13. ABSTRACT

This report describes five computer programs that are being used at the Naval Ordnance Laboratory for analyzing satellite magnetism. The programs contain numerical analysis algorithms for the spherical harmonic analysis of the magnetic field emanating from a satellite. The analysis is directed at determining the components of the magnetism which correspond to the dipole moment, quadrupole moment, etc. The first three programs were devised to analyze data from magnetic field measurements around the satellite. The fourth program was devised to generate simulated measurement data for a specified system of multipole magnets. The last program is a combination of the data generation and the data analysis programs. Sample problems are included in the discussion to illustrate the techniques of using the programs with a CDC 6400 Computer including the INTERCOM time-sharing system. A brief description is also included of data acquisition techniques and of principal subprograms.

Computer Programs for the Analysis of Spacecraft Magnetism

During the past several years techniques have been developed for measuring and analyzing the magnetism of spacecraft. The techniques are directed, first, at estimating the spacecraft's magnetic dipole moment and, second, at compensating the dipole moment to allow the spacecraft to maintain a stable orientation while in orbit. This procedure requires accurate measurements of the magnetic field emanating from the spacecraft. The Naval Ordnance Laboratory is currently involved in the development of a facility to conduct sophisticated magnetic tests of spacecraft. The facility will contain instrumentation which will automatically record and analyze the test data. This report has been published to document the numerical techniques to be used in the analysis of the data. Techniques are also described which can be used to predict the accuracy of different types of measurement and analysis techniques.

The development and testing of the computer programs required a considerable amount of effort. Mr. H. W. Korab contributed much to this effort, including the development of the BASIC version of the analysis procedure. He also assisted in the development of the illustrations included in this report.

This work was funded in part by the Spacecraft Technology Center of the Naval Research Laboratory under task number NOL-786-GO1-53.

Chapter 1

INTRODUCTION

1. A major effort has been applied to the development of computer programs and subprograms to assist in the analysis of satellite magnetism. The analysis is part of a procedure directed at determining and compensating the magnetic dipole moment of a satellite. The procedure involves four steps. The first step is to measure the normal component of the satellite's magnetic field on the surface of a sphere enclosing the satellite. The second step involves the spherical harmonic analysis of the measured data to determine the magnitude and the direction of the satellite's dipole moment. The third step is to attach an opposing dipole to the satellite with equal magnitude and opposite direction. The final step is to repeat the measurement and analysis procedures to verify the compensation.

2. The five programs described in this report have been devised to perform a variety of data analysis tasks. One of the programs is coded in the BASIC computer language. The other four are coded in FORTRAN IV. The first three programs are used to analyze data representing the normal component of the magnetic field on the surface of a sphere enclosing the satellite. The fourth program is used to generate simulated measurement data for a specified system of multipole magnets. The program also allows the simulation of measurement errors. The last program is a combination of the data generation and the analysis programs. The programs have been designed to allow a variety of options including:

a. Reading the input data from paper tape or from a data file

b. Using either an algebraic or geometric integrating scheme to perform the analysis

c. Printing the data after preliminary data processing

d. Interpolating and plotting the processed data curves.

3. The discussion begins with a brief description of data acquisition techniques. This is followed by a description of the five programs including sample problems which demonstrate the use of the programs. Finally, a description is given of some of the primary subprograms. These are listed separately since they can be used as building blocks for other programs. The discussion is supplemented by several illustrations, many of which are the actual computer outputs from the execution of the computer programs. The majority of the data curves are output from the CALCOMP 570 digital incremental plotter. A description of the data units for the programs has also been included in paragraph 33. Appendix A contains a glossary of symbols and terms used in the report.

Chapter 2

DATA ACQUISITION TECHNIQUES

4. A brief description of spherical coordinates and the techniques used in the data acquisition will assist in the description of the parameters used in the data analysis and the computer programs. Figure 1 illustrates the relationship between rectilinear and spherical coordinates. An arbitrary point $\bar{R}$ (or vector) in space can be defined in terms of the spherical coordinates of R, θ, and φ representing the radial distance, the colatitude and the (easterly) longitude respectively. (θ is sometimes called the polar angle, and φ is sometimes called the dihedral angle.) Appendix A gives the definitions of these coordinates in terms of rectilinear coordinates.

5. Figure 2 shows a simplified diagram of the test setup for conducting the measurements of a satellite's magnetism. The degrees of freedom illustrated in the figure are defined to correspond to the spherical angles. The rotation axis, provided by a horizontal turntable, allows a variation in colatitude. The tilt axis, provided by a gimballing fixture attached to the satellite, allows a variation in longitude. Analog curves are made of the sensor reading versus the colatitude for a fixed set of positions of longitude. The curves are recorded while the satellite is in a zero magnetic field environment. Notice that the sensor in Figure 2 is radially aligned. This setup generates analog curves representing the normal component of the satellite magnetism along great circles of longitude as shown in Figure 3.

6. Let the <u>parameter NO</u> represent the number of curves of data to be recorded. These curves correspond to measurements along great circles spaced (180/NO) degrees apart. Figure 3 shows an example when NO = 6. There will be six analog curves of data corresponding to the six great circles. Figure 4 shows the initial positions for each of the curves.

7. As a sample problem consider the system of dipoles illustrated in Figure 5. The first curve begins with the +z-axis directed at the magnetic sensor and the +y-axis pointed up. The turntable is rotated clockwise. Prior to beginning each succeeding curve, the satellite is tilted (180/NO = 30) degrees around the z-axis. Figure 6 shows a typical set of six data curves for the sample problem. Each curve is marked with 25 data points. The parameter N1 is used to represent the number of data points per curve (N1 = 25 in the example). The points are spaced (360/(N1-1)) = 15 degrees apart. The value at each measurement point is automatically recorded via analog-to-digital (A/D) conversion equipment in the satellite measurements.

8. Notice that the curves in Figure 6 do not all begin with the same value, although, theoretically they should. This is typical of the type of measurements that are made on satellites. The curves represent relative measurements instead of absolute measurements. It would be possible to insure that the curves all begin with the same value, but it would not necessarily be the correct value. Nevertheless, the data analysis is independent of the starting value of each curve. Therefore, no concern is given to this problem in the acquisition of the data.

9. Reference (a) lists several considerations in the determination of the parameters for the data acquisition including NO, N1, and the radius R1 of the measurement sphere. The considerations include:

a. The smoothness of the data curves

b. The analysis method

c. The accuracy of the measuring apparatus

d. The round-off errors of the computing machine.

The parameters are not all independent. They must be determined by making certain compromises. For instance, the data curves can be smoothed by increasing R1 (i.e., by increasing the minimum distance between the surface of the measurement sphere and the satellite), but this will decrease the relative accuracy of the data. Also, the total number of data points NO•N1 may be increased, but computing machine errors will become more significant. An increase in the number of data points will also increase the computing time and data storage.

10. Experience has shown that the dipole moment for most problems can be approximated accurately enough if the following conditions hold:

a. Let the minimum distance between the surface of the measurement sphere and the satellite be at least half the maximum diameter of the satellite to insure sufficient smoothness of the data curves. For example, the radius of the measurement sphere for a body with maximum diameter of 50 inches, and centered at the origin, should be at least 50 inches.

b. Let NO be ≥ 8 and N1 be ≥ 16 to insure that the errors from the numerical approximation are smaller than the measurement errors. (This condition can be relaxed in cases where the satellite magnetism gives simple sine-cosine curves. In the past, NO = 4 and N1 = 25 has been sufficient in many cases.)

c. Use the simplest analysis procedure (i.e., the geometric integrating scheme) for the preliminary analysis since it is relatively accurate and easy to use.

Chapter 3

MAIN PROGRAMS

PROGRAMS SA1024 AND SA2024

Introduction

11. The programs labeled SA1024 and SA2024 (Appendices B and C) are BASIC and FORTRAN IV versions, respectively, of the basic one-term data analysis procedure. The procedure is simple because only the dipole moment term is computed for the satellite magnetism and only the approximate method of numerical integration is used. The programs print the measurement data and the computed dipole moment in rectilinear and spherical coordinates. They also print data which assists in calibrating and aligning the compensating dipoles. The major difference between the two versions is the manner of entering the data. The BASIC version is set up to take the data from DATA statements. The FORTRAN IV version accepts data from paper tape or from a data file.

Input Data

12. The data is entered into the programs in the order of the following definitions:

a. First line of data or data card - format: (3I5)

NO - The number of curves of data (NO is even and ≤ 16.)

N1 - The number of equally spaced data points per curve from 0 thru 360 degrees colatitude (N1 is odd and ≤ 33. The first and last data points for each curve correspond to measurements at 0 degrees colatitude.)

IR - The parameter that determines whether or not to read the data from a data file. IR ≠ 0 means that the data will be read from the data file DAT024. (This parameter is used only with the FORTRAN IV version.)

b. Second line of data or data card - format: (2F6.1)

R1 - The radius of the measurement sphere in inches

C6 - The value of the calibration signal (C7-C8) in gamma

c. Third line of data or data card - format: (I5)

N2 - The parameter that determines whether or not to print the measured data ($N2 \neq 0$ means that the data will be printed.)

d. Measurement data - format: (9F6.1) (These cards are deleted if $IR \neq 0$.)

C7 - The static measurement with the calibration signal

C8 - The static measurement without the calibration signal

F(I,J) - The measurement data for I = 1,2,···,N1 and J = 1,2,···,N0.

The input data cycle may be repeated by starting with new data N0, N1, and IR again. The program execution is terminated by setting the new value for N0 equal to zero.

Output Data

13. The programs SA1024 and SA2024 then perform a numerical integration of the equation

$$\bar{D} = (3\cdot R1^3/8\pi)\int_0^{\pi}\int_0^{2\pi} f(\theta,\varphi)\,\sin\theta\,d\theta\,\partial\varphi \qquad (1)$$

for the dipole moment $\bar{D}$. The numerical equation is

$$\bar{D} \approx (3\cdot R1^3/8\pi)\sum_{J=1}^{N0}\sum_{I=1}^{N1} F(I,J)\cdot\pi(\theta(I),\varphi(J))\cdot X(I) \qquad (2)$$

where

$$\bar{D} \equiv (D_1,\ D_2,\ D_3) \text{ is in gauss-centimeters}^3$$

$$F(I,J) \equiv f(\theta(I),\varphi(J)) \text{ is in gammas}$$

$$\bar{n}(\theta(I),\varphi(J)) \equiv \begin{bmatrix} \sin(\theta(I))\cdot\cos(\varphi(J)) \\ \sin(\theta(I))\cdot\sin(\varphi(J)) \\ \cos(\theta(I)) \end{bmatrix}$$

$\theta(I) \equiv 2\pi(I - 1)/(N1 - 1)$ is the colatitude (turntable angle) (3a)

$\varphi(J) \equiv \pi(J - 1)/NO$ is the longitude (tilt angle) (3b)

$X(I) \equiv [\sin(\pi/(2\cdot N1 - 2))]^2/(2\cdot NO)$ if $I = 1$ or $N1$ (4a)

$\equiv [\sin(\pi/(2\cdot N1 - 2))]^2/NO$ if $I = (N1 + 1)/2$ (4b)

$\equiv |\sin(\theta(I))\cdot\sin(\pi/(N1 - 1))|/(2\cdot NO)$ if $I \neq 1$, $(N1 + 1)/2$, or $N1$. (4c)

14. Next, the dipole moment is transformed into spherical coordinates as

$$D \equiv (D_1^2 + D_2^2 + D_3^2)^{\frac{1}{2}}$$

$$\theta \equiv \tan^{-1}\left[(D_1^2 + D_2^2)^{\frac{1}{2}}/D_3\right]\cdot 180/\pi = \text{colatitude}$$

$$\varphi \equiv \tan^{-1}(D_2/D_1)\cdot 180/\pi = \text{longitude}$$

15. Finally, the program computes the values of two compensating magnets: one in the xy-plane and one along the z-axis. The value of the dipole field at one meter is also given to assist in charging the magnets to the desired values.

Sample Problem for SA2024

16. Appendix D contains the input and output data for SA2024 using the sample problem represented in Figures 5 and 6. The file BN2024, which is used for execution, is the binary version of SA2024. This example was executed in two different ways on the INTERCOM time-sharing system using the CDC 6400 computer. The information typed in at the teletype terminal has been underlined. Data tapes representing the measurement data are generated by the A/D equipment during the measurements. The program automatically reads the data in the proper format; converts the data into gammas using the calibration parameters C6, C7, and C8; and adjusts the data so that the beginning and ending points for all the curves have nearly the same value. The result of this procedure is visible in the data print-out on page 2 of Appendix D.

17. The first method of data input in Appendix D was from the file DAT024. This complete problem required only the first three lines of data. The measurement data was read into the file from an earlier execution of SA2024. (The program execution automatically generates the file DAT024 if the data is read in from tape.) The remaining lines of data initiated the computation of the solution to the same problem except that the measurement data was read in from a data tape.

PROGRAM SA3024

Introduction

18. The program SA3024, listed in Appendix E, allows a more complete analysis to be performed on the data. The program can be used to compute the dipole, quadrupole, and higher order multipole terms. Also included is an optional method of integrating the data and a data plotting option. The optional integrating scheme is labeled "exact" although it is exact only for magnetic data from a finite number of multipole magnets centered at the origin. This scheme is discussed in more detail in paragraphs 25 through 32 and in reference (a).

19. The program uses several special subprograms to perform such tasks as:

a. The computation of spherical harmonic coefficients for magnetic field data

b. The generation of values of associated Legendre polymomials and Schmidt functions

c. The inversion of an n x n matrix

d. The interpolation and plotting of data.

Some of these subprograms will be discussed in more detail in later sections.

Input Data

20. The method for entering the data into SA3024 is very similiar to the method for SA2024 with several additional variables. The data is entered in the following order:

a. First line of data or data card - format: (6I5)

NO - The number of curves of data (NO is even and ≤ 16.)

N1 - The number of equally spaced data points per curve from 0 thru 360 degrees colatitude (N1 is odd and ≤ 33. The first and last data points for each curve correspond to measurements at 0 degrees colatitude.)

NH - The highest degree spherical harmonic term to be computed from the data (NH = 1 for dipoles, 2 for quadrupoles, etc.)

IR - The parameter that determines whether or not to read the data from a data file ($IR \neq 0$ means that the data will be read from the file DAT024.)

IP1 - The parameter that determines whether or not the data is to be interpolated and plotted ($IP1 \neq 0$ means that the data will be interpolated and plotted.)

IW - The parameter that determines which integrating scheme is to be used (IW = 0 means that the exact, algebraic scheme is to be used.)

b. Second line of data or data card - format: (3F8.4)

R1 - The radius of the measurement sphere in inches

CV - The value of the calibration signal (CS-CZ) in gamma

PY - The scale factor (gammas/inch) for the y-axis if the data is to be plotted (If PY = 0.0 a factor will be computed from the data.)

c. Third line of data or data card - format: (I5)

IP2 - A parameter that determines whether or not to print the measured data ($IP2 \neq 0$ means that the data will be printed.)

d. Measurement data - format: (9F6.1) (These cards are deleted if $IR \neq 0$.)

CS - The static measurement with the calibration signal

CZ - The static measurement without the calibration signal

$F(I,J)$ - The measurement data for $I = 1,2,\cdots,N1$ and $J = 1,2,\cdots,N0$.

The input data cycle may be repeated by starting with new data N0, N1, $\cdots$, etc. The program is terminated by setting the new value for N0 equal to zero.

Output Data

21. The program then computes the spherical harmonic coefficients A_n^m and B_n^m based on the equation

$$\begin{Bmatrix} A_n^m \\ B_n^m \end{Bmatrix} = \left[(2n + 1)\cdot R1^{n+2}/(4\pi\cdot(n + 1))\right] \int_0^{\pi}\int_0^{2\pi} f(\theta,\varphi)\cdot P_n^m(\cos\theta) \begin{Bmatrix} \cos(m\varphi) \\ \sin(m\varphi) \end{Bmatrix} \cdot \sin\theta\, d\theta\, d\varphi \tag{5}$$

for $n = 0,1,\cdots,NH$ and $m = 0,1,\cdots,n$. The numerical equivalent of equation (5) is

$$\begin{Bmatrix} A_n^m \\ B_n^m \end{Bmatrix} = \left[(2n + 1)\cdot R1^{n+2}/(4\pi\cdot(n + 1))\right] \sum_{J=1}^{N0} \sum_{I=1}^{N1} F(I,J)\cdot P_n^m(\cos(\theta(I)))\cdot \cdot\begin{Bmatrix} \cos(m\cdot\varphi(J)) \\ \sin(m\cdot\varphi(J)) \end{Bmatrix}\cdot Y(I) \tag{6}$$

where

n is the degree of the spherical harmonic term

m is the order of the spherical harmonic term

$P_n^m(\cos(\theta(I)))$ is the Schmidt function of degree n and order m. (These functions are discussed in Appendix K.)

$Y(I)$ is the array of weighting factors for the numerical integration. (One of two methods can be used to determine the values for $Y(I)$ depending on the parameter IW.)

$\theta(I) \equiv 2\pi(I - 1)/(N1 - 1)$ is the colatitude (turntable angle)

$\varphi(J) \equiv \pi(J - 1)/N0$ is the longitude (tilt angle).

Equation (5) gives an expansion for the function $f(\theta,\varphi)$ as

$$f(\theta,\varphi) = \sum_{n=0}^{\infty} (n+1)/(R1^{n+2}) \sum_{m=0}^{n} \left[A_n^m \cos(m\varphi) + B_n^m \sin(m\varphi)\right] P_n^m(\cos(\theta)). \qquad (7)$$

If the expansion is written as $f(\theta,\varphi) = \sum_{n=0}^{\infty} f_n(\theta,\varphi)$ then each $f_n(\theta,\varphi)$ represents the field from a multipole magnet of degree n. (Reference (a) contains more details on the expansion of the function $f(\varphi,\theta)$.)

22. In general, the coefficients A_n^m and B_n^m can be stored as two-dimensional arrays A(n,m) and B(n,m), or, they may be packed into single-dimensional arrays as

$$A(m + 1 + (n^2 + n)/2) \equiv A_n^m \text{ for } n = 0,1,2,\cdots \text{ and } m = 0,1,\cdots,n$$

$$B(m + (n^2 - n)/2) \equiv B_n^m \text{ for } n = 1,2,\cdots \text{ and } m = 1,2,\cdots,n.$$

23. The program SA3024 is set up to conserve storage by computing and storing the coefficients for only one degree term at a time (i.e., for each fixed n) using the equations

$$A(m+1) \equiv A_n^m \text{ for } m = 0,1,\cdots,n$$

$$B(m) \equiv B_n^m \text{ for } m = 1,2,\cdots n. \qquad (8)$$

It should be noted that the coefficient A_0^0, corresponding to the monopole moment, would be zero if the numerical integration was exact and the data F(I,J) was correct. If the monopole moment is not zero, then the data is corrected prior to being printed and prior to further analysis. Also for n = 1 and Y(I) = X(I) it can be shown that Eqs. (1) (or (2)) and (5) (or (6)) are identical if

$$D_1 = A_1^1$$

$$D_2 = B_1^1$$

$$D_3 = A_1^0. \qquad (9)$$

24. The dipole moment $\bar{D} = (D_1, D_2, D_3)$ is computed and printed out separately in the program in both rectilinear and spherical coordinates. The program is also

set up to compute the quadrupole moment Q_{ij} for i and j = 1, 2, and 3. This is computed and printed separately if NH ≥ 2. The computation is based on the equations

$$Q_{11} = \sqrt{3} \cdot A_2^2 - A_2^0 \tag{10a}$$

$$Q_{22} = -\sqrt{3} \cdot A_2^2 - A_2^0 \tag{10b}$$

$$Q_{33} = 2A_2^0 \qquad (\text{i.e., } Q_{11} + Q_{22} + Q_{33} = 0) \tag{10c}$$

$$Q_{12} = \sqrt{3} \cdot B_2^2 \tag{10d}$$

$$Q_{13} = \sqrt{3} \cdot A_2^1 \tag{10e}$$

$$Q_{23} = \sqrt{3} \cdot B_2^1 \tag{10f}$$

$$Q_{ij} = Q_{ji} \text{ for i and j = 1, 2, and 3.} \tag{10g}$$

The higher degree coefficients for n = 3,4,···,NH are printed only in their spherical form.

Integrating Schemes

25. The program SA3024 is set up to allow a choice between two numerical integration schemes for Eq. (6). These two schemes are based on two different methods for determining the weighting factors $\{Y(I)\}$. The factors actually correspond to the elements of spherical surface area assigned to each data point F(I,J). Therefore, a geometrical description of the two different sets of weighting factors will provide some insight into the two methods of numerical integration. Figure 7 shows an example of the areas assigned to a data point for both integrating methods. The dashed lines are boundaries for areas when the parameter $IW \neq 0$. The areas have values $\{X(I)\}$ as defined in Eq. (4). (The weighting factors $\{Y(I)\}$ in Eq. (6) are then set equal to $\{X(I)\}$.) The dashed lines are equally spaced between data points with equal intervals of longitude (= π/NO) and equal intervals of colatitude (= 2π/N1). The weighting factors $\{Y(I) = X(I)\}$ are easier and faster to calculate by computer than the factors when IW = 0. The resulting integration has good numerical stability and gives fairly accurate answers.

26. If the parameter IW = 0, then a more exact integrating scheme is used. The weights $\{Y(I)\}$ are still elements of area on the surface of the unit sphere, and they still consist of equal intervals of longitude. But the intervals of colatitude (dotted lines in Figure 7) are varied to make certain surface integrals exact if the integrand consists of a finite number of spherical harmonic terms. The highest degree term that can be contained in the integrand (or highest degree magnet that can be represent by the data F(I,J)) and still be exact depends on the parameters NO and N1. The relationship of NO and N1 to the degree n and order m of the coefficients A_n^m and B_n^m are

$$\begin{aligned} NO &\geq m + 1 \\ N1 &\geq 4n + 1. \end{aligned} \tag{11}$$

Since $m \leq n$, as seen in Eqs. (5) and (7), the coefficients for a multipole magnet of degree n can be approximated accurately only if

$$\begin{aligned} NO &\geq n + 1 \\ N1 &\geq 4n + 1. \end{aligned} \tag{12}$$

This means that the dipole terms ($n = 1$) require that $NO \geq 2$ and $N1 \geq 5$. The following table shows values for several multipole magnets.

TABLE 1 EXAMPLES OF MINIMUM VALUES OF NO AND N1

n	NO≥	N1≥
1 (dipole)	2	5
2 (quadrupole)	3	9
3	4	13
4	5	17
5	6	21
6	7	25
7	8	29
8	9	33

27. It should be noted here that setting NO, N1 = 2, 5 will not generally give the dipole term very accurately unless the higher degree terms are all zero. For example, consider a problem which has only dipole and quadrupole terms, and assume

that only the dipole coefficients are to be computed. Then NO, N1 $\geq$ 3, 9 is required to insure the accuracy of the dipole computations. In general a problem contains an infinite number of terms. The only cases when the expansion in Eq. (7) contains a finite number of terms are when there are only a pure dipole (of insignificant length), a quadrupole, and/or, a finite number of other multipole magnets which are centered at the origin. An offset dipole or a dipole of considerable length (or any offset multipole magnet of degree n) requires an infinite number of terms for representation by Eq. (7). In general, it is best to select NO and N1 as large as possible with

$$NO = (N1 - 1)/2. \qquad (13)$$

28. For IW = 0, the weights Y(I) are composed of two factors D(I) and C, i.e.,

$$Y(I) = D(I) \cdot C \qquad (14)$$

for I = 1,2,$\cdots$,N1 and J = 1,2,$\cdots$,NO (see reference (a)). The constant C represents the equally spaced intervals of longitude with value

$$C = \pi/NO. \qquad (15)$$

The factors D(I) are determined by solving a set of simultaneous linear equations. The equations can be set up in a number of ways since the factors are symmetric with respect to the values of colatitude of $\theta = \pi/2$ and $\theta = \pi$. The method used in SA3024 is to set up and solve the equations for factors representing the intervals between $\theta = 0$ and $\pi/2$, and then to use symmetry to determine the other weights. This procedure involves two different cases based on the odd integer N1. Figure 8 shows the intervals of colatitude for two examples; one when (N1 + 1) is a multiple of 4 and one when it is not. The examples give rise to two different sets of equations for the factors D(I) as follows:

a. <u>Equations when (N1 + 1) is a multiple of 4</u>

Let

$$\theta(I) \equiv 2\pi(I - 1)/(N1 - 1) \qquad (3a)$$

$$N3 \equiv \text{largest integer} \leq (N1 + 3)/4 \qquad (16)$$

Then

$$\sum_{J=1}^{N3} D(J) = 1 \tag{17a}$$

$$\sum_{J=1}^{N3} (\cos \theta(J))^{(2I - 2)} \cdot D(J) = 1/(2I - 1) \tag{17b}$$

for I = 2,3,···,N3

$$D[(N1 + 3)/2 - J] = D(J) \tag{17c}$$

for J = 2,3,···,N3

$$D(N1 + 1 - J) = D(J) \tag{17d}$$

for J = 1,2,···,(N1 - 1)/2

$$D[(N1 + 1)/2] = 2D(1) \tag{17e}$$

b. Equations when (N1 + 1) is not a multiple of 4

Let θ(I) and N3 be defined as in Eqs. (3a) and (16). Then

$$\sum_{J=1}^{N3} 2D(J) + D(N3 + 1) = 2 \tag{18a}$$

$$\sum_{J=1}^{N3} (\cos \theta(J))^{(2I - 2)} \cdot D(J) = 1/(2I - 1) \tag{18b}$$

for I = 2,3,···,N3 + 1. Equations (17c), (17d), and (17e) remain unchanged.

29. In Eqs. (17a) and (17b) the I and J "subscripts" can be considered to designate the row and column for the coefficient matrix for N3 simultaneous linear equations in N3 unknowns. This also follows in Eqs. (18a) and (18b) except for an (N3 + 1) x (N3 + 1) system of linear equations. The system of equations for two examples are given below.

30. Let N1 = 7. Then (N1 + 1) = 8 is a multiple of 4, and

$$N3 = 2 \leq (7 + 3)/4 = 2.5$$

$$\theta(1),\theta(2) = 0,\ 60^\circ$$

$$\cos(60) = 1/2.$$

Therefore Eqs. (17a) and (17b) imply that

$$D(1) + D(2) = 1$$

$$D(1) + D(2)/4 = 1/3.$$

These equations are satisfied by

$$D(1) = 1/9,\quad D(2) = 8/9.$$

The remaining equations, (16c), (16d), and (16e), imply that

$$D(1),\ D(2),\ \cdots,\ D(7) = 1/9,\ 8/9,\ 8/9,\ 2/9,\ 8/9,\ 8/9,\ 1/9.$$

31. Next, let N1 = 9. Than (N1 + 1) = 10 is not a multiple of 4, and

$$N3 = 3 \le (9 + 3)/4 = 3.0$$

$$\theta(1),\theta(2),\theta(3) = 0,\ 45^\circ,\ 90^\circ$$

$$\cos(45^\circ) = 1/\sqrt{2}.$$

Therefore, Eqs. (18a) and (18b) imply that

$$2D(1) + 2D(2) + D(3) = 2$$

$$D(1) + D(2)/2 = 1/3$$

$$D(1) + D(2)/4 = 1/5.$$

The solution to these equations is

$$D(1),\ D(2),\ D(3) = 1/15,\ 8/15,\ 4/5.$$

The remaining equations, (17c), (17d), and (17e), imply that

$$D(1),\ D(2),\ \cdots,\ D(9) = 1/15,\ 8/15,\ 4/5,\ 8/15,\ 2/15,\ 8/15,\ 4/5,\ 8/15,\ 1/15.$$

32. Reference (a) gives a more theoretical approach to the methods of integration and describes another method for determining the factors D(I) using a polynomial approach. This method was compared with the direct inversion of the Eqs. (16) and (17). The results indicated that the direct inversion method was more stable numerically and took less computer time.

Units

33. All the programs use a mixed system of units. In general, the magnetic units are in the cgs system, e.g., the magnetic field intensity $\bar{H}$ ($f(\theta,\varphi)$ in Eq. (5)) is in gammas (10^{-5} oersted with a permeability of one). The units for a multipole moment of degree n is pole-centimeter^n, e.g., monopole moment is in poles, dipole moment is in pole-centimeters (cm), quadrupole moment is in pole-cm^2. The unit pole is equivalent to gauss-cm^2. The unit of length is inches. This is used for the measurement radius R1 and the multipole position vectors P (for programs SA4024 and SA5024). The unit of gammas is used for the data array F(I,J) and for the error parameters EG and ED (for programs SA4024 and SA5024). Any parameters that represent angles or angular errors are in degrees.

Sample Problems

34. Appendix F contains the input and output data for SA3024 using the same measurement data as in SA2024 (Figures 5 and 6). The file BN3024, used in the execution, is the binary version of SA3024. Only the first 16 binary records (subprograms) are used when executing via INTERCOM. As before, the example was executed in two different ways on the INTERCOM System. The problem was also submitted to BATCH processing via INTERCOM to demonstrate a method of using the plotting option of the program. One of the two identical plots that resulted from the BATCH processing is included in Figure 9. Although the example in Section II of Appendix F was set up to use the GOULD electrostatic plotter, the data was later plotted on the CALCOMP to simplify reproduction problems.

35. Several characteristics of the analysis can be observed by comparing Appendices D and F and Figures 6 and 9. The first characteristic is the data processing. This involves the conversion of the data units and the adjustment of the curves so that all the curves begin and end as near as possible to the beginning and ending of the first curve. The curve adjustment can be observed by comparing the print out of the data tape on page D-1 and the data printed on page D-2. The first points of curves 1 and 2 on the data tape are -504.3 and -902.8. After the data processing these points are -504.3 and -502.8. Another data adjustment in SA3024 has to do with the monopole moment. Since the monopole moment should be zero if the data has absolute accuracy, then the data is adjusted to produce this condition. The procedure involves the computation of the monopole moment, and then, the subtraction of the magnetic field of the monopole component from the data. A comparison of the data printed on page D-2 and on pages F-2 and

F-3 show a difference of about 24 gammas. This appears as the monopole moment of 14.3··· printed on page F-2. The data plotted in Figure 9 represents the data that would have been measured if absolute accuracy was attainable.

36. An example of the method of printing out the spherical harmonic coefficients is shown on page F-3. For each nth degree harmonic term, the coefficients A_n^m for m = 0,1,···,n are printed on the first line, and the coefficients B_n^m for m = 1,2,···,n are printed on the second line. It should be noted that in the definitions related to Eqs. (5) and (6), the coefficients A_n^m and B_n^m are coefficients for the Schmidt polynomials and not for the associated Legendre polynomials. The relationship is discussed in more detail in Appendix K.

PROGRAM SA4024

Introduction

37. The program SA4024, listed in Appendix G, was devised to assist in the conduct of error studies relating to the analysis of satellite magnetism. The program is set up to generate data simulating measurements around a specified system of multipole magnets representing the satellite. Simulated errors can be inserted into the generated data to represent position and instrumentation errors. The generated data is written on a data file (DAT024) in the same format as the one used in the data acquisition procedures with the punched paper tape. The data file is generated in a form that can be used with programs SA2024 and SA3024. The program SA4024 also contains the plotting option.

38. Special subprograms used in the program perform such tasks as:

a. The computation of the magnetic field vector at a remote location from a multipole magnet

b. The generation of values of associated Legendre polynomials and Schmidt functions

c. The interpolation and plotting of the magnetic data.

Input Data

39. The input data for SA4024 varies considerably from the preceding programs since it includes specifications for multipole magnets and data errors. The data is entered in the following order:

a. First line of data or data card - format: (4I5)

NO - The number of curves of data (NO is even and ≤ 16.)

N1 - The number of equally spaced data points per curve from 0 thru 360 degrees colatitude (N1 is odd and ≤ 33. The first and last data points for each curve correspond to measurements at 0 degrees colatitude.)

NH - The total number of different harmonics (degrees) of multipole magnets to be considered

IP - The parameter that determines whether or not the data is to be interpolated and plotted ($IP \neq 0$ means that the data will be interpolated and plotted.)

b. Second line of data or data card - format: (5F8.4)

R1 - The radius of the measurement sphere in inches

EG - The error (in gamma) to be randomly inserted into the data to represent instrumentation inaccuracies

EA - The angular error (in degrees) to be randomly inserted into the data to represent measurement position errors

ED - The constant error (in gammas) to be inserted into the data to represent offset in the instrumentation. (This will be analyzed as monopole moment.)

PY - The scale factor (gammas/inch) for the y-axis if the data is to be plotted. (If PY = 0.0 a factor will be computed from the data.)

c. Third line of data or data card - format: (7A10)

F9 - The format for reading and printing the spherical coefficients A(I) and B(I), e.g., (1H ,7E10.4)

All of the following data is repeated "NH" times:

d. Next line of data or data card - format: (2I5)

NN - The harmonic number (degree) of the multipole data being read in (NN = 1 for dipoles, 2 for quadrupole, etc.)

NM - The number of multipoles with harmonic number NN

The following data is repeated "NM" times:

e. Next lines of data or data cards - format: (3F8.4)

P - The position vector (in inches) of the multipole in rectilinear coordinates (P_x, P_y, P_z.)

f. Next lines of data or data cards - format: F9

A(I) - The spherical coefficients A_{NN}^{I-1} for the multipole of degree NN where I = 1,2,···,NN + 1 (The order of the Ith coefficient is I - 1.)

g. Next lines of data or data cards - format: F9

B(I) - The spherical coefficients B_{NN}^{I} for the multipole of degree NN where I = 1,2,···,NN (The order of the Ith coefficient is I.).

(The relationships between spherical and rectilinear coefficients for dipoles and quadrupoles are given in Eqs. (9) and (10).)

Output Data

40. The program computes data representing measurements of the specified system of multipole magnets. There are NO curves of data computed, each containing N1 data points. The computations are made by using Eq. (7). For instance assume that the system has NM multipoles of degree N and that $f_{nj}(\theta,\varphi)$ represents (as in Eq. (7)) the normal component of the magnetic field from the jth multipole of degree N. Then the total magnetic field $f_n(\theta,\varphi)$ for all multipoles of degree N is

$$f_n(\theta,\varphi) = \sum_{j=1}^{NM} f_{nj}(\theta,\varphi) \qquad (19)$$

If NH is the total number of different degrees for the system of multipoles then the normal component of the magnetic field for the total system is

$$f(\theta,\varphi) = \sum_{N=1}^{NH} f_n(\theta,\varphi) . \tag{20}$$

The program sets up the data array F(I,J) in this manner. (F(I,J) is defined in Eq. (2).) The data array is then written onto the data file DAT024. The file can then be used with either program SA2024 or program SA3024. A data tape can also be made of this file by listing the file under SYSTEM/BASIC with the tape punch unit on.

Sample Problems

41. SA4024 was used to compute the data for several examples. These are listed in Appendix H and in Figures 10 through 24. BN4024 is the binary version of SA4024. When executing the program via INTERCOM only the first nine binary records are used. The first section in Appendix H presents the input and output data for the sample problem illustrated in Figure 5. The instrumentation inaccuracy was assumed to be ±1.0 gamma by setting EG = 1.0. The positions for the measurements of the data were considered to have inaccuracies of ±0.2 degrees (EA = 0.2). The set of data curves were assumed to be offset by 25.0 gammas (ED = 25.0). The data curves representing the simulated measurements are listed on page H-3. Section II of Appendix H contains the data file DAT024 that was generated with this data in a format like the data tape. In Section III of Appendix H the sample problem and several other problems were submitted to BATCH. The resulting data was also plotted. The data in Figure 10 for the sample problem is nearly identical to the data in Figure 9. The remaining examples in section III represent the individual and combined data for the first eight spherical harmonics ($n = 1,2,\cdots\cdots,8$) of the sample problem. These will be discussed in more detail in later paragraphs.

42. SA4024 was also used to show data curves for individual components of dipole and quadrupole moments. These are included in Figures 11 through 24. A small diagram is also included on each figure to illustrate the particular component that is represented by the curves. Curves are shown for components in both spherical and rectilinear coordinates according to Eqs. (9) and (10).

PROGRAM SA5024

Introduction

43. The program SA5024, listed in Appendix I, was devised to simplify the error studies. It performs functions similiar to both programs SA3024 and SA4024, i.e., SA5024 is both a data generation and a data analysis program. A system of multipole magnets is specified in the input data to represent the satellite as in SA4024. Since the data is analyzed as it is generated it is not written onto a data file as in SA4024. However, the program does include the plotting option when executing in the BATCH mode. Also, the integration option discussed in paragraphs 25 through 32 is included. The primary subprograms in SA5024 perform most of the functions already described in the sections on SA3024 and SA4024.

Input Data

44. The input data for SA5024 resembles the input data for the program SA4024 since it consists mostly of specifications for multipole magnets and data errors. The data is entered in the following order:

a. First line of data or data card - format: (7I5)

NO - The number of curves of data (NO is even and ≤ 16.)

N1 - The number of equally spaced data points per curve from 0 through 360 degrees colatitude (N1 is odd and ≤ 33. The first and last data points for each curve correspond to measurements at 0 degrees colatitude.)

NH1 - The total number of different harmonics (degrees) of multipole magnets to be considered

NH2 - The harmonic number (degree) representing the highest degree spherical harmonic term to be computed from the data (NH2 = 1 for dipoles, 2 for quadrupoles, etc.)

IP1 - The parameter that determines whether or not the data is to be interpolated and plotted (IP1 ≠ 0 means that the data will be interpolated and plotted.)

IP2 - The parameter that determines whether or not the magnetic data is to be printed (IP2 $\neq$ 0 means that the data will be printed.)

IW - The parameter that determines which integrating scheme is to be used (IW = 0 means that the exact, algebraic scheme is to be used.)

b. Second line of data or data card - format: (5F8.4)

R1 - The radius of the measurement sphere in inches

EG - The error (in gammas) to be randomly inserted into the data to represent instrumentation inaccuracies

EA - The angular error (in degrees) to be randomly inserted into the data to represent measurement position errors

ED - The constant error (in gammas) to be inserted into the data to represent offset in the instrumentation (this will be analyzed as monopole moment)

PY - The scale factor (gammas/inch) for the y-axis if the data is to be plotted (if PY = 0.0 a factor will be computed from the data.)

c. Third line of data or data card - format: (7A10)

F9 - The format for reading and printing the spherical coefficients A(I) and B(I), e.g., (1H ,7E10.4)

All of the following data is repeated "NH" times:

d. Next line of data or data card - format: (2I5)

NN - The harmonic number (degree) of the multipole data being read in (NN = 1 for dipoles, 2 for quadrupole, etc.)

NM - The number of multipoles with harmonic number NN

The following data is repeated "NM" times:

e. Next lines of data or data cards - format: (3F8.4)

P - The position vector (in inches) of the multipole in rectilinear coordinates (P_x, P_y, P_z)

f. Next lines of data or data cards - format: F9

A(I) - The spherical coefficients A_{NN}^{I-1} for the multipole of degree NN where I = 1,2,···,NN + 1 (The order of the Ith coefficient is I - 1.)

g. Next lines of data or data cards - format: F9

B(I) - The spherical coefficients B_{NN}^{I} for the multipole of degree NN where I = 1,2,···,NN. (The order of the Ith coefficient is i.).

(The relationships between spherical and rectilinear coefficients for dipoles and quadrupoles are given in Eqs. (9) and (10).)

Output Data

45. Initially, the program SA5024 computes the simulated measurement data as in Eqs. (19) and (20). Next, the spherical harmonic coefficients are computed according to Eq. (6). The program also computes the exact dipole moment from the multipole specifications. This value is compared with the dipole moment computed from the simulated measurement data. The percent error is printed as part of the output data.

Sample Problems

46. Appendix J contains the input and output data for several problems using SA5024. As in the other programs the binary version of SA5024 is the file BN5024. When executing the program via INTERCOM, only the first 15 binary records are used. In the first section of Appendix J an analysis was conducted of the sample problem illustrated in Figure 5. The parameters EG, EA, and ED were all set to zero (page J-1) so that no simulated errors were inserted into the data.

47. Figure 25 shows eight curves of the computed data for the three dipoles in the sample problem. Actually, 16 curves, each containing 33 data points, were used in the computations (based on Eq. (12) and Table 1). These values for the

parameters N0 and N1 allowed the computation of the spherical harmonic coefficients for the first eight multipole components. The program SA4024 was used to compute eight data curves for each multipole component to demonstrate the type of curves representing each component. These are presented in Figures 26 through 33. These were also combined and plotted by SA4024. Figure 34 displays the combined data. The first data curve (xz-plane) was chosen to further demonstrate the characteristics of spherical harmonic approximation. Figure 35 contains four curves. The first curve is the original data from the sample problem. Curve 2 represents the dipole component. Curve 3 represents the combination of dipole and quadrupole components. Curve 4 represents the combination of the first eight multipole components. The convergence of the series in Eq. (7) is not obvious from the coefficients computed in Section I of Appendix J. Table 2 summarizes the peak coefficients and the data peaks for each degree n. Although the magnitude of the peak coefficient increases with increasing n, the data peak (magnetic field at 96 inches) decreases. In fact, the first eight multipole components account for about 97 or 98 percent of the original data curves. This indicates that higher degree components are relatively insignificant.

TABLE 2

PEAK DATA FOR THE MULTIPOLE COMPONENTS OF THE SAMPLE PROBLEM

Degree n	$\left(\underset{0\le m\le n}{\mathrm{Max}}\{\lvert A_n^m\rvert, \lvert B_n^m\rvert\}\right)$	Data Peak (for 8 curves)
1	10^{4}	13.79
2	$-.9472\mathrm{X}10^{7}$	803.79
3	$.2341\mathrm{X}10^{10}$	839.34
4	$.1545\mathrm{X}10^{12}$	367.51
5	$-.2812\mathrm{X}10^{14}$	211.03
6	$+.4533\mathrm{X}10^{16}$	189.44
7	$+.3541\mathrm{X}10^{18}$	57.51
8	$-.4517\mathrm{X}10^{20}$	35.47
Original		1817.94
Sum of Components		1786.61

48. Section II of Appendix J demonstrates the procedure for submitting the program SA5024 for BATCH execution. The data specifies two problems consisting of

offset dipoles. In the first problem the dipole is aligned parallel to the x-axis and offset along the x-axis. The resultant curves are presented in Figure 36. The second problem is a dipole aligned parallel to the y-axis and offset along the x-axis. These curves are presented in Figure 37. A small diagram is included in each figure to demonstrate the geometric configuration.

49. A small error study was made to demonstrate the relationship between the accuracy of the dipole analysis; the parameters NO, N1, and R1; and the measurement errors (represented by EG and EA). The sample problem in Figure 5 was again selected. This example has a resultant dipole moment of 1000 gauss-cm^3, but the magnetic field from this dipole component is embedded in the large field from quadrupole and higher terms. Curve 2 in Figure 35 demonstrates this condition. Also Table 2 shows that the peak of the dipole curves is only 13.79 gammas out of a total of 1817.94 gammas for the total system. Table 3 contains a summary of the study. Several different values of NO, N1, IW, R1, EG and EA were used. The indications are that increasing R1 doesn't help much if EA and EG are too large. Also, there isn't much improvement in the accuracy of the computations when using the exact integration scheme (i.e., when setting IW = 0). Probably the most significant observation is that the parameter EA, representing position errors, has a much greater effect on the analysis accuracy than the parameter EG, representing instrumentation errors.

TABLE 3

MAXIMUM ERROR VERSUS PARAMETRIC VARIATIONS IN COMPUTING THE DIPOLE MOMENT FOR THE SAMPLE PROBLEM

Dipole Moment Error (gauss-cm^3)

	Parameters IW, R1, EG, EA						
NO, N1	1,96,0,0	1,96,1,1	1,96,5,2	1,72,1,1	1,72,5,2	1,120,1,1	0,72,1,1

8, 17	-.63 (x)	653 (y)	1320 (y)	1760 (y)	3590 (x)	395 (y)	1780 (y)
4, 25	431 (x)	887 (x)	1470 (y)	7420 (x)	8390 (x)	500 (y)	7440 (x)
6, 25	-54 (x)	-734 (y)	1440 (y)	-1160 (y)	-2170 (y)	-462 (y)	-1160 (y)
8, 25	6.3 (x)	-407 (x)	-785 (x)	220 (y)	-505 (x)	-298 (x)	223 (y)
10, 25	-2.8 (x)	-515 (x)	-1030 (x)	-1080 (x)	-2200 (x)	-306 (x)	-1080 (x)
12, 25	-2.7 (x)	-884 (x)	-1730 (x)	-1620 (x)	-3250 (x)	-570 (x)	-1620 (x)
Minimum detectable dipole based on R1 & EG		73	363	31	153	142	31

NO, N1, IW, R1 = 12, 25, 1, 96

EG	ERROR
8	-66 (x)
4	23 (x)
2	-6.8 (x)
1	-10.9 (y)
.5	-2.3 (y)
.25	-2.8 (x)
0	-2.7 (x)

EA	ERROR
4	1003 (y)
2	-854 (x)
1	505 (y)
.5	362 (x)
.25	-197 (x)
.125	56 (x)
0	-2.7 (x)

Note: An error of -1620 gauss-cm^3 means that the program computed a dipole moment of -620 gauss-cm^3 instead of +1000 gauss-cm^3. The letter contained in parentheses indicates the dipole component containing the error.

Chapter 4

PRINCIPAL SUBPROGRAMS

INTRODUCTION

50. The programs described in the preceding sections were constructed to utilize several algorithms which were incorporated into functions and subroutines. These include algorithms for computing the spherical harmonic coefficients, computing the vector magnetic field emanating from a multipole magnet, computing the associated Legendre Polynomials, computing the Schmidt polynomials, and interpolating and plotting data curves. The subprograms have been code in a manner which makes them useful as building blocks for other programs. They are discussed separately in the following paragraphs.

SUBROUTINE AMPMNT

51. The subroutine AMPMNT is used to compute the spherical coefficients A_n^m and B_n^m for the data array F(I,J). The computation is based on Eq. (6). The subroutine is constructed to compute the coefficients for only one degree at a time. The calling sequence is

```
CALL AMPMNT (NO, N1, N, R1, F, P, A, B)
```

where the arguments are defined as follows:

a. Input

NO - The number of curves of data

N1 - The number of equally spaced data points per curve from 0 through 360 degrees colatitude

N - The degree of the spherical harmonic coefficients to be computed

R1 - The radius of the measurement sphere in inches

F(IJ) - The measured data for IJ = I + (J - 1)·N1, I = 1,2,···,N1, and J = 1,2,···,NO (The data is stored in a one-dimensional array to conserve storage, i.e., equating the one-dimensional array to the two-dimensional array in Eq. (6) gives F(IJ) ≡ F(I,J).)

P(I) - The first "(N1 + 1)/2" weighting factors Y(I) in Eq. (6), i.e., P(I) = Y(I) for I = 1,2,···,(N1 + 1)/2.

b. Output

A(M + 1) - The spherical coefficients A_n^m for M = 0,1,2,···,N (see Eq. (8))

B(M) - The spherical coefficients B_n^m for M = 1,2,3,···,N (see Eq. (8)).

52. There are several other subroutines that are used to support AMPMNT in addition to the standard FORTRAN IV machine routines. AMPMNT internally calls a subroutine labeled POLVAL which in turn uses functions labeled SPNM, PNM, and ANF. These routines are used to compute the appropriate values for the Schmidt polynomials $P_n^m(\cos(\theta(I)))$ in Eq. (6). Also, the weights P(I) are set up externally by special subroutines before being input to the AMPMNT subroutine. This process requires the use of subroutines labeled WGT1, WGT2, WGT3, and GAUSEL. Listings of all of these subroutines are included in Appendix I.

SUBROUTINE AMPFLD

53. The subroutine AMPFLD is used to compute the magnetic field at the point $\bar{R}$ from a multipole magnet of degree n centered at the point $\bar{P}$. The magnet is specified in terms of the spherical harmonic coefficients A_n^m and B_n^m. The calling sequence is

CALL AMPFLD (R, P, N, A, B, F)

where the arguments are defined as follows:

a. Input

R(I) - The rectilinear coordinates (in inches) of the point at which the field is to be computed (R(1) = x-coor., R(2) = y-coor., and R(3) = z-coor.)

P(I) - The rectilinear coordinates (in inches) of the center position of the multipole magnet (P(1) = x-coor., P(2) = y-coor., and P(3) = z-coor.)

N - The harmonic degree of the multipole magnet

A(M + 1) - The spherical coefficients A_n^m for M = 0,1,2,···,N (see Eq. (8))

B(M) - The spherical coeficients B_n^m for M = 1,2,···,N (see Eq. (8))

b. Output

F(I) - The total magnetic field in rectilinear coordinates (H_x = F(1), H_y = F(2), and H_z = F(3)).

54. The subroutine computes the total magnetic field vector for a single multipole magnet. The computations are based on relationships that are similiar to Eq. (7) except that only a single multipole magnetic (N is fixed) is considered. Also, the subroutine gives all three rectilinear components of the magnetic field instead of just the radial component. The relationships are presented below using terminology that can be found in references (b) and (c). Let $\bar{R}_1$ be defined as the vector from the magnet to the point $\bar{R}$, i.e.,

$$\bar{R}_1 = \bar{R} - \bar{P} \tag{21}$$

where $\bar{R}$ and $\bar{P}$ are as defined above. Next, let

$$\bar{R}_1 = (R_1, \varphi, \theta) \tag{22}$$

be the representation of $\bar{R}_1$ in spherical coordinates where R_1 is the vector length, θ is the colatitude, and φ is the longitude relative to a system of coordinates centered at the multipole position. Now, define an orthonormal set of vectors $\bar{r}$, $\bar{\theta}$, and $\bar{\varphi}$ in spherical coordinates as

$$\bar{r} = \cos\varphi \sin\theta \ \bar{i} + \sin\varphi \sin\theta \ \bar{j} + \cos\theta \ \bar{k} \tag{23a}$$

$$\bar{\theta} = \cos\varphi \cos\theta \ \bar{i} + \sin\varphi \cos\theta \ \bar{j} - \sin\theta \ \bar{k} \tag{23b}$$

$$\bar{\varphi} = -\sin\varphi \ \bar{i} + \cos\varphi \ \bar{j} \tag{23c}$$

where $\bar{i}$, $\bar{j}$, and $\bar{k}$ represent the orthonormal set of vectors along the x, y, and z-axis, respectively (see Figure 1). It can be seen that

$$\bar{r} = \bar{R}_1/R_1. \tag{24}$$

Then, the total field vector $\bar{H}_n(\bar{R})$ for the nth degree multipole is given as

$$\bar{H}_n(\bar{R}) = H_{nr}(\bar{R})\bar{r} + H_{n\theta}(\bar{R})\bar{\theta} + H_{n\varphi}(\bar{R})\bar{\varphi} \tag{25}$$

where

$$H_{nr}(\bar{R}) \equiv [(n + 1)/R_1{}^{n+2}] \sum_{m=0}^{n} (A_n^m \cos m\varphi + B_n^m \sin m\varphi)P_n^m(\cos \theta) \tag{26a}$$

$$\begin{aligned} H_{n\theta}(\bar{R}) \equiv (1/R_1{}^{n+2}) \sum_{m=0}^{n} (A_n^m \cos m\varphi + B_n^m \sin m\varphi)[C_n^m P_n^{m+1}(\cos \theta) \\ -m \cos \theta\, P_n^m(\cos \theta)/\sin \theta] \end{aligned} \tag{26b}$$

$$H_{n\varphi}(\bar{R}) \equiv (1/R_1{}^{n+2}) \sum_{m=0}^{n} m(A_n^m \sin m\varphi - B_n^m \cos m\varphi)P_n^m(\cos \theta)/\sin \theta. \tag{26c}$$

The coefficient C_n^m, in Eq. (26b), has the value

$$\begin{aligned} C_n^m &= [(n - m)(n + m + 1)]^{\frac{1}{2}} \text{ for } (m > 0) \\ &= [n(n + 1)/2]^{\frac{1}{2}} \text{ for } (m = 0). \end{aligned}$$

Also, the terms which have sin θ as a divisor are computed using the following identities:

$$\begin{aligned} 2mP_{n,m}(\cos \theta)/\sin \theta &= (n - m + 1)(n - m + 2)P_{n+1,m-1}(\cos \theta) + P_{n+1,m+1}(\cos \theta) \\ &\qquad \text{for } (m > 0) \\ &= 0 \text{ for } (m = 0) \end{aligned} \tag{27}$$

$$\begin{aligned} P_n^m(\cos \theta) &= \left\{2\,\frac{(n - m)!}{(n + m)!}\right\}^{\frac{1}{2}} P_{n,m}(\cos \theta) \text{ for } (m > 0) \\ &= P_{n,0}(\cos \theta) \text{ for } (m = 0). \end{aligned} \tag{28}$$

The function $P_{n,m}(\cos\theta)$ represents the associated Legendre polynomial of degree n and order m. $P_n^m(\cos\theta)$ represents the Schmidt polynomial of degree n and order m. These polynomials are discussed in more detail in Appendix K. The radial component $f_n(\varphi,\theta)$ of the magnetic field at the point $\bar{R}$ is computed from the total field $\bar{H}_n(\bar{R})$ as

$$f_n(\varphi,\theta) = \bar{H}_n(\bar{R}) \cdot \bar{R}/(\bar{R} \cdot \bar{R})^{\frac{1}{2}}. \tag{29}$$

55. The subroutine AMPFLD uses several external subprograms including SPNM, PNM, ANF, SPCOOR, and SUM. These are listed in Appendix I. The subprograms SPNM, PNM, and ANF are used to compute the Schmidt and associated Legendre polynomials. The subroutines SPCOOR and SUM are used in mathematical operations with vectors. SPCOOR transforms a vector from rectilinear to spherical coordinates. SUM multiplies vectors and scalars, and then, adds the products.

FUNCTIONS PNM, SPNM, AND ANF

56. The function subprograms PNM, SPNM, and ANF are used in the generation of values for spherical polynomials. PNM computes the value of the associated Legendre polynomial $P_{n,m}(x)$ of degree n and order m at the point x for $|x| \le 1$. (If m = 0 the subprogram computes the value of the regular Legendre polynomial.) SPNM converts this value into the Schmidt function $P_n^m(x)$. ANF simply computes the factorial value for the integer N. Let y represent a variable used in a computer program which is to be set equal to a polynomial value. Then the calling sequence for the subprograms is defined as follows:

$y = P_n(x)$ is written as Y = PNM(N,0,X) for $N \ge 0$ and $|X| \le 1$

$y = P_{n,m}(x)$ is written as Y = PNM(N,M,X) for $N \ge 0$, $M \ge 0$, and $|X| \le 1$

$y = P_n^m(x)$ is written as Y = SPNM(N,M,X) for $N \ge 0$, $M \ge 0$, and $|X| \le 1$.

The factorial subprogram is used as follows:

$y = n!$ is written as Y = ANF(N) for $N \ge 0$.

The development and use of these subprograms was reported in more detail in an internal technical note. This is included in Appendix K.

SUBROUTINE DATPLT

57. The subroutine DATPLT is used to interpolate and plot the curves of data. It is written to make use of either the GOULD electrostatic plotter or the CALCOMP 570 pen plotter. Most of the data curves in the enclosed figures were plotted on the CAPCOMP plotter. Figure 38 shows a set of data curves plotted on the GOULD plotter. These correspond to the curves in Figure 6. The routine sets up x and y-coordinate arrays for the magnetic field data F(IJ). A plotting symbol (the curve number) is used to mark each data point along the data curves. The data is plotted as magnetic field versus the angle of colatitude as shown in Figure 6. The calling sequence is

CALL DATPLT (NO, N1, F, YDIST)

where the argument list is defined of follows:

NO - The number of curves of data

N1 - The number of data points per curve

F(IJ) - The array of data curves for $IJ = J + (I - 1)\cdot N1$; $J = 1,2,\cdots,N1$; and $I = 1,2,\cdots,NO$

YDIST - The value in gamma to be used for one inch of the y-axis (If YDIST = 0.0 the subroutine PKY is used to determine a suitable scale for the y-axis.).

58. The subroutine uses the external subprograms CALCM1, FNCTON, and PKY for execution. CALCM1 is contained in special plotting packages of subprograms that is in the NOL subroutine library. There are two separate packages that can be loaded when using the subroutines DATPLT and CALCM1. The package labeled GOULD1 is loaded when plotting with the GOULD electrostatic plotter. The package labeled CALCM1 is loaded when plotting with the CALCOMP plotter. Also a tape (TAPE99) must be loaded with the CALCM1 package. The subprograms FNCTON and PKY are listed in Appendix I. FNCTON computes the Fourier coefficients for each curve of data. These are used to increase the point density of the data to be plotted to one point for every five degrees of colatitude. This turns out to be 12 points per inch on the graphs or a total of 73 points per curve. The subprogram PKY is used to determine a suitable scale for the y-axis if YDIST is zero.

SUBROUTINE FNCTON

59. The subroutine FNCTON is used to perform a Fourier analysis on a single-dimensioned array of data that represents the values along a curve at equally spaced intervals. The program is used primarily for interpolating data. The calling sequence is

```
CALL FNCTON (F, N, C, CO, PHI, N2, DEV)
```

where the argument list is defined as follows:

a. Input

F(I) - The data array representing the values of the curve at N equally space values $\theta(I) = 2\pi(I - 1)/N$ for $I = 1,2,\cdots,N$

N - The number of data points

b. Output

C(I) - The array of Fourier amplitudes for $I = 1,2,\cdots,N2$

CO - The zero degree Fourier amplitude

PHI(I) - The array of Fourier phase angles for $I = 1,2,\cdots,N2$

N2 - The number of terms in the approximating Fourier series

DEV - The maximum difference between the data points and the curve defined by the Fourier series.

60. The coefficients are obtained by the following equations:

$$C_0 \equiv (1/N) \sum_{I=1}^{N} F(I) \tag{30}$$

$$S1_j \equiv (2/N) \sum_{I=1}^{N} F(I) \cdot \sin\left[2nj(I - 1)/N\right] \tag{31a}$$

$$C1_j \equiv (2/N) \sum_{I=1}^{N} F(I) \cdot \cos\left[2\pi j(I - 1)/N\right] \tag{31b}$$

$$\begin{aligned} C_j &\equiv (S1_j^2 + C1_j^2)^{\frac{1}{2}} \text{ for } j \neq N/2 \\ &\equiv (S1_j^2 + C1_j^2)^{\frac{1}{2}}/2 \text{ for } j = N/2 \end{aligned} \qquad (32)$$

$$PHI_j \equiv \tan^{-1}(C1/S1) \qquad (33)$$

for $j = 1,2,\cdots,N/2 + 1$.

61. This results in the approximation

$$F(I) \approx C_0 + \sum_{j=1}^{N2} C_j \sin\left[2\pi j(I - 1)/N + PHI_j\right] \text{ for } I = 1,2,\cdots N. \qquad (34)$$

Any other set of N' equally spaced values which begin at $\theta(1) = 0$ can be computed by substituting N' in place of N in Eq. (34). DATPLT uses the value of 72 for N'.

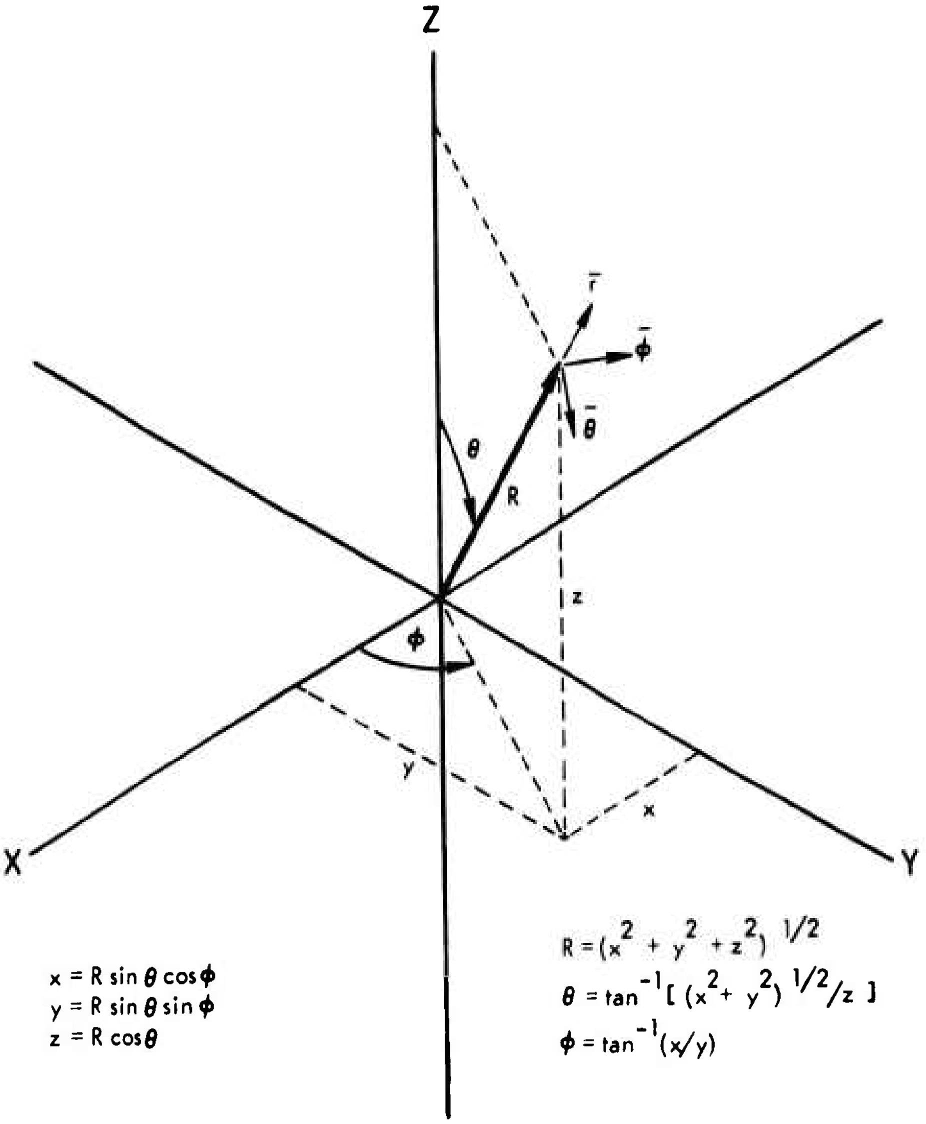
Chapter 5

CONCLUSIONS

62. The computer programs presented in this report are part of a major effort at NOL to develop and improve magnetic test procedures on spacecraft. The effort involves the development and evaluation of both data acquisition and data analysis procedures. The Spherical Field Coil Facility at NOL is being instrumented to handle both the acquisition and analysis of the test data. The proposed specifications for the instrumentation were presented i reference (d). More detailed specifications for the data acquisition and analysis system were forwarded to NRL as an enclosure to reference (e). The facility is scheduled to be operational by the beginning of fiscal year '75. A technical report describing the facility should be published shortly thereafter.

63. There are other analysis projects to be completed. One is the compilation and publication of a reference manual containing the mathematical equations for dipole and quadrupole computations. This will simplify slide-rule calculations which are made during testing. Another project involves the conduct of a more elaborate error analysis using the computer programs described above. This will be necessary to evaluate the minimum detectable dipole moment under several different conditions.

64. It should be noted here that there are several other methods for estimating the dipole moment of spacecraft. The most effective method to use in any particular case depends on a number of things including the size of the spacecraft, the availability of a gimballing system, the desired accuracy of the compensation, the complexity and permanence of the spacecraft's magnetism, etc. The procedure based on the spherical harmonic analysis of the spacecraft's magnetism has proven to be both fast and accurate for NRL satellites. Many of the tests have been completed in less than four hours and with an accuracy which allows dipole moment compensation of all but about 100 out of 6000 gauss-cm^3.



$$x = R \sin\theta \cos\phi$$
$$y = R \sin\theta \sin\phi$$
$$z = R \cos\theta$$

$$R = (x^2 + y^2 + z^2)^{1/2}$$
$$\theta = \tan^{-1}[(x^2 + y^2)^{1/2}/z]$$
$$\phi = \tan^{-1}(x/y)$$

APPENDIX A

GLOSSARY OF SYMBOLS AND TERMS

A(I) - is the spherical harmonic coefficient A^{I}_{NN} in the form used by the computer programs. Eqs. (5) and (8) define the relationships.

A(n,m) - is the spherical harmonic coefficient A^{m}_{n} as an element of a two-dimensional array.

A^{m}_{n} - is the spherical harmonic coefficient as defined by Eq. (5).

B(I) - is the spherical harmonic coefficient B^{I}_{NN} in the form used by the computer programs. Eqs. (5) and (8) define the relationships.

B(n,m) - is the spherical harmonic coefficient B^{m}_{n} as an element of a two-dimensional array.

B^{m}_{n} - is the spherical harmonic coefficient as defined by Eq. (5).

C - is the constant factor in the set of weighting factors {Y(I)}. C has the value (π/NO) representing the interval of longitude. (see Eqs. (14) and (15)).

C(I) - is the Fourier coefficient representing the amplitude of the I<u>th</u> term in the expansion of the data curves. Eqs. (32) and (34) define the relationships.

C^{m}_{n} - is the coefficient used in Eq. (26b). It originates in the identity

$$\frac{dP^{m}_{n}(\cos\theta)}{d\theta} = m\cos\theta\, P^{m}_{n}(\cos\theta)/\sin\theta - C^{m}_{n}\, P^{m+1}_{n}(\cos\theta)$$

where

$$C^{m}_{n} = \left[(n-m)(n+m+1)\right]^{\frac{1}{2}} \text{ for } (m > 0)$$
$$= \left[n(n+1)/2\right]^{\frac{1}{2}} \text{ for } (m = 0)$$

CS - is the parameter in the program SA3024 that represents the data value resulting from a static measurement by the magnetic sensor with a calibration signal turned on.

CV - is the value (in gammas) of the calibration signal. The values of CS, CV, and CZ are used to convert the measured data into gammas, i.e., each data value is multiplied by CV/(CS-CZ).

CZ - is the parameter in the program SA3024 that represents the data value resulting from a static measurement by the magnetic sensor with the calibration signal turned off.

C0 - ($= C_o$) is the Fourier coefficient representing the constant component of the data curves. It is defined in Eq. (30).

$C1_j$ - is the Fourier coefficient for the jth cosine term in the expansion of the data curves. It is defined in Eq. (31b.).

C6 - is the parameter in the BASIC program SA1024 which corresponds to CV.

C7 - is the parameter in the BASIC program SA1024 which corresponds to CS.

C8 - is the parameter in the BASIC program SA1024 which corresponds to CZ.

D - is the magnitude of the dipole moment $\bar{D}$. It is equal to $(D_1^2 + D_2^2 + D_3^2)^{\frac{1}{2}}$.

$\bar{D}$ - is the dipole moment vector (D_1, D_2, D_3) defined by Eq. (1).

D(I) - is the Ith factor of the set of weighting factors {Y(I)}. It is a measure of the interval of colatitude assigned to the data points {F(I,J), J = 1,2,···,NO}. (See Eqs. (14) through (18).)

D_1, D_2, D_3 - are the x, y, and z-components, respectively, of the dipole moment $\bar{D}$.

DEV - is the maximum difference between data points of a measured curve and the corresponding points of the curve defined by the approximated Fourier coefficients.

EA - is the parameter in programs SA4024 and SA5024 that represents the angular error (in degrees) to be randomly inserted into the simulated measurement data. It represents the measurement position errors.

ED - is the parameter in programs SA4024 and SA5024 that represents a constant offset (in gammas) of the measurement instrumentation. The analysis procedure handles this value as the magnetic field from a monopole moment.

EG - is the parameter in programs SA4024 and SA5024 that represents the error (in gammas) to be randomly inserted into the simulated measurement data. It represents instrumentation inaccuracies.

F(I) - is the argument representing the x, y, and z-component of the magnetic field vector computed by the subroutine AMPFLD. F(I), for $I = 1,2,\cdots,N$ is also the array of data for the subroutine FNCTON.

F(IJ) - is the single-dimensioned array of data values representing the normal component of the magnetic field on the surface of the measurement sphere surrounding the satellite. The relationship is $F(IJ) = f(\theta(I), \varphi(J))$ for $IJ = I + (J - 1) \cdot N1$, $I = 1,2,\cdots,N1$, and $J = 1,2,\cdots,NO$.

F(I,J) - is the two-dimensional array of numbers representing discrete values of the normal component of the magnetic field on the surface of the measurement sphere surrounding the satellite. The values are actually stored in the single-dimensioned array $F(IJ) = F(I,J) = f(\theta(I), \varphi(J))$ for $IJ = I + (J - 1) \cdot N1$, $I = 1,2,\cdots,N1$, and $J = 1,2,\cdots,NO$.

$f(\theta,\varphi)$ - represents the normal component of the total magnetic field on the surface of the measurement sphere of radius R1 surrounding the satellite.

$f_n(\theta,\varphi)$ - represents the normal component of the magnetic field on the surface of the measurement sphere from the multipole moment of degree n.

$f_{nj}(\theta,\varphi)$ - represents the normal component of the magnetic field on the surface of the measurement sphere from the jth multipole magnet of degree n.

F9 - is the format for reading and printing the spherical coefficients A(I) and B(I), e.g., F9 = (1H ,7E10.4).

$\bar{H}(\bar{R})$ - represents the total magnetic field vector at the point $\bar{R}$.

$\bar{H}_n(\bar{R})$ - represents the magnetic field vector at the point $\bar{R}$ from a multipole magnet of degree n.

$\bar{i}$ - represents the unit vector along the x-axis.

IP - is the parameter in the program SA4024 that determines whether or not the simulated measurement data is to be interpolated and plotted. $IP \neq 0$ means that the data will be interpolated and plotted.

IP1 - is the parameter in the programs SA3024 and SA5024 which corresponds to IP.

IP2 - is the parameter in the programs SA3024 and SA5024 that determines whether or not the measurement data is to be printed. $IP2 \neq 0$ means that the data will be printed.

IR - is the parameter in the programs SA2024 and SA3024 that determines whether or not to read the measurement data from a data file. $IR \neq 0$ means that the data will be read from the file DAT024.

IW - is the parameter in programs SA3024 and SA5024 that determines which integrating scheme is to be used. $IW = 0$ means that the exact, algebraic scheme is to be used.

$\bar{j}$ - represents the unit vector along the y-axis.

$\bar{k}$ - represents the unit vector along the z-axis.

m - is the order of the coefficients A_n^m and B_n^m, and the polynomials $P_n^m(\cos\theta)$ and $P_{n,m}(\cos\theta)$.

M - is the program parameter representing the order of the coefficients and polynomials associated with multipole magnets.

n - is the degree of the coefficients A_n^m and B_n^m, and the polynomials $P_n^m(\cos\theta)$ and $P_{n,m}(\cos\theta)$.

N - is the program parameter representing the degree of the coefficients and polynomials associated with multipole magnets. N is also used to define the number of distinct data points for the subroutine FNCTON.

NO - is the number of curves of data. It is an even integer (≤ 16) corresponding to the number of great circles of data on the measurement sphere.

N1 - is the number of equally spaced data points per curve ranging from 0 through 360 degrees in colatitude. N1 is an odd integer (≤ 33).

N2 - is the parameter in the BASIC program SA1024 which corresponds to IP2. N2 is also used in the subroutine FNCTON to designate the number of Fourier terms that produces the minimum error (DEV) between the data and the computed curve.

N3 - is the number of distinct factors {D(I)} of the weights {Y(I)}. N3 is the largest integer that is less than or equal to (N1 + 3)/4, i.e., $N3 = \Big[\max\limits_{1 \le i} i$ such that $i \le (N1 + 3)/4\Big]$.

$\bar{n}(\theta,\varphi)$ - is the unit normal vector on (exterior to) the surface of the measurement sphere at the point ($R1$, θ, φ). It has rectilinear components ($\sin\theta \cos\varphi$, $\sin\theta \sin\varphi$, $\cos\theta$).

NH - is the parameter in the program SA3024 that represents the highest degree spherical harmonic term to be computed from the data (NH = 1 for dipoles, 2 for quadrupoles, etc.). NH is also the parameter in the program SA4024 that represents the total number of different harmonics (degrees) of multipole magnets to be considered.

NH1 - is the parameter in the program SA5024 that represents the total number of different harmonics (degrees) of multipole magnets to be considered.

NH2 - is the parameter in the program SA5024 that represents the highest degree spherical harmonic term to be computed from the data (NH2 = 1 for dipoles, 2 for quadrupoles, etc.)

NM - is the parameter in the programs SA4024 and SA5024 that represents the number of multipole magnets with harmonic number (degree) NN.

NN - is the parameter in the programs SA4024 and SA5024 that represents the harmonic number (degree) for the multipole data being read in (NN = 1 for dipole, 2 for quadrupoles, etc.).

P - represents the multipole position vector in the programs SA4024 and SA5024. It also represents the weighting factors in the subroutine AMPMNT.

P4 - is the parameter in programs SA3024, SA4024, and SA5024 that represents the scale factor in gammas/inch for the y-axis if the data is to be plotted. If PY = 0.0, and if the data is to be plotted, a suitable factor will be computed from the data.

$P_{n,m}(\cos\theta)$ - represents the associated Legendre polynomial of degree n and order m. Reference (b) gives the definition as $P_{n,m}(\cos\theta) \equiv \sin^m\theta\, d^mP_n(\cos\theta)/d(\cos\theta)^m$ where. $P_n(\cos\theta)$ is the regular Legendre polynomial of degree n. (See also Eq. (2) of Appendix K.)

$P_n^m(\cos\theta)$ - represents the Schmidt polynomial of degree n and order m. They are defined in Eq. (3) of Appendix K.

PHI(I) - is the Fourier coefficients in the subroutine FNCTON which represent the phase angles defined by Eqs. (31) and (33).

$Q_{11},\cdots,Q_{33}$ - represent the coefficients of the quadrupole moment term in rectilinear coordinates.

$\bar{r}$ - represents an element of the orthonormal set of vectors defined by Eq. (23).

$\bar{R}$ - represents the position vector for a point at which the magnetic field is to be computed by the subroutine AMPFLD. Coordinate transformations are included in Figure 1.

$\bar{R}_1$ - represents the vector between a multipole position and the point at which the magnetic field is to be computed by the subroutine AMPFLD.

R1 - is the parameter in the programs SA1024,$\cdots$,SA5024 that represents the radius of the measurement sphere in inches.

$S1_j$ - is the Fourier coefficient for the jth sine term in the expansion of the data curves. It is defined by Eq. (31a).

X(I) - represents the surface area or weight assigned to the data points $\{F(I,J), J = 1,2,\cdots,NO\}$ when the geometric or approximate integrating scheme is used. It is defined in Eq. (4).

Y(I) - represents the surface area or weight assigned to the data points $\{F(I,J), J = 1,2,\cdots,NO\}$ when either integration scheme is used.

YDIST - is the parameter in the subroutine DATPLT that corresponds to the parameter PY.

θ - represents the spherical coordinate of colatitude defined in terms of rectilinear coordinates as $\theta = \tan^{-1}\left[(x^2 + y^2)^{\frac{1}{2}}/z\right]$.

$\bar{\theta}$ - represents an element of the orthonormal set of vectors defined by Eq. (23).

$\theta(I)$ - represents the Ith element in the set of values of colatitude at which the data F(I,J) is recorded.

φ - represents the spherical coordinate of longitude defined in terms of rectilinear coordinates as $\varphi = \tan^{-1}(x/y)$.

$\bar{\varphi}$ - represents an element of the orthonormal set of vectors defined by Eq. (23).

$\varphi(J)$ - represents the jth element in the set of values of longitude at which the data F(I,J) is recorded.

1. The file BN2024 is the binary version of SA2024. It consists of six binary records (subprograms).

2. The information typed in by the user has been underlined.

APPENDIX E

LISTING OF SA3024

```
      PROGRAM DIPANL(INPUT=65,OUTPUT=65,DAT024=65,TAPE5=INPUT,
     + TAPE6=OUTPUT,TAPE7=DAT024,TAPE99)

C                        SATELLITE ANALYSIS PROGRAM

C      THIS PROGRAM ANALYZES MAGNETIC DATA REPRESENTING THE NORMAL COMPON-
C    ENT OF THE MAGNETIC FIELD FROM A SATELLITE. THE DATA IS ENTERED IN
C    THE FOLLOWING ORDER --

C    NO - THE NUMBER OF GREAT CIRCLES OF DATA. (NO IS USUALLY EVEN, E.G.,
C         NO=(N1-1)/2. THE PROGRAM STOPS IF NO=0.)

C    N1 - THE NUMBER OF DATA POINTS PER GREAT CIRCLE. (N1 IS ALWAYS ODD.
C         THE FIRST DATA POINT IS THE SAME AS THE LAST FOR EACH GREAT CIR-
C         LE.)

C    NH - THE HARMONIC NUMBER (DEGREE) REPRESENTING THE HIGHEST DEGREE
C         SPHERICAL HARMONIC TERM TO BE COMPUTED FROM THE DATA. (NH=1 FOR
C         DIPOLES, 2 FOR QUADRUPOLES, ETC.)

C    IR - DETERMINES WHETHER OR NOT TO READ THE DATA FROM THE FILE
C         DAT024. (IR=0 MEANS THAT THE DATA WILL NOT BE READ FROM
C         THE FILE.)

C    IP1 - DETERMINES WHETHER OR NOT THE MAGNETIC DATA IS TO BE PLOTTED.
C         (IP1=0 MEANS THAT THE DATA WILL NOT BE PLOTTED.)

C    IW - DETERMINES THE TYPE OF INTEGRATING SCHEME TO BE USED. (IW=0
C         MEANS THAT THE EXACT, ALGEBRAIC SCHEME IS TO BE USED.)

C    R1 - THE RADIUS OF THE MEASUREMENT SPHERE IN INCHES.

C    CV - THE VALUE OF THE CAL SIGNAL (CS-CZ) IN GAMMAS.

C    PY - THE SCALE FACTOR (GAMMAS/INCH) FOR THE Y-AXIS IF THE DATA IS TO
C         BE PLOTTED. (IF PY=0.0 A FACTOR WILL BE COMPUTED FROM THE DATA.)

C    IP2 - DETERMINES WHETHER OR NOT THE MAGNETIC DATA IS TO BE PRINTED.
C         (IP=0 MEANS THAT THE DATA WILL NOT BE PRINTED.)

C    CS - THE STATIC MEASUREMENT WITH THE CAL SIGNAL.

C    CZ - THE STATIC MEASUREMENT WITHOUT THE CAL SIGNAL.

C    F(I) - THE DATA REPRESENTING THE NORMAL COMPONENT OF THE MAGNETIC
C           FIELD ALONG GREAT CIRCLES ON THE MEASUREMENT SPHERE.

Notes:

1. The data is stored in DAT024 in a way that allows the file to be read in a (9F6.1) format.

2. The first two data points on the first line are values representing the calibration and zero readings, CS and CZ. The value of the calibration signal CV should be set to 1.0 when using data generated from SA4024.

APPENDIX I

LISTING OF SA5024

```
      PROGRAM DIPSTD(INPUT=65,OUTPUT=65,TAPE5=INPUT,TAPE6=OUTPUT,TAPE99)

C                        SPHERICAL HARMONIC PROGRAM

C     THIS PROGRAM GENERATES AND ANALYZES DATA REPRESENTING THE NORMAL
C   COMPONENT OF THE MAGNETIC FIELD FROM A SATELLITE. THE DATA IS ENTERED
C   IN THE FOLLOWING ORDER --

C   NO - THE NUMBER OF GREAT CIRCLES OF DATA. (NO IS USUALLY EVEN, E.G.,
C        NO=(N1-1)/2. THE PROGRAM STOPS IF NO=0.)

C   N1 - THE NUMBER OF DATA POINTS PER GREAT CIRCLE. (N1 IS ALWAYS ODD.
C        THE FIRST DATA POINT IS THE SAME AS THE LAST FOR EACH GREAT CIR-
C        LE.)

C   NH1 - THE TOTAL NUMBER OF DIFFERENT HARMONICS (DEGREES) OF MULTIPOLE
C         MAGNETS TO BE CONSIDERED.

C   NH2 - THE HARMONIC NUMBER (DEGREE) REPRESENTING THE HIGHEST DEGREE
C         SPHERICAL HARMONIC TERM TO BE COMPUTED FROM THE DATA. (NH2=1
C         FOR DIPOLES, 2 FOR QUADRUPOLES, ETC.)

C   IP1 - DETERMINES WHETHER OR NOT THE MAGNETIC DATA IS TO BE PLOTTED.
C        (IP1=0 MEANS THAT THE DATA WILL NOT BE PLOTTED.)

C   IP2 - DETERMINES WHETHER OR NOT THE MAGNETIC DATA IS TO BE PRINTED.
C        (IP2=0 MEANS THAT THE DATA WILL NOT BE PRINTED.)

C   IW - DETERMINES THE TYPE OF INTEGRATING SCHEME TO BE USED. (IW=0
C        MEANS THAT THE EXACT, ALGEBRAIC SCHEME IS TO BE USED.)

C   R1 - THE RADIUS OF THE MEASUREMENT SPHERE IN INCHES.

C   EG - THE ERROR (IN GAMMAS) TO BE RANDOMLY INSERTED INTO THE DATA TO
C        REPRESENT INSTRUMENTATION INACCURACIES.

C   EA - THE ERROR (IN DEGREES) TO BE RANDOMLY INSERTED INTO THE DATA TO
C        REPRESENT MEASUREMENT POSITION ERRORS.

C   ED - THE CONSTANT ERROR (IN GAMMAS) TO BE INSERTED INTO THE DATA.
C        (THIS WILL BE ANALYZED AS MONOPOLE MOMENT.)

C   PY - THE SCALE FACTOR (GAMMAS/INCH) FOR THE Y-AXIS IF THE DATA IS TO
C        BE PLOTTED. (IF PY=0.0 A FACTOR WILL BE COMPUTED FROM THE DATA.)

C   F9 - THE FORMAT FOR READING AND PRINTING THE SPHERICAL COEFFICIENTS
```

```
C         A(I) AND B(I).                                                SA500490
                                                                        SA500500
                                                                        SA500510

Magnetic Structures Group

Asgmt: Task No. NOL-786/NPL (Magnetic Calibration for NPL)
TWP No. 530-524

Abst: This report describes computer subroutines for the generation of Legendre polynomials and spherical functions. The subroutines are coded in the FORTRAN IV computer language. A brief description of the functions and some of their properties is also included. A comparison is given of the numerical stability of two different methods of generating the functions.

INTRODUCTION

1. Computer subroutines have been devised to compute values for three special types of polynomials including regular and associated Legendre polynomials, and Schmidt functions. The functions have special orthogonality properties which make them especially useful for interpolation and approximation. Techniques in spherical harmonic analysis can be defined in terms of the associated Legendre polynomials (spherical functions). The computer subroutines can be used to develop numerical methods for the harmonic analysis techniques. A listing of the subroutines in FORTRAN IV is included in Appendix A.

2. The subroutines are based on a finite series definition for the polynomials. It was determined that the series definition produced a more stable method than methods based on recurrence formulas.

POLYNOMIAL DEFINITIONS

3. There are a variety of ways to define the polynomials depending on the use intended for them. The definitions and terminology used in the following definitions conform to the usage in references (a) and (b). Some of the recurrence formulas were obtained from reference (c).

4. The regular Legendre polynomials $P_n(x)$ can be defined on the interval $-1 \le x \le 1$ by Rodrique's formula,

$$P_n(x) - \frac{1}{2^n n!}\left(\frac{d}{dx}\right)^n (x^2-1)^n \qquad (1)$$

for $n \ge 0$ and $|x| \le 1$. The associated Legendre polynomials or spherical functions $P_{n,m}(x)$ can now be defined as

$$P_{n,m}(x) = (1-x^2)^{m/2}\left(\frac{d}{dx}\right)^m P_n(x) = \frac{(1-x^2)^{m/2}}{2^n n!}\left(\frac{d}{dx}\right)^{m+n}(x^2-1)^n \qquad (2)$$

for $m \ge 0$, $n \ge 0$, and $|x| \le 1$. The index n designates the degree of the polynomial and the index m designates the order. It should be noted that some definitions of $P_{n,m}(x)$ contain a factor of $(-1)^m$ depending on whether the polynomials are considered to be functions of x on the interval $-1 \le x \le 1$ or as functions of θ (with $x = \cos\theta$) on the interval $0 > \theta \le \pi$. In this report the factor is dropped in keeping with the definitions in reference (a).

5. A comparison of Equations (1) and (2) show that the regular Legendre polynomials $P_n(x)$ are a subset of the associated Legendre polynomials $P_{n,m}(x)$, i.e., $P_n(x) = P_{n,0}(x)$. Also Equation (2) leads to the fact that $P_{n,m}(x) = 0$ for $m > n$.

6. Graphs of typical families of the polynomials are shown in Figures 1 and 2.

The regular Legendre polynomials shown in Figure 1 include P_0, P_1, ..., P_7. The polynomial values $P_n(\cos\theta)$ are plotted as functions of θ for $0 \le \theta \le 180^\circ$. Figure 2 shows the family $P_{7,m}(\cos\theta)$ for $m = 0, 1, 2, \ldots, 7$. Notice the variation in the value of the peaks of each curve. The curves for $m < 4$ appear as straight lines coinciding with the zero axis. This extensive variation in the order of magnitude for different polynomials $P_{n,m}(x)$ has disadvantages, especially in the development of numerical analysis procedures. This led Schmidt (see reference (a)) to develop a new set of polynomials.

7. The <u>Schmidt polynomials $P_n^m(x)$</u> are defined by scaling the associated Legendre polynomials as follows

$$\left\{ \begin{array}{l} P_n^0(x) = P_{n,0}(x) = P_n(x) \\ P_n^m(x) = \left\{ \dfrac{2\cdot(n-m)!}{(n+m)!} \right\}^{1/2} P_{n,m}(x) \end{array} \right\} \qquad (3)$$

for $m > 0$ and $|x| \le 1$. The resulting polynomials all have values of the same order of magnitude. Also, $|P_n^m(x)| \le 1$ for $|x| \le 1$. A typical family of Schmidt polynomials $P_7^m(\cos\theta)$ for $m = 0, 1, 2, \ldots, 7$ is shown in Figure 3.

NUMERICAL METHODS

8. There are many ways of numerically generating sets of polynomials. One of the most common methods is the use of recurrence formulas. The associated Legendre polynomials satisfy several recurrence formulas including

$$P_{n,m}(x) = [(2n-1)\cdot x\cdot P_{n-1,m}(x) - (n+m-1)P_{n-2,m}(x)]/(n-m) \text{ for } m\ne n \text{ and } n>1 \qquad (4)$$

$$P_{n,m}(x) = [(m-n-1)\cdot x\cdot P_{n,m-1}(x) + (n+m-1)P_{n-1,m-1}(x)]/(1-x^2)^{1/2} \text{ for } |x|<1,$$
$$m>0, \text{ and } n>0 \qquad (5)$$

$$P_{n,m}(x) = 2(m-1)\cdot x\cdot(1-x^2)^{-1/2}P_{n,m-1} - (n+m-1)(n-m+2)P_{n,m-2}(x) \text{ for } |x|<1$$
$$\text{and } m>1. \qquad (6)$$

Equation (4) represents a recurrence formula with varying degree, Equation (5) represents both varying degree and varying order, and Equation (6) represents varying order.

9. Another method for generating the associated Legendre polynomials is given

in reference (a). The polynomials are expressed as a finite (alternating) series in powers of x. The expression is:

$$P_{n,m}(x) = \frac{(2n)!(1-x^2)^{m/2}}{2^n \cdot n!(n-m)!} \left\{ x^{n-m} - \frac{(n-m)(n-m-1)x^{n-m-2}}{2(2n-1)} \right. \tag{7}$$

$$\left. + \frac{(n-m)(n-m-1)(n-m-2)(n-m-3)x^{n-m-4}}{2\cdot 4(2n-1)(2n-3)} - \dots \right\}$$

where the last term inside the bracket is constant if (n-m) is even; or is a multiple of x if (n-m) is odd.

NUMERICAL STABILITY

10. Several different methods based on the recurrence formulas were used to test the numerical stability for large values of n and m, and for small values of (x^2-1). The only recurrence formula with any stability was Equation (4) which has varying degree. This formula can be used by itself only to generate the regular Legendre polynomials. When either Equation (5) or (6) is added the method becomes unstable. For example, Figure 4 shows a family of $P_n^{n-1}(\cos\theta)$ for n = 15, 16, ..., 20. Notice that instability becomes worse as $|x|$ approaches 1 and as n increases.

11. Instead of trying to stabilize the methods using the recurrence formulas it was decided to try the series Equation (7). Although the equation appears to be unstable itself (alternating series can be unstable) the results indicate the opposite. Figure 5 shows the same polynomials displayed in Figure 4 but generated by Equation (7). There seems to be no problem for $|x|$ near one or for large n. It was therefore decided to use Equation (7) for the subroutine. The computing time using Equation (7) was about the same as methods using recurrence formulas.

SUBROUTINE CALL STATEMENTS

12. The polynomial values can be computed as follows: Assume that y is a variable used in a computer program and that y is to be set equal to a polynomial value. Then

$y = P_n(x)$ is written as Y = PNM(N,0,X) for N≥0 and $|x| \le 1$.

$y = P_{n,m}(x)$ is written as Y = PNM(N,M,X) for N≥0, M≥0, and $|x| \le 1$.

$y = P_n^m(x)$ is written as Y = SPNM(N,M,X) for N≥0, M≥0, and $|x| \le 1$.

There are three function subprograms in the package. These include:

```
FUNCTION SPNM(N,M,X)
FUNCTION PNM(N,M,X)
FUNCTION ANF(N)
```

The subroutine ANF(N) is the factorial subroutine, i.e,

$y = n!$ is written as Y = ANF(N) for $N \geq 0$.

The factorial value is return as a floating point number based on the integer N. The subroutine SPNM uses both PNM and ANF as external functions. The subroutine PNM uses ANF as an external function. The subroutine ANF requires no external functions (machine functions only).

USES OF THE FUNCTIONS $P_n^m(x)$

13. It can be shown that the set of polynomials $\{P_n^m(x)\}$ of fixed order m are orthogonal on the interval $-1 \leq x \leq 1$ for all $n \geq m$. In fact:

$$\int_{-1}^{+1} P_n^m(x) P_{n'}^m(x)dx = \delta_{nn'} \frac{1}{2n+1} \tag{8}$$

for $n \geq m$ where $\delta_{nn'}$ is the Kronecker delta. The polynomials can therefore be normalized and used for interpolation and expansion of arbitrary functions on the interval $-1 \leq x \leq 1$.

14. The polynomials are of primary importance in areas of spherical harmonic analysis and potential theory. If we define two new sets of functions as

$$\{\sin(m\varphi)P_n^m(\cos\theta)\}, \{\cos(m\varphi)P_n^m(\cos\theta)\} \tag{9}$$

and consider φ and θ to be the spherical angles representing longitude and colatitude respectively, then the functions are called spherical surface harmonics, and are orthogonal and complete on the surface of the unit sphere. They satisfy the condition

$$\int_0^{\pi}\int_0^{2\pi} \left[P_n^m(\cos\theta)\begin{Bmatrix}\cos m\varphi\\ \sin m\varphi\end{Bmatrix}\right]\left[P_{n'}^{m'}(\cos\theta)\begin{Bmatrix}\cos m'\varphi\\ \sin m'\varphi\end{Bmatrix}\right]\sin\theta d\theta d\varphi = \delta_{nn'}\delta_{mm'}\left\{\frac{4\pi}{2n+1}\right\} \tag{10}$$

for n, n', m, m' ≥ 0 (see reference (a)). Then any continuous function $f(\theta,\varphi)$ on the surface of the unit sphere can be expanded into a uniformly convergent series of surface harmonics as

$$f(\theta,\varphi) = \sum_{n=0}^{\infty} S_n(\theta,\varphi) = \sum_{n=0}^{\infty} \left\{ \sum_{m=0}^{n} (A_n^m \cos m\varphi + B_n^m \sin m\varphi) P_n^m(\cos\theta) \right\} \qquad (11)$$

where $S_n(\theta,\varphi)$ represents a general surface harmonic of degree n. The constants A_n^m and B_n^m are determined from the equations

$$\left\{ \begin{matrix} A_n^m \\ B_n^m \end{matrix} \right\} = \frac{2n+1}{4\pi} \int_0^{\pi} \int_0^{2\pi} f(\theta,\varphi) P_n^m(\cos\theta) \left\{ \begin{matrix} \cos m\varphi \\ \sin m\varphi \end{matrix} \right\} \sin\theta \, d\varphi \, d\theta \qquad (12)$$

for $m \geq 0$ and $n \geq 0$.

15. Numerical integrating schemes for uniformly spaced data $f_{ij} = f(\theta_i,\varphi_j)$ on the surface of the unit sphere are discussed in reference (d).

SUMMARY

16. This report has discussed briefly some of the properties of Legendre polynomials and some of their uses. The subroutines listed in Appendix A can be used in a variety of ways including interpolation, approximation, and spherical harmonic analysis. Plans are being made to develop other subroutines to perform the spherical harmonic analysis and extrapolation of potential functions.
