IMPORTANT INFORMATIVE STATEMENTS

PROVE-IT (FRiV) Pilot and Research on Operational Video-based Evaluation of Infrastructure and Technology: Face Recognition in Video project, PSTP 03-401BIOM, was supported by the Canadian Safety and Security Program (CSSP) which is led by Defence Research and Development Canada's Centre for Security Science, in partnership with Public Safety Canada. Led by Canada Border Services Agency partners included: Royal Canadian Mounted Police, Defence Research Development Canada, Canadian Air Transport Security Authority, Transport Canada, Privy Council Office; US Federal Bureau of Investigation, National Institute of Standards and Technology, UK Home Office; University of Ottawa, Université Québec (ÉTS).

The CSSP is a federally-funded program to strengthen Canada's ability to anticipate, prevent/mitigate, prepare for, respond to, and recover from natural disasters, serious accidents, crime and terrorism through the convergence of science and technology with policy, operations and intelligence.

Abstract

This report is a supplement to Division Report 2014-27 (TR) ‘Evaluation methodology for face recognition technology in video surveillance applications’ (by E. Granger and D. Gorodnichy) [1]. It presents complete evaluation results of three Commercial Off-The-Shelf (COTS) Face Recognition (FR) systems: Cognitec, PittPatt and Neurotechnology — obtained on the Checkpoint public data-set using the multi-level evaluation methodology introduced in the previous report. Four levels of details are examined according to the methodology for each target person from the Checkpoint data-set: Level 0 or score-based analysis illustrates the probability distribution of the genuine scores against that of the impostors at different face resolutions, which visually illustrates the discrimination power of the system for each target individual. Level 1 or transaction-based analysis provides the averaged description of the system in terms of false positive and false negative rates aggregated over all transactions, expressed using Receiver Operative Curves (ROC), Detection Error Trade-off (DET), and Precision-Recall Operating Characteristic (PROC) curves. Level 2 or subject-based analysis describes the performance of the system using the-so-called “Doddington’s Zoo” categorization of individuals, which detects whether an individual belongs to an easier or a harder classes of people that the system is able to recognize [2, 3]. Finally, Level 3 or temporal analysis allows one to examine the overall discrimination power of the system by accumulating the positive predictions while tracking a person over time and computing the recognition confidence based thereon. Two-page Report Cards summarizing the performance of the system for each target individual are published, thus providing an exhaustive report of the systems performance on a variety of different target subjects. As highlighted in previous report [1] and other publications [4, 5], such exhaustive reporting of the biometric system performance is required when the variation of system performance from one target individual to another is suspected. Our results show that this is indeed the case for all three tested COTS FR systems.

Keywords: video-surveillance, face recognition in video, instant face recognition, watch-list screening, biometrics, reliability, performance evaluation

Community of Practice: Biometrics and Identity Management

Canada Safety and Security (CSSP) investment priorities:

1. Capability area: P1.6 – Border and critical infrastructure perimeter screening technologies/ protocols for rapidly detecting and identifying threats.
2. Specific Objectives: O1 – Enhance efficient and comprehensive screening of people and cargo (identify threats as early as possible) so as to improve the free flow of legitimate goods and travellers across borders, and to align/coordinate security systems for goods, cargo and baggage;
3. Cross-Cutting Objectives CO1 – Engage in rapid assessment, transition and deployment of innovative technologies for public safety and security practitioners to achieve specific objectives;
4. Threats/Hazards F – Major trans-border criminal activity – e.g. smuggling people/ material

1 Introduction

This report is a supplement to Division Report 2014-27 (TR) ‘Evaluation methodology for face recognition technology in video surveillance applications’ (by E. Granger and D. Gorodnichy) [1]. It presents the evaluation results of three widely deployed Face Recognition (FR) Commercial Off-The-Shelf (COTS) systems: Cognitec (FaceVACS-SDK 8.5 Release Date: 2011-12-19), PittPatt (Face Detection, Tracking and Recognition FTR SDK 5.2.2, Release Date: 2010) and Neurotechnology (Verilook SDK 5.4, Release Date: 2011). A multi-level performance analysis introduced in [1] is performed to evaluate and compare the system performance to one another. Four levels of details are examined according to the methodology for each target person from the Checkpoint data-set: Level 0 or score-based analysis illustrates the probability distribution of the genuine scores against that of the impostors at different face resolutions, which visually illustrates the discrimination power of the system for each target individual. Level 1 or transaction-based analysis provides the averaged description of the system in terms of false positive and false negative rates aggregated over all transactions, expressed using Receiver Operative Curves (ROC), Detection Error Trade-off (DET), and Precision-Recall Operating Characteristic (PROC) curves. Level 2 or subject-based analysis describes the performance of the system using the-so-called “Dodgington’s Zoo” categorization of individuals, which detects whether an individual belongs to an easier or a harder classes of people that the system is able to recognize [2, 3]. Finally, Level 3 or temporal analysis allows one to examine the overall discrimination power of the system by accumulating the positive predictions while tracking a person over time and computing the recognition confidence based thereon. Two-page Report Cards summarizing the performance of the system for each target individual are published, thus providing an exhaustive report of the systems performance on a variety of different target subjects. As highlighted in previous report [1] and other publications [4, 5], such exhaustive reporting of the biometric system performance is required when the variation of system performance from one target individual to another is suspected. Our results show that this is indeed the case for all three tested COTS FR systems.

2 Chokepoint dataset

System performance is evaluated using portal 2 data from the Chokepoint dataset [6], which simulates the Type 2 surveillance environments similar to those observed in airports [1] where individuals pass in a natural free-flow way in a narrow corridor.

To capture the data, the array of three cameras is mounted above a door, used for simultaneously recording the entry of a person from three viewpoints (see Figure 1).

The data consists of 25 subjects (19 male and 6 female) in portal 1, and 29 subjects (23 male and 6 female) in portal 2. Videos were recorded over two sessions 1 month apart. In total, it consists of 54 video sequences and 64,204 labeled face images. Each sequence was named according to the recording conditions, where P, S, and C stand for portal, sequence and camera, respectively. E and L indicate subjects either entering or leaving the portal. Frames were captured with the 3 cameras at 30 fps with an SVGA resolution (800X600 pixels), and faces incorporate variations of illumination, expression, pose, occlusion,

sharpness and misalignment due to automatic frontal detection.

In the test sequences, 29 known individual walk through a chokepoint for a total of 1281 events.

As discussed in [1], the Chokepoint data set is suitable for medium- to large-scale benchmarking of systems for mono-modal recognition and tracking of faces over one or more cameras in watch-list applications. It is provided with the ground truth (person ID, eye location and ROIs for each frame), as well as a high resolution mug shot for each individual in the data set (see Figure 3)

Table 1 presents a list of the Chokepoint video sequences used for evaluations. Figure 2 shows some frames for target individual 1 from the Chokepoint sequence P2L-S4-C1.1.

Figure 1: Setup used to capture the Chokepoint video data set.

For the testing, ten individuals are randomly selected from the Chokepoint dataset as target individuals and included in the watch list. The target individuals include six males and four females, and have the following identification numbers (id) in the Chokepoint dataset: 1, 4, 5, 7, 9, 10, 11, 12, 16 and 29. For each

Figure 2: Frames corresponding to individual #1 from the Chokepoint data set sequence P2L-S4-C1.1.

Figure 3: Gallery of still images used to create a watch list in the Chokepoint data set.

target individual, the remaining 28 individuals are considered as impostors. The performance is evaluated based on a fixed operating point (face matching threshold) of 5% false positive rate, using three different distances between the eyes: 10, 20 and 30 pixels. The video streams from Chokepoint dataset portal 2, session 1, camera 1.1 (P2L_S1_C1.1) are considered as a validation set and used to compute matching thresholds for each target individual and each distance between the eyes. These thresholds are then applied to Chokepoint dataset portal 2, session 4, camera 1.1 (P2L_S4_C1.1), to evaluate systems performance for

Table 1: Chokepoint video sequences selected for performance evaluation. The sequences are captured with one of three cameras when subject are leaving portal 2. In all sequences, only one person passes the portal at a time.

Data sequences	no. of subjects	type of scenario
1) P2L_S1_C1, P2L_S1_C2, P2L_S1_C3	1	type 1, with different cameras
2) P2L_S2_C1, P2L_S3_C1, P2L_S4_C1	1	type 1, with different recorded sequence
3) P2L_S4_C1, P2L_S4_C2, P2L_S5_C3	24, crowded	type 2, with different cameras

each target individual.

As emphasized in [1] and further illustrated in this report, user-specific or template-specific thresholds allow for improved system performance since some individuals are naturally more difficult to recognize than others, and the risk associated with recognition errors varies from one individual to another. However, setting (or optimizing) a specific threshold for each target individual makes systems comparison more difficult to illustrate and harder to summarize. In particular, averaging the performances among all target individuals (each with a different matching threshold) may not provide meaningful results. Therefore, the detailed results for each system that are based on each target individual as well as on the distance between the eyes are presented as report cards in special Appendix of this report. For each system, the report cards illustrate the four levels of performance analysis for each individual in the watch list according to the three distances between the eyes.

3 Conclusions

This report presented the results obtained from the evaluation of three COTS FR products (Cognitec, PittPatt and NeuroTechnology) on the publicly available Chokepoint data-set following the evaluation methodology and protocol defined in [1]. The results are presented using the two-page Reports Cards, which are generated for each of ten randomly chosen target individuals from the Chokepoint data-set. These results summarize the ability of the system to automatically detect and recognize target individuals in a surveillance video-stream, while highlighting their strengths and vulnerabilities.

The obtained evaluation results reported here and in report [1], along with the survey of academic and commercial state of art solutions presented in separate reports [7, 8], provided the basis for the assessment of the readiness of the FR technology for video surveillance applications, which was the key objective of the PROVE-IT(FRiV) study and which was reported in [9, 10] and further refined in [11].

Tab. 2: Dodington's zoo based analysis for the detection module associated to individual 1. Columns details the individuals in the data set, while lines detail their detection by the module for each value of distance between the eyes. Colors are as follows: green for sheep like individuals (easy to predict), yellow for goat like individuals (difficult to predict), blue for lamb like individuals (can be impersonated by someone else) and red for wolf like individuals (who can impersonate another user).

Level 3 Analysis

Each of the below figures details the performance of systems by accumulating positive predictions over a time-window on the video stream for different distances between the eyes. The tracker is used to separate faces of different persons, and accumulate their predictions. Matching thresholds are set to provide a 5% false positive rate, and positive individual decision takes place after accumulating 20 detections in a 30 frames window (1 sec). Red stars indicate faces that have not been correctly matched to the target individual, while blue stars indicate that the individual captured in the video has been successfully matched to the target individual.

Tab. 2: Dodington's zoo based analysis for the detection module associated to individual 5. Columns details the individuals in the data set, while lines detail their detection by the module for each value of distance between the eyes. Colors are as follows: green for sheep like individuals (easy to predict), yellow for goat like individuals (difficult to predict), blue for lamb like individuals (can be impersonated by someone else) and red for wolf like individuals (who can impersonate another user).

Level 3 Analysis

Each of the below figures details the performance of systems by accumulating positive predictions over a time-window on the video stream for different distances between the eyes. The tracker is used to separate faces of different persons, and accumulate their predictions. Matching thresholds are set to provide a 5% false positive rate, and positive individual decision takes place after accumulating 20 detections in a 30 frames window (1 sec). Red stars indicate faces that have not been correctly matched to the target individual, while blue stars indicate that the individual captured in the video has been successfully matched to the target individual.

(b)

Tab. 2: Dodington's zoo based analysis for the detection module associated to individual 12. Columns details the individuals in the data set, while lines detail their detection by the module for each value of distance between the eyes. Colors are as follows: green for sheep like individuals (easy to predict), yellow for goat like individuals (difficult to predict), blue for lamb like individuals (can be impersonated by someone else) and red for wolf like individuals (who can impersonate another user).

Level 3 Analysis

Each of the below figures details the performance of systems by accumulating positive predictions over a time-window on the video stream for different distances between the eyes. The tracker is used to separate faces of different persons, and accumulate their predictions. Matching thresholds are set to provide a 5% false positive rate, and positive individual decision takes place after accumulating 20 detections in a 30 frames window (1 sec). Red stars indicate faces that have not been correctly matched to the target individual, while blue stars indicate that the individual captured in the video has been successfully matched to the target individual.

Fig. 5: Accumulated detections for 10 pixels between eyes.

Fig. 6: Accumulated detections for 20 pixels between eyes.

Fig. 7: Accumulated detections for 30 pixels between eyes.

Fig. 8: Variations of quality measures.

Fig. 1: Level 0 – Class scores distributions.

Level 1 Analysis

The figures below detail several performance curves, and the stars indicate the selected operation point for a target $fpr = 5\%$ (for each ed distance between eyes). The table summarizes the number of genuine and impostor samples, as well as face detection related metrics.

Tab. 2: Dodington's zoo based analysis for the detection module associated to individual 7. Columns details the individuals in the data set, while lines detail their detection by the module for each value of distance between the eyes. Colors are as follows: green for sheep like individuals (easy to predict), yellow for goat like individuals (difficult to predict), blue for lamb like individuals (can be impersonated by someone else) and red for wolf like individuals (who can impersonate another user).

Level 3 Analysis

Each of the below figures details the performance of systems by accumulating positive predictions over a time-window on the video stream for different distances between the eyes. The tracker is used to separate faces of different persons, and accumulate their predictions. Matching thresholds are set to provide a 5% false positive rate, and positive individual decision takes place after accumulating 20 detections in a 30 frames window (1 sec). Red stars indicate faces that have not been correctly matched to the target individual, while blue stars indicate that the individual captured in the video has been successfully matched to the target individual.

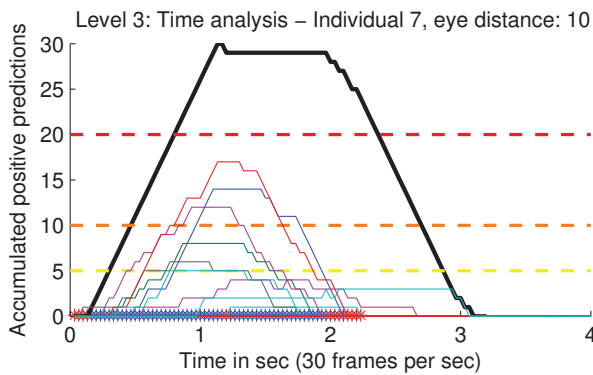

Fig. 5: Accumulated detections for 10 pixels between eyes.

Tab. 2: Dodington's zoo based analysis for the detection module associated to individual 16. Columns details the individuals in the data set, while lines detail their detection by the module for each value of distance between the eyes. Colors are as follows: green for sheep like individuals (easy to predict), yellow for goat like individuals (difficult to predict), blue for lamb like individuals (can be impersonated by someone else) and red for wolf like individuals (who can impersonate another user).

Level 3 Analysis

Each of the below figures details the performance of systems by accumulating positive predictions over a time-window on the video stream for different distances between the eyes. The tracker is used to separate faces of different persons, and accumulate their predictions. Matching thresholds are set to provide a 5% false positive rate, and positive individual decision takes place after accumulating 20 detections in a 30 frames window (1 sec). Red stars indicate faces that have not been correctly matched to the target individual, while blue stars indicate that the individual captured in the video has been successfully matched to the target individual.

Tab. 2: Dodington's zoo based analysis for the detection module associated to individual 9. Columns details the individuals in the data set, while lines detail their detection by the module for each value of distance between the eyes. Colors are as follows: green for sheep like individuals (easy to predict), yellow for goat like individuals (difficult to predict), blue for lamb like individuals (can be impersonated by someone else) and red for wolf like individuals (who can impersonate another user).

Level 3 Analysis

Each of the below figures details the performance of systems by accumulating positive predictions over a time-window on the video stream for different distances between the eyes. The tracker is used to separate faces of different persons, and accumulate their predictions. Matching thresholds are set to provide a 5% false positive rate, and positive individual decision takes place after accumulating 20 detections in a 30 frames window (1 sec). Red stars indicate faces that have not been correctly matched to the target individual, while blue stars indicate that the individual captured in the video has been successfully matched to the target individual.
