This program was conducted under Contract DAAJ02-70-C-0012 with Kaman Aerospace Corporation.

This report contains the theoretical derivation and the presentation of a methodology for system identification of structures. Computer experiments were run to verify this methodology.

The report has been reviewed by this Directorate and is considered to be technically sound. It is published for the exchange of information and the stimulation of future research.

This program was conducted under the technical management of Mr. Arthur J. Gustafson, Technology Applications Division.

FOREWORD

The work presented in this report was performed by Kaman Aerospace Corporation under Contract DAAJ02-70-C-0012 (Task 1F162204AA4301) for the Eustis Directorate, U. S. Army Air Mobility Research and Development Laboratory, Fort Eustis, Virginia. The program was implemented under the technical direction of Mr. Joseph H. McGarvey of the Reliability and Maintainability Division* and Mr. Arthur J. Gustafson of the Structures Division.** The report is presented in four volumes, each describing a separate phase of the balic theory of structural dynamic testing using impedance techniques.

Volume I presents the results of an analytical and numerical investigation of the practicality of system identification using fewer measurement points than there are degrees of The parameters in Lagrange's equations of motion, freedom. mass, stiffness, and damping for a mathematical model having fewer degrees of freedom than the linear elastic structure it represents may be determined directly from measured mobility data. Volume II describes the method of system identification wherein the necessary impedance data are experimentally determined by applying a force excitation at a single point on the structure. Volume III presents a method of determining the free-body dynamic responses from data obtained on a constrained structure. Volume IV describes a method of obtaining the equations for the combination of measured mobility matrices of a helicopter and its subsystems. The response of the combination of a helicopter and its subsystems is determined from data based on the experimental results of the main system and subsystems separately.

INTRODUCTION

The success of a helicopter structural design is highly dependent on the ability to predict and control the dynamic response of the fuselage and mechanical components. Conventionally, this involves the formulation of intuitively based equations of motion. Ideally, this process would reduce the physical structure to an analytical mathematical model which would predict accurately the dynamic response characteristics of the actual structure. Obviously, the creation of such an intuitive abstraction of a complicated real structure requires considerable expertise and inherently includes a high degree of uncertainty. Structural dynamic testing is required to substantiate the analytical results. The analysis is modified until successful correlation is obtained between the analytical predictions and the test results.

This report describes the theory of structural dynamic testing using impedance techniques as applied to a mathematical model having fewer degrees of freedom than the structure it represents. The test information is obtained with single point excitation of the model. Reference 1 describes the method of obtaining a model directly from test measurements for a hypothetical structure which has the same number of degrees of freedom as the mathematical model. In reality, the number of degrees of freedom of a physical structure is infinite, therefore, the usefulness of model identification, necessarily with a finite number of degrees of freedom, using impedance testing techniques depends on the ability to simulate the real structure with a small Reference 2 illustrates the method of mathematical model. obtaining a model, using impedance testing techniques, that is comprised of less degrees of freedom than the physical structure it approximates. That method required measured mobility data obtained at selected points of the structure with the force input applied at each of the prescribed The present theory is similar to that of Reflocations. erence 2 except that the excitation is applied at only one point on the model, thereby substantially reducing the mobility data essential to the analysis.

The process of deriving the equations of motion from test data is referred to as system identification. The only input information required in this theory is measured mobility data obtained with the excitation at only one point on the model and the approximate natural frequency of each mode. This information can be readily obtained from impedance testing of the actual structure over the frequency range of interest yielding the second order, structurally damped linear equations of motion.

System identification theories of any practical engineering significance must be functional with a reasonable degree of experimental error. In this report, a series of computer experiments incorporating experimental errors was documented. This report presents an extension of the analysis derived in Reference 2 whereby an identified model with a finite number of degrees of freedom, obtained from impedance type testing with excitation at only one point on the structure, simulates the actual structure wherein the number of degrees of freedom is infinite.

THEORY

DERIVATION OF THE SINGLE-POINT ITERATION PROCESS

As indicated in References 1 and 2, the mobility of a structure is given by

$$[Y_{\omega}] = [\Phi] [Y_{i(\omega)}^{*} J [\Phi]^{T}$$
(1)

With excitation at station k, the responses at station j, including k, are obtained. These provide the k-th column of the mobility at a particular forcing frequency ω_1 :

$$\{Y_{j(k)1}\} = \sum_{i=1}^{N} Y_{i(1)}^{*} \phi_{ki} \{\phi\}_{i} = [\phi] \{Y_{i1}^{*} \phi_{ki}\}$$
(2)
$$1 \le j \le J, 1 \le i \le N$$

This represents a column of mobility values, each element of which is the response at a point of interest on the structure with excitation at station k and at forcing frequency ω_1 .

Similarly, with the exciter remaining at station k, the k-th column of the mobility at another frequency, ω_2 , can be obtained:

$$\{Y_{j(k)2}\} = \sum_{i=1}^{N} Y_{i(2)}^{*} \phi_{ki} \{\phi\}_{i} = [\phi] \{Y_{i2}^{*} \phi_{ki}\}$$
(3)

The mobility columns represented by (2) and (3) may be combined into one matrix:

$$[\{Y_{j(k)1}\}\{Y_{j(k)2}\}] = [\Phi] \{\{Y_{i1}^{*}\phi_{ki}\}\{Y_{i2}^{*}\phi_{ki}\}\}$$

$$Jx^{2} = [\Phi] [\phi_{ki}J [\{Y_{i1}^{*}\}\{Y_{i2}^{*}\}]$$

$$JxN NxN Nx^{2}$$
(4)

In general, for P forcing frequencies $(1 \le p \le P)$,

$$[Y_{j(k)p}] = [\Phi] [\phi_{ki}] [Y_{ip}^{*}]$$

$$JxP \qquad JxN NxN \qquad NxP$$
(5)

If J > P, Equation (5) is a set of more equations than unknowns for which there is no solution. Equation (5) can then be written as

$$\begin{bmatrix} Y_{j(k)p} \end{bmatrix} = \begin{bmatrix} \phi \end{bmatrix} \begin{bmatrix} \phi_{ki} \end{bmatrix} \begin{bmatrix} Y_{ip}^{*} \end{bmatrix} + \begin{bmatrix} R_{jp} \end{bmatrix}$$
(6)
JXP JXN NXN NXP JXP

where R_{jp} is the residual associated with the j-th station and the p-th forcing frequency.

As described in References 1 and 2, the imaginary displacement mobility contains significant information relating to modes associated with natural frequencies in proximity to the forcing frequency. As shown in Reference 3, accurate estimates of the modal vectors may be obtained by considering only the effects of modes proximate to the forcing frequency. Therefore the analysis will employ only Q modes, where Q is less than N. Consider the imaginary displacement mobility

$$[Y_{j(k)p}^{I}] = [\Phi] [\phi_{ki}] [Y_{ip}^{*I}] + [R_{jp}]$$
(7)

The dominant element in each row of the ^{[Y}ip[]] matrix will be the modal mobility measured at the forcing frequency in proximity to a particular natural frequency. Normalizing the rows of the aforementioned matrix on the largest element yields

$$[S_{ip}] = \begin{bmatrix} Y_{ip}^{*I} \\ Y_{in}^{*I} \end{bmatrix}$$
(8)

Y^{*I}
where Y in is the maximum value of the i-th row. Equation (7)
may be rewritten, incorporating Equation (8):

$$[Y_{j(k)p}^{I}] = [\Phi] [\phi_{ki} Y_{in}^{*I}] [S_{ip}] + [R_{jp}]$$
(9)

The [S_{ip}] matrix can be evaluated by considering the expression for the imaginary displacement modal mobility

$$Y_{i(\omega)}^{*I} = -\frac{g_{i}}{m_{i}\Omega_{i}^{2}\{g_{i}^{2} + (1 - \frac{\omega^{2}}{\Omega_{i}^{2}})^{2}\}}$$
(10)

Therefore from Equation (8),

$$s_{ip} = \frac{g_i^2 + (1 - \frac{\omega_n^2}{\Omega_i^2})}{\frac{g_i^2 + (1 - \frac{\omega_p^2}{\Omega_i^2})}{\frac{\omega_p^2}{\Omega_i^2}}$$
(11)

Because g_i , the structural damping coefficient of the i-th mode, is generally quite small, typically of the order 5 percent, the [S] matrix can be accurately estimated by assuming $g_i = 0$, thus, requiring knowledge of only the forcing frequencies and the natural frequencies. It will be shown that an accurate estimate of S is not necessary, although helpful, as iterations will converge on the best values in S in the least-squares sense.

The matrix Equation (9) has no solution. An approximation to a solution may be defined as that which makes the Euclidian norm of the matrix of residuals a minimum. This, as will be proved later, is given through use of the pseudoinverse.

Equation (9) will be solved utilizing matrix iteration techniques using $[S_{ip}^{(0)}]$ as a first estimate. As indicated in the following sections, the modal vector matrix with

respect to which the Euclidian norm of the residuals is a minimum is given by

$$[\Phi^{(1)}] = [Y_{j(k)p}^{I}][S_{ip}^{(0)}]^{\dagger}[\frac{1}{\phi_{ki}Y_{in}^{*I}}]$$
(12)

where $[S_{ip}^{(0)}]^+$ is defined as the generalized inverse or pseudoinverse of $[S^{(0)}]$ and is given by

$$[s_{ip}^{(0)}]^{+} = [s_{ip}^{(0)}]^{T} ([s_{ip}^{(0)}] [s_{ip}^{(0)}]^{T})^{-1}$$
(13)

where

$$[s_{ip}^{(0)}][s_{ip}^{(0)}]^{+} = [I_{L}]$$

1

It follows then that

$$[Y_{j(k)p}^{I}] = [\Phi^{(1)}] [\Phi_{ki}Y_{in}^{*I}] [S_{ip}^{(0)}] + [R_{jp}^{(0)}]$$
(14)

in which the Euclidian norm of $[R_{jp}^{(0)}]$ is a minimum with respect to $[\Phi^{(1)}]$.

Using $[\phi^{(1)}]$, a matrix $[S_{ip}^{(1)}]$ can be found to give an equation

$$[Y_{j(k)p}^{I}] = [\Phi^{(1)}] [\Phi_{ki}Y_{in}^{*I}] [S_{ip}^{(1)}] + [R_{jp}^{(1)}]$$
(15)

such that the Euclidian norm of $[R_{jp}^{(1)}]$ is a minimum with respect to $[S_{ip}^{(1)}]$. This is given by

$$[s_{ip}^{(1)}] = \left[\frac{1}{\phi_{ki}Y_{in}^{*T}}\right] \left[\phi^{(1)}\right]^{+} \left[Y_{j(k)p}^{T}\right]$$
(16)

where

$$[\phi]^{+} = ([\phi]^{T}[\phi])^{-1}[\phi]^{T} \text{ and } [\phi]^{+}[\phi] = [I_{R}]$$
 (17)

It is apparent from the first cycle of the iteration, by comparing Equations (11) and (15), that the process consists of alternately dealing with the left and right identity matrices. At each successive iteration, a solution is found that minimizes the Euclidian norm of the residual matrix with respect to the newly found matrix of either [S] or [ϕ]. In simplified notation, the q-th iteration becomes

$$[\Phi^{(q)}] = [Y^{I}][S^{(q-1)}]^{+} \begin{bmatrix} 1 \\ \phi_{ki} Y_{in}^{*I} \end{bmatrix}$$
(18)

and

$$[s^{(q)}] = \begin{bmatrix} \frac{1}{\phi} & y^{\dagger I} \end{bmatrix} \begin{bmatrix} \phi^{(q)} \end{bmatrix}^{\dagger} \begin{bmatrix} y^{I} \end{bmatrix}$$

The next iteration is

$$[\Phi^{(q+1)}] = Y^{I} [S^{(q)}]^{+} [\frac{1}{\phi_{ki}Y_{in}^{*I}}]$$

$$[S^{(q+1)}] = [\frac{1}{\phi_{ki}Y_{in}^{*I}}] [\Phi^{(q+1)}]^{+} [Y^{I}]$$

$$(19)$$

This is the basic algorithm used in the matrix iteration procedure.

DETERMINING THE MODAL PARAMETERS

From Equation (6) of the previous section, one column, which is at a particular forcing frequency, p, with the excitation at station k, can be written as

$$\{Y_{j(kp)}\} = [\phi] [\phi_{ki}] \{Y_{i(p)}^{*I}\} + \{R_{j(p)}\}$$
(20)

The number of modes, Q, included in Equation (20) cannot be greater than the number of points of interest on the specimen, J, and generally will be much less since only those modes which have significant effect on the mobility at the forcing frequency, ω_p , will be considered. Ordinarily, the number of modes used will not be greater than 3 or 4 for any given forcing frequency, and these will be the modes in the vicinity of the forcing frequency in question.

The real and imaginary modal mobilities are calculated from

$$\{\mathbf{Y}_{i(p)}^{\star R}\} = \left[\frac{1}{\phi_{ki}}\right] \left[\phi\right]^{+} \{\mathbf{Y}_{j(kp)}^{R}\}$$
(21)

and

$$\{Y_{i(p)}^{*I}\} = \begin{bmatrix} \frac{1}{\phi_{ki}} \end{bmatrix} \begin{bmatrix} \phi \end{bmatrix}^{+} \{Y_{j(kp)}^{I}\}$$
(22)

From Reference 1 the real displacement mobility can be calculated as

$$\mathbf{x}_{i\omega_{p}}^{*R} = \frac{1}{K_{i}} \frac{1 - \omega_{p}^{2} / \Omega_{i}^{2}}{g_{i}^{2} + (1 - \omega_{p}^{2} / \Omega_{i}^{2})^{2}}$$
(23)

and the imaginary modal mobility by

$$Y_{i\omega p}^{*I} = \frac{1}{K_{i}} \frac{-g_{i}}{g_{i}^{2} + (1 - \omega_{p}^{2}/\Omega_{i}^{2})^{2}}$$
(24)

The real modal impedance can be written as

$$z_{i\omega_{p}}^{*R} = \frac{Y_{i\omega_{p}}^{*R}}{(Y_{i\omega_{p}}^{*R})^{2} + (Y_{i\omega_{p}}^{*I})^{2}}$$
(25)

Substituting Equations (23) and (24) into (25) yields

$$\mathbf{z}_{\mathbf{i}\omega_{\mathbf{p}}}^{\mathbf{*R}} = \mathbf{K}_{\mathbf{i}} (1 - \omega_{\mathbf{p}}^{2} / \Omega_{\mathbf{i}}^{2})$$
(26)

From Equation (26) it is observed that the modal impedance is a linear function of the square of the forcing frequency.

The forcing frequency at which the modal impedance becomes zero is, therefore, the natural frequency. From a leastsquares analysis of modal impedance as a function of forcing frequency squared, proximate to the natural frequency, the generalized stiffness of the i-th mode and the natural frequency of the i-th mode can be calculated.

The generalized mass associated with the i-th mode is given by

$$\mathbf{m}_{i} = \mathbf{K}_{i} / \Omega_{i}^{2}$$
(27)

The structural damping coefficient may be determined from

$$g_{i} = \left(\frac{\omega_{p}}{\Omega_{i}^{2}} - 1\right) \frac{Y_{i\omega_{p}}^{*I}}{Y_{i\omega_{p}}^{*R}}$$
(28)

EQUATIONS OF MOTION

There are two basic types of dynamic mathematical models describing structures. The conventional type, covering as many modes as degrees of freedom, is called "Complete Models" and is considered in References 1 and 2. The other type labelled "Incomplete Models" considers fewer modes than points of interest on the structure and was first described in Reference 5. Using the methods described herein, it is possible to identify either a complete model or a form of incomplete model.

Incomplete Models

Consider a rectangular identified modal matrix which has J rows indicating the points of interest on the structure and Q columns representing the modes being considered where J > Q. The influence coefficient matrix for the incomplete model is given by

$$[C_{inc}] = [\Phi] \begin{bmatrix} \frac{1}{K_i} \end{bmatrix} \begin{bmatrix} \Phi \end{bmatrix}^T$$
(29)

The above matrix, similar to all incomplete model parameter matrices, is singular, being of rank Q and order J. The mass, stiffness and damping matrices for the incomplete model are

$$[m_{inc}] = [\Phi]^{+T} [m_i J [\Phi]^+$$

$$[K_{inc}] = [\Phi]^{+T} [K_i J [\Phi]^+$$

$$[d_{inc}] = [\Phi]^{+T} [g_i K_i J [\Phi]^+$$
(30)

The classical modal eigenvalue equation has the analogous incomplete form

$$[c_{inc}][m_{inc}]\{\phi_i\} = \frac{1}{\Omega_i^2}\{\phi_i\}$$
 (31)

Complete Models

For the complete model the identified modal vector matrix is square, having the same number of degrees of freedom as mode shapes; that is, J = Q. The influence coefficient matrix is given by

$$[c] = [\phi] [1/\mathbf{K}_{i}] [\phi]^{T} = \sum_{i=1}^{N} \frac{1}{\mathbf{K}_{i}} \{\phi_{i}\} \{\phi_{i}\}^{T}$$
(32)

The mass, stiffness and damping matrices for the complete model are

$$[m] = [\phi]^{-T} t_{\mathcal{M}_{i}} J [\phi]^{-1}$$

$$[k] = [\phi]^{-T} t_{\mathcal{K}_{i}} J [\phi]^{-1}$$

$$[d] = [\phi]^{-T} t_{g_{i}} \chi_{i} J [\phi]^{-1}$$
(33)

as indicated in Reference 1.

Full Mobility Matrix

The full mobility matrix of either complete or incomplete models is given by

$$[Y] = [\Phi] [Y_{i}^{*} J [\Phi]^{T}$$
(34)

where for the complete model the $[\Phi]$ matrix is square, having J columns and J rows. However, in the case of the incomplete model the modal matrix $[\Phi]$ is rectangular, having J rows and Q columns, where J > Q.

PROOF THAT THE PSEUDOINVERSE MINIMIZES THE NORM OF THE RESIDUALS

Take the transpose of Equation (9) and write the equation for one column of the transpose of the mobility matrix:

$$[Y_{j(k)p}^{I}]^{T} = [S_{ip}]^{T} [\Phi_{ji}]^{T} + [R_{jp}]^{T}$$

$$\{Y_{(jk)p}\} = [S_{ip}]^{T} \{\phi_{(j)i}\} + \{R_{(j)p}\}$$

$$(35)$$

$${R_{(j)p}} = {Y_{(jk)p}} - {[S_{ip}]}^{T_{\phi}}(j)i^{\beta}$$
(36)

$$\{ R_{(j)p} \}^{T} \{ R_{(j)p} \} = \{ Y_{(jk)p} \}^{T} \{ Y_{(jk)p} \} - \{ Y_{(jk)p} \}^{T} [S_{ip}]^{T} \{ \phi_{(j)i} \} - \{ \phi_{(j)i} \}^{T} [S_{ip}] \{ Y_{(jk)p} \} + \{ \phi_{(j)i} \}^{T} [S_{ip}] \{ S_{ip} \}^{T} \{ \phi_{(j)i} \}$$

$$(37)$$

Equation (37) is, of course, a scalar product and it is recognized that the derivative of a scalar with respect to a vector is a vector; in other words, Equation (36) is a vector in p-dimensional space and Equation (37) is its dot produce on itself - that is, its length squared. We wish to find the vector $\{\phi\}$ which makes the length of the residuals vector a minimum.

Take the partial derivative of Equation (37) with respect to $\{\phi_{(j)i}\}^T$ and set equal to zero to obtain the modal vector for which the Euclidian norm of the residuals is a minimum:

$$0 = -2[s_{ip}^{(0)}] \{Y_{(jk)p}\} + 2[s_{ip}^{(0)}] [s_{ip}^{(0)}]^{T} \{\phi_{(j)i}^{(1)}\}$$

or

$$\{\phi_{(j)i}^{(1)}\} = ([s_{ip}^{(0)}][s_{ip}^{(0)}]^{T})^{-1}[s_{ip}^{(0)}]\{Y_{(jk)p}\}$$
(38)

and

$$\{\phi_{(j)i}^{(1)}\}^{T} = \{Y_{(jk)p}\}^{T} [s_{ip}^{(0)}]^{T} ([s_{ip}^{(0)}] [s_{ip}^{(0)}]^{T})^{-1}$$
(39)

as the inverted matrix is symmetrical. Equation (39) is any row in Equation (12). The sum of the minimum Euclidian norms of the rows of a matrix is, by definition, the minimum Euclidian norm of the matrix, and it therefore follows from Equation (39) that

$$[\Phi^{(1)}] = [Y_{j(k)p}] [S_{ip}^{(0)}]^{T} ([S_{ip}^{(0)}] [S_{ip}^{(0)}]^{T})^{-1}$$

which is given by Equations (12) and (13). Q.E.D. The basic observation which makes the above proof of the pseudoinverse possible should be credited to Klosterman, Reference (4).

To show that the [S] matrix obtained using the pseudoinverse of $[\Phi]$ minimizes the norm of the residual, write the equation for a column of Equation (9):

$$\{Y_{j(kp)}\} = [\phi]\{S_{i(p)}\} + \{R_{j(p)}\}$$

$$\{R_{j(p)}\} = \{Y_{j(kp)}\} - [\phi]\{S_{i(p)}\}$$

$$\{R_{j(p)}\}^{T}\{R_{j(p)}\} = \{Y_{j(kp)}\}^{T}\{Y_{j(kp)}\} - \{Y_{j(kp)}\}^{T}[\phi]\{S_{i(p)}\}$$

$$= \{S_{i(p)}\}^{T}[\phi]^{T}\{Y_{j(kp)}\} + \{S_{i(p)}\}^{T}[\phi]^{T}[\phi]\{S_{i(p)}\}$$

$$(41)$$

Set $\frac{\partial \{R_{j}(p)\}^{T}\{R_{j}(p)\}}{\partial \{S_{i}(p)\}^{T}} = 0 \text{ and solve for } \{S_{i}(p)\}$

$$\{s_{i(p)}^{(1)}\} = ([\phi]^{T}[\phi]^{-1} [\phi]^{T}\{Y_{j(kp)}\}$$
(42)

or

$$[s_{ip}^{(1)}] = ([\phi]^{T} [\phi])^{-1} [\phi]^{T} [Y_{j(k)p}]$$
(43)

which is the same as Equation (16). Q.E.D.

PROOF THAT ITERATIONS USING THE PSEUDOINVERSE OF S AND ϕ CONVERGE MONOTONICALLY ON MINIMUM SUM OF RESIDUAL SQUARES

In the q-th iteration, where q is odd,

$$[Y_{j(k)p}^{I}] = [\Phi^{(q-1)}][S_{ip}^{(q-1)}] + [R_{jp}^{(q-1)}]$$
(44)

$$[\phi^{(q)}] \equiv [Y_{j(k)p}^{I}][s_{ip}^{(q-1)}]^{+} = [\phi^{(q-1)}] + [R_{jp}^{(q-1)}][s^{(q-1)}]^{+}$$
(45)

because $[S][S]^+ = [I_L]$. Then

$$[Y_{j(k)p}^{I}] = [\phi^{(q)}][S_{ip}^{(q-1)}] + [R_{jp}^{(q)}]$$
(46)

Substitute Equation (45) into Equation (46):

$$[Y_{j(k)p}^{I}] = [\Phi^{(q-1)}] [S_{ip}^{(q-1)}] + [R_{jp}^{(q-1)}] [S_{ip}^{(q-1)}]^{+} [S_{ip}^{(q-1)}]$$

or
$$[Y_{j(k)p}^{I}] = [Y_{j(k)p}^{I}] - [R_{jp}^{(q-1)}] + [R_{jp}^{(q-1)}] [S_{ip}^{(q-1)}]^{+} [S_{ip}^{(q-1)}]$$

Therefore
$$[R_{jp}^{(q)}] = [R_{jp}^{(q-1)}] ([I] - [S_{ip}^{(q-1)}]^{+} [S_{ip}^{(q-1)}])$$
(48)
$$[R_{jp}^{(q)}] = [R_{jp}^{(q-1)}] ([I] - [S_{ip}^{(q-1)}]^{+} [S_{ip}^{(q-1)}])$$
(48)

PxP

The p-th row of
$$[R_{jp}^{(q)}]$$
 is

$$\{ R_{j(p)}^{(q)} \}^{T} = \{ R_{j(p)}^{(q-1)} \}^{T} (TI - [s_{ip}^{(q-1)}]^{+} [s_{ip}^{(q-1)}])$$

$$\{ R_{j(p)}^{(q)} \}^{T} \{ R_{j(p)}^{(q)} \} = \{ R_{j(p)}^{(q-1)} \}^{T} (TI - [s_{ip}^{(q-1)}]^{+} [s_{ip}^{(q-1)}]) ([I] - [s_{ip}^{(q-1)}]^{+} [s_{ip}^{(q-1)}]^$$

But [I] - $[S_{ip}^{(q-1)}]^+[S_{ip}^{(q-1)}]$ is symmetrical and, from Equation (13),

$$[S_{ip}^{(q-1)}][S_{ip}^{(q-1)}]^{+} = [I_{L}].$$
 Therefore,

$$\{ R_{j}^{(q)} \}^{T} \{ R_{j}^{(q)} \} = \{ R_{j}^{(q-1)} \}^{T} \{ R_{j}^{(q-1)} \}$$

$$- \{ R_{j}^{(q-1)} \}^{T} [s_{j}^{(q-1)}]^{+} [s_{j}^{(q-1)}] \{ R_{j}^{(q-1)} \}$$

$$= \{ R_{j}^{(q-1)} \}^{T} [s_{j}^{(q-1)}]^{+} [s_{j}^{(q-1)}] \{ R_{j}^{(q-1)} \}$$

$$= \{ R_{j}^{(q-1)} \}^{T} [s_{j}^{(q-1)}]^{+} [s_{j}^{(q-1)}] \{ R_{j}^{(q-1)} \}$$

$$= \{ R_{j}^{(q-1)} \}^{T} [s_{j}^{(q-1)}]^{+} [s_{j}^{(q-1)}] \{ R_{j}^{(q-1)} \}$$

$$= \{ R_{j}^{(q-1)} \}^{T} [s_{j}^{(q-1)}]^{+} [s_{j}^{(q-1)}] \{ R_{j}^{(q-1)} \}$$

$$= \{ R_{j}^{(q-1)} \}^{T} [s_{j}^{(q-1)}]^{+} [s_{j}^{(q-1)}] \{ R_{j}^{(q-1)} \}$$

$$= \{ R_{j}^{(q-1)} \}^{T} [s_{j}^{(q-1)}]^{+} [s_{j}^{(q-1)}] \{ R_{j}^{(q-1)} \}$$

$$= \{ R_{j}^{(q-1)} \}^{T} [s_{j}^{(q-1)}]^{+} [s_{j}^{(q-1)}] \{ R_{j}^{(q-1)} \}$$

$$= \{ R_{j}^{(q-1)} \}^{T} [s_{j}^{(q-1)}]^{+} [s_{j}^{(q-1)}] \{ R_{j}^{(q-1)} \}$$

$$= \{ R_{j}^{(q-1)} \}^{T} [s_{j}^{(q-1)}]^{+} [s_{j}^{(q-1)}] \{ R_{j}^{(q-1)} \}$$

$$= \{ R_{j}^{(q-1)} \}^{T} [s_{j}^{(q-1)}]^{+} [s_{j}^{(q-1)}] \{ R_{j}^{(q-1)} \}$$

$$= \{ R_{j}^{(q-1)} \}^{T} [s_{j}^{(q-1)}]^{+} [$$

 $[S_{ip}^{(q-1)}]$ is maximally ranked in its rows, of rank Q where $1 \leq i \leq Q$. Therefore $[S_{ip}^{(q-1)}][S_{ip}^{(q-1)}]^T$ and its square root $([S_{ip}^{(q-1)}][S_{ip}^{(q-1)}]^T)^{1/2}$ are nonsingular of rank Q and symmetrical. Now, $[S_{ip}^{(q-1)}]^+[S_{ip}^{(q-1)}]$ is real, symmetric and singular. It is known that a real symmetric matrix [A] of rank Q is positive semidefinite if and only if there exists a matrix [C] of rank Q such that [A] = [C]^T[C]. Let $([S_{ip}^{(q-1)}][S_{ip}^{(q-1)}]^T)^{-1/2}[S_{ip}^{(q-1)}] \equiv [C]$, rectangular of rank Q. $[S_{ip}^{(q-1)}][S_{ip}^{(q-1)}][S_{ip}^{(q-1)}]^T]^{-\frac{T}{2}}([S_{ip}^{(q-1)}][S_{ip}^{(q-1)}]]^T]^{-\frac{1}{2}}[S_{ip}^{(q-1)}]$

$$= c^{T}c = [s_{ip}^{(q-1)}]^{T}([s_{ip}^{(q-1)}][s_{ip}^{(q-1)}]^{T})^{-1}[s_{ip}^{(q-1)}]$$
$$= [s_{ip}^{(q-1)}]^{+}[s_{ip}^{(q-1)}] \qquad (50)$$

Therefore $[S_{ip}^{(q-1)}]^+[S_{ip}^{(q-1)}]$ is positive semidefinite and $\{R_{j}^{(q-1)}\}^T[S_{ip}^{(q-1)}]^+[S_{ip}^{(q-1)}]\{R_{j}^{(q-1)}\}$ in Equation (49) must be a nonnegative number. But the first term on the right side and the left side of Equation (49) are also necessarily nonnegative. Therefore

15

$$\{ R_{j}^{(q)} \}^{T} \{ R_{j}^{(q)} \} < \{ R_{j}^{(q-1)} \}^{T} \{ R_{j}^{(q-1)} \} \text{ and }$$

$$\int_{\Sigma}^{J} P_{\Sigma} (R_{jp}^{(q)})^{2} < \int_{\Sigma}^{J} P_{\Sigma} (R_{jp}^{(q-1)})^{2}$$

$$j=1 p=1 \quad j=1 \quad j=1 \quad j=1 \quad j=1 \quad (51)$$

For the alternate calculation, q odd $[s_{ip}^{(q)}] = [\phi^{(q)}]^{+}[Y_{j(k)p}^{I}]$ (18)

But
$$[X_{j(k)p}^{I}] = [\Phi^{(q)}][S_{ip}^{(q-1)}] + [R_{jp}^{(q)}], so$$
 (46)

$$[s_{ip}^{(q)}] = [s_{ip}^{(q-1)}] + [\phi^{(q)}]^{+} [R_{jp}^{(q)}]$$
(52)

Substituting $[S_{ip}^{(q)}]$ for $[S_{ip}^{(q-1)}]$, we obtain

$$[\mathbf{x}_{j(k)p}^{I}] = [\Phi^{(q)}][\mathbf{s}_{ip}^{(q)}] + [\mathbf{R}_{jp}^{(q+1)}]$$

= $[\Phi^{(q)}][\mathbf{s}_{ip}^{(q-1)}] + [\Phi^{(q)}][\Phi^{(q)}]^{+}[\mathbf{R}_{jp}^{(q)}] + [\mathbf{R}_{jp}^{(q+1)}]$
(53)

From Equations (46) and (53),

$$[Y_{j(k)p}^{I}] = [Y_{j(k)p}^{I}] - [R_{jp}^{(q)}] + [\Phi^{(q)}][\Phi^{(q)}]^{+}[R_{jp}^{(q)}] + [R_{jp}^{(q+1)}]$$

or

$$[R_{jp}^{(q+1)}] = ([1] - [\Phi^{(q)}][\psi^{(q)}]^{+})[R_{jp}^{(q)}]$$
(54)

Compare Equation (54) to Equation (48).

Consider a column of Equation (54) $\{R_{j(p)}^{(q+1)}\}$. Because of Equation (18),

$$\frac{\partial \{R_{j(p)}^{(q+1)}\}^{T}\{R_{j(p)}^{(q+1)}\}}{\partial \{S_{i(p)}\}} = 0$$

$$\{ R_{j(p)}^{(q+1)} \}^{T} \{ R_{j(p)}^{(q+1)} \} = \{ R_{j(p)}^{(q)} \}^{T} \{ [I] - [\phi^{(q)}] [\phi^{(q)}]^{+} \}^{T} ([I] - [\phi^{(q)}] [\phi^{(q)}]^{+}]^{T} ([I] - [\phi^{(q)}] [\phi^{(q)}] [\phi^{(q)}]^{+}]^{T} ([I] - [\phi^{(q)}] [\phi^{(q)}] [\phi^{(q)}]^$$

$$- \{ R_{j}^{(q)} \} [\phi^{(q)}] [\frac{\pi}{2}^{(q)}]^{+} \{ R_{j}^{(q)} \}$$
(55)

because $[\Phi]^+[\Phi] = [I_R]$ (Equation 15) and $[\Phi^{(q)}][\Phi^{(q)}]^+$ is symmetrical. Now $[\Phi^{(q)}][\Phi^{(q)}]^+ = [\Phi^{(q)}]([\Phi^{(q)}]) - \frac{T}{2}$ $([\Phi^{(q)}])^{-1/2}[\Phi^{(q)}]^T$ and $[\Phi^{(q)}]$ is necessarily maximally column ranked. Therefore, $[\Phi^{(q)}][\Phi^{(q)}]^+$ is positive semidefinite. The left side of Equation (55) is the positive

definite. The left side of Equation (55) is the positive difference between two positive numbers, and it follows that

$$J P \qquad J P \qquad J P \qquad J P \qquad J \qquad p \qquad (q) \qquad 2 \qquad (q) \qquad 2 \qquad (q) \qquad$$

Equation (51) shows that the Euclidian norm of residuals with odd index q is less than the norm of residuals of index q-1; Equation (56) shows that the norm of residuals of index q+1 is less than the norm of residuals of index q. Equations (51) and (56) show that it is immaterial whether q is odd or even.

$$\begin{array}{cccc} \mathbf{J} & \mathbf{P} & \mathbf{J} & \mathbf{P} \\ \boldsymbol{\Sigma} & \boldsymbol{\Sigma} & \left(\mathbf{R_{jp}^{(q+1)}}\right)^2 < \boldsymbol{\Sigma} & \boldsymbol{\Sigma} & \boldsymbol{\Sigma} & \left(\mathbf{R_{jp}^{(q)}}\right)^2 < \boldsymbol{\Sigma} & \boldsymbol{\Sigma} & \boldsymbol{\Sigma} & \left(\mathbf{R_{jp}^{(q-1)}}\right)^2 \\ \mathbf{j=1 \ p=1} & \mathbf{j=1 \ p=1} & \mathbf{j=1 \ p=1} & \mathbf{j=1 \ p=1} & \mathbf{jp} \end{array}$$
(57)

Equation (57) covers a complete iteration cycle. Q.E.D.

17

NOTE ON THE DERIVATIVE OF A SCALAR WITH RESPECT TO A VECTOR

Let [S] be a square matrix of order R

$$\{\chi\}^{T}[S]\{Y\} = \sum_{i=1}^{R} \sum_{j=1}^{R} S_{ij}\chi_{i}\gamma_{j}$$

$$\{\mathbf{y}\}^{\mathrm{T}}[\mathbf{S}]^{\mathrm{T}}\{\boldsymbol{\chi}\} = \sum_{i=1}^{\mathrm{R}} \sum_{j=1}^{\mathrm{R}} s_{ji} \mathbf{y}_{i} \mathbf{\chi}_{j}$$

$$\frac{\partial \{\chi\}^{T}[S]\{y\}}{\partial \{\chi\}^{T}} = \sum_{j=1}^{R} S_{ij}Y_{j} = [S]\{y\}$$

$$- \frac{\partial \{\chi\}^{\mathrm{T}}[\mathbf{S}]\{\gamma\}}{\partial \{\gamma\}} = \sum_{i=1}^{\mathrm{R}} \mathbf{s}_{ij} \chi_{i} = [\mathbf{S}]^{\mathrm{T}}\{\chi\}$$

$$\frac{\partial \{\chi\}^{T}[S]\{Y\}}{\partial \{Y\}^{T}} = \frac{\partial \{Y\}^{T}[S]^{T}\{\chi\}}{\partial \{Y\}^{T}} = \frac{\partial \{Y\}^{T}[S]^{T}\{\chi\}}{\partial \{Y\}^{T}} = \frac{\partial i=1 \ j=1}{\partial \{Y\}^{T}} = [S]^{T}\{\chi\}$$

$$\frac{\partial \{\chi\}^{T}[S]\{\chi\}}{\partial \{\chi\}^{T}} = [S]\{\chi\} + [S]^{T}\{\chi\} = ([S] + [S]^{T})\{\chi\}$$

IDENTIFIED GENERALIZED MASSES

A REAL PROPERTY IN THE REAL PROPERTY OF THE REAL PR

Typical generalized mass identifications are shown in Tables I through VI. Table VII describes the various models for which data is presented in Tables I through VI. Table VIII presents a lumped mass description of the twenty-point specimen which was used to generate the simulated experi-The model stations used in the various models mental data. refer to the corresponding stations in the twenty-point specimen. Table I presents results for model 5C, which are typical of the results obtained for other five-point models. Data are presented for conditions of zero experimental error and for simulated experimental displacement mobility data recorded with a random error of +5 percent and a bias error of +5 percent. For the cases involving error, the random displacement error was computed using a uniformly distributed probability density function. This error was applied to both the real and imaginary components of the displacement Table I presents the effects of random number, mobility data. the seed used in generating the random error. The results indicate the method is extremely insensitive to measurement errors as applied herein.

Table II shows results for several different five-point models. It is apparent that no outstanding differences exist among the models considered. The results for the twenty-point specimen, the simulated actual structure, are also given in the table for comparison. The generalized mass distribution associated with each of the models is in excellent agreement with the twenty-point results.

Tables III and IV present results for the nine-point models studied. Again, the calculations of the generalized masses for the various nine-point models under consideration are in agreement with the simulated structure.

Tables V and VI describe the results of the computer experiments conducted employing the twelve-point models. The calculations produced acceptable results except for identification of the generalized masses of the 10th and 11th modes. The generalized masses associated with these models are extremely small in comparison to the remaining modal generalized masses. Further, the mode shape of the 10th mode indicates lack of response at all points of interest on the structure other than the first station. Therefore, the effect of the 10th mode is difficult to evaluate in the calculation of the generalized parameters.

Computer experiment 309 yielded a negative 10th generalized mass. All computer experiments that failed in this respect gave drastically unrealistic values of generalized mass. Ordinarily, using different stations or forcing frequencies produced proper identification of all modes.

RESPONSE FROM IDENTIFIED MODEL

Figures 1 through 12 portray typical real and imaginary acceleration mobility response obtained from the various models considered in the present study. In each instance, the exact curve represents the simulated experimental data for the twenty-point structure, obtained with zero error. Figures 1 and 2 provide the effect of random number seed for a typical five-point model. Figures 3 and 4 present the results obtained for one of the nine-point models considered in the investigation. Figures 5 and 6 show the effect of the random error seed on a twelve-point model. All computer experiments which incorporated error used a +5 percent random and a +5 percent bias on the real and Imaginary displacement mobility data.

Figures 7, 8, 9, 10, 11 and 12 present the reidentified acceleration mobility, both real and imaginary, for typical five-, nine-, and twelve-point models respectively. The models varied in that different spanwise masses were considered. Some of the models employed in the study are given in Table VII showing the various points of interest for each model. For each model, the computer experiments were executed using the same random number seed and the aforementioned errors were incorporated. As evidenced by the figures, the various models provided acceptable reidentification of the twenty-point specimen simulated experimental displacement mobility data.

ACCELERATION (G/LB-FORCE)

AND MARKED V. CONSIGNATION

CONCLUSIONS

- Single-point excitation of a structure yields the necessary mobility data to satisfactorily determine the mass, stiffness and damping characteristics for a mathematical model having less degrees of freedom than the linear elastic structure it represents.
- 2. The method does not require an intuitive mathematical model and uses only a minimum amount of impedance-type test data.
- 3. The eigenvector or mode shape associated with each natural frequency is also determined in the analysis.
- 4. Computer experiments using simulated test data indicate the method is insensitive to the level of measurement error inherent in the state of the measurement art.
- 5. A fully populated mass matrix should be assumed for an accurate analytical model of a real structure.

APPENDIX COMPUTER PROGRAM DESCRIPTION

A digital computer program was designed for computer experiment to investigate the proper physical interpretation of identified parameters for use in helicopter engineering. The program was written for the IBM 360/40 operating system using FORTRAN IV language. A flow chart indicating the program logical procedure is shown in Figure 13. A description of the input cards and a program source listing are included in this appendix.
