FOREWORD

The work reported herein was done at the request of the Aeronautical Systems Division (ASD), Air Force Systems Command (AFSC), for the Lockheed-Georgia Company under Program Element 41119F.

The test results were obtained by ARO, Inc. (a subsidiary of Sverdrup & Parcel and Associates, Inc.), contract operator of the Arnold Engineering Development Center (AEDC), AFSC, Arnold Air Force Station, Tennessee, under Contract AF40(600)-1200. The tests were conducted from July 12 to 14, 1967, under ARO Project No. PB0760. The manuscript was submitted for publication on November 11, 1967.

Information in this report is embargoed under the Department of State International Traffic in Arms Regulations. This report may be released to foreign governments by departments or agencies of the U. S. Government subject to approval of the Aeronautical Systems Division (ASZZT), Wright-Patterson AF Base, Ohio, or higher authority within the Department of the Air Force. Private individuals or firms require a Department of State export license.

This technical report has been reviewed and is approved.

Director of Test

ABSTRACT

Tests were conducted in the 16-ft transonic tunnel to determine the effects of Reynolds number variation on the aerodynamic characteristics of a 0.0226-scale model of the C-5A aircraft with fixed and free transition. The results show that Reynolds number variation from 2.1 to 4.2 million had little effect on the lift and pitching-moment coefficients and generally caused a decrease in drag coefficient.

This document is subject to special export controls and each transmittal to foreign governments or foreign nationals may be made only with prior approval of Aeronautical Systems Division (ASZZT), Wright-Patterson AF Base, Ohio.

SECTION I INTRODUCTION

A wind tunnel investigation of a 0.0226-scale model of the Lockheed-Georgia C-5A aircraft was conducted in the Propulsion Wind Tunnel, Transonic (16T). The tests were conducted at Mach numbers 0.700, 0.767, and 0.785, angles of attack from -3 to +3 deg, and Reynolds numbers of 2.1, 2.8, and 4.2 million based on the wing mean aerodynamic chord.

Previous test data obtained with 0.040-scale models (Refs. 1, 2, and 3) had indicated higher drag than that measured on 0.0226-scale models tested at other test facilities. In an attempt to determine the cause for the data differences, a testing technique and data correlation study was initiated to be conducted in the NASA-Ames Research Laboratory 11-ft Unitary Plan Wind Tunnel, the Cornell Aeronautical Laboratory 8-ft Transonic Tunnel, and the AEDC-PWT Tunnel 16T. The same support sting, internal strain-gage balance, and model were used at all test facilities, thus eliminating those items as potential causes of the differences. The test results reported herein constitute the AEDC-PWT portion of the correlation study.

SECTION II APPARATUS

2.1 TEST FACILITY

Tunnel 16T is a variable density wind tunnel capable of operating at Mach numbers between 0.55 and 1.60. The tunnel is equipped with a plenum evacuation system, and the test section is formed by fixed, parallel top and bottom perforated walls and perforated variable angle sidewalls. A more complete description of the wind tunnel, its operating characteristics, and support equipment is given in Ref. 4. The results of the most recent calibration of the tunnel are provided in Ref. 5. The location of the test model and model support system in the test area is indicated in Fig. 1 (Appendix), and a photograph of the model installed in the tunnel is shown in Fig. 2.

2.2 TEST ARTICLE

Details of the 0.0226-scale C-5A model are presented in Fig. 3, where the complete configuration is shown and the individual components

are identified. The engine nacelles were hollow-contoured pipes that allowed unobstructed airflow through them.

Except for the portion of the test during which the effects of free transition were investigated, the tests were conducted with transition strips consisting of 0.0038-in. -diam glass spheres applied with an adhesive. The locations of the leading edge of the transition strips were as follow:

<u>Model Component</u>	<u>Distance Aft of Leading Edge</u>
Fuselage	2 in. aft of nose
Wing	10-percent chord
Vertical stabilizer	10-percent chord
Horizontal stabilizer	10-percent chord
Bullet	10-percent length
Pylons	10-percent chord
Nacelles	10-percent length

All transition strips were 0.05 in. wide, except that on the fuselage, which was 0.10 in. wide. A photograph of the wing transition strip is presented in Fig. 4.

During the portion of the test in which the empennage assembly was attached to the model, the horizontal stabilizer incidence angle was set at -1 deg (trailing edge up).

2.3 INSTRUMENTATION

A six-component, internal strain-gage balance was used to measure forces and moments of the entire model during the investigation. Pressures in the model cavity were measured at two locations by differential pressure transducers. The model gravimetric angle of attack was measured by a strain-gaged pendulum located forward of the balance in the model cavity.

SECTION III

TEST CONDITIONS AND PROCEDURE

3.1 GENERAL

The test was conducted at Mach numbers of 0.700, 0.767, and 0.785 at Reynolds numbers of 2.1, 2.8, and 4.2 million based on the wing mean aerodynamic chord. The total pressure ranged from 1645 psf at $M_\infty = 0.785$ and $Re = 2.1$ million to 3545 psf at $M_\infty = 0.700$ and $Re = 4.2$ million. The total temperature was maintained at 105°F for all Mach numbers.

Tunnel conditions were held constant at each Mach number, while angle of attack was varied from -3 to +3 deg. Data were recorded at each selected angle of attack.

3.2 ACCURACY OF MEASUREMENTS

The uncertainties associated with the various tunnel conditions and aerodynamic coefficients presented in the report are listed below. The uncertainties in force and moment coefficients include errors associated with balance or flexure zero shifts and calibration curve fits and are given for $M_\infty = 0.767$, $Re = 2.8 \times 10^6$.

M_∞	=	± 0.003
q_∞	=	± 2 psf
α	=	± 0.03 deg
T_t	=	$\pm 3^\circ\text{F}$
C_L	=	± 0.004
C_m	=	± 0.001
C_D	=	± 0.0006

3.3 CORRECTIONS

Tests were conducted with the model both upright and inverted to define flow angularity in the vicinity of the model. The results of these tests, presented in Fig. 5, indicate the existence of a positive (upflow) flow angle which varied primarily with Reynolds number and to a lesser extent, with Mach number and model configuration. Angle of attack was

corrected for the flow angle, and the coefficient data were computed with the corrected model angle.

The axial-force contribution to the lift, drag, and pitching-moment coefficients was computed with the model base pressure corrected to the value of free-stream static pressure. The difference ($p_{\infty} - p_b$) varied from $-0.023 q_{\infty}$ at $M_{\infty} = 0.700$ and $Re = 2.1 \times 10^6$ to $-0.047 q_{\infty}$ at $M_{\infty} = 0.785$ and $Re = 4.2 \times 10^6$.

SECTION IV RESULTS AND DISCUSSION

The measured aerodynamic characteristics are presented in stability axis coefficient form in Figs. 6 through 12, showing the effects of Reynolds number variation from 2.1×10^6 to 4.2×10^6 for both free and fixed transition.

The effects of Reynolds number variation on the lift and pitching-moment coefficients presented in Figs. 6 through 9 show that the greatest effect occurred for the fixed transition configuration with empennage, pylons, and nacelles off, where at $M_{\infty} > 0.700$ and $\alpha > 0$ deg, C_L increased (Fig. 6) and C_m became more negative at $Re = 2.1 \times 10^6$ (Fig. 8).

The most pronounced effect of Reynolds number variation is noted in the drag coefficients, as may be seen in Figs. 10, 11, and 12. The forebody drag coefficients decreased with increasing Reynolds number at all values of C_L , except at $M_{\infty} = 0.785$ where, for the empennage, pylons, and nacelles-off configuration with fixed transition, C_{DF} at $Re = 2.8 \times 10^6$ is larger than that for $Re = 2.1 \times 10^6$ for $C_L > 0.475$. An increase in C_{DF} at $M_{\infty} = 0.785$ with increasing Reynolds number may also be noted for the complete model with fixed transition for $C_L > 0.55$. As shown in Fig. 12, the forebody drag coefficients showed essentially a linear decrease with increasing Reynolds number for both fixed and free transition.

13. ABSTRACT

Tests were conducted in the 16-ft transonic tunnel to determine the effects of Reynolds number variation on the aerodynamic characteristics of a 0.0226-scale model of the C-5A aircraft with fixed and free transition. The results show that Reynolds number variation from 2.1 to 4.2 million had little effect on the lift and pitching-moment coefficients and generally caused a decrease in drag coefficient.
