            Development, Evaluation and Demonstrations at IMCOM Facilities”

## Abstract

The corrosion of reinforced concrete in wastewater systems is a costly ongoing problem for the Department of Defense (DoD). Capillary action makes concrete vulnerable to penetration by highly corrosive chemicals transported by wastewater. Progressive corrosion of embedded steel reinforcement greatly increases internal stresses on the concrete, ultimately causing premature fractures and spalls. Researchers hypothesized that corrosion in such aggressive environments could be mitigated using a hydrophobic concrete admixture to inhibit penetration of corrosive liquids into wastewater treatment infrastructure, thereby reducing stresses on the materials and extending service life. This study tested and evaluated one such admixture, a patented material called Hycrete.

This evaluation exposed test coupons within the sewage effluent system at Fort Detrick, MD. Under the two year duration of this test, the presence of Hycrete had no noticeable influence on performance of concrete exposed to sewer effluent or gasses. Visual appearance did not dramatically differ and there were no significant changes chemical composition. The results suggest that neither the Hycrete nor the reference concrete specimens were affected by chemical leaching or intrusion during the two-year demonstration period. The return on investment for this effort was, therefore, zero.

## Preface

This demonstration was performed for the Office of the Secretary of Defense (OSD) and U.S. Army Installation Management Command (IMCOM) under Department of Defense (DoD) Corrosion Prevention and Control Project F09-AR05B, “Integral Waterproofing for Concrete Structures Research, Development, Evaluation and Demonstrations at IMCOM Facilities”; and Military Interdepartmental Purchase Requests MIPR9ACERL1043 (FY09) and MIPR10005161 (FY10). The proponent was the U.S. Army Office of the Assistant Chief of Staff for Installation Management (ACSIM), and the stakeholder was IMCOM. The technical monitors were Daniel J. Dunmire (OUSD(AT&L)), Bernie Rodriguez (IMPW-FM), and Valerie D. Hines (DAIM-ODF).

The work was performed by the Materials and Structures Branch of the Facilities Division (CEERD-CFM), U.S. Army Engineer Research and Development Center, Construction Engineering Research Laboratory (ERDC-CERL), Champaign, IL. The laboratory testing was performed by Tourney Consulting Group, Kalamazoo, MI. At the time this report was prepared, Vicki L. Van Blaricum was Chief, CEERD-CFM; Donald K. Hicks was Chief, CEERD-CF; and Kurt Kinnevan, CEERD-CZT, was the Technical Director for Adaptive and Resilient Installations. The Deputy Director of ERDC-CERL is Dr. Kirankumar Topudurti and the Director is Dr. Ilker Adiguzel.

The Commander of ERDC is COL Bryan S. Green and the Director is Dr. David W. Pittman.

# 1 Introduction

## 1.1 Problem statement

The corrosion of reinforced concrete in wastewater systems is a costly ongoing problem for the Department of Defense (DoD). Because concrete is a porous material, capillary action makes it vulnerable penetration by water and highly aggressive chemicals. Progressive corrosion of embedded steel reinforcement greatly increases internal stresses on the concrete, ultimately causing premature fractures and spalls. DoD spends about \$7 million annually to repair damage caused by this type of corrosion on military installations (Herzberg, O'Meara, and Stroh 2014, p N-17).

One approach to preventing or controlling corrosion of sewage and wastewater infrastructure is to design high-performance concrete mixes that are less permeable to intrusion by liquids. One approach is to include densifiers such as silica fume in the mix. Silica fume is very effective, but it can be expensive, and in hot environments it can cause shrinkage cracking. A newer approach is available through the use of a patented hydrophobic admixture that is claimed by the manufacturer to prevent water intrusion into reinforced concrete, thereby protecting the embedded reinforcement steel from exposure to water and corrosion-promoting chemicals it may contain. To investigate the efficacy of this concrete admixture, which is called Hycrete,\* two related demonstration/validation projects were performed under the auspices of the DoD Corrosion Prevention and Control Program. One project, designated F09-AR05A, was initiated to investigate the efficacy of Hycrete added to the concrete mix for an ocean-front seawall at an Army facility in a highly corrosive, chloride-infused environment (Sweeney and McInerney 2017). The other project, designated F09-AR05B, is documented in the present report. This work, supported through funding from the U.S. Army Installation Management Command (IMCOM), consisted of laboratory testing of concrete specimens exposed to a wastewater-treatment chemical environment. The test specimens were made from concrete mixes with and without Hycrete to compare the performance of the demonstrated admixture.

\* Hycrete is a trademark of Hycrete, Inc., <http://www.hycrete.com/>.

## **1.2 Objective**

The objective of this test program was to determine whether the use of Hycrete in reinforced concrete wastewater transport and treatment systems can reduce the amount of aqueous and gaseous corrosive chemical species absorbed by the concrete and, thereby, reduce the potential for corrosion-related degradation and associated maintenance costs for DoD.

## **1.3 Approach**

The testing program was executed for ERDC-CERL by Turney Consulting Group, Kalamazoo, MI. The test site was the wastewater treatment facility at Fort Detrick, MD, which was identified as a representative facility for the testing parameters. The specific location within the treatment facility was selected on the basis of scheduling, access, and other logistical considerations.

A total of 96 test specimens (48 references and 48 prepared with Hycrete) were fabricated. The experiment was planned to provide three exposure conditions: below the water line, partially submerged, and above the water line. The coupons were mounted at a location within the system near the effluent tank. After exposures of 6, 12, 18, and 24 month, 12 reference samples and 12 Hycrete samples were removed and tested for the presence of corrosion-promoting compounds.

## **1.4 Metrics**

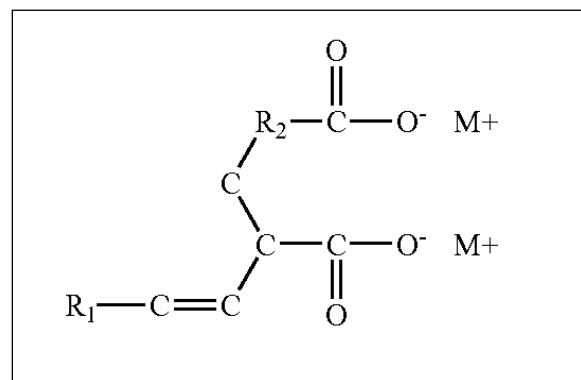

Performance of the Hycrete additive was assessed by comparing the chemical composition and pH of the Hycrete specimens to the reference specimens at intervals of 6, 12, 18, and 24 months. Of specific interest for these tests were two chemical compounds common to wastewater treatment plants that have a deteriorating effect on concrete: sulfur trioxide and phosphate (as pentoxide). The metric for success of the demonstrated additive was an observed lower rate of absorption of these chemicals by the Hycrete specimens than the standard concrete ones. The absorption data would be used to estimate the relative service lives of the compared materials.

## 2 Technical Investigation

### 2.1 Technology overview

The composition of Hycrete includes a proprietary aqueous solution of an alkali salt of a dioic acid. As shown in Figure 1,  $M^+$  is selected from the group that consists of  $Na^+$  and  $K^+$ .  $R_1$  and  $R_2$  represent the linear aliphatic hydrocarbons within Hycrete. In an attempt to prevent the active ingredient in Hycrete from precipitating, the molecules include each of the alkali metal constituents  $Na^+$  (90–95%) and  $K^+$  (5–10%) (Rhodes et al. 2007).

Figure 1. Chemical composition of Hycrete.

When added to a concrete mix, Hycrete uses water within the concrete to migrate to the anodic surface of the reinforcing steel. One of the molecular ends uses its polarity to protect the positively charged anode of the reinforcement during the corrosion process. The reinforcement in concrete attracts the hydrophilic end of the additive. Once the additive reaches the surface of the reinforcement it adheres to the iron in the reinforcement material to form a slightly soluble hydrophobic layer. This layer helps to protect the anode potential of steel from chlorides, sulfates, carbon dioxide, oxygen, and moisture.

In an aqueous solution, Hycrete reacts with metallic or other ions it encounters in the concrete or the reinforcement. These reactions form molecules that have long, hydrophobic hydrocarbon chains with limited water solubility. These hydrocarbon chains fill the capillaries, cracks, and fissures of the post construction structure and help to repel water and prevent or reduce the capillary absorption of moisture (Rhodes et al. 2007).

## 2.2 Field work

A total of 96 specimens (48 reference coupons and 48 containing Hycrete) were fabricated. On or about 25 October 2011 the specimens were inserted into or near the effluent tank at Fort Detrick. For each group of 48 specimens, 12 were placed below the wastewater level, 12 were approximately halfway submerged, 12 were suspended above the wastewater level, and 12 were placed at the site, away from the effluent tank, for exposure to normal weathering.

At 6, 12, 18, and 24 months after initial exposure (approximately mid-April 2012; mid-October 2012; mid-April 2013; mid-October 2013), 24 specimens—3 specimens of each concrete type and location—were removed for testing. The specimens were removed, rinsed with tap water, and placed in zip-seal plastic bags clearly marked with concrete type (i.e., reference mix or Hycrete) and exposure conditions (above, at, or below water line, or normal weathering). The specimens were then shipped to the testing lab for analysis.

## 2.3 Testing and analysis

At the laboratory, the specimens were photographed and chemical tests on each specimen were conducted. At the three depth increments (0 – 0.125 in.; 0.125 – 0.25 in.; and 0.25 – 0.375 in.), the concentrations of sulfur trioxide and phosphate (as pentoxide) were tested. The analysis was performed via x-ray fluorescence (XRF). Based on the strength of the experimental design, the test results were expected to be quantitatively accurate and repeatable. The hypotheses were that sulfur trioxide would be stripped out of the concrete if the sewage were attacking the concrete; and that phosphate content would increase if sewage was penetrating the concrete during exposure.

The Appendix of this report presents the contractor's final report on the testing program, including photographs, data, analysis, and conclusions.

### **3 Results**

As stated in the TCG final report on the testing program (see Appendix), the presence of Hycrete in the concrete specimens had no noticeable influence on the performance of concrete exposed to sewer effluent and/or gases over the duration of the testing period for this project. The visual appearance of the reference and Hycrete concrete test specimens was not dramatically different. Concrete pH was not impacted during the exposure period, and there were no sizeable changes in chemical composition. These results suggest that no significant leaching of chemicals from specimens of either type occurred during the exposure period. Complete test results are shown in the Appendix.

## 4 Economic Summary

### 4.1 Costs and assumptions

No initial return on investment calculation was required by the sponsor for this portion of CPC Project F09-AR05. All work on this portion of the project was performed under contract at a total cost of \$170,853.

The research hypothesis was that use of Hycrete in a concrete mix intended for constructing a wastewater treatment system would reduce the degradation of concrete and steel caused by the liquid-borne penetration of highly corrosive chemicals. Any extended concrete service life that could be validated through the testing program would result in a positive return on investment.

### 4.2 Projected return on investment (ROI)

The results of this testing showed no significant improvement in the performance of the specimens treated with Hycrete versus the untreated specimens. Due to the project design, especially the limited coupon exposure time and differences between how the coupons were exposed versus concrete exposure in a real-world wastewater treatment facility, the results are considered to be inconclusive. Consequently, the ROI for this effort was determined to be zero.

## 5 Conclusions and Recommendations

### 5.1 Conclusions

The results of this study demonstrated no observed benefits related to the use of Hycrete to reduce the permeability of concrete to aggressive aqueous chemical species found in wastewater treatment systems. However, the two-year duration of the testing program represents potential limitation of the study in terms of the possible time required for Hycrete performance benefits to become clear. Because the results of this study must be considered inconclusive, the project produced a zero return on investment.

These results do not address any other benefits attributed to the use of Hycrete by the manufacturer or other independent testers.

### 5.2 Recommendations

Because the results of this testing program were inconclusive, ERDC/CERL offers no recommendations about the applicability of Hycrete in wastewater treatment systems and, therefore, offers no recommendations pertaining to DoD implementation of the product.

### **Introduction/Overview:**

Tourney Consulting Group (TCG) is pleased to present this report summarizing the laboratory testing results related to the evaluation of concretes (with and without a waterproofing admixture) exposed to a sewer environment. Concrete was cast approximately 2 years ago. Half of the specimens were a conventional concrete (Control). Half of the specimens contained Hycrete but were of the same concrete mix design, proportions, and materials as the control. The test series consisted of 4 unique exposure conditions: 1) A location near the sewage effluent tank but not exposed to sewage or gases; 2) submerged in the sewage effluent tank; 3) suspended at the “water line” (partial submerged/partially above) of the sewage effluent tank; and 4) suspended above the high water level of the sewage effluent tank. Note: The tank used for this experiment is a large open topped effluent tank located at Fort Detrick, Maryland.

Sewage and sewer gasses are very aggressive and have historically resulted in deterioration of concrete that is exposed to sewage and/or gasses. This phenomenon has been well documented and researched. Generally, it is theorized that if the concrete can be made less permeable, the effect of the sewage and/or gasses can be lessened. This is often accomplished via higher performance mix designs or the inclusion of densifiers, such as silica fume. Hycrete is a “water proofing” additive that slows the ingress of moisture; this mechanism (slowing ingress of moisture and hence “aggressive materials”) may have promise to lessen the degradation of concrete in harsh environments, such as sewers.

It should be noted that while sewage can be aggressive, the most pronounced degradation occurs when sewer gases are trapped in an enclosed space (such as the free space above the linear flow of sewage in a pipe). This is a bacterially mediated process which forms hydrogen sulfide gas and then subsequently converts to form sulfuric acid (by sulfur oxidizing bacteria) that attacks concrete. This “classic” sewer condition could not be duplicated given the configuration of the sewage tanks at the Fort Detrick location. Hence, the “above” sewage and “partially submerged” conditions do not represent the common exposure conditions associated with sewers.

The scope of TCG’s work was to perform laboratory testing specifically photography, determination of pH, and chemical analysis of the concrete. One-quarter of the specimens were removed from the various exposure conditions every 6 month (after exposure lengths of 6-month, 12 months, 18-months, and 24 months) for destructive testing. Reports have been issued after each destructive testing cycle. This report represents the 24-month data set and is the final report for this task order.

### **Project Background**

The technical leads for the project agreed that at the 6, 12, 18, and 24 month intervals for sampling/analysis the following would be the testing approach: At the three depths increment: 0"-1/8"; 1/8" – ¼"; and ¼" – 3/8"), the concentration of sulfur trioxide and phosphate (as pentoxide) were tested. The analysis was performed via XRF. Given the novelty of this experimental design, it was felt that this will be highly quantitative and repeatable. It was theorized that sulfur trioxide would be “stripped out” of the concrete if the sewage was “attacking” the concrete. Conversely, phosphate would increase if sewage was leaching into the concrete during exposure. Note: Given the nature of

---

XRF analysis, concentrations of several additional materials were also determined. These are reported as well.

The test site was the Fort Detrick Water Treatment facility. The overall project schedule was subject to site availability aspects associated with construction at the test site. A kick-off, site inspection occurred on March 21<sup>st</sup>, 2011 where the overall project scope and direction was reviewed with the team. In addition, several possible exposure site conditions were examined and assessed. It was mutually decided by all parties that the test area should be selected based on logistical and operations issues. There did not appear to be any tank locations that would be exceptionally well suited or poorly suited for the experiment. Therefore, there was not a technical recommendation as to location of the specimens. The location was selected based on ease of access, consistency of liquid level, and to minimize interference with plant operations.

A total of 96 specimens (48 references + 48 containing Hycrete) were fabricated. These specimens were cast (under the supervision of Hycrete personnel) in the summer of 2011.

The main focus of the test program was to assess the performance of the concrete specimens when exposed to effluent. During the site visit, TCG, in consultation with the other team members, agreed that a racking or similar system would be overly complicated and would limit the possible locations where the test could be conducted and possibly interfere with plant operations. Instead, the test procedure was to cast a rugged hook/loop or embedded anchoring point in the top of each cylindrical specimen from which the specimens can be suspended from a chain, wire or similar at varying heights that correspond to the exposure conditions outlined in the RFP. The chains, wire or similar were fastened to the top edge of the effluent tank or anchored as appropriate based on site restrictions and as designed and installed by MEC. It is important that there is the ability to periodically remove or inspect specimens during the course of the test. As agreed by all parties, a simple approach that exposes the specimens to the prescribed conditions is desired and will be accomplished by this proposed method.

### **Specimen Configuration**

On or about October 25<sup>th</sup>, 2011, the specimens were inserted into the effluent tank. The specimens are organized as follows:

- 48 Reference Specimens
  - 12 below the waste water level
  - 12 at the mean waste water level (approximately ½ of the specimen length above approximately ½ of the specimen length below)
  - 12 above the waste water level but still in close proximity
  - 12 stored at the test facility but removed from the immediate test structure and exposed to normal weathering
- 48 Hycrete Specimens
  - 12 below the waste water level
  - 12 at the mean waste water level (approximately ½ of the specimen length above approximately ½ of the specimen length below)

- 
- 12 above the waste water level but still in close proximity
  - 12 stored at the test facility but removed from the immediate test structure and exposed to normal weathering

TCG personnel observed the installation of the test specimens and provide a recommended location for the specimens that will be stored at the test facility but removed from the immediate test structure location. The specimens on site but not in the test structure should be clearly identified with "Test Specimens – Do Not Move."

#### **QC Monitoring:**

While the bulk of the subsequent test effort is related to chemical testing, there were some periodic QC inspections that were performed on-site by local and/or MEC personnel to ensure test program integrity. These were conducted between the sampling increments described below (months 3, 9, 15, 21) and consisted of:

- Visual inspection of the specimens on site but not in the test structure to ensure they have not been disturbed or removed. Any issues should be reported to MEC.
- Visual inspection of the specimens within the effluent tank to ensure the hook/loop or embedded anchoring point; as well as the chain, wire or similar has not been compromised by exposure to the effluent. Any issues should be reported to MEC.
- Identify (count) any specimens which have fallen to the tank bottom. Any issues should be reported to MEC.
- Monitor the effluent levels within the tank to assess if specimen levels require adjustment to maintain the prescribed exposure conditions.

#### **Periodic Testing at TCG**

At 6, 12, 18, and 24 months after initial exposure, specimens were removed for testing. At each time period (approximately mid-April 2012; mid-October 2012; mid-April 2013; mid-October 2013), the following specimens were pulled from the test site:

- 12 Reference Specimens
  - 3 from below the waste water level
  - 3 from at the mean waste water level (approximately  $\frac{1}{2}$  of the specimen length above approximately  $\frac{1}{2}$  of the specimen length below)
  - 3 from above the waste water level but still in close proximity
  - 3 from the area at the test facility but removed from the immediate test structure and exposed to normal weathering
- 12 Hycrete Specimens
  - 3 from below the waste water level
  - 3 from at the mean waste water level (approximately  $\frac{1}{2}$  of the specimen length above approximately  $\frac{1}{2}$  of the specimen length below)
  - 3 from above the waste water level but still in close proximity

- 
- 3 from the area at the test facility but removed from the immediate test structure and exposed to normal weathering

The specimens were removed, rinsed with potable water, and individually sealed in ZipLoc (or similar) storage bags that are clearly marked with concrete type (Reference or Hycrete) and exposure conditions (above, at, or below water line or offsite). The specimens were then shipped to TCG's Kalamazoo's offices for analysis.

Upon sample receipt, TCG photographed and conducted chemical tests on each specimen. TCG determined (individually) Ammonia and Phosphate content profile at three (3) unique depth increments per specimen. Depth increments were: [surface to 1/8"], (1/8" to 1/4"], [1/4" – 3/8"]). In addition, TCG will determine the pH at three (3) unique depth increments per specimen: [surface to 1/8"], (1/8" to 1/4"], [1/4" – 3/8"] ).

**Conclusions:** It would not appear that the presence of Hycrete had a noticeable influence on performance of concrete exposed to sewer effluent and/or gasses. Visual appears was not dramatically different, pH was not impacted during exposure, and there were not sizeable changes chemical composition suggesting that neither the Hycrete and references concretes had materials leech in our out during exposure.

**Conclusions:**

There does not appear to be any obvious visual differences between the controls and the Hycrete containing concrete. There is some progressive deterioration based on exposure but none would be classified as severe.

**Lab Test Results - pH:** The side of core samples were milled with a drill-press to obtain pulverized concrete. The milling involved three depth of :1/8", 1/4" and 3/8" from the surface of concrete cylinders. Next, 5 gram samples were diluted with 15 ml of de-ionized water and stirred for 15 minutes. After stirring, the mixtures were filtrated through medium-coarse filter paper and immediately tested for pH with a pH-meter. The testing procedure and sample preparation method followed guidelines published in the Concrete International Journal (April 2007, page 78 - 83).

**Lab Test Results - Chemical Testing:** Samples were prepared for analysis by drying each replicate in the oven for 1 hour at 60°C and allowed to cool in the desiccator to room temperature. Weighed out 9 grams of sample to 1.5 grams of dry cellulose, using a ring and puck apparatus ground the sample for 30 seconds. The sample composite was then pressed into a pellet with the aid of a hydraulic press. To aid the pellet strength, the composite was pressed into a thin aluminum container. Each sample was pressed using a press at 25 tons for 1 minute. The subsequent pellet was then analyzed by X-Ray Fluorescence (XRF) using a Bruker Model S4 Explorer in ASTM CI14 mode. analysis was performed using X-Ray Fluorescence (XRF) against the ASTM C 114 calibration mode to determine the oxide composition. Thus, a relative composition of oxides are presented. Graphs of average data are presented below. Full data sets are presented as attachments (for ease of reading).

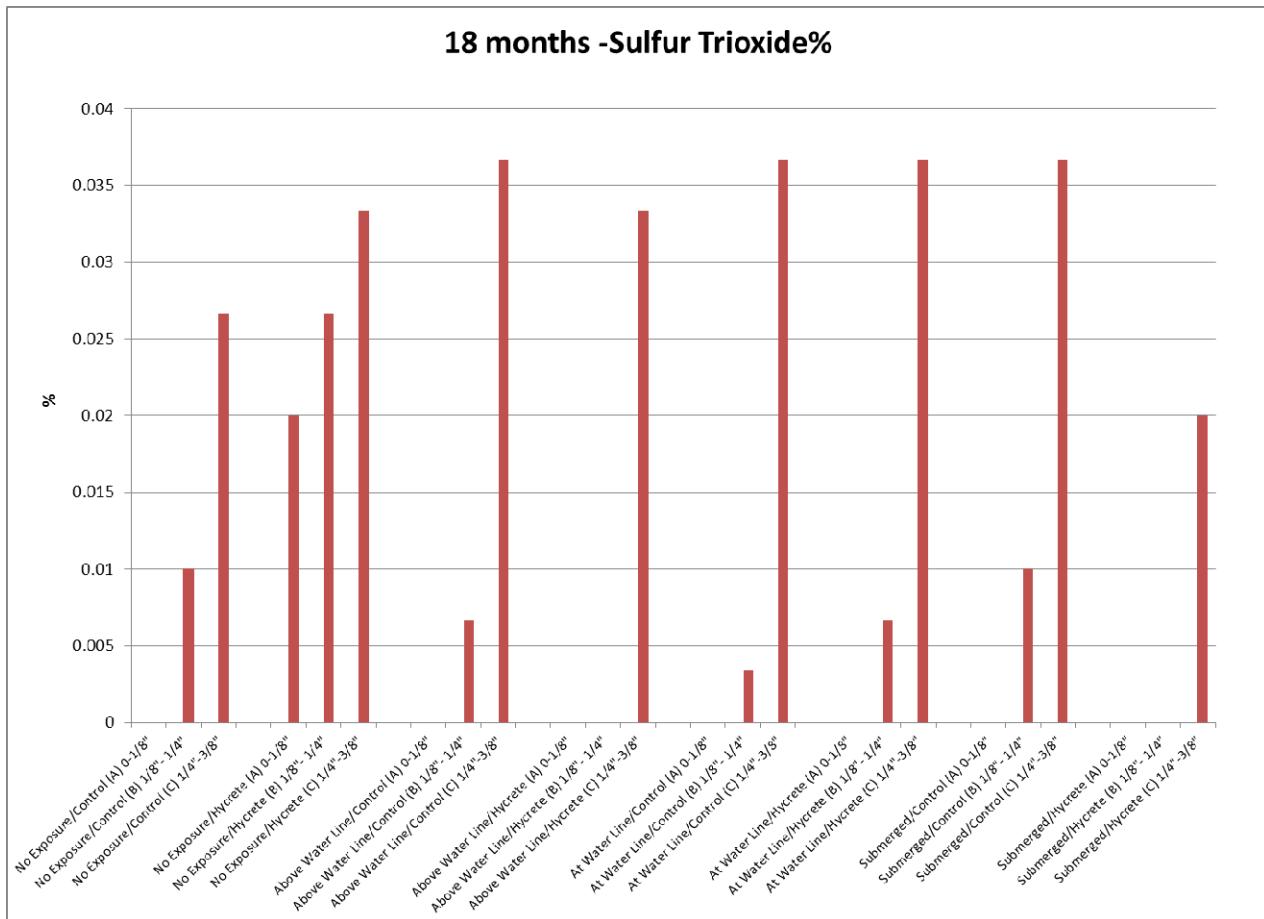

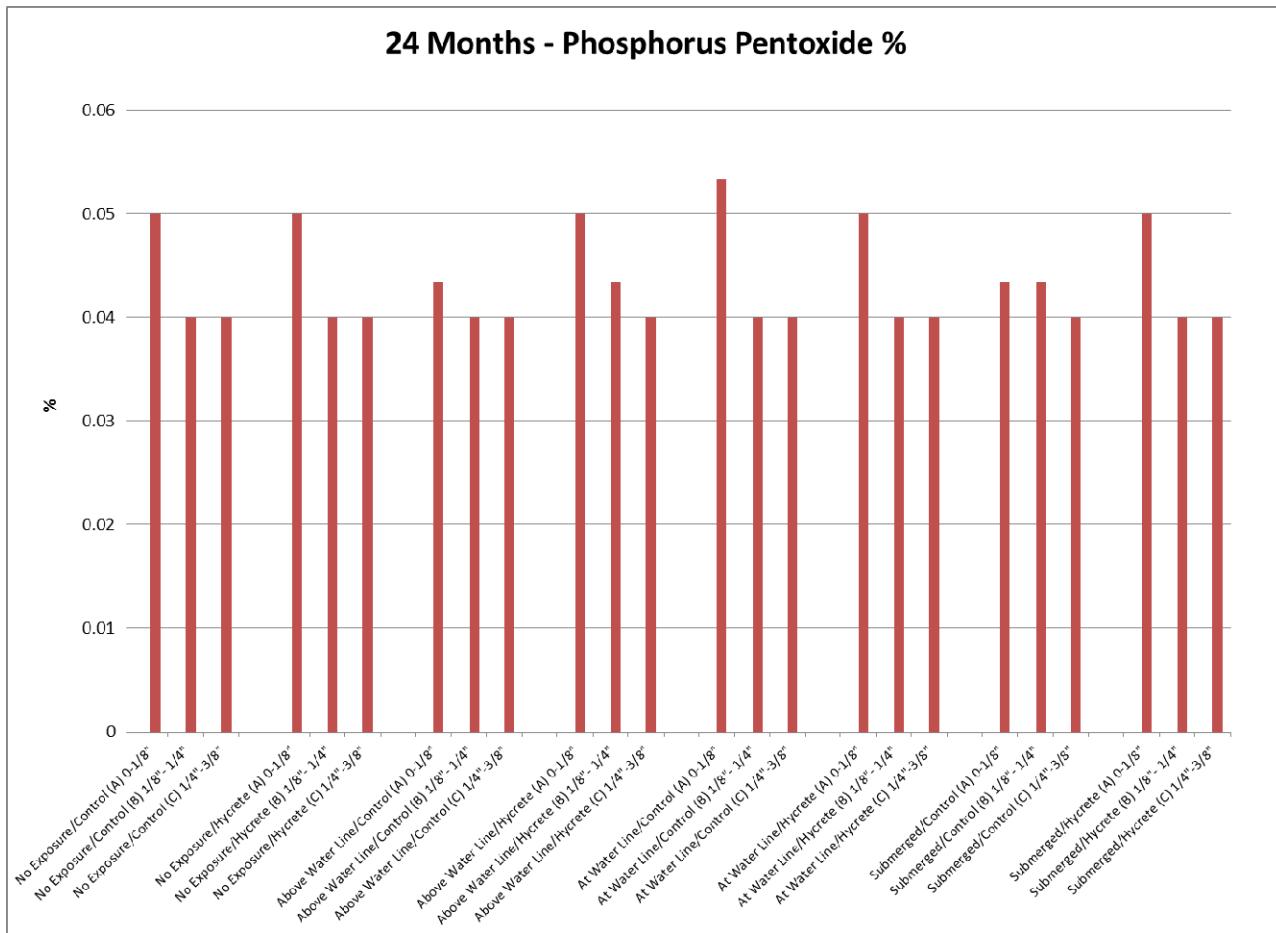

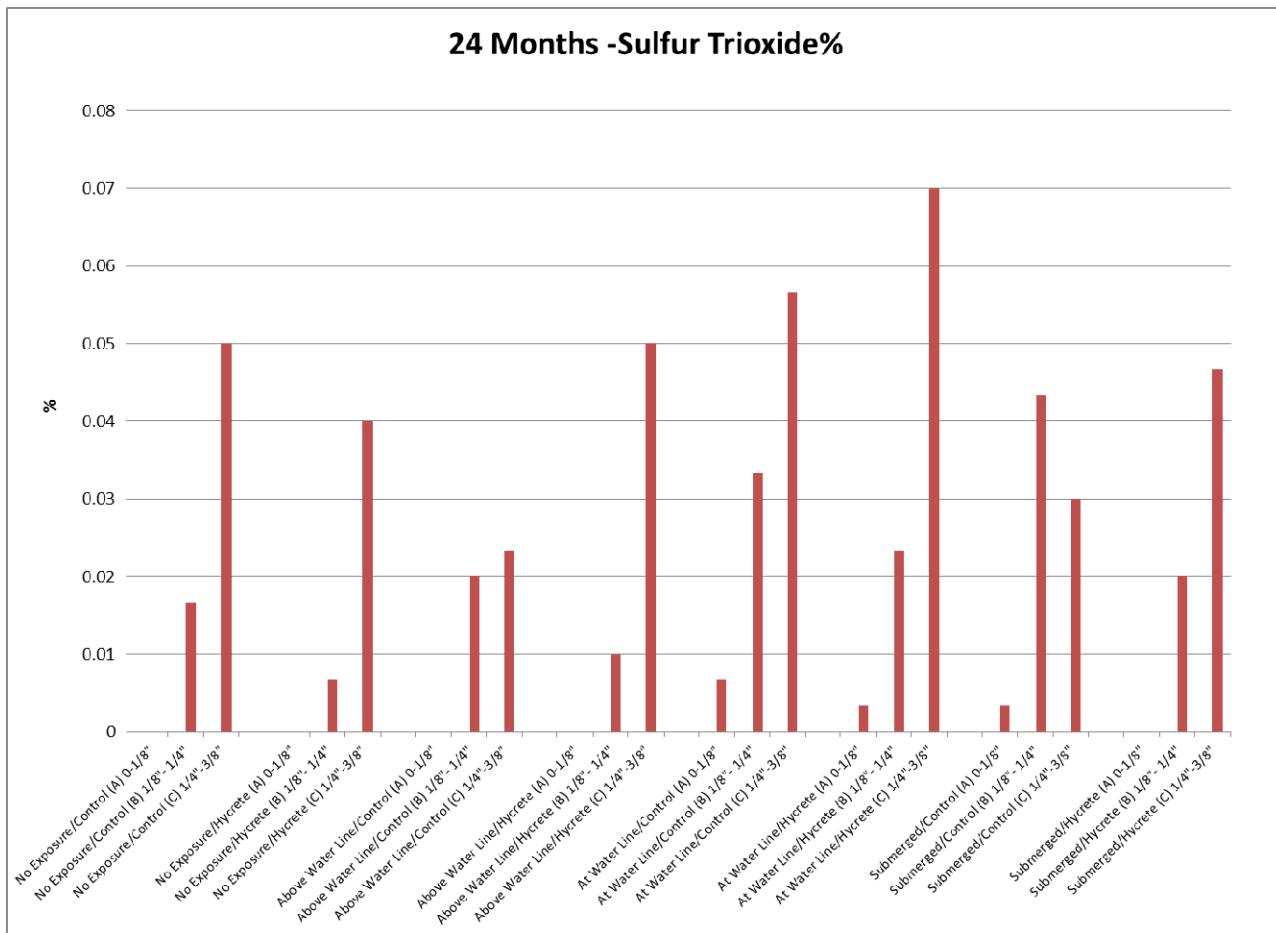

### Analysis:

**Changes in concentration over time are noted in the appendix. The primary test values associated with the program are summarized below.**

OMB No. 0704-0188*

Public reporting burden for this collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing this collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden to Department of Defense, Washington Headquarters Services, Directorate for Information Operations and Reports (0704-0188), 1215 Jefferson Davis Highway, Suite 1204, Arlington, VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to any penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number. PLEASE DO NOT RETURN YOUR FORM TO THE ABOVE ADDRESS.

<b>13. SUPPLEMENTARY NOTES</b>					
<b>14. ABSTRACT</b>  The corrosion of reinforced concrete in wastewater systems is a costly ongoing problem for the Department of Defense (DoD). Capillary action makes concrete vulnerable to penetration by highly corrosive chemicals transported by wastewater. Progressive corrosion of embedded steel reinforcement greatly increases internal stresses on the concrete, ultimately causing premature fractures and spalls. Researchers hypothesized that corrosion in such aggressive environments could be mitigated using a hydrophobic concrete admixture to inhibit penetration of corrosive liquids into wastewater treatment infrastructure, thereby reducing stresses on the materials and extending service life. This study tested and evaluated one such admixture, a patented material called Hycrete.  This evaluation exposed test coupons within the sewage effluent system at Fort Detrick, MD. Under the two year duration of this test, the presence of Hycrete had no noticeable influence on performance of concrete exposed to sewer effluent or gasses. Visual appearance did not dramatically differ and there were no significant changes chemical composition. The results suggest that neither the Hycrete nor the reference concrete specimens were affected by chemical leaching or intrusion during the two-year demonstration period. The return on investment for this effort was, therefore, zero.
