_w}(\lambda.2)}{(\overline{t}' - \lambda)^{3/2}} d\lambda$$
(7.49)

Thus the local Nusselt number becomes

$$N_{\text{N}} = \frac{hL}{K} = \frac{K_{\text{S}}}{K} \frac{L}{2\sqrt{\pi d} \left(\overline{T_{\text{long}}} - \overline{T_{\text{N}}}\right)} \int_{0}^{\overline{t'}} \frac{T_{\text{N}}(\lambda, \xi)}{\left(\overline{\xi'} - \lambda\right)^{3/2}} d\lambda \qquad (7-50)$$

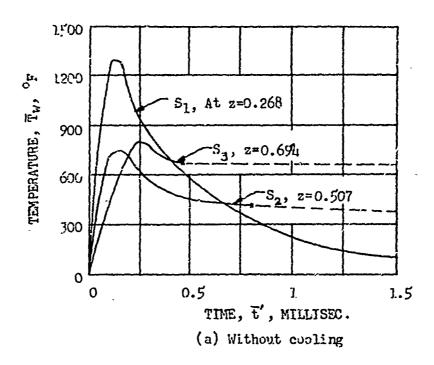

where

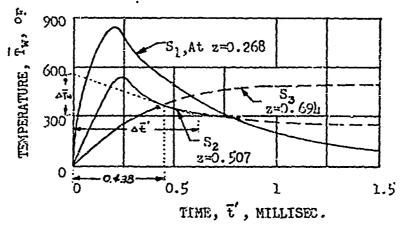

k_g = Concuctivity of solid wall

k = Conductivity of gas boundary layer

 $\bar{T}_{w}(\hat{t},z)$  = internal surface temperature of the barrel which is given in Fig VII-1

Due to the irregularity of the experimental curves it is very difficult to provide an approximated curve to represent  $\overline{T}_{\mathbf{u}}(\overline{\mathbf{t}}^{\dagger},\mathbf{z})$  properly. However numerically integration of Eq(7-50) may be performed to find the local Nusslet number. It should be noted that for this Nusselt number the heat transfer calculation should follow the conventional Newton's cooling law given in Eq. (7.46).

(b) with cooling

Note: (1)  $\overline{T}_w = T_w - T_o$ , where  $T_w$  = absolute wall temperature,  $T_o = \frac{r_o m}{t_o}$  temperature.

(2)  $\overline{t} = \overline{t} - \overline{t}_o$ , where  $\overline{t} = any$  time from 0 to 2.3 millisec.,  $\overline{t}_p = time$  interval for the projectile passes a given

position after firing,  $\overline{t} \not\geq \overline{t}_p$ .

(3) Dashed Lines indicate  $\overline{t} > 2.3$  millisec., which does not apply to the present problem.

Internal Wall temperatures,  $\overline{T}_{w}$ , With and Without Cooling Fig. VII-1 v.s. Time, t.

The study of the last fifteen months under the contract recommends the following continuing studies:

- (A) The experimental results obtained up to now show that the modified projectile with coolant does have substantial cooling effect. However, much more data is needed in order to understand the mechanism of cooling and to calculate heat transfer. An improvement in measuring the interior surface temperature is needed. In particular, at the breech end a high temperature probe with fast response should be installed. This measurement is important since it is one of the boundary conditions needed in the heat transfer analysis. A measurement of the core temperature behind the projectile can be made by implanting a thermocouple in the projectile flush with its base. The thermocouple wire protected in plastic tube is lcd through the gun barrel to the muzzle end and is then connected to the recording device. To the present investigator's knowledge the measurement of core temperature following a projectile has not been done before.
- (B) Movie pictures may be used to record the spreading of the coolant when it comes out of the muzzle end.
- (C) Hot wire measurements of velocity and Schlieren pictures can be used to study the gas dynamic behavior of the mixing of the coolant and the propellant gas at the exit.
- (D) A series of continuous firing should be continued at the Rock Island
  Arsenal to determine the cooling effect of the modified projectile No. 2.

  That is to find for the modified projectile the maximum interior and exterior wall temperature, maximum heat transfer, maximum rounds of continuous firing within the limits of yield stress and cook-off.

tentoring timblingsbirgs Bernal to 1937 and residence absorbets service the more than a singuish desiration of the service of the contraction of t

- (E) From the measured data, the friction between the modified projectile and the gun barrel, a parameter heretofore unavailable can be calculated. Hence, the efficiency of lubrication by the coolant may be determined.
- (F) The mathematical analysis obtained under the present contract is preliminary in nature. Further study is certainly needed in order to achieve a better prediction. Refinement of the core solution can be achieved by considering that the density is both time and spatially dependent. The present laminar solution of unsteady, compressible flow should be extended to the turbulent region so that the effect of the mixing of the coolent and the propellant gas can be included.
- (G) A suitable integral method can be developed for the turbulent, unsteady compressible gun barrel flow. This is not the conventional Karman Pohlhausen method since in the present case there are three independent variables namely, the axial variable, z, the radial variable, r, and the time, t. The derivation can be made specifically for the interior ballistics problem.
- (H) Study of the flow in front of the projectile has little effect on heat transfer between the propellant gas and the gun barrel. However, in case of continuous firing gas dynamics in front of a projectile may appreciably affect the amount of heat transfer. These gas dynamic effects include the shock formation and the propagation of expansion waves.
- (I) Eq. (7-37) should be computed to compare with the assumed experimental one.
- (J) Some form of study on the mixing of the cooling liquid and the propellant gas should be initiated since it is important for the calculation of heat transfer.
- (K) The effect of rifling groove must be considered in order that a better prediction of heat transfer coefficient can be achieved.

### APPENDIX IIA

## DETERMINATION OF MODIFIED PROJECTILE

consider a total amount of water  $M_{\chi} = 0.039$  lbm in a modified projectile to be squeezed out in a time interval of 2.3 milliseconds.

Based on Fig. II-3 we choose a mean pressure difference,  $\Delta p$ , between both ends of the small hole to be  $\Delta p = 10$  KPSi approximately.

Substituting into the formula

$$V = \sqrt{\frac{\Delta p}{\gamma}} \cdot 2g$$
 , where V is the water velocity at the exit of the small-hole.

We have 
$$V = \sqrt{\frac{10 \times 10^3 \times 144}{62.4}} \times 2 \times 32.2 = 1220 \text{ ft/sec.}$$

Then the total area needed for the small holes is

If the number of the small holes is 8, then their diameter is

$$E = \sqrt{\frac{A}{4 \times 8}} = 2.0715$$

This leads us to use a dispersor of  $\frac{3}{32}$  " ( $\approx 0.094$ ")

Water and the contract of the

## APPENDIX YA.

DETERMINATION OF CONSTANTS FOR EQS. (5-6) AND (5-11)

Pressure, see Fig II-3 and Fig III-1

 $P_2 = 10.2 \text{ KPSi}, \text{ at } z = 0.26804$ 

 $P_e = 3$  KPSi, at z = 1, i.e., at exit

Temperature, estimated from Fig. II-2 and Ref. [3] Fig. 9

$$T_{s1} = 2100^{\circ} F$$
, at  $z = 0.26804$ 

$$T_{ge} = .1200^{\circ} F$$
, at  $z = 1$ 

Then dimensionless density

$$\rho = \frac{\overline{\rho}}{\rho_r} = \frac{P_2^T_{se}}{P_e^T_{s1}} = 2.21$$

From Eq. (5-11) C' is determined as

$$C' = \rho z_p = 2.21 \times 0.25804 = 0.5928$$

DERIVATION OF EQS. (6-13) THROUGH (6-15) BY THAILARLTY TRANSFORMATION

Let new variables (One Parameter Group Theory)

$$\widetilde{\tau} = a^{3} + \widetilde{\eta} = a^{3} + \widetilde{\eta}$$

where a is a parameter,  $\alpha_1$ ,  $\alpha_2$ ,  $\gamma_1$ ,  $\gamma_2$ ,  $\gamma_3$  are constants. In terms of the above new variables Eqs (6-9) through (6-11) are written as follows

$$\alpha \frac{\partial_1 - \partial_1}{\partial \mathcal{E}} + \alpha \frac{\partial_2 - \partial_1 - \partial_2}{\partial \mathcal{E}} (\widetilde{\alpha} \widetilde{\beta}) + \alpha \frac{\partial_1 - \partial_2}{\partial \mathcal{H}} = 0$$
 (6A-2)

$$a^{3_1-1_3-1_1} \rho \frac{3\pi}{3\tau} + a^{3_2-1_1-1_2-1_3} \frac{3\pi}{2\tau} + a^{-1_1-2t_3} \frac{3\pi}{\rho} + a^{-1_1-2t_3} \frac{3\pi}{\rho}$$

$$= a^{-1_3-1_1} \rho \frac{3\pi}{2\tau} + a^{3_2-1_1-1_2-1_3} \frac{3\pi}{\rho} + a^{-1_1-2t_3} \frac{3\pi}{\rho}$$

$$= a^{-1_3-1_1} \rho \frac{3\pi}{2\tau} + a^{3_2-1_1-1_2-1_3} \frac{3\pi}{\rho} + a^{-1_1-2t_3} \frac{3\pi}{\rho}$$

$$= a^{-1_3-1_1} \rho \frac{3\pi}{2\tau} + a^{3_2-1_1-1_2-1_3} \frac{3\pi}{\rho} + a^{-1_1-2t_3} \frac{3\pi}{\rho}$$

$$= a^{-1_3-1_1} \rho \frac{3\pi}{2\tau} + a^{3_2-1_1-1_2-1_3} \frac{3\pi}{\rho} + a^{-1_1-2t_3} \frac{3\pi}{\rho}$$

$$-a^{2} = \frac{1}{62} - \frac{1}{12} = \frac{1}{12} =$$

In order to have a conformal invariance the index of parameter a in each term of the equation must be equal . That is

$$d_1 - d_1 = d_2 - d_1 - d_2 = -d_1 - d_3$$
 (6A-5)

$$a_1 - b_1 - b_3 = a_2 - b_1 - b_3 - b_3 = -b_2 - b_3 = -b_1 - b_3 = -b_2 - b_3$$
(6A-6)

$$d_2 - d_1 - d_2 = 2 d_2 \tag{6A-7}$$

The constants in the above equations, can be determined as follows

$$\frac{3}{3} = A \tag{6A-8}$$

from Eq. (6A-5) we obtain

$$\frac{4_2}{\alpha_1} = A - 1 \qquad \frac{4_3}{\alpha_1} = -1 \tag{6A-9}$$

from Eq. (6A-7)

$$\frac{d_i}{d_i} = 1 - 2A \tag{6A-10}$$

from Eq. (6A-6)

$$\frac{1}{d_1} = 2A - N \tag{6A-11}$$

from Eqs (6A-9) and (6A-11)

$$2A-n=-1$$
  $A=\frac{n-1}{2}$  (5A-12)

Now we can define two new invariant variables  $\xi$  and  $\eta$  as follows:

$$\xi = \tilde{\epsilon}, \quad \eta = \frac{\tilde{y}}{\tilde{\epsilon}^{c_2}/\alpha_1} = \frac{\tilde{y}}{\tilde{\epsilon}^{A}}$$

and let the dependent yariables be

$$.\tilde{p} = 3^{\frac{1}{2}} \cdot f_{1}(\eta) = \tilde{t}^{3-2A} f_{1}(\eta) \qquad (6A-13)$$

$$\bar{u} = s^{\frac{1}{2}} f_{2}(\eta) = \hat{\tau}^{A-1} f_{2}(\eta) \tag{6A-14}$$

$$\widehat{H} = \widehat{f}^{\frac{\eta_1}{2}} f_{\frac{\eta}{2}}(\eta) = \widehat{f}^{-\frac{1}{2}} f_{\frac{\eta}{2}}(\eta)$$
 (6A-15)

where f₁, f₂, and f₃ are functions of n

By the chain rule we have

STATE OF THE PERSON NAMED IN

W. W. Cont.

- STATE

$$\frac{\partial \hat{H}}{\partial z} = (-f_3 - A\eta f_3)\hat{t}^{-2}$$
 (64-16)

Substituting Eqs (6A-12) into Eqs(6A-2), (6A-3) and (6A-4) we obtain a set of transformed ordinary differential equation

$$(f_2 - \frac{x^{-1}}{2}\eta)f_1^1 + f_1f_2^1 + (f_3 + n+2)f_1 = 0$$
 (6-13)

$$(f_1f_2 - \frac{w-1}{2}vf_1)f_3' + (f_3-1)f_1f_3 - f_3'' = wc'$$
 (6-14)

$$= f_1 + f_2 + f_1 - f_1 + f_1 = 0$$
 (6-15)

where the parameter a's cancel one another.

and the Proposition is in the Market of the State of the

DETERMINATION OF  $f_1(\eta)$  AT  $\eta=0$  FOR EQ. (6-16)

From the transformation Eq (6-12)

$$f_1(n) = \rho t^{1.65}$$
 (6B-1)

At the wall, y = 0,  $\eta = 0$ , by equation of state

$$f_1(0) = \frac{p}{\theta_0 \times 0.726} t^{1.65}$$
 (5B-2)

The pressure,  $\phi$  obtained from core solution Eq. (5-12) can be readily fed in. The wall temperature  $\theta_{w}$  in Eq. (68-2) is measured from Fig II-2 at positions  $z=0.26804,\ 0.50763$ , and 0.69451, for various time, t,. Then  $f_{1}(o)$  at different time are determined by a computer program. The resulted output for  $f_{1}(o)$  (we used c in the place of  $f_{1}(o)$  in the computer program) is tabulated in the following computer program. Since,  $f_{1}(o)$  should be a constant in equations (6-13) through (6-15), hence the approximated value of  $f_{1}(o)$  which is taken as average of various  $f_{1}(o)$  is computed. This resulted in  $f_{1}(o)=3.2$ .

earlies and the consideration of a consideration of the form of the consideration of the consideration of the constant of t

DERIVATION OF  $m_{\chi}$  (t) FOR Eq. (7-2) AND  $h_{\chi}$  (t) FOR Eq. (7-6)

The liquid film thickness right behind the projectile is h; and total liquid flow rate squeezed from the small holes on the projectile is

$$M_{R} = \frac{1}{R} A \sqrt{\frac{2aP3}{R_{R}}}$$
 (7A-1)

where

 $\ddot{\hat{\rho}}_{0}$  = density

 $\overline{A}_{\cdot}$  = total cross-section area of the small holes

 $\Delta \bar{p}$  = pressure difference between two ends of the small holes

In dimensionless, Eq (7A-1) is written as

$$\dot{m}_{R} = \rho_{R} \alpha \sqrt{\frac{2\Delta p}{\rho_{R}}}$$
 (7A-2)

where (See also Nomenclature)

$$\dot{m}_{z} = \frac{\dot{M}_{0}}{\rho_{s} L^{2} U_{s}} \qquad \alpha = \frac{\ddot{A}}{L^{2}}$$

$$e_{R} = \frac{e_{\theta}}{e_{r}}$$

$$p = \frac{e_{r} \overline{u}_{r}^{2}}{3}$$

Therefore the total amount of the liquid from the breech to the base of the projectile which is at  $z=z_p(t)$  is  $w_{k}(t)=e_k\alpha\int_{c}^{c}\sqrt{\frac{dp(x)}{e^k}}\,dx$   $t\leq 1.4cq$ 

If  $\Delta p = \frac{p}{2}$  is assumed the difference in the pressure between the base of the projectile and exit hele of the projectile. We have

$$m_{\ell}(t) = \ell_{\ell} \alpha \int_{0}^{t} \sqrt{\frac{pu}{\ell_{\ell}}} d\lambda \qquad t \leq 1.409 (2.5 \text{ millisse})$$

To estimate the rate of coating on the wall of the barrell we mote that

$$\dot{m}_{\lambda} = (f_{\lambda} \pi d_{0} d_{\lambda}) \dot{J}_{p} \tag{7A-3}$$

where

$$d_0 = \frac{D}{L} = diameter of the barrel$$

 $\dot{z}_{p}$  = velocity of the projectile

For conservation, Eq (7A-2) and Eq (7A-3) must be equal. Then

$$R_{\lambda} = \frac{\alpha}{\pi d_{0} \partial_{p}} \sqrt{\frac{2\Delta P}{P_{0}}}$$
 (7A-4)

If we assume  $\Delta p = \frac{p}{2}$ , p is obtained from the core solution Eq (5-12), Eq. (D-4) is rewritten as

$$h_{a} = \frac{\alpha}{\pi d_{a} \delta_{p}} \sqrt{\frac{p}{f_{a}}}$$
 (7A-5)
