INTRODUCTION

An important tool for analyzing the relative effectiveness of gun air defense systems is a plot of lines of constant (ISO) probability of kill (PK) in the volume of space surrounding the planned deployment of the system; hence, the name ISO-PK. These plots are usually presented as two-dimensional sections taken at selected places in the volume. The lines of constant kill probability sometimes form elliptical traces and, perhaps, for this reason, they are commonly referred to as "footprints". This report presents the computer program and explains the algorithm which calculates the burst-kill probability and automatically plots the footprints on a computer line printer. Also included in this report is an analysis of weapon pointing errors which includes the effects of lead angle generation. This model, which may be termed an error budget model, was originally developed for the Air Defense Evaluation Board (ADEB)¹.

The expression for burst-kill probability represents a considerable improvement in methodology for performing sensitivity analyses of performance parameters of certain gun air defense weapon systems. This expression is combined into a computer program that produces plots on a line printer, thus greatly reducing the amount of manual effort needed to perform footprint studies. The program has been used most extensively for sensitivity analyses.

Sections of the report describe, in order, the operation of the program called "ISO-PK", the error analysis which determines the weapon pointing error, and the input data requirements for the ISO-PK program. The program logic diagram, program FORTRAN source listing, and a sample problem

¹WECOM ADEB Task Force, Analysis of Air Defense Gun Systems, Technical Note RE-TR-70-191, Research and Engineering Directorate, HQ, US Army Weapons Command, Rock Island, IL, October 1970.

are in the final sections.

FOOTPRINT GEOMETRY

Consider a coordinate system with an air defense gun system at the origin of the axes as shown in Figure 1. The azimuth angle, a , is measured counterclockwise from $+X$ in the X - Y plane. The elevation angle, e , is measured upward from the X - Y plane to the line from the origin to P (this line is called the slant range, r).

Let the X - Y plane represent the ground plane and z represent altitude. The target is assumed to be at a point in space with velocity components $(\dot{x}, 0, 0)$ (the dot notation here refers to the first time derivative of the variable). It is of particular interest to know how certain performance characteristics of the gun affect its overall performance in tracking and firing at a given target at points along straight lines parallel to the X -axis. These lines may be at various altitudes or at various values of Y (crossing ranges).

The air space around the gun is divided into a 3-dimensional grid so that only a discrete number of points P need to be considered. The user may select any plane parallel to the X - Y plane ($Z \geq 0$) or any plane parallel to the Z - X plane ($Y \geq 0$), see Figures 2 and 3. Given the volume of space to be considered in terms of limits on X , Y , Z , the ISO-PK program establishes a grid in two quadrants of the selected plane. The grid contains 100 increments horizontally and 50 increments vertically, corresponding roughly to the size of one page of computer paper on a printer with spacing increments of $1/10''$ by $1/6''$, respectively.

In the plane there are $51 \times 101 = 5151$ points denoted by P_{ij} ; $i=1,2,\dots, 101$; $j=1,2,\dots, 51$. If the plane under consideration is parallel to the

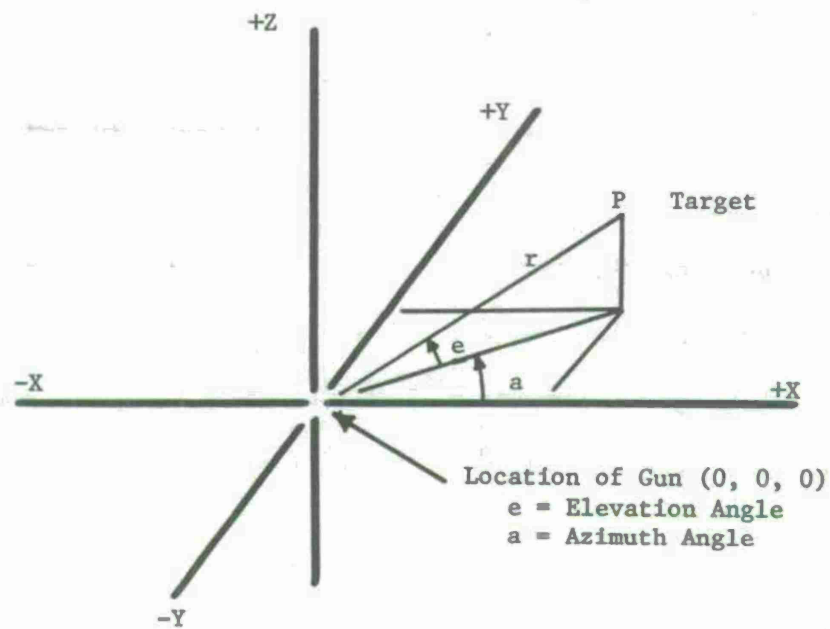

Figure 1. Gun-Target Geometry - Isometric View

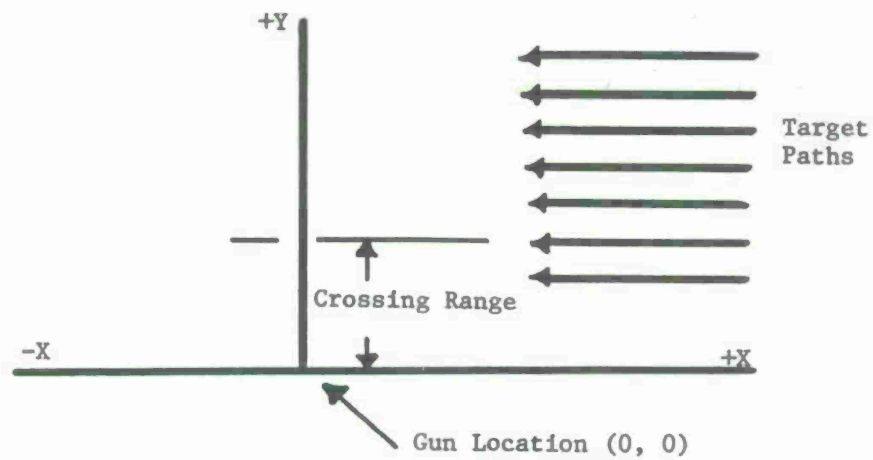

Figure 2. Gun-Target Geometry - X-Y Plane

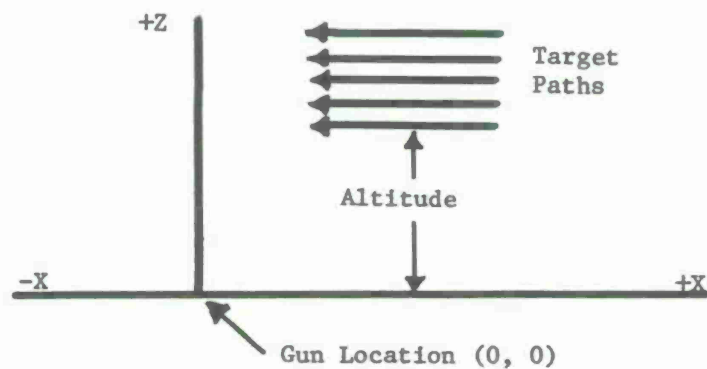

Figure 3. Gun-Target Geometry - X-Z Plane

X-Y plane ($Z \geq 0$), the Y position refers to the crossing range, (see Figure 2). If the plane is parallel to the Z-X plane ($Y \geq 0$), the Z position refers to the altitude (see Figure 3).

The ISO-PK program computes the variables $x, y, z, a, e, r, \dot{a}, \dot{e}, \dot{r}$, at each point P_{ij} . The gun system errors are determined as a function of these variables from gun system performance data which is provided as input. The resulting gun system errors are used to compute the burst-probability of kill (BPK) from the analytic formula in reference 2. The BPK is calculated about the point of predicted intercept of the target and the projectile. However, the value of the BPK is affixed to the point corresponding to the present position of the target (P_{ij}). Certain values of BPK (e.g., 0.05, 0.1, 0.5) and corresponding characters (e.g., H, I, K) are specified in the program to correspond to the constant BPK lines printed for the footprints. A character corresponding to the numerical value of the BPK is printed whenever the computed value of BPK at a point P_{ij} equals or crosses-over one of the specified values. The lines of constant-kill probability then appear as traces of printer characters in the plane of the paper. The matrix of computed BPK is saved during the horizontal raster scan and is scanned again in vertical order to fill in the contour lines and eliminate any apparent discontinuities in the printed lines when the lines have infinite slope.

Two separate computations are performed at each point P_{ij} and the results of both are superimposed on the computer plot. The first computation performed is the BPK determination as previously discussed. The

²Banash, Robert C., An Analytic Procedure for the Computation of Burst-Kill Probabilities in Air Defense. Technical Note SY-TN9-70, Systems Analysis Directorate, HQ, US Army Weapons Command, Rock Island, IL, October 1970.

second is a determination of possible dead zones caused by gun system constraints. The azimuth and elevation rates of the gun are computed and compared with maximum values allowed as specified in the input data. If either are greater than the maximums allowed, the letter A (azimuth) or E (elevation) will be printed corresponding to the type of constraint violated (if both are violated, only an A will appear). The gun elevation is also calculated and compared with the maximum elevation allowed. If the limit is exceeded, an E is printed. The program also prints the boundary formed by the maximum effective range of the gun. The range which is used in this comparison is the range at predicted intercept and not the slant range at time of burst. The character R is printed to signify violation of this constraint. Next, at each point P_{ij} a hypothetical situation concerning total system reaction time is evaluated. The letter T is printed if the target could, at its present velocity, move outside the range of the weapon if it was first detected at that point. This provides a means of making a comparative evaluation of a system's ability to initiate an engagement against a target suddenly appearing within the lethal volume of the system. In any particular problem, the analyst may also insert additional constraint conditions into this part of the program.

ERROR ANALYSIS

The BPK subroutine used in the ISO-PK program requires the means and standard deviations of the errors associated with the gun system. These errors are divided into two classes. One is the within-burst errors. These are the errors associated with the projectile (e.g., the residual dispersion and muzzle velocity variation). The other class of errors is the burst-to-burst errors due to inaccurate gun pointing.

The gun-pointing errors can be further subdivided into two categories. One is the error in the gun position due to errors in sensing the present position of the target. It is assumed that a gun system will measure the present position of the target and then, based upon these measurements, determine the lead angle necessary to achieve a hit on the target, given a certain open fire time. If these measurements are in error, the system will produce an incorrect lead angle (a gun pointing error).

The other source of gun pointing error is the gun servo mechanism. This error is due to the inaccuracies which are usually present in the servo system which positions the gun at a generated lead angle. Figure 4 shows a schematic of a gun air defense system with the various error sources noted (the "Ballistic Errors" are the within-burst errors). The program will accept the mean (bias), the standard deviation, and the covariances of the random components of each of the error sources.

An analysis of the gun pointing errors was reported in reference 2. This analysis assumed that sensor errors produced gun pointing errors of equal magnitude. Also, it assumed there was no lead angle generation. Consequently, the time of sensing, the time of fire, and the time of predicted intercept were all the same (no time of flight). A modification to this analysis is presented here which includes the time of flight and the effects of lead angle generation and approximates the lead angle error due to sensor error. The azimuth and elevation errors produced from this analysis is combined with the gun servo errors. These combined errors are then projected into a two dimensional plane at the target at the time of predicted intercept. Note that the target position at predicted intercept is not the same as the present position of the target.

²Ibid.

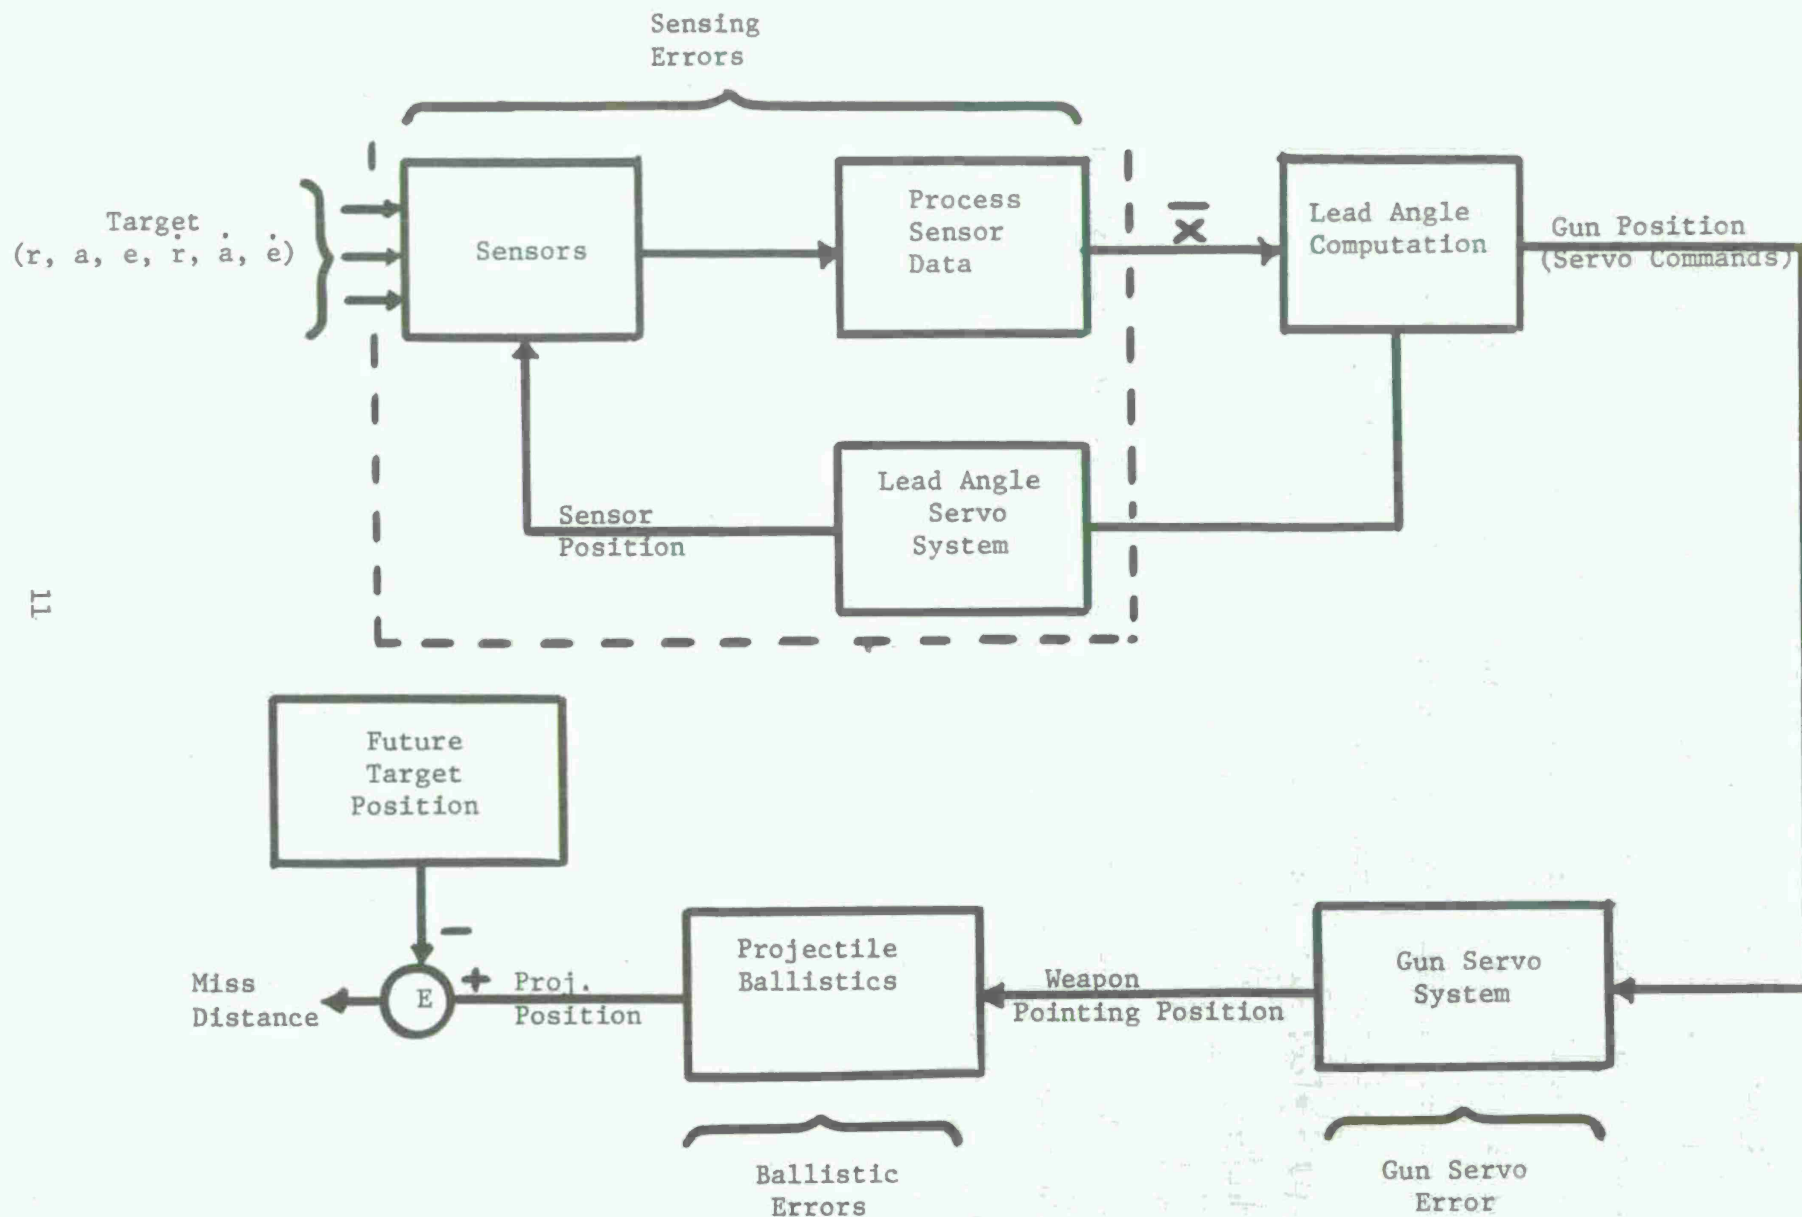

Figure 4. Schematic of the Basic Components of a Gun Air Defense System

Sensor Errors

To determine the gun pointing error due to sensor errors, a first-order error analysis is performed on the equations defining the position of the gun. The independent variables in this analysis are the measurements of the present position of the target $(r, a, e, \dot{r}, \dot{a}, \dot{e})$, and the dependent variables are the azimuth and the elevation of the gun.

Define the gun barrel position by the vector \bar{Z} , ($Z(1)$ = azimuth, $Z(2)$ = elevation), and the vector of functions which define \bar{Z} to be $f(\bar{X})$. This is

$$\bar{Z} = f(\bar{X})$$

Where \bar{X} is the vector of measurements taken at the present position of the target

$$\bar{X} = (r, a, e, \dot{r}, \dot{a}, \dot{e})^T .$$

The functions which define the gun position are derived in the Appendix.

The first-order approximation of the change in the dependent variables ($\Delta\bar{Z}$) resulting from a small change in the independent variable ($\Delta\bar{X}$), about a nominal point $\bar{X} = \bar{X}_0$ can be expressed as

$$\Delta\bar{Z} = \frac{\partial f(\bar{X})}{\partial \bar{X}} \bigg|_{\bar{X}_0} \Delta\bar{X} .$$

The small change $\Delta\bar{X}$ may be interpreted to be a random error associated with the measurements of the present position of the target. That is, $\Delta\bar{X}$ is a random variable with mean \bar{M}_X and covariance matrix $\text{COV}(\bar{X})$. Therefore, $\Delta\bar{Z}$ is also a random variable describing the errors in the gun pointing position. Define the mean value of $\Delta\bar{Z}$ to be \bar{M}_Z and its covariance matrix to be $\text{COV}(\bar{Z})$.

Let

$$F = \left. \frac{\partial f(\bar{X})}{\partial \bar{X}} \right|_{\bar{X}_0},$$

which is the Jacobian matrix evaluated at the nominal value \bar{X}_0 . Then the mean value of $\Delta \bar{Z}$ is

$$E[\Delta \bar{Z}] = F E[\Delta \bar{X}]$$

or

$$\bar{M}_Z = F \bar{M}_X.$$

$E[\cdot]$ denotes expected value of the random variable. Also, the covariance matrix of the errors $\Delta \bar{Z}$ is given by

$$\text{COV}(\bar{Z}) = F \text{COV}(\bar{X}) F^T.$$

The partial derivatives necessary to define F in FORTRAN notation are listed in the section titled FORTRAN Program Source Listing, page 56.

The statistics of the measurement errors (\bar{M}_X and $\text{COV}(\bar{X})$) are assumed to be constant (in time). However, provisions have been made in the ISO-PK program for a user-supplied subroutine which can modify these errors as a function of the engagement parameters ($a, e, r, \dot{a}, \dot{e}, \dot{r}$). This subroutine is called MESIG.

Gun Servo Errors

The gun servo errors will be considered next. Define the mean servo error to be the two-vector \bar{M}_S and the (2×2) covariance matrix for the servo errors to be $\text{COV}(\bar{S})$. The first row in \bar{M}_S and $\text{COV}(\bar{S})$ corresponds

to azimuth while the second row corresponds to elevation error. The mean values of the gun servo errors are assumed to be constant for a gun system. These bias type errors may be likened to a bore sight error. The covariance matrix is assumed to be a function of the gun rates. It is also assumed that the azimuth and elevation errors are independent of one another, so the off-diagonal terms of the matrix $\text{COV}(\bar{S})$ are zero. The standard deviations of the errors on the azimuth and elevation directions are input to the ISO-PK program as a table of values which are a function of gun rates. A corresponding table of gun rates is also input to the program. In the program, the appropriate standard deviations are determined by looking up the rates in the table and linearly interpolating between the tabular values. They are then squared to obtain the variances. It is expected that detailed system performance models of the servos of future gun systems will be developed and represented by these tables for evaluations with the ISO-PK program.

Combining Gun System Errors

The errors from the gun servo system are assumed to add to the gun pointing errors resulting from sensor errors. Therefore, since these two error sources are assumed to be independent, their statistics can be added to obtain the mean and covariance of the total gun pointing error.

The gun pointing errors produced by the above analysis are in angular units. However, the errors required by the BPK subroutine are in units of length, in a coordinate system centered at the center-of-vulnerability of the target. This coordinate system is perpendicular to the line

from the gun to the target at time of predicted intercept. The conversion in the elevation direction, from angular units to meters, is achieved by multiplying the elevation error by the range (R) to the target at predicted intercept. In the azimuth direction, the conversion is obtained by multiplying by $R \cos(E)$, where E is the elevation of the target at predicted intercept. The cosine term is needed to convert the azimuth error in the ground plane to an azimuth-like (transverse) error in the elevated coordinate system.

The statistics describing the errors, in meters, in the elevated coordinate system are as follows:

Among-Burst Error:

$$\text{Mean: } \begin{bmatrix} M_A \\ M_E \end{bmatrix} = (\bar{M}_Z + \bar{M}_S) \cdot \begin{bmatrix} R \cos(E) \\ R \end{bmatrix}$$

$$\text{Covariance: } \begin{bmatrix} \sigma_A^2 & \text{COV}(A,E) \\ \text{COV}(A,E) & \sigma_E^2 \end{bmatrix} = \begin{bmatrix} R \cos(E) & 0 \\ 0 & R \end{bmatrix} (\text{COV}(\bar{Z}) + \text{COV}(\bar{S})) \begin{bmatrix} R \cos(E) & 0 \\ 0 & R \end{bmatrix}^T$$

These combined statistics are those required to describe the among-burst errors. The BPK subroutine uses the correlation coefficient instead of the covariance term $\text{COV}(A,E)$. This correlation coefficient is defined as:

$$\rho_{A,E} = \frac{\text{COV}(A,E)}{\sigma_A \sigma_E}$$

Within-Burst Errors

A brief derivation of the within-burst errors is presented here. A similar, more complete derivation can be found in reference 3. The angular residual dispersion error and range variation error of the projectile must be projected into the elevated coordinate system centered at the target. Define the errors as follows:

Δ_A - azimuth-like (transverse) angular dispersion

Δ_E - elevation angular dispersion

Δ_R - projectile range error

These errors are assumed to be independent, normally distributed with zero means and variances of σ_a^2 , σ_e^2 , σ_r^2 , respectively. The variance of the projectile range error is due to the muzzle velocity variation.

$$\sigma_r^2 = \left(\frac{R}{V_m}\right)^2 \sigma_V^2$$

Where

V_m = muzzle velocity of the projectile

σ_V^2 = variance of the muzzle velocity

Since there is an error in the range coordinate, the time to equal range of the target and projectile must be determined. This time can be approximated by the following if $V_S \gg \dot{R}$.

$$\Delta t = - \frac{\Delta R}{(-R + V_S)} \approx \frac{\Delta R}{V_S}$$

³ Banash, Robert C., Notes of the University of Michigan Analytic Gun Model, Technical Note SY-TN3-70, Systems Analysis Directorate, HQ, US Army Weapons Command, Rock Island, IL, April 1970.

where

\dot{R} = range rate of the target

V_S = velocity of the projectile at range R

The velocity components of the target in the elevated coordinate system are $(\dot{A}\cos(E), \dot{R}, \dot{E}R)$. Where \dot{A} and \dot{E} are the azimuth and elevation rates of change of the target at the time of predicted intercept. The velocity components of the projectile are $(0, V_S, 0)$. Therefore, the relative velocity components between the target and projectile are $-(\dot{A}\cos(E), -V_S, \dot{E}R)$. The errors, in meters, at the time when the projectile and target are at equal range are

$$\begin{aligned}\Delta A' &= R \Delta A - \Delta t \dot{A}\cos(E) \\ &= R \Delta A + \frac{\Delta R}{V_S} \dot{A}\cos(E)\end{aligned}$$

and

$$\Delta E' = R \Delta E + \frac{\Delta R}{V_S} \dot{E}R$$

$\Delta A'$ is the error in the traverse direction and $\Delta E'$ is the error in the elevation direction. Since these quantities are sums of independent, normal random variables, they have a bivariate normal distribution with the following parameters.

Within-Burst Errors:

Means:

$$E [\Delta A'] = 0$$

$$E [\Delta E'] = 0$$

Variances:

$$\sigma_{A'}^2 = R^2 \sigma_A^2 + \left(\frac{R \cos(E) \dot{A}}{V_S} \right)^2 \sigma_r^2$$

$$\sigma_{E'}^2 = R^2 \sigma_E^2 + \left(\frac{R \dot{E}}{V_S} \right)^2 \sigma_r^2$$

Correlation coefficient:

$$\begin{aligned} \rho_{A', E'} &= \frac{\text{COV}(\Delta A', \Delta E')}{\sigma_{A'} \sigma_{E'}} \\ &= \frac{1}{\sigma_{A'} \sigma_{E'}} \text{COV} \left(\left(R \Delta A + \frac{R \cos(E) \dot{A}}{V_S} \Delta R \right), \left(R \Delta E + \frac{R \dot{E}}{V_S} \Delta R \right) \right) \\ &= \frac{1}{\sigma_{A'} \sigma_{E'}} \frac{\ddot{A} E R^2 \cos(E)}{V_S^2} \sigma_r^2 \end{aligned}$$

At this point all the necessary inputs are presented for the computation of burst-probability of kill (BPK) as presented in the form in reference 2, starting at page 6. The following relates the notation used in this report to that of reference 2:

For Within-Burst Errors:

$$M_1 \equiv E[\Delta A']$$

$$M_2 \equiv E[\Delta E']$$

$$\sigma_1^2 \equiv \sigma_{A'}^2$$

$$\sigma_2^2 \equiv \sigma_{E'}^2$$

$$\rho_\omega \equiv \rho_{A', E'}$$

²Loc. Cit.

For Among-Burst Errors:

$$M_3 \equiv M_A$$

$$M_4 \equiv M_E$$

$$\sigma_3^2 \equiv \sigma_A^2$$

$$\sigma_4^2 \equiv \sigma_E^2$$

$$\rho \equiv \rho_{A,E}$$

Before presenting the equation used for BPK from references 2, 3 or 4, the basic assumption limiting the validity of this equation is reiterated:

a. Target vulnerability area is small compared to the within-burst dispersion.

b. Rounds can be grouped within bursts such that the burst centers can be considered independently distributed while the rounds are distributed independently about the burst centers.

The ' notation used in the following equations means transpose of the indicated matrix.

Under these assumptions, the equation for BPK is given as:

$$\text{BPK} = \sum_{j=1}^n \binom{n}{j} (-1)^{j+1} \left(\frac{A_V}{2\pi\sigma_1\sigma_2} \right)^j \left| I + jA \right|^{-1/2} \cdot \exp \left\{ -\frac{j}{2} v' A [I - j(I + jA)^{-1} A] v \right\}$$

where n is the number of rounds in the burst and

$$A = K'P' \begin{bmatrix} \sigma_2^2 & \rho_{\omega} \sigma_1 \sigma_2 \\ \rho_{\omega} \sigma_1 \sigma_2 & \sigma_2^2 \end{bmatrix} PK$$

P is the matrix of characteristic vectors of

$$V = \begin{bmatrix} \sigma_3^2 & \rho \sigma_3 \sigma_4 \\ \rho \sigma_3 \sigma_4 & \sigma_4^2 \end{bmatrix},$$

$$P'VP = \begin{bmatrix} \frac{1}{\alpha_1} & 0 \\ 0 & \frac{1}{\alpha_2} \end{bmatrix} \equiv K^2.$$

Finally,

$$v = K^{-1}P \begin{bmatrix} M_3 \\ M_4 \end{bmatrix}.$$

A_V is the target vulnerable area.

INPUT DATA DEFINITION

The input data is divided into three sections:

(1) data to control the planes, (2) gun system data, at which the plots are to be made and (3) target data. The program is set up such that the data for each category is read from a different numbered data set. Each category is explained with regard to data content, meaning, and format, as follows:

Control of Selected Planes.

This data controls the size and location of the planes on which the footprint is printed. It also determines the velocity (magnitude and direction) of the target. Each card is described in the order in which it is read. In the following discussion, the paragraphs are headed by the list of variables whose values are read. Detailed description of the variables and how they relate to the program are also presented. This format is also used in the next two sections -- Gun Systems Data and Target Data.

NVEL, NCR, NALT, PLOTXY, PLOTXZ
(3I5,2L5)

NVEL - The number of different velocities which will appear on a later card. One plot will be made for each velocity.

NCR - The number of different crossing ranges at which XZ plots are to be made. The actual values of the crossing ranges appears on a later card. Also, this data only has meaning when an XZ plot is to be made.

NALT - The number of different altitudes at which X-Y plots are to be made. Again the actual values of the altitudes appear on a later data card, and this card is of concern only when X-Y plots are to be made.

PLOTXY - This logical constant should be set equal to T (true) if X-Y plots (at various altitudes) are to be made. If no X-Y plots are required, it should be set equal to F (false).

PLOTXZ - This logical constant should be set equal to T (true) if XZ plots (at various crossing ranges) are to be made. If no X-Z plots are required, it should be set equal to F (false).

XMIN, XMAX, YMIN, YMAX, ZMIN, ZMAX
(6F10.0)

XMIN - The combination of all the data on this card sets the size of the plots which are to be made. XMIN contains the minimum value of the X-axis.

XMAX - The maximum value of the X-axis.

YMIN - If an X-Y plot is to be made, the minimum value of Y (i.e., the minimum crossing range) is contained in the variable YMIN.

YMAX - The maximum value of the Y-axis. The combination of XMIN, XMAX, YMIN, and YMAX describes the size of the X-Y plane.

ZMIN - If an X-Z plot is to be made, the minimum value of the Z-axis (minimum altitude) is contained in this variable.

ZMAX - The maximum value of the Z-axis. The combination of XMIN, XMAX, ZMIN, and ZMAX describes the size of the X-Z plane.

VEL (I), I = 1, NVEL
(7F10.0)

The VEL array contains the actual values of the different velocities for which plots are to be made. The number of velocities which will be read is equal to NVEL.

CRANGE(I), I = 1, NCR
(7F10.0)

The CRANGE array contains the actual values of the different crossing ranges for which X-Z plots are to be made. The number of values which will be read equals NCR.

ALT(I), I = 1, NALT

The ALT array contains the actual values of the different altitudes at which X-Y plots are to be made. The number of values which will be read is equal to NALT.

Altogether, there will be $(NVEL * (NCR + NALT))$ plots made if both PLOTXY and PLOTXZ are initialized to T (true). If only PLOTXY is equal to true, then there will be $(NVEL * NALT)$ plots. Where, if only PLOTXZ is equal to true, there will be $(NVEL * NCR)$ plots. The size of all plots is determined by the parameters on the second card.

Gun Systems Data

The data contained in this data set describe the parameters related to the gun system. This includes the gun constraints as well as the description of the random errors of the system. The same format will be used in this discussion as was used in the previous section in describing the data, card by card.

TITLE
(20A4)

This is an 80-character verbal title which appears on all the plots. It may contain such identifying information as the name of the system being investigated or some particular configuration of a system. The actual content of the information on this card is optional but must be limited to 80 characters.

CALIB
(15)

The value of variable CALIB is used to determine from which numbered data set the target data is to be read. In doing this, 10 is added to the value of CALIB to determine the data set number.

SIGVO, SIGXD, SIGYD, VO
(4F10.0)

The standard deviation of the muzzle velocity of the projectile (σ_{VO}). The units are meters/sec.

SIGXD - The standard deviation of the residual dispersion of the projectiles in the traverse direction (σ_A). This variable should be in units of radians.

SIGYD - The standard deviation of the residual dispersion of the projectiles in the elevation direction (σ_E). This variable should be in units of radians.

VO - The mean value of the muzzle velocity of the projectile in meters per second.

EDMAX, ADMAX, TREAC, RNDS, RMAX, ELMAX
(6F10.0)

EDMAX - The maximum elevation rate which can be achieved by the gun in radians per second.

ADMAX - The maximum azimuth rate which can be achieved by the gun in radians per second.

TREAC - The reaction time for the gun system in seconds. This reaction time is defined as the time from initial detection of a target to the time when the system can begin firing.

RNDS - The number of rounds in a burst from the gun.

RMAX - The maximum effective range of the projectile in meters. This is usually determined by the range at which the velocity of the projectile is at such a low level that it can no longer inflict damage to the target.

ELMAX - The maximum elevation angle in radians, to which the gun can elevate.

R, TF
(2F10.0)

These two variables are used to determine the ballistic drag coefficient of the projectile. R is a range in meters and TF is the time of flight in seconds to that range. These two parameters can be taken from anywhere on the range - time of flight curve of a projectile, especially if the projectile obeys the "3/2 law" for the drag force. If the projectile doesn't follow this law, a good approximation is usually achieved at a range which is 2/3 the maximum range.

DYNAM, DYNEM, MAXAZ, MAXEL
(2F10.0,2I5)

DYNAM - The mean gun servo error in the azimuth direction. This error is usually considered to be a bore sight error since servo mechanisms are usually not designed with a mean error in them. The units are radians.

DYNEM - The mean gun servo error in the elevation direction. This is usually the result of a bore sight error. The units are radians.

MAXAZ - The number of entries in the azimuth rate - standard deviation tables. (MAXAZ \leq 10)

MAXEL - The number of entries in the elevation rate - standard deviation tables. (MAXEL \leq 10)

ELDOT(I), I = 1, MAXEL
(7F10.0)

The ELDOT array contains the elevation rate entries in the elevation rate vs. standard deviation tables. The units are radians per second and the number of entries should equal the value of MAXEL.

DYEL(I), I = 1, MAXEL
(7F10.0)

The DYEL array contains the standard deviations (in radians) in the elevation direction of the gun servo system error. The quantities of this array must correspond in order to the elevation rates in the ELDOT array. The combination of these two arrays (ELDOT - DYEL) describes a curve relating the standard deviation of the gun servo error in the elevation direction to the gun elevation rate. A linear interpolation between the quantities in these arrays is used to achieve the standard deviation of the elevation error at any particular value of elevation rate.

AZDOT(I), I = MAXAZ
(7F10.0)

The AZDOT array contains the gun azimuth rate entries in the azimuth rate vs. standard deviation tables. The units are radians per second and the number of entries should equal the value of MAXAZ.

DYAZ(I), I = MAXAZ
(7F10.0)

The DYAZ contains the standard deviations (in radians) in the azimuth direction of the gun servo system error. As was the case with the DYEL array, the entries in the DYAZ array should correspond to the rates in the AZDOT array, and a linear interpolation is used to find the standard deviation at any particular value of azimuth rate.

XM (I)
(6F10.0)

The XM array contains the mean value of the measurement errors. Earlier in the text of this report these quantities were described with the symbol \bar{M}_x . The units are radians - meters - seconds. The order is: 1) range, 2) azimuth, 3) elevation, 4) range rate, 5) azimuth rate, 6) elevation rate.

SIG (I, J)
(6F10.0)

The SIG matrix contains the standard deviations and correlation coefficients of the measurement errors. The terms on the diagonal of this 6 x 6 symmetric matrix are the standard deviations of the errors. The off diagonal terms are the correlation coefficients. The matrix is read in one row at a time (i.e., one row per card) following the same order as the mean errors. This is, range first, azimuth second, etc. The units are radians - meters - seconds. To illustrate the order of the cards, the information on the first three cards is as follows:

1st card - σ_r $\rho_{r,a}$ $\rho_{r,e}$ $\rho_{r,\dot{r}}$ $\rho_{r,\dot{a}}$ $\rho_{r,\dot{e}}$

2nd card - $\rho_{r,a}$ σ_a $\rho_{a,e}$ $\rho_{a,\dot{r}}$ $\rho_{a,\dot{a}}$ $\rho_{a,\dot{e}}$

3rd card - $\rho_{r,e}$ $\rho_{a,e}$ σ_e $\rho_{e,\dot{r}}$ $\rho_{e,\dot{a}}$ $\rho_{e,\dot{e}}$

etc.

Target Data

The target is described as a combination parallelepipeds which represent the vulnerable components which make up the target. There may be as many as seven components which make up the target. Three values

of each of the six faces of the components are input to the program. The three values of each area correspond to the vulnerable area presented as a function of projectile striking velocity. Presently, the program is set up so that the first area for each face is for striking velocity of 500 ft/sec and the second area is for 1000 ft/sec. The third value is not currently being used; however, space must be allowed for it on the data cards. As was mentioned in the previous section, the value of the variable CALIB is used to determine the numbered data set on which this target data is found. A card by card description of the data is given below.

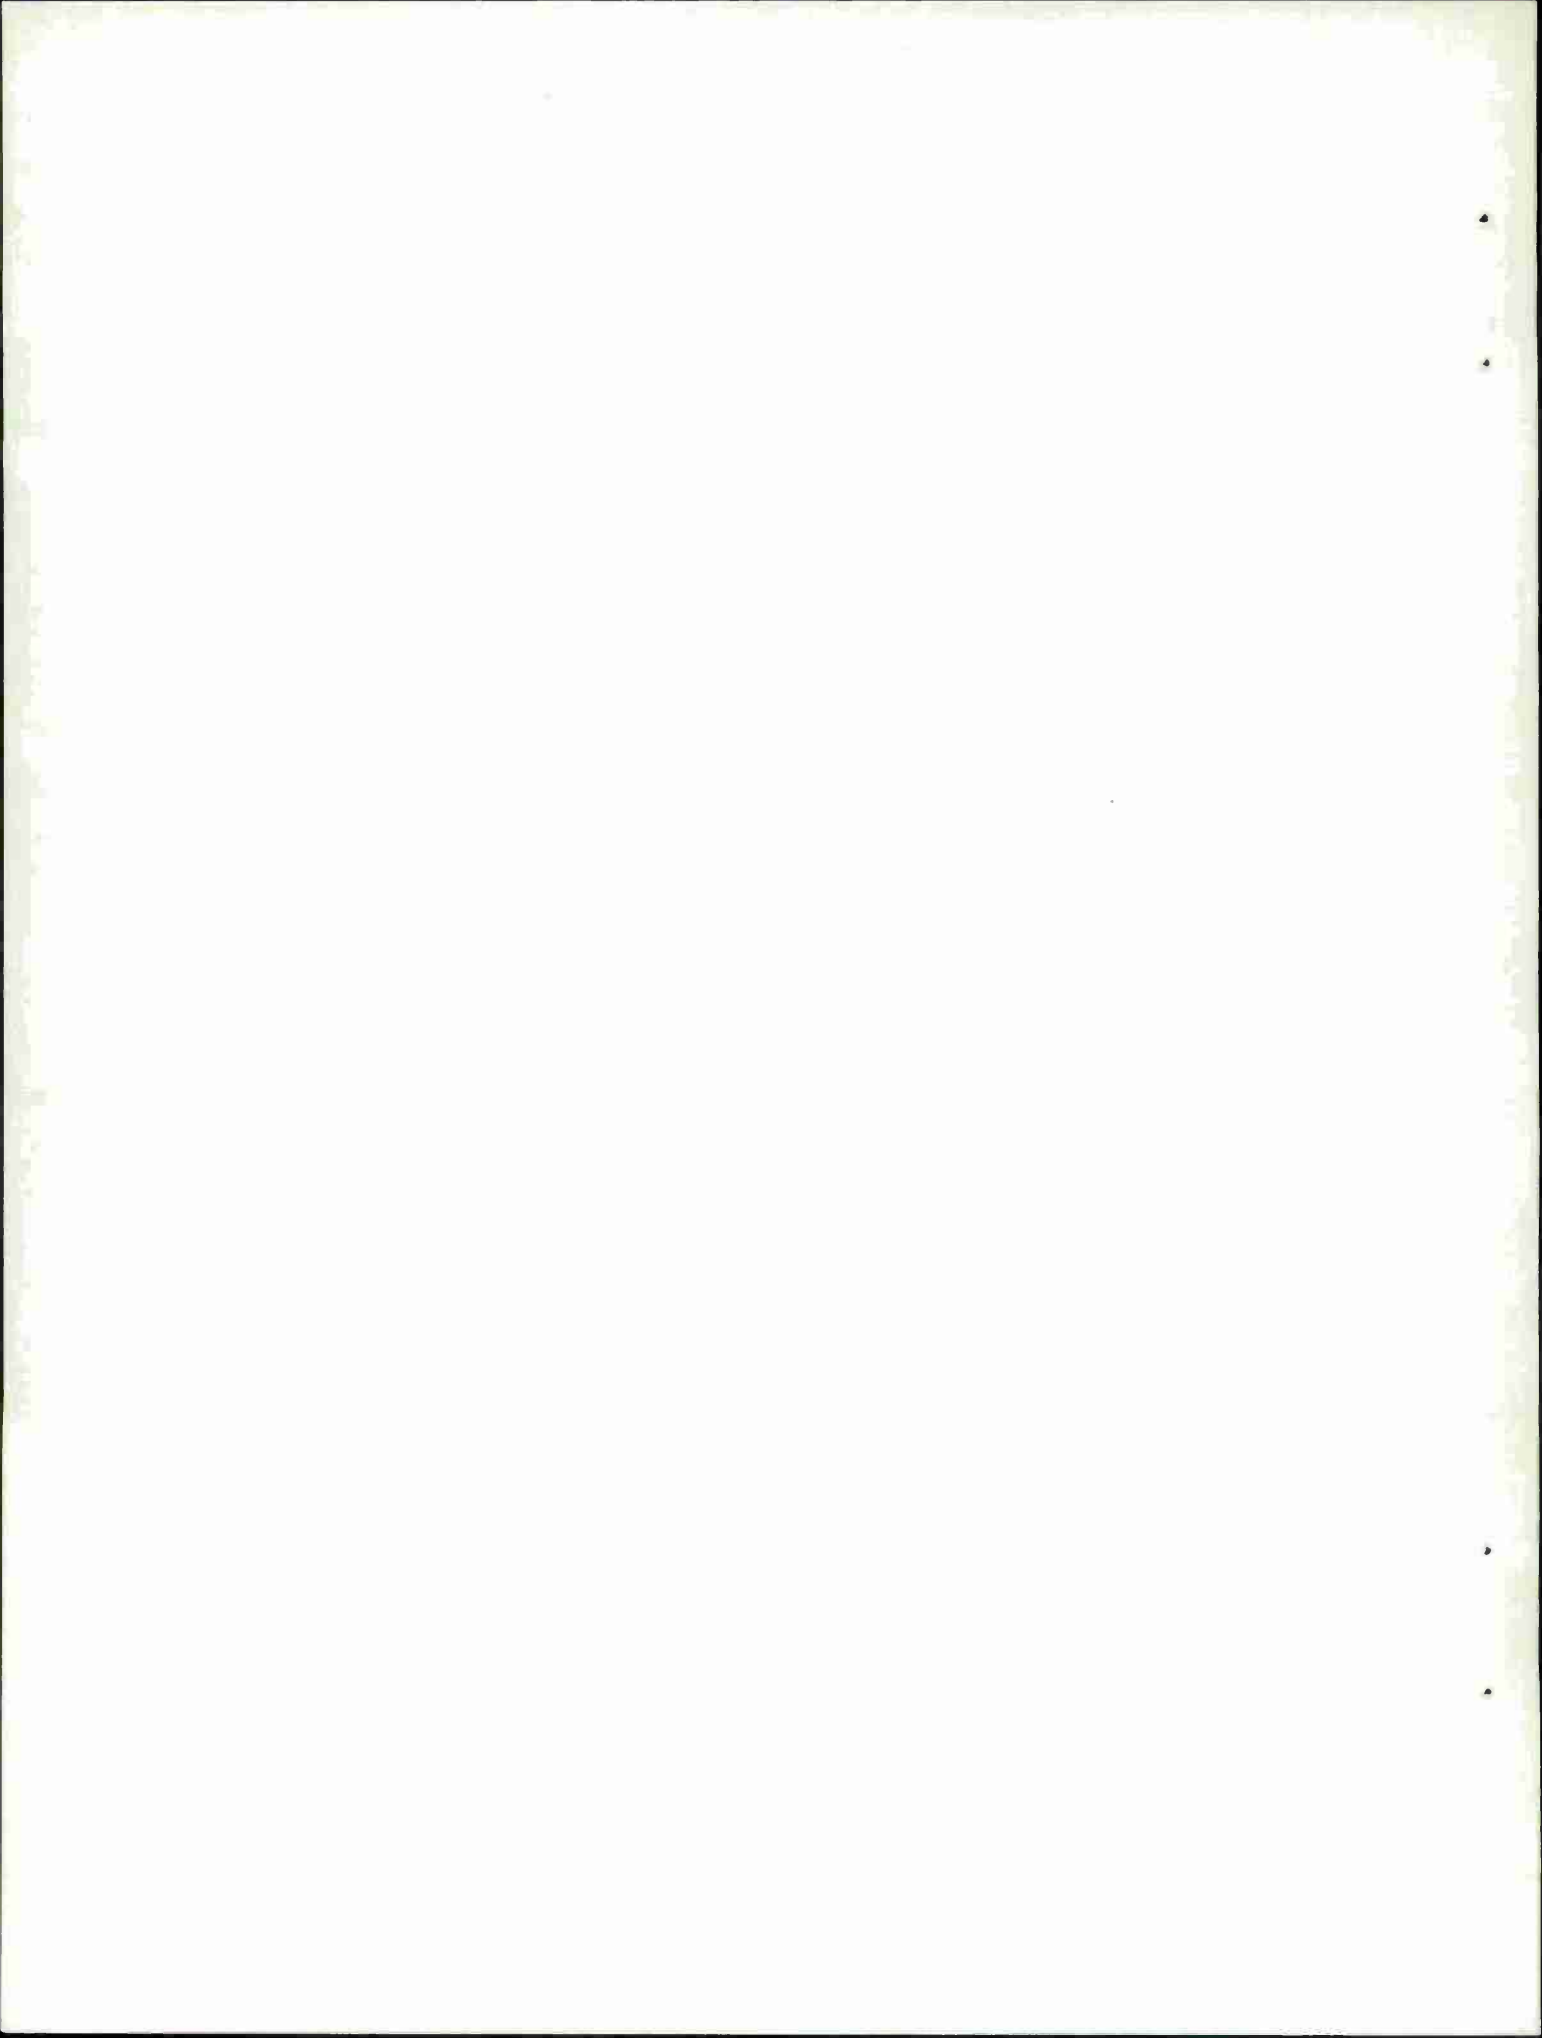

EMAX
(I5)

The number of vulnerable components from which the target is made should be read into the variable EMAX.

S(I, J, K)
(6F10.5)

The S array contains the values of the areas of the faces of the vulnerable components in units of square meters. Because of the format by which these quantities are read, three cards are required to define each of the (EMAX) components. The first three quantities on the first card are the three areas of the front side of the component, while the second three are the areas of the rear of the component. On the second card are the areas of the port and starboard sides of the component (in that order). And on the last card the areas of the bottom and top sides of the component are given (in that order).

C =====
0001 SUBROUTINE PLOT(RMIN,RMAX,B,LABEL)
C =====
C
C THIS SUBROUTINE PLOTS THE PK CONTOURS AND SYSTEM CONSTRAINTS IN
C THE PLANE WITH X AS THE HORIZONTAL AXIS AND B AS THE VERTICAL
C AXIS. IF RMIN RMAX AND R HAVE THE VALUES OF THE RESPECTIVE
C VARIABLES OF Y, THE PLOT WILL BE A "GROUND PLOT". IF THE DUMMIES
C RMIN, RMAX AND R CONTAIN THE ASSOCIATED VALUES FOR Z, THE PLOT
C WILL BE IN THE VERTICAL PLANE ("SKY PLOT").
C
C THE PROGRAM WORKS BY INCREMENTING THE DUMMY VARIABLE R BETWEEN
C RMIN AND RMAX DURING THE PROCESS OF SWEEPING THE PLOT. THE
C VARIABLE IN THE CALLING LIST FOR R WILL BE CHANGED ACCORDINGLY,
C THUS ALLOWING FOR THE FREEDOM OF CHOICE TO EITHER SWEEP Y OR Z
C MERELY BY PLACING THE VARIABLE NAME IN THE LIST.

APPENDIX
DERIVATION OF THE GUN POSITION EQUATION

Next page is blank.

INTRODUCTION

The expressions used to define the position of the gun necessary to score a hit on the target are derived in this appendix. The equations are based upon linear prediction methods and are, therefore, correct only if the target is flying at a constant speed. The expressions must, of necessity, be in terms of the measured quantities ($a, e, r, \dot{a}, \dot{e}, \dot{r}$) (see Figure 1, p. 7) at the present position of the target; for only then can the necessary partial derivations be taken.

Azimuth Angle of the Gun

The azimuth position of the gun (and target) is a rather artificial quantity since there usually is no reference on the gun from which it can be measured. However, it is a required mathematical necessity. It will be shown that the actual measurement of an azimuth angle is not required in determining the lead angle of the gun. The position of the gun can be expressed as:

$$A_G = a + \lambda_A$$

where

$$A_G = \text{azimuth angle of the gun}$$

$$\lambda_A = \text{azimuth lead angle measured in the ground plane}$$

Mathematically, A_G and " a " are both measures from the same arbitrary reference.

The lead angle λ_A is defined: Consider the projection of the path of the target into the ground plane as shown in Figure A-1. The \overline{XY} plane defines the arbitrary coordinate system in which the azimuth angle, a , is measured. The xy plane is not arbitrary; however, it is set up so that the y -axis coincides with the reference position on the gun from which the lead angle is measured. This axis also lines up with the measured position of the target ($T(t)$). The velocity vector v to signify the path of the target, and the position of the target at the time of predicted intercept ($T(t+\Delta t)$) is shown in Figure A-1.

In the xy plane and in terms of the measured quantities,

$$\dot{x} = \dot{r} \cos(e)$$

$$y_0 = r \cos(e)$$

$$\dot{y} = \dot{r} \sin(e) - r \dot{e} \cos(e)$$

The lead angle λ_A can be expressed as

$$\lambda_A = \tan^{-1} \left[\frac{-\dot{x}(t + \Delta t)}{y(t + \Delta t)} \right] = \tan^{-1} \left[\frac{-\dot{x} \Delta t}{y_0 + \dot{y} \Delta t} \right]$$

Δt is time of flight of the projectile to the point of intercept.

It is more convenient to leave the expression for the lead angle in this form. Note that all of the terms in this equation (except Δt) are functions of the measured quantities. Δt will be treated later, and will be shown to be a function of the measured quantities.

The azimuth angle of the gun is defined as

$$A_G = a + \tan^{-1} \left[\frac{-\dot{x} \Delta t}{y_0 + \dot{y} \Delta t} \right]$$

The various partial derivatives of this expression with respect to the measured quantities can be obtained by application of the chain rule for partial differentiation. Note that the lead angle calculation is independent of the azimuth angle measurement, but that the gun position can be wrong if there is a measurement error involved with the azimuth angle α . This error can be likened to a tracking error in the azimuth direction.

Elevation Angle of the Gun

The elevation angle of the gun is shown in Figure A-2. The ω -axis in this figure coincides with the one shown in Figure A-1. The expression for the elevation of the gun (E_G) is given by

$$E_G = \sin^{-1} \left[\frac{z(t + \Delta t)}{R_f} \right]$$

Where

$z(t + \Delta t)$ = the altitude of the target at time of predicted intercept,

R_f = the range to the target at time of predicted intercept

In terms of the measured quantities:

$$z(t + \Delta t) = z_0 + \dot{z}\Delta t$$

Where

$$z_0 = r \sin(e)$$

$$\dot{z} = r\dot{e} \cos(e) + \dot{r} \sin(e)$$

and (referring to Figure A-1)

$$\begin{aligned} R_f^2 &= (\dot{x}\Delta t)^2 + (y_0 + \dot{y}\Delta t)^2 + (z_0 + \dot{z}\Delta t)^2 \\ &= (\dot{x}^2 + \dot{y}^2 + \dot{z}^2) \Delta t^2 + 2 r \dot{r} \Delta t + r^2 \end{aligned}$$

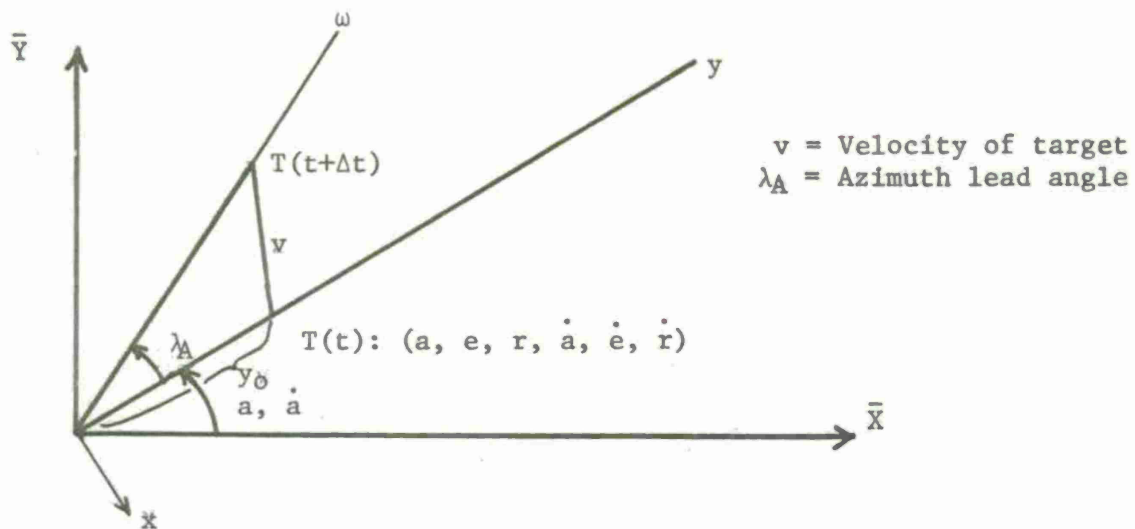

Figure A-1. Ground Plane Projection Of An Aircraft Flying At A Constant Speed.

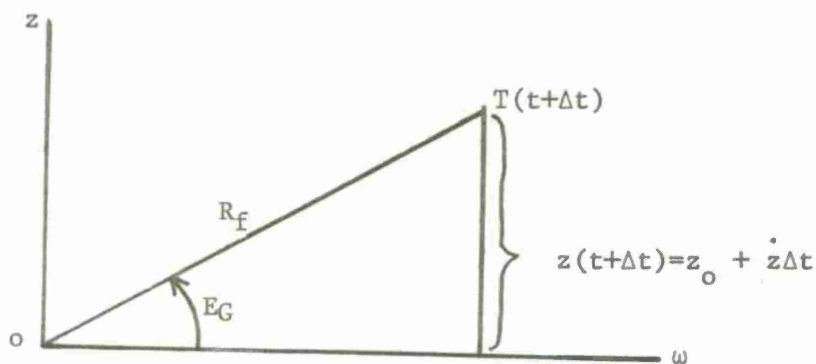

Figure A-2. Elevation View Of The Target At Time Of Predicted Intercept

The terms defining E_G can be expressed in terms of the measured quantities; therefore, the necessary partial derivatives can be obtained using the chain rule. Note that the actual measurement of the present elevation angle of the target is required here to calculate the elevation angle of the gun.

Time of Flight

The time of flight of the projectile to the point of predicted intercept must also be expressed in terms of the six measured quantities. This is required because the partial derivatives of this quantity are necessary to complete the total partial derivatives of the expressions for A_G and E_G .

This derivation is based upon the two assumptions:

1. Linear prediction (i.e., the target is not accelerating)
2. The projectile obeys the following equation

$$\Delta t = \frac{R_f}{V_m - \bar{K}R_f}$$

The derivation proceeds as follows:

Solving the R_f from the equation for Δt

$$R_f = \frac{\Delta t V_m}{1 + \bar{K}\Delta t}$$

Referring to Figure A-1

$$R_f^2 = V_t^2 \Delta t^2 + 2r\dot{r} \Delta t + r^2$$

and equating to obtain

$$\frac{V_m^2 \Delta t^2}{(1 + \bar{K} \Delta t)^2} = V_t^2 \Delta t^2 + 2r\dot{r} \Delta t + r^2$$

Carrying out the indicated multiplications and combining coefficients of powers of Δt yields

$$\begin{aligned} \Delta t^4 (\bar{K}^2 V_t^2) + (2 r \dot{r} \bar{K}^2 + 2 V_t^2 \bar{K}) \Delta t^3 + (r^2 \dot{K}^2 + 4 r \dot{r} \bar{K} + V_t^2 - V_m^2) \Delta t^2 \\ + (2 r^2 \dot{K} + 2 r \dot{r}) \Delta t + r^2 = 0 \end{aligned}$$

where

\bar{K} = ballistic coefficient of the projectile

V_t = velocity of the target

V_m = muzzle velocity of the projectile

The only term in this quartic equation which must be expressed in terms of the measured quantities is V_t , the velocity of the target. This can be expressed as

$$\begin{aligned} V_t^2 &= \dot{x}^2 + \dot{y}^2 + \dot{z}^2 \\ &= (\dot{r} \cos(e))^2 - r^2 \dot{e}^2 + \dot{r}^2 \end{aligned}$$

This completes the derivation of the equations defining the position of the gun in terms of the measured quantities. The partial derivatives of the expressions for A_G and E_G can be obtained by application of the chain rule for partial differentiation. Similarly, the partial derivative of Δt with respect to the measured quantities can be obtained and used in the expressions for E_G and A_G .

Angular Rates of Guns

The angular rates of the gun in the azimuth and elevation directions are required so checks in the ISO-PK program can be made against maximum rates allowed. These rates can be obtained from the expression derived earlier in this appendix.

The partial differential equations necessary to obtain F on page 13 are contained in the section titled FORTRAN Source Program Listing on pages 56, 57, and 58 of the listing in subroutine GFUNC. The derivation of these partials is straight forward but very tedious. It was felt that inclusion of the derivation of these partials would be of little interest to readers or users of this report. Therefore, only the final form of the partials in FORTRAN notation is included. The terms are given FORTRAN names which make a mnemonic interpretation of the quantity easy. For example, PAXD stands for the partial of azimuth with respect to X-dot or $\frac{\partial A}{\partial \dot{x}}$.
