various irradiance levels up to 6.7 KW/cm^2 . ^{sq cm} These samples may be exposed safely at about 20 watts/cm². For kilowatt level exposures, dark finished samples are more robust than bright finished samples of the same material. At 6.7 KW/cm^2 , all materials are penetrated in less than one second with the exception of 430SS and DH242 wet with water.

INTRODUCTION

The development of the CO₂ laser presents a variety of problems in laser protective shielding, including materials for routine laboratory baffles. There are potentially useful lightweight materials commercially available which can be easily cut and formed into any desired shape. The purpose of this study is to determine whether several commercially available shielding materials hold promise for protection against high energy laser radiation.

MATERIALS TESTED

Experimental studies were conducted on a number of commercially available metal fiber materials to determine the feasibility of their use as high energy laser barriers. The materials were obtained from the Brunswick Corporation, Sugar Grove, Virginia. The company furnished a woven graphite cloth and four sets of paired samples. Within each pair the sample designation is the same except for the surface appearance, that is, one is dark and the other is bright. The dark finishes were obtained by preoxidizing bright samples. A summary of their physical properties is included in Table I. These materials vary in texture from the soft matted DH242 and 304SS to the platelike FM515. The matted cloth, DH242, is made up of very fine metal fibers rendering it flexible, soft, and spongy. Because of these qualities, it can be impregnated with laser attenuating materials, such as water for absorbing the CO₂ laser, to further attenuate the laser beam. The 304SS, which is made of stainless steel fibers, is not as flexible as the DH242 because its fibers are more closely woven, thus rendering it not as spongy. The other samples are composed of large fibers that are solidly compressed into a rigid metal board (430SS) or onto a metal plate (FM515). The latter resembles a granular surface. The graphite sample consists of spun fibers woven into a black cloth.

PROCEDURE

The experimental setup is shown in Figure 1. The laser is a Coherent Radiation, Model 40, single mode, CO₂ laser. The laser output beam was used at full width, 1.905 cm, for irradiances between 1.75 to 35 watts/cm²; and focused down with a water cooled germanium lens to obtain a 0.137 cm diameter spot for higher irradiances. The irradiances were determined by first measuring the energy output of the laser with a Coherent Radiation Laboratory, Model 203, thermopile detector and dividing it by the burn spot area and the time of incidence on the detector ($H = \text{joules/cm}^2 \text{ sec}$). In the diagram, M is a 100% mirror, used to deflect the laser beam into the thermopile. The helium-neon laser is necessary to align the sample to the CO₂ laser in order to assure that a different area of each sample was used for each exposure. The conditions of the exposures are given in Tables II and III.

Table I. Properties of Lightweight Materials Tested

SAMPLE #	ALLOY	FIBER DIA. (microns)	DENSITY (lbs/ft. ²)	TENSILE STRENGTH (PSI)	THICKNESS (in.)	OTHER PROPERTIES
1	DH242	8.0	.205	---	.400	Needle punches and rolled to final density
2	304SS	8.0	.219	---	.220	Stainless-steel web, sintered and rolled to final density
3	430SS/ FM1311	46.1- 62.0	1.97	---	--- ±.015	No tensile strength specification, ±2% tolerance on density, ±.015 tolerance on thickness
4	FM515 with Inconel 600	6.0	---	950-2,800	.250	.190" FM515 - backed with .060" Inconel 600
5	Graphite	---	.063	360,000	---	Modulus → 34 x 10 ⁶ lbs/in ² , Breaking Strength → 13.5 lbs, % Elongation → 1.1%, Specific Heat → 1.7

RESULTS

The observed behavior of each sample under test is described in Tables II and III, and the damage sustained by each sample is shown in Figures 2 through 10.

The results for the darkly finished samples are presented in Table II. With increasing irradiance, all samples sustained surface discoloration before exhibiting further damage or penetration. The onset of surface burns and penetration damage was preceded by incandescence of the fibers which varied in intensity with the laser power output. The samples 430SS and FM515 showed appreciable resistance to the unfocused CO₂ laser for a time duration of a little over one minute. The irradiance thresholds of the materials for damage exceeding mere discoloration, an excerpt of Table II, are shown in Table IV. All of the samples were also subjected to 6.8 KW/cm², whereupon most suffered complete penetration in less than one second. The exceptions are DH242 which took nearly two seconds to damage, and sample 430SS which underwent complete penetration damage in twenty-two seconds. Taking advantage of the spongy quality of DH242, it was soaked with water and then exposed to the 6.8 KW/cm² beam. After eighty seconds the wet DH242 sample had sustained only minimal surface damage.

The brightly finished samples show lower damage thresholds than the dark ones discussed above. These results are detailed in Table III, and damage thresholds are summarized in Table V. Again the samples 430SS and the FM515 have little damage at 35 W/cm². At an irradiance of 1.0 KW/cm², all samples were completely penetrated by the CO₂ laser beam within one second except the 430SS metal fiber board which was damaged within this period but not completely penetrated. Penetration of this sample occurred sixteen seconds later. The bright sample of DH242 is also spongy and was also soaked with water to determine its barrier properties at higher power irradiance. Using the laser beam at 1.0 KW/cm², this sample was penetrated in eight seconds, therefore this material is not as good as its dark counterpart when treated similarly.

It must be pointed out that for both FM515 samples (dark and bright), which have an Inconel backing, complete penetration involves penetration of the fiber cover only. It could not be determined whether the Inconel backing was damaged, since the samples were not cut out to determine if any damage occurred there. However, at all the laser power ranges used, no complete penetration of the metal backing was observed.

NOTE: High power density exposures at 6,768 watts/cm² completely penetrated for dry sample, but not for wet sample.

Table IV. CO₂ Laser Irradiance Damage Threshold of Dark Finished Lightweight Materials

SAMPLE #	TIME (sec)	POWER IRRADIANCE (Watts/cm ²)	DESCRIPTION OF DAMAGE
DH242 (dry)	2	35	Surface
304 S _λ S _λ	1	35	Penetration begins
430SS/ FM1311	64	35	Superficial
FM515	64	35	Discoloration and surface cracks
Graphite Cloth	16	17.5	Surface
DH242 (wet)	80	6,768.00	Superficial

Table V. CO₂ Laser Irradiance Damage Threshold of
Bright Finished Lightweight Materials

SAMPLE #	TIME (sec)	POWER IRRADIANCE (Watts/cm ²)	DESCRIPTION OF DAMAGE
DH242 (dry)	8	7.0	Surface
304 S _λ S _λ	2	35.0	Surface
430SS/ FM131	4	17.5	Surface
FM515	4	17.5	Surface
DH242 (wet)	2	1,000.00	Penetration

CONCLUSIONS AND RECOMMENDATIONS

The above results illustrate that these metal-fiber materials offer very little protection against CO₂ laser damage. The only exception is the water impregnated dark DH242 which sustained minimal surface damage at power densities of 6.8 KW/cm². This capability renders this sample useful as a probable barrier material to CO₂ laser radiation.

Further investigations of the DH242 (dark, water impregnated) sample are recommended to determine the extent of its usefulness as a CO₂ laser barrier. Studies should be conducted to find out the temperature gradients through and across the sample when the material is irradiated by the laser. Laser damage threshold should be determined. Since the metal fiber of this sample is steel, environmental studies should be conducted to assess corrosion and its effects on the CO₂ laser barrier properties of the material. For this reason, water impregnation may be impractical. A search of other impregnating materials should also be conducted.
