1. Abstract: Layered inorganic materials (LIMs) such as transition metal dichalcogenides (TMDs) (eg. MoS₂, WS₂, MoSe₂, ZrTe₂), transition metal oxides (TMOs) (eg. Ti oxides, Nb oxides) and boron nitride (BN) have been of great attraction due to their unique structures and intriguing properties. The layer-dependent properties of LIMs varying from topological insulators to wide-gap semiconductors and metals have endow exciting prospects for a variety of emerging applications in a broad range of fields, such as electronics, energy conversion and storage, catalysis and polymer nanocomposites (PNCs). In particular, the preparation of PNCs with good dispersion of LIM nanosheets within the polymer matrix is of prime importance to realize the intrinsic properties of individual sheets of LIM. In this report, we demonstrate the physical and chemical interactions of two-dimensional nanosheets of LIMs with polymers with the emphasis on controlling the interactions by designing the molecular and architectural structures of the polymers for potential practical applications such as nanocomposites and thin film fabrications. Our approaches are based on the modification of LIMs with end-functionalized polymers. First, an end-functionalized polymer with conjugated end-molecule, pyrenes, is successfully employed to boron nitride nanosheets (BNNS), and non-covalent interaction arising from π - π interaction gives rise to well dispersed BNNS with high concentration. Second, the non-destructive modification of TMDs sheets with amine-terminated polymers is introduced and the strong Lewis acid-base interaction between transition metal and non-pair electrons of amine allows us to develop scalable, stable and uniform composite films with numerous combinations of TMD nanosheets and end-functionalized polymers.

2. Introduction.

Research objectives: This research aims to study the physical (van der Waals forces: crystal epitaxy and π - π interaction) and chemical (acid-base force) interactions of two-dimensional nanosheets of layered inorganic materials (LIMs) with polymers with the emphasis on controlling the interactions by designing the molecular and architectural structures of the polymers for potential practical applications such as nanocomposites and thin film fabrications.

Background: LIMs exist in three dimensional forms as stacks of two constituent dimensional layers with strong in-plane covalent bond and weak out-of-plane interactions between the layers. The layer-dependent properties of LIMs such as transition metal dichalcogenides (TMDs) (eg. MoS₂, WS₂, MoSe₂, ZrTe₂), transition metal oxides (TMOs) (eg. Ti oxides, Nb oxides) and boron

nitride (BN) varying from topological insulators to wide-gap semiconductors and metals have endow exciting prospects for a variety of emerging applications in a broad range of fields, such as electronics, energy conversion and storage, catalysis and polymer nanocomposites. In particular, the impressive and extraordinary mechanical, electrical and barrier properties of LIMs make them attractive as nanofillers to reinforce polymers to prepare multifunctional composites. The preparation of polymer nanocomposites (PNC) with good dispersion of LIM nanosheets within the polymer matrix is of prime importance to realize the intrinsic properties of individual sheets of LIM. In general, the dispersion is, however, very difficult due to high stacking of layers in agglomerated states which make them incompatible with most of the polymers. In addition, no specific chemical interaction between polymers and LIMs hinders the exfoliation and thus development of highly dispersed LIM sheets in polymers remains great challenge, which requires more fundamental understanding of the interaction between LIMs and polymers. Further control of the interaction based on this understanding will offer fruitful opportunities for utilizing emerging LIMs

Importance: To achieve stable exfoliation of LIM nanosheets in different solvents and polymer matrixes, without disrupting the structural integrity, the nature of the interaction between polymer and LIM should be understood and appropriate materials design including chain conformations, site selective chemical structures and molecular architectures of polymers should be made for promoting the interaction with the LIMs. The effective exfoliation of LIMs should be accompanied with favorable attraction of polymer segments on the surface of LIMs which overcomes self-layer-layer van der Waal's attraction of LIM. Beside this enthalpic interaction, sufficient physical separation between two layers should be guaranteed with entropically driven polymer chains to avoid re-aggregation of the layers. The successful manipulation the LIM nanosheets by polymers, therefore, mainly relies upon understanding their physical and chemical interactions with the polymer and furthermore rational design of polymers to control both segmental enthalpic and conformational entropic contributions to the total free energy at the same time

Ultimate goal: There is the necessity to produce large quantities of highly exfoliated LIMs uniformly distributed in polymer matrix with their intrinsic properties maintained to fully harness the desired properties for further practical applications. By analogy with graphene which has been extensively studied for effective separation to individual layers in liquid state, liquid phase exfoliation of LIMs by polymers will advance the development of PNCs. This method brings considerable advantages; long and flexible chains of the polymers can readily adhere to the surface of sheets when the interaction between polymer and sheet properly controlled. In addition, extended polymer chains from the sheets can be readily entangled with other chains of the matrix polymer, thereby ensuring homogeneous PNC formation. The solvent medium offers an extra driving force for mixing between layers and the matrix. In addition, solution processes such as spin coating, dip coating and layer-by-layer coating are in great demand for fabricating thin films with the thickness of a few hundred nanometers or less, such thin films can in turn be readily combined with various thin film electronic, optic and mechanical applications.

3. Experiment

3-1) LIMs / pyrene-terminated polymer

Materials: Stacked *h*-boron nitride (BN) was purchased from Alpha Aesar. Molybdenum disulfide (MoS₂), *N,N*-dimethyl formamide (DMF), 1-pyrenemethanol, 4-vinylpyridine (4-VP), 4-cyano-4-[(dodecylsulfanylthiocarbonyl)sulfanyl]pentanoic acid, 4-(dimethylamino)pyridine (DMAP), 2,2-azobis(2-methylpropionitrile) (AIBN) and dicyclohexylcarbodiimide (DCC) were purchased from Sigma-Aldrich. *N*-butoxycarbonylhydrazine-1,4-butanediamine (C4-Boc) was purchased from TCI. AIBN was used after precipitating in the cold methanol and 4-VP was purified with basic aluminum oxide and vacuum distillation. The others were used as received.

Polymerization of poly(4-vinylpyridine) (P4VP) derivatives: The pyrene-terminated poly(4-vinylpyridine) (P4VP-Py), 1,4-butanediamine-terminated poly(4-vinylpyridine) (P4VP-C4-amine) and *N*-butoxycarbonylhydrazine-1,4-butanediamine-terminated poly(4-vinylpyridine) (P4VP-C4-Boc) were functionalized from P4VP chain as shown in **Figure 1**. P4VP was polymerized by RAFT where 4-cyano-4-[(dodecylsulfanylthiocarbonyl)sulfanyl]pentanoic acid and AIBN were used as chain transfer agent (CTA) and initiator, respectively. The mixtures (Monomer : CTA : initiator = 200 : 1 : 0.1) and small amount of DMF were charged in a round-bottom flask, subsequently the solution was conducted by 3 times with freeze-pump thaw. After reacting in coil-bath for 1 day at 68 °C, the crude was precipitated by the co-solvent with ether and *n*-hexane. The yellow powder of P4VP (M_w: 16 kg/mole and PDI: 1.16) was analyzed by gel permeation chromatography (GPC). Note that functionalization of end group can be achieved by DCC coupling from a carboxylic acid-terminated P4VP according to the RAFT mechanism. The 1-pyrenemethanol and C4-Boc were used for functionalization of P4VP-Py and P4VP-C4-Boc, respectively. The *N*-butoxycarbonylhydrazine (Boc) group of P4VP-C4-Boc was additionally removed by trifluoroacetic acid (TFA) for preparing P4VP-C4-amine.

Exfoliation & Dispersion: To exfoliate and disperse the BN or MoS₂, P4VP-Py was firstly dissolved in DMF (2 mg/ml). Next, ultra-sonication was performed in the iced bath with 50 % of the power for 2 h. After waiting for 1 day to remove the precipitated part, we centrifuged supernatant under 1200 rpm for 30 min.

Characterization: To confirm the amount differences of the dispersed MoS₂, UV-vis spectroscopy (Lambda 750 spectrometer, Perkin-Elmer) was evaluated with 20 times diluted solution.

3-2) TMDs / end-functionalized polymers.

3-2.1) TMDs with mono-end-functionalized polymers

Materials: TMD powders were purchased from Alfa Aesar and Sigma Aldrich. The amine-terminated polymers: polystyrene (PS-NH₂) (9.5~108 kg/mol), polyethylene oxide (PEO-NH₂) (9.5 kg/mol), poly(methyl methacrylate) (PMMA-NH₂) (20 kg/mol), polybutadiene (PBd-NH₂) (15 kg/mol), polyethylene (PE-NH₂) (4.2 kg/mol) and poly(styrene-*b*-isoprene) (PS-*b*-PI-NH₂) (23-*b*-37.5 kg/mol), and polystyrene (PS) (11.5 kg/mol) homopolymer were procured from Polymer Source Inc., Doval, Canada. The detail physical properties of the polymers and TMD powders are listed in the **Tables 1 and 2**, respectively. All of the solvents

were purchased from Sigma Aldrich.

Exfoliation & Dispersion: In a typical procedure, 250 mg of bulk MoSe₂ powder and 25 mg of PS-NH₂ were added into a 30-ml glass vial containing 25 ml of toluene. The solution was sonicated for 45 min by using a tip sonicator with a 10-s On pulse and a 5-s OFF pulse at an amplitude of 50% in an ice bath. The dispersions were allowed to settle for 24 h, and then the top dispersion was decanted and centrifuged for 30 min at 1,500 rpm to remove the unexfoliated and large particles. After centrifugation, the top half of the dispersion was collected and the concentration of MoSe₂ nanosheets was determined by standard gravimetric analysis.

Film Preparation: (1) MoSe₂ with various amine-terminated polymers such as PEO-NH₂, PMMA-NH₂, PBd-NH₂, PE-NH₂ and PS-*b*-PI-NH₂, and (2) PS-NH₂ based composite films containing various TMDs including MoS₂, WS₂, ReS₂, WSe₂, ZrTe₂ and NbSe₂ were fabricated by spin-coating on a Si substrate.

Simulation method: The model systems are constructed by generating a chain molecule under interest on a 5x3 rectangular 1T-TiS₂ supercell with toluene molecules, where the density of molecules in the simulation cell is set to be 1.2 g/cm³ to approximate PS/TiS₂ in toluene. The geometry optimization of the model system was performed according to density functional tight binding (DFTB) theory using DFTB+ package with the tiorg and mio parameter set and UFF-based dispersion corrections. The optimized systems were then equilibrated by DFTB-MD simulation in NVT ensemble at 298 K for 10 ps. The concentration profiles were obtained from the time averaging of MD samples for extra 5 ps run after the equilibration.

Characterization: A horn probe tip sonicator (VibraCell CVX;750 W) was used to exfoliate the TMDs with amine-terminated polymers. Centrifugation was carried out using a Hettich Mikro 22R centrifuge. The optical absorbance spectra were measured by ultraviolet-visible-NIR spectrophotometer (JASCO V-530) using 1-cm quartz cuvettes. FT-IR studies were performed using a JASCO FT-IR 300E apparatus (Tokyo, Japan) with KBr as a standard. The thermogravimetric analysis (TGA) of the samples was carried out using a TA Q500 thermal analyser at a heating rate of 10-Cmin-1 under a nitrogen atmosphere. X-ray photoelectron spectroscopy (K-alpha Thermo VG, .K.) measurements were acquired using a monochromated Al X-ray source (Al Ka line: 1486.6 eV). Raman and PL measurements (LabRamAramis) were carried out using a 532-nm laser at a power of 0.5mW and an exposition time of 10 s. X-ray diffraction patterns were recorded using a Dmax/2500-H (Rigaku, Japan). The nanostructures of the TMDs were examined by tapping mode atomic force microscopy (Nanoscope IV Digital Instruments) in the height and phase contrast mode, field emission scanning electron microscopy (FESEM, JEOL JSM-7001F) with an acceleration voltage of 10 kV and high resolution transmission electron microscopy (HRTEM, JEOL 2100F) at 200 kV in the bright field. TEM samples were prepared by drop casting the dispersions on a holy carbon grid, followed by drying under vacuum for 24 h at 50 °C. Selected area electron diffraction patterns were obtained in the HRTEM analysis. Energy dispersive X-ray (EDX) spectra of the TMD/polymer composite films were obtained using an EDX spectrometer by FESEM with an acceleration voltage of 10 kV.

4. Results and Discussion

4-1) Supramolecular π - π interactions

: Exfoliation and dispersion of LIMs with Py-P4VP

Non-covalent functionalization by physical π - π -interactions with LIMs is a promising method because it offers the possibility of attaching functional groups to nanosheets without disturbing the structural and electronic properties. The hexagonal arrangement of the carbon atoms in polymer chain or functional group is isomorphic to graphite like layered BN and TMDs, which shows hexagonal (2H) polymorphs, and thus, π - π -interactions between them is reasonably expected. We examined how π interaction sterically shields attractive forces between the surface of the LIM nanosheets such as BN and MoS₂, the effect on the structure, and properties of both nanosheets and polymers to design the nanoelectronic devices. In fact, the LIM nanosheets were functionalized with P4VP-Py by π - π interaction between pyrene molecule and surface of nanosheet as schematically shown in **Figure 1**, showing the most successful dispersions of the MoS₂ and BN in various solvents such as DMF, ethanol and IPA. As shown in **Figure 1**, all batches using the P4VP derivatives showed characteristic peaks of MoS₂ because the MoS₂ nanosheets were well-dispersed in the polymer solution due to the electron donating and accepting interaction between the amine of 4-VP and d orbital of transition metal. In fact, the batch with the P4VP-Py exhibited the best absorption peak and stable dispersion comparing to the P4VP-C4-amine. It is expected that the planar geometry of pyrene leads the π - π interaction with the 2-dimensional structure of BN and MoS₂, which results in the stable dispersion of nanosheets in organic solvents. (**Figure 2**)

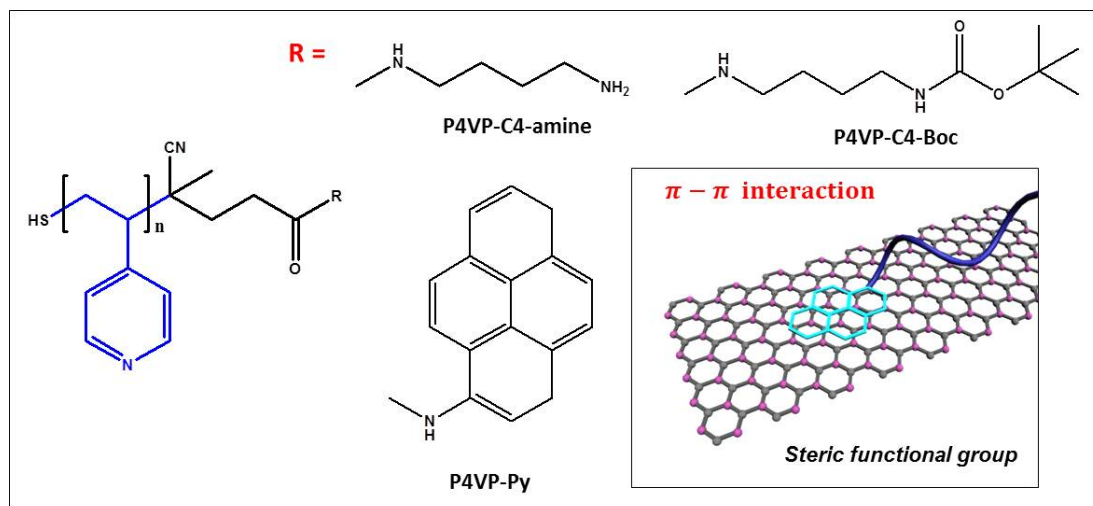

Figure 1. The chemical structures of polymers used in this study for ensuring π - π interaction with LIMs. Scheme representatives the mechanism of the exfoliated LIMs using a pyrene-terminated polymer in an organic solvent.

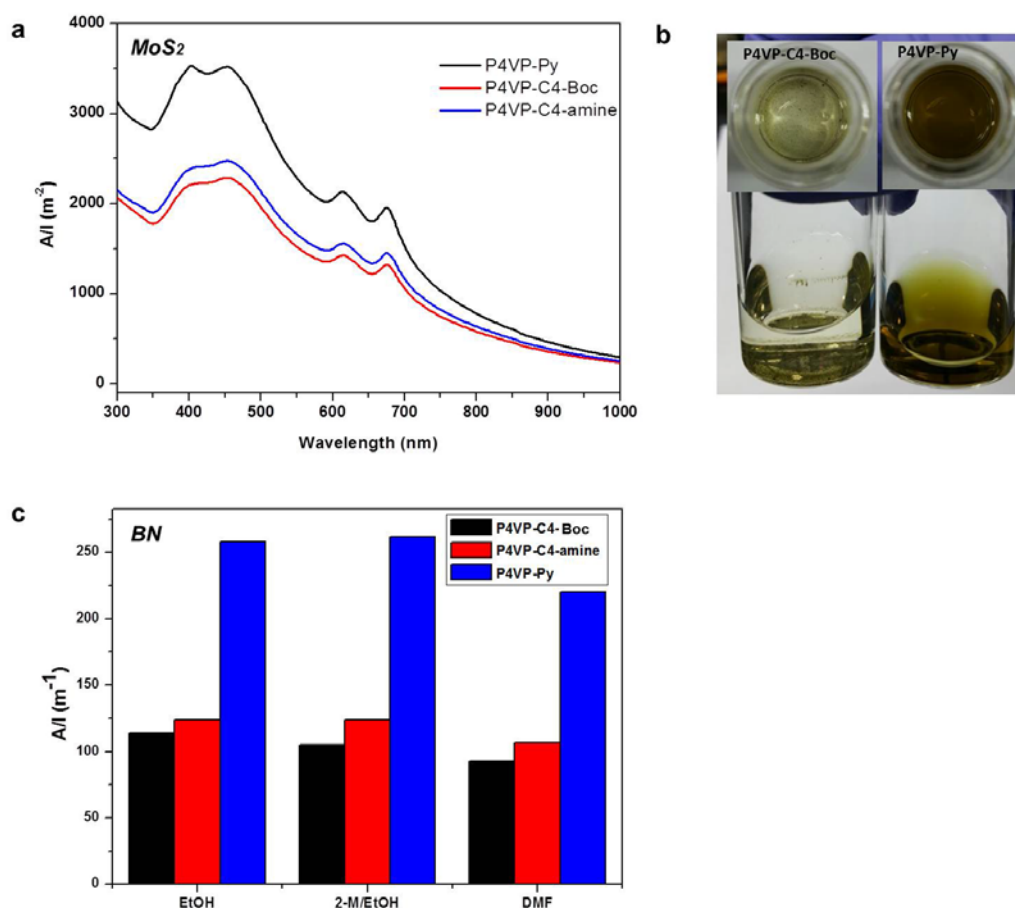

Figure 2. a) Absorbance spectra of MoS_2 composite films dispersed with pyrene (black), C4-Boc (red) and C4-amine (blue) terminated P4VP polymers, respectively. The strongest intensities of MoS_2 peaks at 450, 462, 675 and 734 nm were detected from the P4VP-Py/ MoS_2 film, which indicates the well-dispersed nanosheets within the steric end-group terminated polymer. b) Photographs of MoS_2 solutions with P4VP-C4-Boc (left) and P4VP-Py (right) in DMF for comparing the different degree of exfoliation and dispersion as function of end-groups. c) Absorbance intensities at 550 nm of the exfoliated BNs solutions in various organic solvents according to the end-functional groups.

4-2) Electron donating and accepting interaction

End-functionalized polymers with chemical functional groups at the end are promising candidates as model materials because functional groups are expected to strongly interact to the LIMs surface while the polymer provides good solubility in various solvents, polymer matrices. In this approach, numerous combinations of various polymers and functional chemical groups with different polymer chain lengths can be designed, depending upon the chemical nature of different LIMs. For instance, the amine functional groups and metal ions are possible for different types of interactions, (e.g. acid-base interactions). Various polymers such as amorphous, crystalline and elastomeric and insulating, semiconducting and conducting ones are applicable, depending on their final usages.

4-2.1) Universal exfoliation of TMDs with amine-terminated polymers

Our method is based on the non-destructive modification of TMD sheets with amine-terminated polymers. The universal interaction between amine and transition metal resulted in scalable, stable and high concentration dispersions of a single to a few layers of numerous TMDs. We achieved successful exfoliation of numerous TMD nanosheets such as MoS₂, WS₂, MoSe₂, WSe₂, ReS₂, ZrTe₂ and NbSe₂ with amine-terminated polymers. The principle is based on the Lewis-like acid-base interaction between the transition metal and primary amine, as shown in the scheme in **Figure 3**. The representative amine-terminated polymers employed here are glassy PS-NH₂, PMMA-NH₂, rubbery PBd-NH₂, semi-crystalline PE-NH₂, PEO-NH₂ and PS-*b*-PI-NH₂.

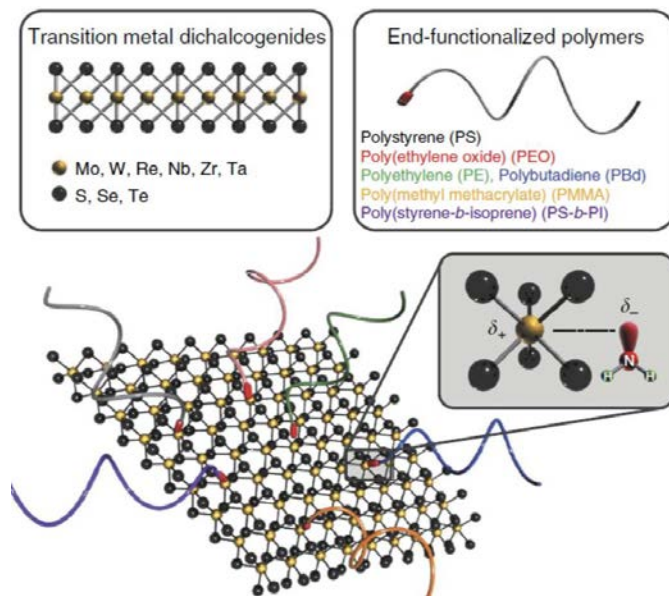

Figure 3. Liquid phase exfoliation of TMDs with end-functionalized polymers. Schematic representation of the proposed mechanism for the exfoliation of various TMDs using different types of amine-terminated end-functionalized polymers in organic solvents. Hexagonal layers of transition metal atoms (M) sandwiched between two layers of chalcogenides (X) are represented by a stoichiometry of MX₂ by the yellow and grey spheres, respectively. The amine-terminated polymers are simplified for clarity. Interaction between the lone electron pairs of nitrogen atoms and the electron-accepting metal atoms weakens the self-layer-layer attraction and the polymer chains provide further separation between the layers, thereby ensuring good exfoliation and dispersion.

We selected MoSe₂ and PS-NH₂ as examples and investigated them in detail to demonstrate the effectiveness of our proposed strategy. The interaction between the donated lone pairs of nitrogen atoms and electron-accepting metal atoms was evidenced by Fourier transform infrared

spectroscopic (FT-IR) for model systems (PS-NH₂, MoSe₂/PS-NH₂) based on density functional theory (DFT) frequency calculation employing B3LYP functional with LANL2DZ basis set as implemented in Gaussian 09 program. For the sake of simplicity, the PS-NH₂ is modeled as an amine-terminated styrene monomer (H-Styrene-CH₂-NH₂) and the (MoSe₂) nanosheet is modeled as a Mo₄Se₈ cluster. The geometries were first optimized in the gas phase and the frequency calculations of the optimized geometries were then performed with the consideration of solvent (toluene) effect using IEF-PCM solvent model. As seen in **Figure 4**, the peak at 1673.94 cm⁻¹ for scissoring (bending) vibration of the NH₂ in the absence of MoSe₂ is shifted to higher frequency (1684.61 cm⁻¹) in the MoSe₂/PS-NH₂ bound state, which consolidates our experimental observation.

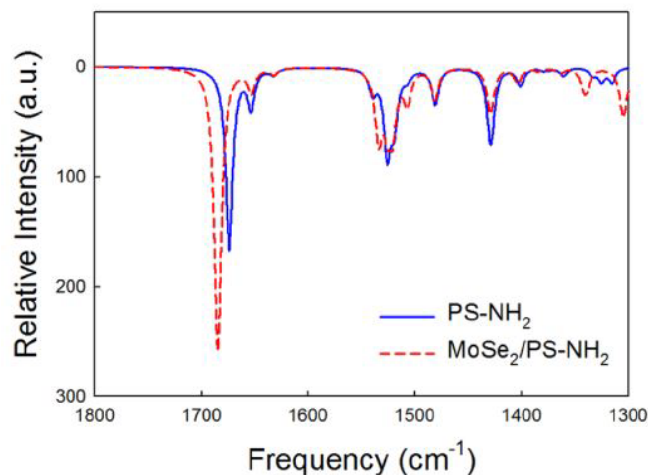

Figure 4. IR simulation spectra of interaction between polymers and TMDs. Comparison of the simulated IR spectra of PS-NH₂ (Blue line) and MoSe₂/PS-NH₂ (dotted red line).

Our method is different from metal ions and small molecules intercalation and further sonication assisted exfoliation methods, because there is no intercalation step of TMDs with amine-terminated polymers in our process. It is indeed difficult to imagine that polymer molecules highly swollen in solvent medium with their radius of gyration of approximately a few nanometers are inserted into such a small gap of two stacked nanosheets (~1 nm). The root mean square radius of gyration ($\langle s^2 \rangle^{1/2}$) of the PS-NH₂ (9.5 kg/mol) is approximately 4 nm in toluene, based on the equation of $\langle s^2 \rangle^{1/2} = \alpha (C_\infty)^{1/2} n^{1/2} l$, where α is expansion parameter in toluene, C_∞ characteristic ratio of PS, n the number of bonds and l corresponds to C-C bond length. Instead, amine groups of polymers more efficiently interact with transition metals when surface of TMD nanosheets is exposed upon sonication step and the anchored polymers on the surface of TMDs in turn stabilize the dispersion of nanosheets in solvent.

To confirm our argument, we separated the processes. A solution of bulk MoSe₂ in toluene was sonicated without the addition of PS-NH₂ and subsequently mixed with PS-NH₂ solution which had been prepared. (**Figure 5a**) While a solution without polymer was immediately settled down in few minutes, the mixed solution exhibited TMDs well dispersed in toluene. (**Figure 5b**) The quantitative analysis of the dispersion of MoSe₂ suggests that no significant difference in the dispersion was observed between single and two step processes, which implies that amine terminated polymers play a role of mainly stabilizing TMD sheets in solvent and preventing them from re-aggregating upon film formation. Another experiment we designed was to examine the dispersion of MoSe₂ with PS-NH₂ without sonication step. When a mixture of MoSe₂ and PS-NH₂ was gently stirred in toluene, nanosheets were rarely dispersed in solvent as expected. (**Figure 5b**). □

Figure 5. Exfoliation and dispersion of TMDs with end-functionalized polymers. a) Schematic illustration of the proposed mechanism for the exfoliation and dispersion of various TMDs using different types of amine-terminated end-functionalized polymers. A solution of bulk MoSe₂ in toluene was sonicated without the addition of PS-NH₂ and subsequently mixed with PS-NH₂ solution (sonicated and mixed solution). Compared to MoSe₂ solution sonicated in toluene without polymer and simple mixing of bulk MoSe₂ and PS-NH₂ in toluene, which were immediately settled down in few minutes, the sonicated and mixed solution exhibited MoSe₂ well dispersed in toluene. b) Photograph of (i) bulk MoSe₂ in toluene was sonicated without the addition of PS-NH₂ (ii) simple mixing of bulk MoSe₂ and PS-NH₂ in toluene (iii) bulk MoSe₂ in toluene was sonicated and subsequently mixed with PS-NH₂ solution.

The (002) peak shift to low theta angle observed due to the efficient intercalation of TMDs by small molecules in the previous study was not, therefore, observed in our process but the (002) peak was substantially reduced in intensity due to highly exfoliated nanosheets separated by intervening polymers. (**Figure 6a and b**) The absorbance spectra of the MoSe₂ dispersions obtained under two step process (**Figure 6c**) shows similar characteristic peaks of exfoliated MoSe₂ obtained by one step process and other methods without PS-NH₂, confirming the exfoliation and stable dispersion of MoSe₂ in toluene by our method.

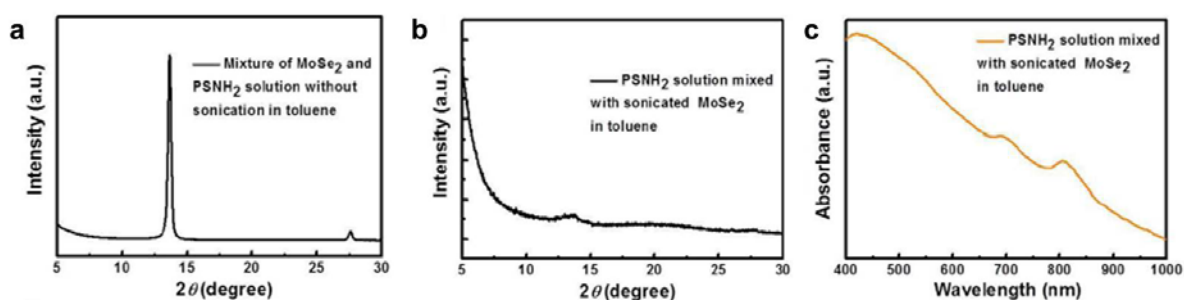

Figure 6. XRD results of c) Mixture of bulk MoSe₂ and PS-NH₂ in toluene without sonication and d) bulk MoSe₂ in toluene was sonicated and subsequently mixed with PS-NH₂ solution. e) Absorbance spectra of bulk MoSe₂ in toluene was sonicated and subsequently mixed with PS-NH₂ solution.

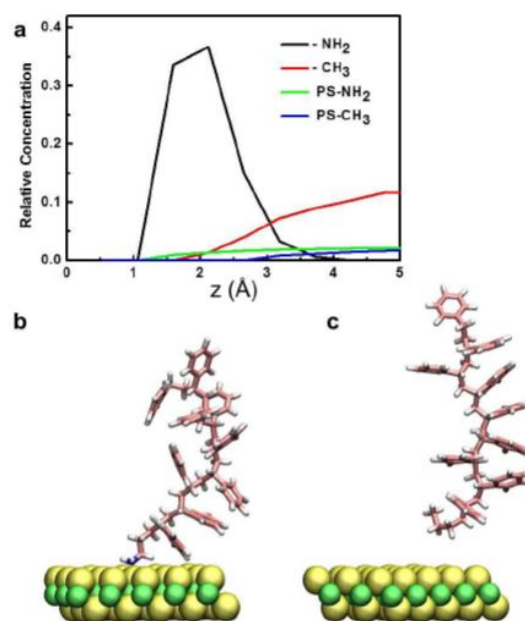

Figure 7. Simulation results of interaction between polymers and TMDs. a, Comparison of the simulated concentration profile of -NH₂, -CH₃, PS-NH₂ and PS-CH₃ in the direction perpendicular to the TMD surface (z). Simulation snapshot of typical conformational states for b, PS-NH₂ and c, PS-CH₃ on the TMD surface.

To further investigate the effect of amine-terminated end-functionalized polymers as a dispersant, we simulate the physisorption of amine terminated PS (PS-NH₂) and methyl-terminated PS (PS-CH₃) onto TMD (TiS₂) surface using density functional tight binding (DFTB) combined with Born-Oppenheimer molecular dynamics (MD) simulation. Since DFTB parameter sets for Mo and Se interacting with amine were not available in our system, we instead examined a common TMD, TiS₂ whose electronic structure is similar to MoSe₂. **Figure 7a** compares the simulated concentration profile of PS-NH₂ and PS-CH₃ in the direction perpendicular to the TMD surface (z). The profiles are obtained from the time averaging of MD samples for 5 ps after 10 ps equilibration. The profiles clearly indicate that the amine terminal groups are strongly physisorbed onto the surface showing a pronounced peak at ~ 2 Å, whereas PS-CH₃ does not show any peak near the surface. This suggests that non-functionalized PS simply wanders away from the surface at the urging of thermal and stirring force while PS-NH₂ can be anchored onto the TMD surface forming brush-like molecular clusters. Two simulation snapshots (**Figure 7b and c**) demonstrate typical conformational states for PS-NH₂ and PS-CH₃ on the TMD surface.

4-2.2) Exfoliation and dispersion of MoSe₂ with amine terminated polymers

: Determination of the optimal conditions for dispersion

To demonstrate the effectiveness of our strategy, we extensively investigated the dispersion of MoSe₂ nanosheets with PS-NH₂. Initially, the exfoliation of MoSe₂ in toluene, which is a poor solvent for MoSe₂, was tested with PS, PS-NH₂, and without polymer by tip sonication with a 10-s pulse on and a 5-s pulse off with amplitude of 50% in an ice bath. MoSe₂ in neat toluene and with PS began to precipitate immediately after sonication and completely settled down within few minutes, whereas the dispersion with PS-NH₂ became visually non-scattering with a dark brown color and remained stable, which indicates the preferential attraction between MoSe₂

and the amine groups of PS-NH₂. The results prove that PS-NH₂ can enhance the dispersion of the exfoliated nanosheets in non-solvents of MoSe₂. (**Figure 8a**)

In order to optimize the dispersion conditions, we further investigated the MoSe₂ dispersions in detail in terms of the sonication time, initial MoSe₂ concentration, and centrifugation rate with 1 mg/mL PS-NH₂ (**Figure 8b-f**). The quality of the exfoliation and dispersion was initially determined by the absorbance per unit length, A/l, using UV-vis spectrometry. The optimized dispersion conditions were sonication for 45 min with an initial concentration of 10 mg/mL bulk MoSe₂, followed by centrifugation at 1,500 rpm for 30 min. The absorbance spectra of the MoSe₂ dispersions obtained under these conditions are shown in Figure 2a. Different from pure PS-NH₂, discernible peaks were observed at 800 and 690 nm, which are similar to the characteristic peaks of exfoliated MoSe₂ obtained by other methods without PS-NH₂, confirming the stable exfoliation and dispersion of MoSe₂ in toluene

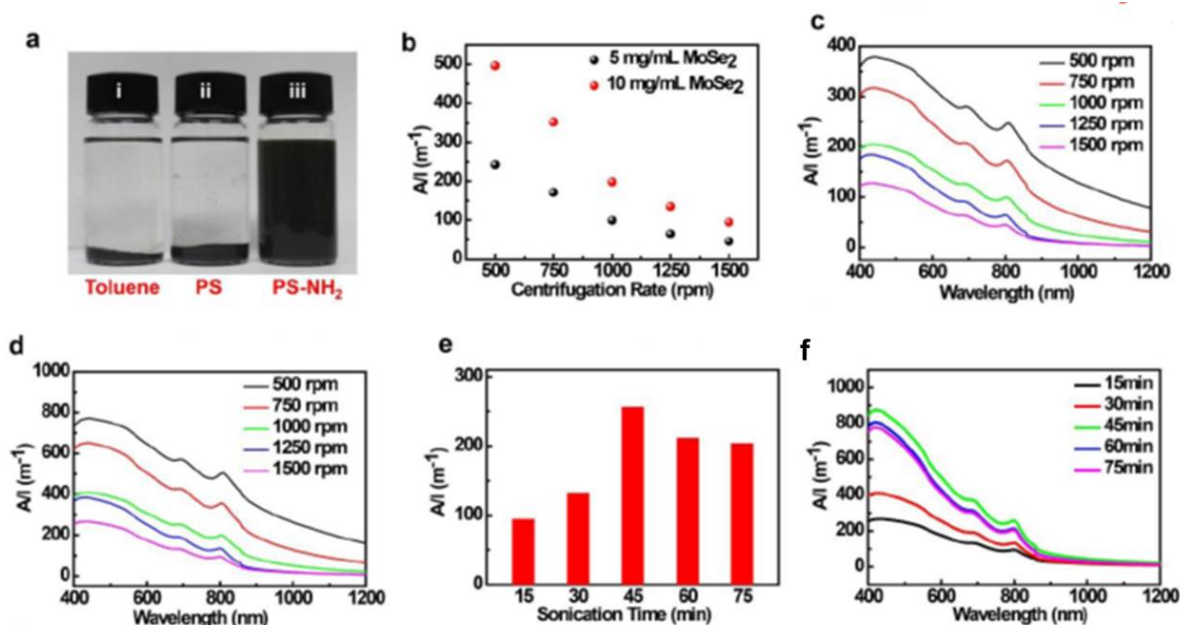

Figure 8. Optimization of the MoSe₂ dispersions with PS-NH₂. a) Photographs of the MoSe₂ dispersion in toluene (i) without any dispersant, (ii) with PS, and (iii) with PS-NH₂. b) Effect of the centrifugation rate on the MoSe₂ dispersion. Absorbance spectra of two different initial MoSe₂ concentrations were evaluated: c) 5 mg/mL and d) 10 mg/mL. Sonication time was 15 min. e) Effect of the sonication time and f) the corresponding absorbance spectra of MoSe₂ dispersion in toluene. For all of the sonication times evaluated, the initial concentrations of MoSe₂ and PS-NH₂ were kept constant at 10 and 1 mg/mL, respectively, and the solutions were centrifuged at 1,500 rpm for 30 min.

: Characterization of MoSe₂ dispersion with PS-NH₂

The interaction of amine groups of PS-NH₂ with MoSe₂ and the resulting exfoliation into nanosheets was confirmed by X-ray diffraction (XRD) analysis, Raman spectroscopy, and X-ray photoelectron spectroscopy (XPS) and. The XRD patterns of bulk MoSe₂ and MoSe₂/PS-NH₂ are shown in the Supplementary **Figures 9a** and **b**. The abrupt decrease and broadening of the (002) reflection in the XRD patterns of MoSe₂/PS-NH₂ indicates that MoSe₂ was exfoliated into a few layers with different dimensions. The Raman spectra of MoSe₂/PS-NH₂ deposited on the SiO₂ substrate were compared with the spectra of bulk MoSe₂ (**Figure 9c**). The exfoliated MoSe₂ nanosheets with PS-NH₂ showed characteristics out-of-plane A_{1g} and in-plane E_{2g1} Raman modes at 239 and 287.5 cm⁻¹, respectively. These values are consistent with results reported for monolayer MoSe₂. The observed characteristic out-of-plane A_{1g} mode at 239 cm⁻¹, not be

observed in 1T-MoSe₂, indicates the 2H polymorph structure of the exfoliated MoSe₂ nanosheets. In addition, the peak at about 221 cm⁻¹, associated to a distorted 1T phase, is absent, again indicative of the 2H phase.

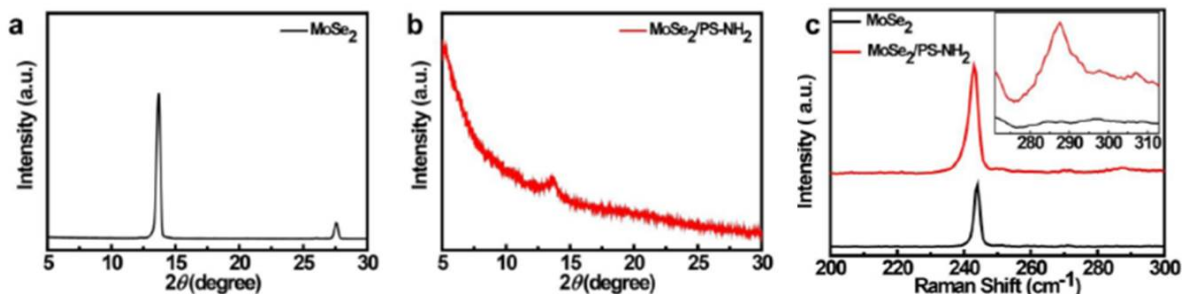

Figure 9. XRD characterizations of a) bulk MoSe₂ and b) exfoliated MoSe₂ nanosheets with PS-NH₂. c) Raman spectra of bulk MoSe₂ and MoSe₂/PS-NH₂.

The XPS spectra of the MoSe₂/PS-NH₂ confirm the stoichiometry of MoSe₂ (**Figure 10a-c**). The two characteristic peaks at 228.8 and 232 eV are attributed to the doublet Mo 3d_{5/2} and Mo 3d_{3/2} binding energies, respectively, for Mo⁴⁺. The peaks corresponding to the Se 3d_{5/2} and Se 3d_{3/2} orbitals of divalent selenide ions (Se²⁻) are observed at 54.4 and 55.2 eV, respectively. These XPS signals are consistent with values reported elsewhere, corroborating the formation of defect-free MoSe₂. The N1s spectrum of PS-NH₂ was deconvoluted into three individual peaks, which are assigned to N⁻ (398.48 eV), -NH⁻ (399.38 eV), and -NH₂ (399.78 eV). These peak positions of the N1s spectrum were shifted after interaction with MoSe₂. The binding energies for N⁻, -NH⁻, and -NH₂ were shifted to 399.08, 399.78, and 400.48 eV, respectively. The shift of the binding energy of -NH₂ is due to the effect of the interaction between the Mo ions and the donating lone pair electrons of -NH₂.

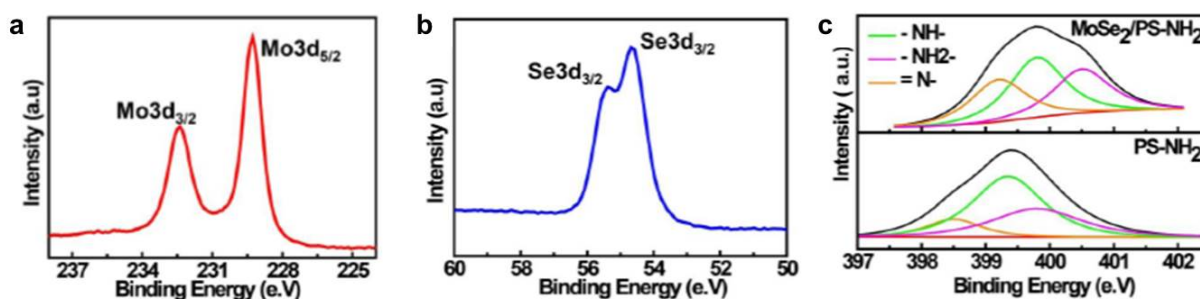

Figure 10. XPS of the MoSe₂ nanosheets exfoliated with PS-NH₂. a) Mo 3d spectrum, b) Se 3d spectrum, and c) N 1s spectra of PS-NH₂ and MoSe₂/PS-NH₂.

: Effect of the molecular weight of PS-NH₂ on MoSe₂ dispersion

The effect of the molecular weight of PS-NH₂ on the MoSe₂ exfoliation was also investigated with four different molecular weights (9.5 k, 25 k, 40 k, and 108 k g mol⁻¹) of PS-NH₂. The initial concentration of PS-NH₂ was kept constant at 1 mg/mL and the final concentration of exfoliated MoSe₂ was measured (**Figure 11**). As expected, the effectiveness of PS-NH₂ in exfoliation decreases with increasing molecular weight of PS-NH₂. The steric hindrance resulting from the entangled conformations of high molecular polymer chains decreases the reactivity of amine groups and restricts the mobility of the polymer chains in the solvents. Therefore, the

lower the molecular weight of PS-NH₂, the more favorable the amine interactions and thus, better exfoliation and dispersion of MoSe₂ nanosheets occurs. PS-NH₂ with a molecular weight of 9.5 kg/mol was further utilized for all of the analyses.

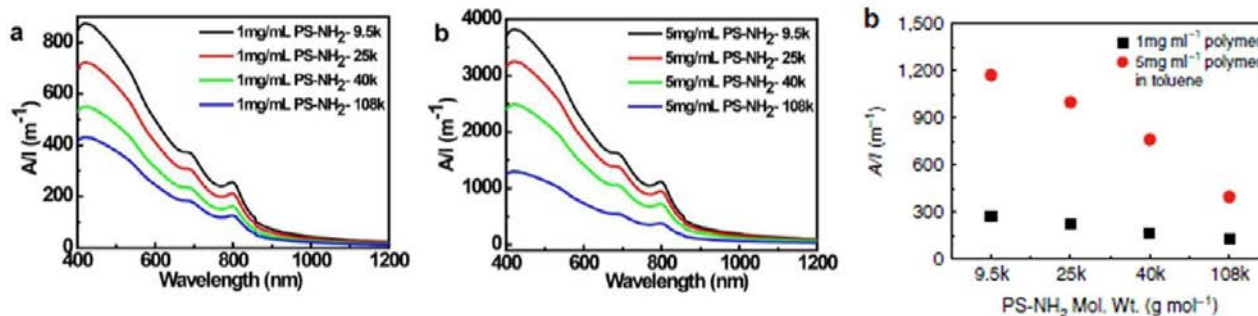

Figure 11. Effect of the PS-NH₂ molecular weight on the MoSe₂ dispersion. Absorbance spectra of MoSe₂ dispersions depending on PS-NH₂ with different molecular weights for initial polymer concentrations of a) 1 mg/mL, and b) 5 mg/mL. c) Effect of the molecular weight of PS-NH₂ on the efficiency of the MoSe₂ dispersion in toluene characterized by the absorbance values of the dispersions at 800 nm. The initial concentrations of MoSe₂ and PS-NH₂ were kept constant at 10mg/mL and 1mg/mL, respectively, for all of the molecular weights of PS-NH₂ evaluated. Increasing the molecular weight of PS-NH₂ leads to a decrease of the efficiency of the MoSe₂ dispersion.

: Determination of the concentrations

The concentration of the dispersed MoSe₂ nanosheets with PS-NH₂ in toluene was determined by a traditional gravimetric method. A precisely measured volume of the MoSe₂ dispersion was poured into a crucible and the solvent was removed in a vacuum oven overnight. Then, the mass of the crucible was measured and used to determine the concentration of MoSe₂ in the dispersion according to the following **equation (1)**.

$$\text{Concentration} = \frac{\text{Final crucible mass} - \text{Initial crucible mass (mg)}}{\text{Volume of the solvent (mL)}} \dots\dots\dots (1)$$

TGA was utilized to determine the dispersed amount of MoSe₂ nanosheets in the PS-NH₂-modified MoSe₂ composite (**Figure 12**). From the TGA results of the PS-NH₂-modified MoSe₂ composite, the quantity of the MoSe₂ nanosheets was estimated to be 26%, which allowed us to determine the final concentration of the MoSe₂ nanosheets in the dispersion without PS-NH₂ to be 0.22 mg/mL. The extinction coefficient (α) of the MoSe₂ nanosheets with PS-NH₂ in various organic solvents was determined using the Lambert–Beer law.

(**Equation 2 and 3**)

$$A = \alpha lc \dots\dots\dots (2)$$

$$\alpha = A/lc \dots\dots\dots (3)$$

Here, A is the measured absorbance, l is the cell length, and c is the dispersed concentration.

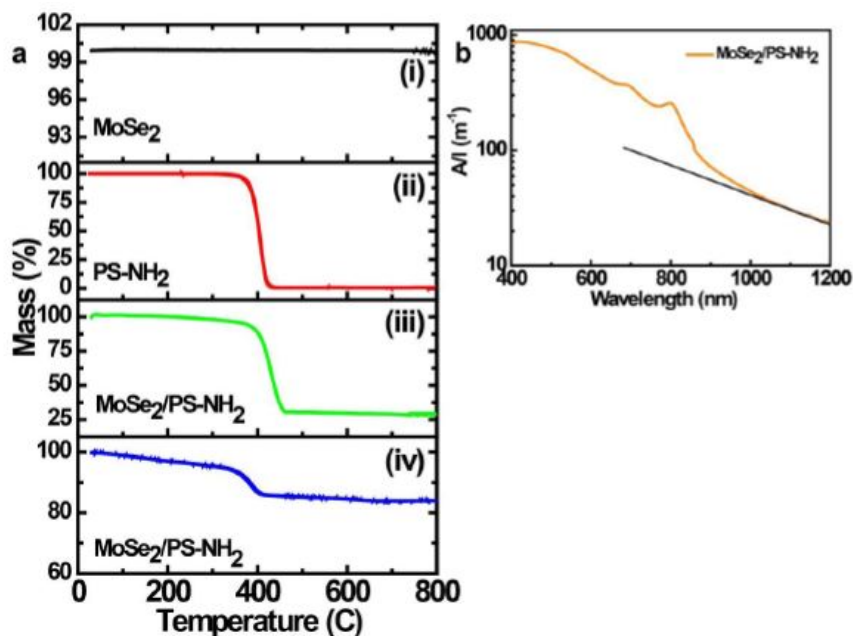

Figure 12. Determination of the MoSe₂ concentration. a) Thermogravimetric analysis for (i) the MoSe₂ powder, (ii) PS-NH₂, (iii) MoSe₂ modified with PS-NH₂, and (iv) after removing the excess PS-NH₂ at 15,000 rpm for 90 min in the MoSe₂ dispersion. b) Absorbance spectrum of the MoSe₂ dispersion with 1 mg/mL PS-NH₂ on the log scale.

The samples were controllably diluted in series and the absorbance per unit length (A/l) as a function of the MoSe₂ concentration was measured. The background scattering illustrated by the line in the plot of the absorbance spectrum of MoSe₂ with PS-NH₂ (**Figure 12b**) was subtracted from the spectrum. The background subtracted A/l value at 800 nm was plotted as a function of the MoSe₂ concentration (**Figure 13a**) and the A/l values linearly increased with increasing measured concentration. The calculated absorption coefficient (α) was determined from the slope of the curve to be $932 \text{ L g}^{-1} \text{ m}^{-1}$, which was used to determine the concentrations of the further dispersions.

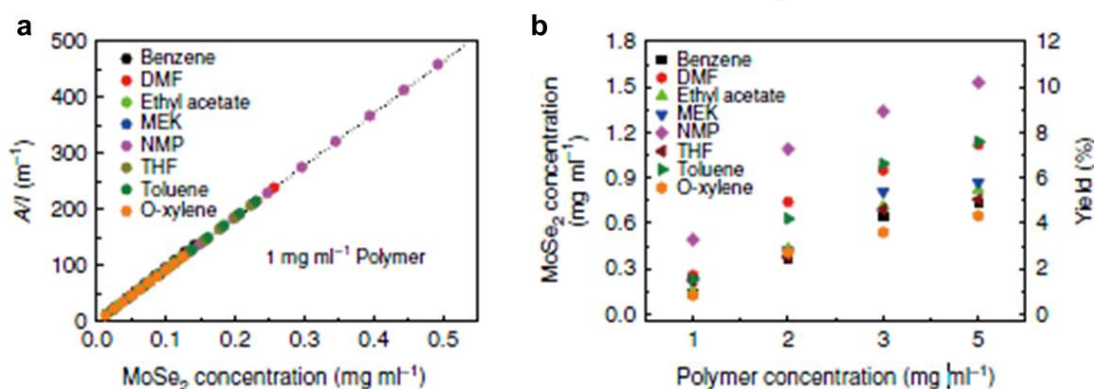

Figure 13. (a) Absorbance at a wavelength of 800 nm as a function of the MoSe₂ concentration in each solvent. The absorbance linearly increased with the amount of MoSe₂ following Lambert–Beer behaviour, which implies uniform dispersion of MoSe₂ without aggregation in all of the solvents. (b) Plots of the concentration of MoSe₂ as a function of the initial concentration of PS-NH₂ in different organic solvents. Yield of one to three layers (70%) of the exfoliated MoSe₂ nanosheets with PS-NH₂ as a function of the initial concentration of PS-NH₂ in different organic solvents are also shown.

MoSe₂ dispersed with PS-NH₂ in various solvent media

The absorbance variations of the MoSe₂ dispersions were measured at an excitation wavelength of 800 nm with 1 mg/mL PS-NH₂ as a function of the MoSe₂ concentration in each solvent (**Figure 14**). The absorbance linearly increased with the amount of MoSe₂ in accordance with Lambert-Beer behavior and the results imply that the MoSe₂ nanosheets are uniformly dispersed without aggregation in all of the solvents.

We further investigated important dispersion properties such as the maximum amount of MoSe₂ dispersed in a solvent and the amount of PS-NH₂ required for MoSe₂ dispersion at a certain concentration dependent upon the solvent (**Figure 15**). The dispersed MoSe₂ concentration increased monotonically with increasing PS-NH₂ concentration due to the increase of reactive amine functional groups.

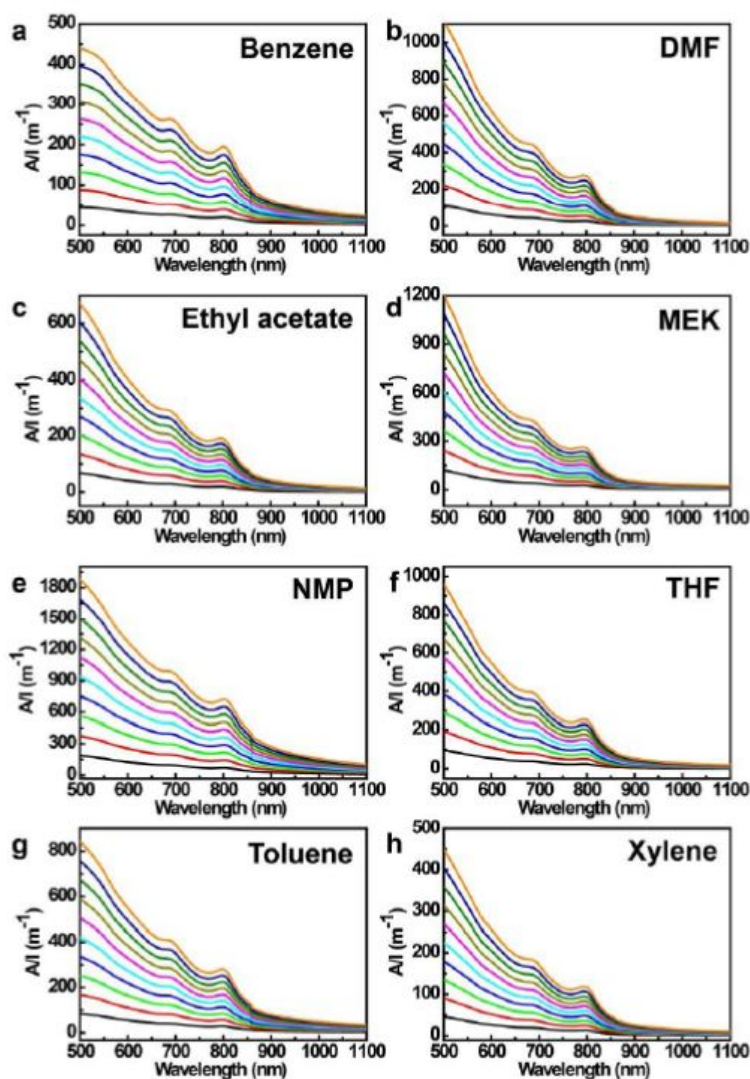

Figure 14. MoSe₂ dispersion in various solvents. Absorbance spectra of the series of diluted MoSe₂ dispersions with 1 mg/mL PS-NH₂ in various solvents.

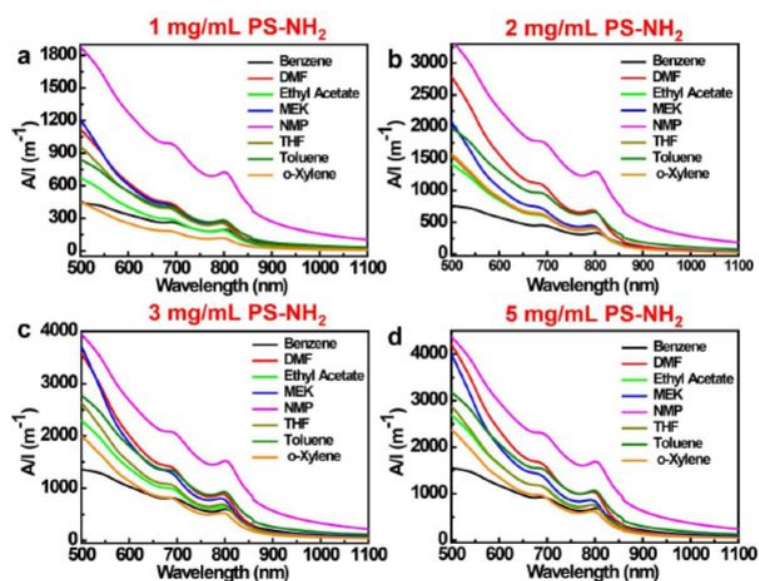

Figure 15. MoSe₂ dispersions with different PS-NH₂ concentrations. Absorbance spectra of MoSe₂ dispersions in various solvents as a function of the PS-NH₂ concentrations.

: Stability of MoSe₂ dispersed with PS-NH₂

The stability of the MoSe₂ dispersions after centrifugation in solvents with 5 mg/mL PS-NH₂ was monitored by optical absorbance at 800 nm as a function of time, as shown in **Figure 16**. The absorbance of the MoSe₂ dispersions did not significantly change, indicating that the dispersed MoSe₂ was highly stable without re-aggregation and sedimentation for a period of more than 3 weeks. The high-concentration dispersion and long-term stability of MoSe₂ can be ascribed to the strong interaction of the amine groups with the MoSe₂ nanosheets as well as the long and flexible chains of polymers, which provide good solubility in various solvents.

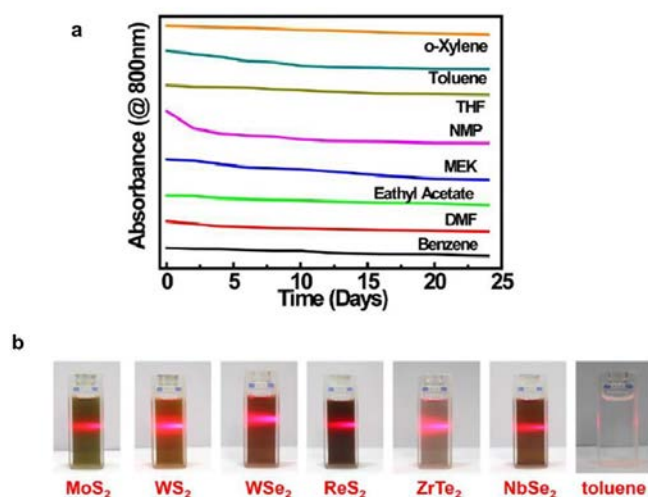

Figure 16. a) Stability of dispersed MoSe₂. Absorbance of MoSe₂ dispersions measured at 800 nm in various solvents with 5 mg/mL PS-NH₂ as a function of time. The absorbance results are vertically shifted for clarity. b) Exfoliation of the different TMDs with PS-NH₂. Photographs of different TMDs dispersed in toluene with 1 mg/mL of PS-NH₂. All of the dispersions were diluted to observe variations of the color. A red laser beam was directed through the TMD dispersions to show the Tyndall effect of the colloidal solutions. For comparison, pure toluene is also shown

The large amount of PS-NH₂ in the PS-NH₂-modified MoSe₂ composite may not be suitable for subsequent electronic applications due to the intrinsic insulating properties of PS-NH₂. To remove the excess amount of the non-interacted PS-NH₂ in the dispersions, the dispersions were centrifuged for 90 min at 15,000 rpm. The precipitate was collected and dried to remove the solvents.

: Morphology of the MoSe₂ nanosheets

The microstructures of the exfoliated nanosheets were investigated using both surface probe and electron microscopy, where the results show that the thickness of the single-layer MoSe₂ was 1.0±0.15 nm, which is thicker than that of pristine MoSe₂ (0.7 nm) due to the attached polymer chains on both sides of the nanosheet. The single crystalline nature of the single- and few-layer MoSe₂ was preserved during the exfoliation process as well (**Figure 17**)

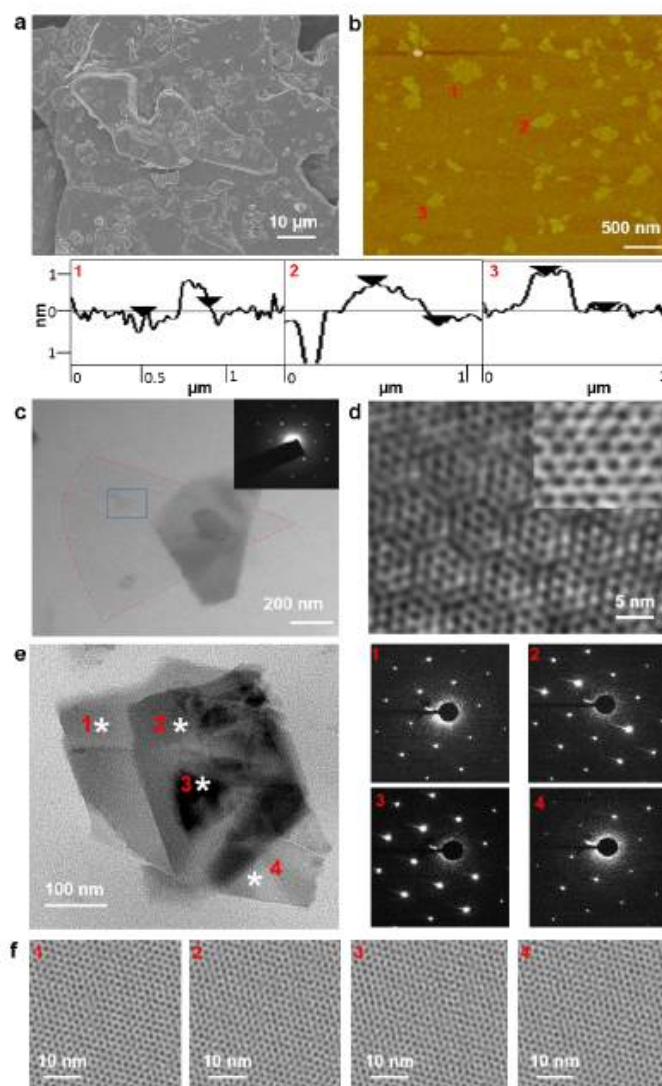

Figure 17. Morphology of the MoSe₂ nanosheets. (a) SEM image of bulk MoSe₂ powder. (b) Tapping mode AFM micrograph along with height profile of distribution of exfoliated MoSe₂ nanosheets in toluene spin-coated on a Si substrate. The height profile measured in clearly shows a monolayer MoSe₂ sheet with a thickness of approximately 1.0 nm. (c) Bright field TEM image of single- and few-layer MoSe₂ nanosheets. The inset shows the selected area electron diffraction (SAED) pattern of a MoSe₂ nanosheet. (d) High resolution TEM (HR-TEM) image of the MoSe₂ nanosheets. The digitally filtered image in the inset clearly shows hexagonal symmetry of the MoSe₂ nanosheets.

The SAED pattern and HR-TEM collected from the marked box region. (e) Bright field TEM image of few-layer MoSe₂ nanosheets and different thickness regions marked with numbers and their corresponding SAED patterns. (f) HR-TEM images of different regions.

As expected, bulk and many layers of MoSe₂ nanosheets prepared by low centrifugation rate do not exhibit any noticeable PL. In addition, electron microscopy results of both bulk and exfoliated TMDs including MoS₂, WS₂, WSe₂, ReS₂, ZrTe₂ and NbSe₂ with PS-NH₂ in toluene evidence the universality of our method (**Figure 18**). Statistical analysis of various samples with different centrifuge rates shows that the mean number of layers decreases with the rate and at an optimized condition, a few layered TMDs dispersion was obtained as shown in **Figure 19**.

Park, "Epitaxial growth of thin ferroelectric polymer films on graphene layer of fully transparent and flexible nonvolatile memory", *Nano Letters*, submitted on 23 September **2015**

2) Presentations

1. The 13th International Nanotech Symposium & Nano-Convergence Expo NANO KOREA 2015, July 1~3, 2015, Coex, Seoul, Korea. "Solution processible MoSe₂ thin films with end functionalized polymers for high performance flexible photodetectors" by Dhinesh Babu Velusamy, **Oral presentation**
2. International Conference on Electronic Materials and Nanotechnology for Green Environment ENGE 2014, November 16-19, 2014, Ramada Plaza, Jeju Hotel, Jeju, Korea. "Solution processible MoS₂ thin film photodetectors with polymers" by Dhinesh Babu Velusamy and Cheolmin Park, **Poster presentation**
3. **AFRL On-site seminar**, September 17, 2015 "Controlled interactions between two dimensional layered inorganic nanosheets and polymers", through Window On Science (WOS) Program

3) Interaction with Air Force

Official invitee and presentation speaker of the AF related meeting, named On Site Discussion of Research Collaboration with AFRL, on September 17-19 2015, entitled "Controlled interactions between two dimensional layered inorganic nanosheets and polymers", through **Window On Science (WOS) Program** for promoting collaborations with Air Force researchers, including discussion of two dimensional layered inorganic materials and progress for planned/ongoing projects.

- One hour presentation at AFRL about the recent research related to the grant of the Basic research for AOARD 144054 entitled "Controlled Interactions between Two Dimensional Layered Inorganic Nanosheets and Polymers".
- The meetings (30 min. each) with 12 AFRL experts in material science and shared common research interests.
- Setting up future research collaboration in the field of 2D materials and their photo-electronic applications. In particular, research collaboration with Dr. McConney's group on the subject of the electrical characterization of TMD films grown in AFRL as well as epitaxial growth of functional polymers on the TMD films.
