Use of Microculture Plates and the Multiple Automated Sample Harvester for In Vitro Microassay of Bacterial Toxins

RICHARD C. KNUDSEN, LYNN T. CALLAHAN III, AFTAB AHMED, AND KENNETH W. SELL

Experimental Immunology Division, Clinical Medical Sciences Department, and the Department of Microbiology, Naval Medical Research Institute, Bethesda, Maryland 20014

Received for publication 8 April 1974

An in vitro cytotoxicity microassay for the measurement of nanogram quantities of *Pseudomonas aeruginasa* exotoxin and *Vibrio cholerae* enterotoxin is described.

An in vitro microassay for lymphotoxin using mouse L-929 fibroblasts (L cells) grown in wells of microculture plates has recently been described (5). Test material is added to the culture medium, and cytotoxic activity is measured as the reduction in incorporation of [methyl-41]thymidine by target cells. Because this assay is sensitive and versatile, and because it requires a minimal amount of time and materials, we thought it might prove useful in studying other naturally occurring toxins known to have cytotoxic properties. Our study illustrates the use of this microassay procedure in measuring cytotoxic activity of two bacterial protein exotoxins: Pseudomonas aeruginosa exotoxin (PE), which has been shown to be toxic for cultivated Vero cells (6); and Vibrio cholerae enterotorin (CE), which has been shown to be cytotoxic for mouse spleon cells (7) and adrenal

The purified cholera toxin (a gift from Stephen H. Richardson, Bowman Gray School of Medicine, Winston-Salem, N.C.) had a specific activity of 7,000 to 10,000 blueing doses per µg of protein, as measured by the skin permeability bioassay in rabbits (3), and contained 440 µg of Lowry protein per ml. PE, purified as described proviously (2), contained 350 µg of Lowry protein per ml and had a mean lethal dose of 4 µg when assayed in mice weighing 20 + 2 g.

The microssay has been described in detail elsewhere (5). For comparative purposes, both Leells and HeLa cells were used as target cells in this experiment. Approximately 1,000 HeLa cells or Leells, in 50 uliters of RPMI 1640 plus supplements (5), was dispensed into each well of several microculture plates. Fifty microliters of twofold serial dilutions of each toxin preparation was subsequently added to the microcultures. Each dilution was dispensed into triplicate cultures. An equivalent amount of medium

was dispensed into three microcultures to serve as controls for normal cell growth. Cultures were incubated for 4 days. Twenty-four hours prior to harvesting, $20~\mu$ liters of medium containing 1 μ Ci of [methyl-3H] thymidine (specific activity 1.9 Ci/mmol) was added to each microculture Target cells were harvested from microculture wells into glass-fiber filter disks using the multiple automated sample harvester (1). Mean counts per manute of triplicate cultures were converted into percent inhibition using the formula:

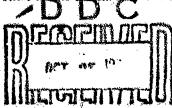

% Inhibition .

mean counts per minute
of toxin wells
mean counts per minute
of control wells

The sensitivity of the microsissay in measuring PE and CE activity for HeLa vells and L cells is shown in Fig. 1. A 50% inhibition of L cell growth required only 1 og of PE and 81.5 og of CE. In contrast, 50% inhibition of HeLa vell growth required 145 og of PE and 352 og of CE.

Microscope observations of microsultures showing 99% inhibition of [methyl44] Rhymidine incorporation revealed that virtually all target cells were destroyed. Complete destruction of Leells required 27 ng of PE and 4.400 ng of CE. Thus, both complete destruction and 50° inhibition of target cell growth were more sensitive to PE than CE, and Leells were far more sensitive to both PE and CE than HeLa cells. In contrast to these results, Escherichia coli endotoxin (Difco Laboratories, Detroit, Mich.) has been found not to affect the growth of Leells at concentrations of 10 µg per microculture.

Those results dampnetized that the micross-

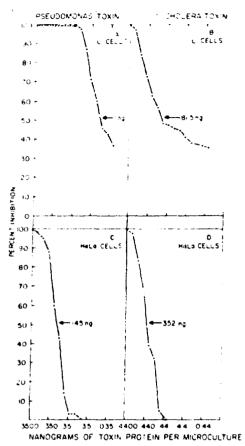

Fig. 1. Inhibition of L cell and HeLa cell growth by dilutions of Pseudomonas and Cholera toxin. Mean counts per minute (\pm standard error) for control microcultures were: (A) $31,060\pm1,167$; (B) $34,409\pm1,106$; (C) $24,512\pm1,755$; and (D) $21,951\pm1,088$. The

say is sensitive and requires small amounts of materials, and that large numbers of assays can readily be performed. Only a few minutes are required to harvest a microculture plate using the multiple automated sample harvester. As many as 30 microculture plates have been assayed at one time in this laboratory. The procedure should be adaptable to different target cells, radioactive labels, and incubation periods, and should prove useful in evaluating the effectiveness of antisera and chemicals in blocking toxic activity of various toxins.

This research was supported by the Bureau of Mcdicine and Surgery Work Unit no. MR041.02.01.0025A2JC and MR-000.01.01.1.779.
