19. KEY WORDS (Continue on reverse side if necessary and identify by block number) Energy, conservation, energy control systems, energy management systems, energy analysis, economic analysis.		
20. ABSTRACT (Continue on reverse side if necessary and identify by block number) The technique and information necessary to analyze an Army installation for the economics of an energy control system are detailed. The various building information, schemes and equipment control are outlined, with an explanatory example of calculating the savings and cost of implementing energy control. Development of the simple payback equations and calculations are outlined.

GUIDANCE FOR ENERGY CONTROL SYSTEM ANALYSIS

1.0 Gather Preliminary Data

1.1 Obtain a copy of the building information schedule (BIS). It is a compilation of various parameters for each building on post. The legend, (first 3 pages), explains the location and meaning of the various codes. Items of special interest are total square feet, system types, use, and utility service to the building. The BIS can be found at the office of Plans and Policies in the FE Shop.

1.2 Locate all electric, gas and oil bills for each facility. This information serves as the base for energy saving through conservation schemes. Obtain base wide energy bills and utility rate schedules spanning 12 months of service. This information is necessary for calculating savings from load shaving, and can be obtained from the budget department of the Post Facility Engineer. Sample electric and gas bills are displayed in Figures 1 and 2, with pertinent information underlined.

1.3 Discuss with the Facility Engineer, system type and control schemes which might apply to the post. Three levels of control are available: Level A, local, Level B, manually operated central centers, and Level C, automatic central systems. Examples of equipment used with each are respectively, time clocks, hardwired microprocessors, and programable minicomputers.

Level A controls are limited in their functions to one conservation scheme such as enthalpy or temperature controls. Level B controls can perform several functions collectively, but any change in the system operation requires hardware alteration. Level C systems are capable of optimizing all conservation schemes plus load management, and preventive maintenance programming. System modifications are performed through software changes, thus limiting expensive hardware modifications.

1.4 The various conservation schemes are described below with applicable control schemes indicated by defining letter.

1.4.1 Scheme 1, Equipment Shutdown. Programmed shutdown of building heating and cooling equipment during unoccupied periods results in significant energy savings. The magnitude of the savings depends on the heat transfer characteristics of the building, equipment capacity, type, and operating efficiency, and outside temperature conditions. (A, B, C)*

1.4.2 Scheme 2, Outside Air Shutoff. Programmed shutoff of outside air consists of closing outside air intakes and shutdown of exhaust fans when the building is unoccupied. For buildings where equipment operates continuously, the savings in energy cost can be large. It is recommended that Scheme 2 be used in conjunction with Scheme 1. (A, B, C)

1.4.3 Scheme 3, Outside Air Reduction. Many building systems have been found to draw in more outside air than is required for adequate ventilation.

*Denotes applicability of Level A, B, and C control.

Therefore, each building system should be investigated to determine how much the outside air quantity may be reduced. An adjustment of the minimum outside air damper setting to decrease the outside quantity could be a one time adjustment or could be combined with variable setting equipment as in Scheme 2, 4 or 5. Scheme 2 and 3 should be used in conjunction.

1.4.4 Scheme 4, Enthalpy Control. A popular energy conserving scheme is that of the air side economizer. The concept utilizes outside air as a source of free cooling whenever it is cool or dry enough. The difficulty comes in activating the economizer when outside air can be used. Measuring the total heat content or enthalpy of outside air allows control of the economizer to achieve the maximum savings possible. (A, B, C)

1.4.5 Scheme 5, Enthalpy Optimization. An extension of the concept described in enthalpy control is that of enthalpy optimization. This control scheme selects the air stream (outside air or return air) which will impose the lowest cooling load on the mechanical equipment. Selection is based on the air stream with the lowest enthalpy. It should be noted that either Scheme 4 or 5 should be used but not both. (A, B, C)

1.4.6 Scheme 6, Temperature Reset. Energy savings are available through reset or adjustment of air temperature in mixed air system like double duct and multizone. The basic concept is to decrease the amount of mixing by reducing the temperature difference between the hot and cold air streams. (A, B, C)

1.4.7 Scheme 7, Chiller Load Optimization. Efficiency decreases as the load decreases. Therefore, it is desirable to load each chiller as much as possible, especially in the case of multiple equipment. (C)

1.4.8 Scheme 8, Forecasting Peak Reduction. Peak reduction under this scheme is accomplished by shutting down selected equipment (shedding) when desirable to reduce a peak during any demand interval. (C)

1.4.9 Scheme 9, Programmed Peak Reduction. Under this scheme the demand of the system is not monitored or projected. The peak demand period is determined by investigating historical data on the system and producing demand profiles. (C)

1.4.10 Scheme 10, Maintenance Programming. This scheme would include an equipment run time program and a preventive maintenance (PM) program). (B, C)

1.4.11 Scheme 11, Fire and Intruder Detection. Self evident. (B, C)

1.4.12 Scheme 12, Equipment Logging. This scheme will chart equipment load characteristics and consumption data. (C)

1.5 Investigate the possibility of using telephone lines. If lines are not available or feasible, obtain prints of the post's maps for optimal placement of cables and equipment location.

1.6 Inquire with the Office of Plans and Policy at the FE Shop about current or future construction and demolition plans. If new facilities are on the horizon, they should be included as candidate buildings. Facilities scheduled for destruction should be passed over.

2.0 Design Plan

2.1 Using the BIS in conjunction with a building survey, tentative candidates should be selected. Four factors must be identified during the selection process; they are as follows:

- (a) Building size
- (b) Usage pattern
- (c) Heating and cooling system
- (d) Relative building location.

2.1.1 Building Size. Building size is usually the most significant factor in the selection process. The greater the total floor area, the greater the energy consumption. One notable exception is in warehouses and shop buildings. By nature these buildings encompass large floor areas which are usually not centrally heated or cooled. In general, the larger buildings with large HVAC systems are the most attractive for connection to a central system. Smaller buildings having a variety of HVAC systems throughout the structure may be more attractive for local control.

2.1.2 Usage Pattern. Patterns of building usage effect energy consumption to a large extent. Recreational centers with heavy part-time occupancy tend to have the greatest potential for conserving energy followed by office buildings. Building savings is almost proportional to the inverse of the hours of occupancy.

2.1.3 Heating and Cooling System. The type of heating and cooling system can influence the energy savings potential as well as the expense of conversion to a central control system. Generally, central heating and cooling systems found in larger, more complex buildings usually produce the greatest savings potential. System components such as air handling units, chillers, and boilers are usually located in the same area of the building, thus simplifying control system modifications.

2.1.4 Relative Building Cost. If telephone lines cannot be employed, the system's cost effectiveness becomes a function of the building's location. Some buildings may require modifications for ECS hook up. These buildings may possess high potential, but must be eliminated because of staggering communication or renovation cost. In such cases, local controls should be considered.

2.2 Investigate the HVAC systems found in the candidate buildings. Pay particular attention to system control and name plate information. If the system is scheduled for renovation or replacement, the future system should be designed with control interfacing in mind. It is advised that personnel from the Facility Engineer Shop accompany the investigators. Generic HVAC system schematic and control point descriptions are included as Figures 3 through 6, and should be consulted during the selection process.

2.3 After completing the investigation, determine applicable saving schemes for each facility. If an accepted method or reliable data for estimating savings from the various schemes exist it can be used to predict saving, otherwise the following method can be used.

DA = DAMPER ACTUATOR
 * = To Central Console

METHODOLOGY FOR CALCULATING ENERGY SAVINGS

Schemes 1, 2, 3, and 4 or 5

The following equation can be used to estimate both cooling and heating saving for schemes 1, 2, 3 and 4 or 5, provide the proper coefficients are used. These coefficients are located in Table 1.

SF_i = Saving Factor; $i = 1, 2, \dots, 5$

AR = Air Reduction, scheme 3 only

T_o = Total Energy Consumed

TS = Total Savings

Recall Schemes 4 and 5 should not be used in conjunction. Either 4 or 5 can be used but not both and these apply only to cooling. It is also assumed that Schemes 2 and 3 are always used in conjunction.

$$TS = T_o \left[SF_1 + SF_2(1-SF_1) + SF_3(1-SF_2)(1-SF_1) + AR + SF_4(1-SF_3)(1-SF_2)(1-SF_1) + SF_5(1-SF_4)(1-SF_3)(1-SF_2)(1-SF_1) \right]$$

Note: $SF_4 = SF_5$, when Scheme 4 is used $SF_5 = 0$, if Scheme 5 is used $SF_4 = 0$ and SF_5 becomes zero.

Example

Suppose an office building consumes 10^6 KBTU/Year (heating) and that Schemes 1, 2 and 3 are favorable. Further assume that the outside air will be reduced by 10%. To calculate the total savings locate savings for office buildings.

$$SF_1 = .18$$

$$SF_2 = .30$$

$$SF_3 = .11$$

$$AR = .10$$

$$T_o = 10^6 \text{ KBTU's/year}$$

$$TS = 10^6 \text{ KBTU's/year} \left[.18 + .30(1-.18) + .11(1-.3)(1-.18)(.10) + 0(1-.11)0(1-.18) + 0(1-0)0(1-.3)(1-.18) \right]$$

$$TS = 10^6 \text{ KBTU's/year} \cdot .43$$

$$TS = 4.3 \times 10^5 \text{ KBTU's/year.}$$

This is the estimated energy saving for the conservation schemes employed. If T_o is unknown the following method can be used to estimate building consumption for both heating and cooling.

BEC = Baseline Energy Consumption

AADD = Average Annual Degree Days

$T_o = BEF \times Area \times AADD/Z$

$Z = 4,258$ for heating (heating degree days)

$Z = 1,659$ for cooling (cooling comfort factor)

BEC's and AADD can be found in Tables 2 and 3 respectively. The values for the SF's and BEC were developed using the ECUBE simulation.

Scheme 6

Generally potential savings from this scheme is difficult to calculate. A method for estimating the savings has been derived (Ref. 1). Care must be taken to use proper values for the flow rate and the enthalpy difference, especially if any conservation measures reduce the design temperature, enthalpy or flow rate.

Cooling Savings: $Kwh = \frac{4.5 \times CFM \times h \times hours}{3412}$

Heating Savings: $BTUh = CFM \times T \times 1.08$

where; CFM = Cubic feet per minute
h = enthalpy difference

Peak Shaving: (Total KWh Reduced) x (Demand metering period/1 hour) x
(Demand Charge) = \$ saved from peak shaving.

All other savings must be either measured or determined by other means. Finally, sum the seasonal energy savings for each fuel.

2.4 Using the unit energy cost calculated in 1.2 convert the above energy savings into dollars. This puts all parameters on a common base, thus allowing comparison.

2.5 Buildings with small savings should be eliminated at this point.

2.6 Choose which level of control should be used. Buildings eliminated in 2.5 may be candidates for local control (time clocks, etc) In many cases, a mix of all these (A, B, & C) may best satisfy installation needs.

3.0 Cost and Savings

3.1 Define the breakeven condition and equipment life time. For most cases, breakeven will be a range rather than a point, since some data will have a subjective bias.

3.2 Determine the amount of building renovation and equipment adaption required to interface the systems with buildings. AR 415-17, Emperical Cost Estimates for Military Construction and Cost Adjustment Factors serves as a guide to renovation cost.

3.3 Tally cost and savings.

3.4 Divide total cost by savings/year, this yields the simple payback period.

3.5 Two methods of life cycle analysis are available. They are the present worth method and non-compounding simple interest method. They are described in Section 9 of the Automation and Centralization of Facilities Monitoring and Control Systems and Engineering Instruction for Preparation of Feasibility Studies for Total Energy Systems, respectively.
