ABSTRACT

This report contains test results from testing of Minuteman III, Stage III propellant manufactured by Aerojet Solid Propulsion Company and Thiokol Corporation, Wasatch Division. These results are compared statistically with propellant of similar ages from Minuteman II Stage II.

Regressions are given for only statistically significant parameters from very low rate tensile, high rate biaxial tensile under pressure, stress relaxation and thermal coefficient of linear expansion tests. There are some significant regressions in each of these tests.

Case liner bonds also show significant changes which are potentially life limiting.

Significant changes in other parameters may be the result of limited testing, both in numbers and ages.

Analysis of covariance for test data from lined and unlined cartons of Stage II and Stage III propellant and for the four tests listed above are given in the statistical appendix.

GLOSSARY OF ABBREVIATIONS AND TERMS

Aging Trend	A change in properties of performance resulting from aging of material or component
ANA	Aerojet Propellant, Stage III (ANB 3066 Formulation)
ANT	Thiokol Propellant, Stage III (ANB 3066 Formulation)
ANB	Aerojet Propellant, Stage II (ANB 3066 Formulation)
ASPC	Aerojet Solid Propulsion Company
CSA	Cross Sectional Area
DB	Dogbone
Degradation	Gradual deterioration of properties or performance
E	Modulus (psi), defined as the slope of the line drawn tangent to the initial linear portion of the curve
EB	End Bonded
EGL	Effective Gage Length
e_m	Strain at Maximum Stress (in/in)
er	Strain at Rupture (in/in)
"F" ratio	The ratio of the variance accounted for by the regression function to the random unexplained variance. The regression function having the most significant "F" ratio is used for plotting data. The ratio is also used in detecting significant changes in random variation between succeeding time points.
JANNAF	Joint Army, Navy, NASA, Air Force Committee
MAGCP	Propellant Laboratory at OOAMA
OOALC	Ogden Air Logistics Command
Post Curing	Period up to 12-16 months after manufacture

GLOSSARY OF ABBREVIATIONS AND TERMS (CONT.)

Regression	The general form of the regression equation is $Y = a + bx$
Regression Line	Line representing mean test values with respect to time
S_b	Standard error of estimate of the regression coefficient
S_e or $S_{Y.X}$	Standard deviation of the data about the regression line
S_m	Maximum Stress (psi)
S_r	Stress at Rupture (psi)
Standard Deviation (S_y)	Square root of variance
Strain Rate	Crosshead speed divided by the EGL
TCC	Thiokol Chemical Corp.
"t" test	A statistical test used to detect significant differences between a measured parameter and an expected value of the parameter (determines if regression slope differs from zero at the 95% confidence level)
Variance	The sum of squares of deviations of the test results from the mean of the series after division by one less than the total number of test results
3 Sigma Band	The area between the upper and lower 3 sigma limit. It can be expected that 99.73% of the inventory represented by the test samples would fall within this range assuming that the population is normally distributed.
90-90 Band	It can be stated with 90% confidence that 90% of the inventory represented by the test samples would fall within this range assuming that the population is normally distributed

SECTION I
INTRODUCTION

A. PURPOSE:

The purpose of testing ANB-3066 propellant, used in Minuteman II Stage II and Minuteman III Stage II and Stage III, is to monitor and evaluate aging effects on this propellant which will contribute to the operational motor serviceability prediction. Testing was performed according to General Test Directive GTD-2C, Amendment 1, and MMWR Project M83257C.

B. BACKGROUND:

Service life testing of ANB-3066 carton propellant from Aerojet production began at Ogden ALC in 1966. When production for Minuteman III Stage II was transferred to Thiokol, the propellant samples from both Aerojet and Thiokol were tested. As lined cartons were produced these also were tested, adding propellant liner bond specimens to the program. The current report contains data from all these sources for propellant aged 13 to 72 months.

Failure criteria for ANB 3066 propellant which were developed from structural stress analysis are reiterated in Aerojet Report 0162-06SAAS-17. Inner bore hoop strain failure is the predicted failure mode. These criteria are shown in Table 1-1.

SECTION II
TEST PROGRAM

Cartons representing raw material combinations were subjected to a random selection process designed to test all material lots within a two year-four test periods interval. When propellant cartons have been aged one year, they are added to the test program.

Propellant cartons are identified by source of manufacture. Stage II and III propellant manufactured by Aerojet Solid Propulsion Company is identified as ANB and ANA respectively. Thiokol Company Stage III propellant is identified as ANT. All regressions used this nomenclature and the additional information as to the type of carton, lined or unlined. Symbols identifying the carton types are given in Table 2-1.

Stage II ANB-3066 propellant has been tested for more than 10 years, but in this report only propellant up to 72 months has been used in covariance analysis to coincide with the age span of Stage III propellant. Lined and unlined cartons of ANB have been combined in regression analysis for comparison purposes and cover the time span from 13 through 137 months.

The physical-mechanical tests which relate directly to stress analysis are limited. Very low rate tensile test is related to storage conditions, and high rate rails tested under pressure relate to ignition. Stress relaxation modulus also relates to storage conditions. Thermal coefficient of linear expansion reflects some of the thermal stresses to which the motor is exposed.

Low rate uniaxial tensile tests and hardness are routine tests for all propellant. The data from these tests do not relate to structural

analyses. Poisson's ratio and cohesive tear energy tests have been applied to only a portion of the cartons. The data from these tests have not been subjected to statistical analyses. Test data for all these tests appear similar to previous test data. All these data will appear in subsequent reports.

SECTION III
STATISTICAL SUMMARY AND CONCLUSIONS

Data analyses of all propellant tested by MANCP having the ANB 3066 formulation are contained in this report. ANB 3066 propellant is divided into three groups, each group pertaining to a specific rocket motor application. The three propellant groups are designated in this report by a three letter code as follows:

Code	Manufacturer and System Application
ANA	Aerojet: MINUTEMAN III, Stage III
ANB	Aerojet: MINUTEMAN II, Stage II
ANT	Thiokol: MINUTEMAN III, Stage III

Propellant specimens for the ANA group were taken from unlined cartons. Specimens for the ANB and ANT groups were taken from unlined cartons and also from cartons having a simulated case liner along one surface of the carton. Each propellant group is further sub-divided into propellant lots.

Laboratory test data were studied to determine if lined cartons differ from unlined cartons. The data were also examined to determine if the propellant groups (ANA, ANB and ANT) differ among themselves. The following comparisons, as directed by the project engineer, were performed to satisfy periodic service life estimate requirements:

1. Compare lined and unlined cartons of MINUTEMAN III Stage III propellant manufactured by Thiokol (ANT propellant group).
2. Compare Aerojet Stage II lined cartons (ANB propellant group) with Thiokol Stage III lined cartons (ANT propellant group).
3. Perform joint comparisons for unlined cartons from ANA, ANB and ANT propellant groups.

4. Perform lot-to-lot comparisons for unlined cartons from ANA, ANB and ANT propellant groups.

5. Perform lot-to-lot comparisons for lined cartons from ANB and ANT propellant groups. (Lined cartons are not available for ANA propellant).

Propellant age is considered a possible source of bias in laboratory test data. That is, part of the observed differences in a given test response might be ascribed to propellant age. Because of the possible age effect it was necessary to provide a means of analysis where the bias, or age effect, could be removed allowing an unbiased evaluation of the true parameter response.

Analysis of covariance was chosen as the method to determine the effect or "significance" of propellant age on the test response. The general linear regression model, $Y = a + b(X_{ij})$, is modified for the analysis of covariance by introducing a "correction term" into the model to adjust the data for the average effect of the variable X_{ij}. Propellant age was assigned to the variable X_{ij} in this report. The F ratio for determing the significance of the propellant age is shown in Tables A-1 thru A-74.

Similarity among carton types and among propellant groups was determined by comparing regression lines for each of the data sets. The purpose was to examine whether the linear regressions of the test response on propellant age could be regarded as the same. It is possible for the regressions to differ in slope, intercept or residual variance. Differences due to slope could indicate dissimilar aging characteristics among groups while differences due to intercept could indicate bias among the data sets.

When the regression lines were statistically similar (slopes and intercepts were not significantly different) the data sets were accepted as being equal and were combined to provide an expanded data base. A "total" or composite regression line was then used to estimate the aging trend for the combined data.

The results of the analysis of covariance used in making propellant group comparisons (previously discussed on p. 3-1) are summarized in Table A-A of the appendix and as follows:

a. ANT lined and unlined cartons are significantly different for all observed test parameters.

b. ANB and ANT lined cartons are significantly different for all test parameters except modulus on very low rate tensile (2×10^{-4} in/min crosshead speed).

c. Joint comparisons of ANA, ANB, and ANT unlined cartons indicate that the three groups are significantly different for all observed test parameters.

d. The individual propellant lots are significantly different (with respect to the observed test data) for unlined cartons from ANA, ANB, and ANT propellant groups.

e. Individual propellant lots are significantly different for lined cartons from ANB and ANT propellant groups.

Analysis of covariance tables included in the appendix may be consulted for information relating to specific F tests used in the above comparisons.

ANB 3066 propellant exhibits incomplete curing and inconsistent test results if aged less than 13 months. All data aged less than 13 months was excluded from analysis in this report.

In those cases where test data from various carton types or propellant groups could be combined, plots of the combined data and regression lines are provided. Carton types or propellant groups are differentiated on these plots with different plotting symbols. These are shown in the applicable test sections. In addition to the combined regression plots, plots of individual group regression lines have been provided for each test parameter where the regression slope is statistically significant.

The results of the linear regression analysis are summarized in Table 3-1. From this table, several conclusions can be drawn.

1. Very low rate tensile:

   a. There is a singificant increase in maximum stress for all types of ANB 3066.

   b. There is a significant decrease in strain at rupture for lined cartons but a singificant increase in unlined cartons except for ANA which showed no change.

   c. There is a significant increase in modulus for ANB lined and ANT lined and unlined cartons.

2. High rate triaxial (rails under 600 psi N_2):

   a. There is a significant increase in maximum stress for all types of cartons except ANA.

   b. There is a significant decrease in strain at rupture for ANT lined cartons.

   c. There is a significant decrease in modulus for ANA and ANB unlined cartons.

3. Stress Relaxation Modulus:

   There is a significant increase in stress relaxation modulus

for ANA and ANB unlined cartons and ANT lined cartons, indicating increased hardness in the propellant.

4. TCLE:

   a. There is a significant increase in TCLE above glass point except for lined cartons of ANB.

   b. There is a significant decrease in glass point for all ANT cartons and an increase for ANB unlined cartons.

5. Case Liner Bond Specimens:

Interface tensile and shear specimens show signs of early failure in some lots. These lots still must be more fully characterized.

6. Testing Conclusions:

The testing shows changes which are potentially life-limiting in the case of liner bonds. Other significant parameters may not present this problem since there is the possibility that the changes are significant because of limited testing in numbers and ages.

ANT(Lined)	Sig	Sig	Sig	Sig	Sig	N.S.	Sig	Sig	Sig	Sig
ANT(Unlined)	Sig	Sig	Sig	Sig	N.S.	N.S.	N.S.	N.S.	Sig	Sig

SECTION IV

VERY LOW RATE TENSILE

This test uses a 1/2 inch thick (1.27 cm) JANNAF dogbone. The specimens are tested at a crosshead speed of 2×10^{-4} in/min (8.5×10^{-2} cm/sec). Very low rate tensile testing is related to strain capability for storage at 60°F.

Lined cartons show a statistically significant decrease in strain at rupture as shown in Figures 4-1, 4-2, and 4-3. The slope for the combined lined samples is less than for ANB lined cartons alone. Unlined cartons of ANB and ANT show a significant increase in strain at rupture with the slope greater for ANT than for ANB while ANA does not show a significant change (Figures 4-4 and 4-5). Strain at rupture for combined lined and unlined cartons of ANB up to 137 months shows a significant increase based upon the preponderance of unlined over lined cartons (Figure 4-6).

Maximum stress shows a significant increase (Figures 4-7 through 4-12). Slopes for ANB and ANT unlined cartons are steeper than for ANA with ANT steepest. Slopes for ANB and ANT lined cartons are similar. When ANB lined and unlined cartons are combined the slope is less than for ANB unlined and greater than for ANB lined.

There are three combinable groups for modulus, two of which have a significant increase. ANB unlined cartons and ANA unlined cartons when combined do not show a significant trend (Figure 4-13). Lined cartons of ANB and ANT show a significant increase (Figure 4-14) as do unlined and lined cartons of ANT (Figure 4-15). In this combined regression the slope and the standard deviation are larger than for dissimilar sources of lined

propellant cartons. There is a significant increase in modulus for ANB lined cartons and ANT unlined and lined cartons (Figures 4-16 thru 4-18). When ANB lined cartons are combined with unlined cartons, there is no significant change (Figure 4-19).

From the data cited, the similarity between lined cartons from different sources is greater than between unlined cartons from the same manufacturer.

At least for very low rate tensile testing, the conclusion that carton preparation has a greater influence on data than the source of the propellant is inescapable.

ANB 3066 PROPELLANT (ALL ANB) TENSILE MODULUS, .0002 IN/MIN, 77 DEG F

SECTION V

HIGH RATE TRIAXIAL

This test uses a 3/4 inch (1.9cm) GL rail, 5 inches (12.7cm) long. The specimens are tested on the MTS at a crosshead speed of 1750 in/min (74.08cm/sec) with 600 psi (421 860 kg/sq m) nitrogen pressure. Strain rate is 1000 in/in/min. This test simulates the condition of the motor at stage ignition.

Only lined cartons of ANT show a significant decrease in strain at rupture (Figure 5-1). No other types of cartons show a significant change, although ANB lined and ANT unlined cartons have negative slopes and ANA and ANB unlined cartons have positive slopes.

Lined cartons of ANB and ANT show a significant increase in maximum stress (Figures 5-2 and 5-3). Unlined cartons of ANB and ANT also show a significant increase (Figures 5-4 and 5-5). ANA does not show a significant change. Composite lined and unlined cartons of ANB do not show a significant change.

Only ANA and ANB unlined cartons show significant decreases in modulus (Figures 5-6 and 5-7).

SECTION VI

STRESS RELAXATION

An end-bonded 1/2" x 1/2" x 4" (1.27 x 1.27 x 10.16cm) is used on the Stress Relaxometer. The specimens are tested at seven different temperatures to derive a master stress relaxation curve.

A strain of 1% at 77°F (25.0°C) was not introduced into the program until Phase 3 of Minuteman III testing and Phase B Series 2 for Minuteman II which has resulted in a relatively short time frame for analysis. Prior to that time strains of 3% and/or 5% were used to form the data base.

ANA unlined cartons show a significant increase in relaxation modulus (Figures 6-1 and 6-2). ANB unlined cartons do not show a significant change at 10 sec. but do at 1000 sec. (Figures 6-3 and 6-4). ANT unlined cartons do not show a significant change.

When ANA and ANB unlined cartons are combined, there is no significant change (Figures 6-5 and 6-6).

There is no significant change for ANB lined cartons. There is a significant increase in relaxation modulus for ANT lined cartons (Figures 6-7 and 6-8). When all ANB is combined there is a significant increase in relaxation modulus (Figures 6-9 and 6-10). The increase in relaxation modulus is consistent with the increase in uniaxial tesile modulus and 10 sec hardness exhibited by this propellant.

Master stress relaxation curves include lined and unlined cartons. The curves are shown in Figures 6-11, 6-12 and 6-13. There is better agreement between ANB and ANT than between ANB and ANA. At lower test temperatures differences are accentuated.

Gradient stress relaxation was run on mini-stress relaxation specimens (0.1 x 0.5 x 2" specimens) at 1% strain and 77°F. Minimum stress relaxation modulus is reached at 2.2 inches from the bond line (Figures 6-14 and 6-15). It is apparent from the graphs that there is a sharp drop in modulus between the first and second specimens. Several cartons had liner which penetrated several samples which caused much disparity in the data.

SECTION VII

Thermal Coefficient of Linear Expansion

Thermal coefficient of linear expansion (TCLE) is run using an expansion probe on the DuPont 990 TMA. The specimen is a 0.200" wafer (.508cm) which is cooled to -110°C with liquid nitrogen then heated at 5°C/min. The glass point (Tg) and TCLE above glass point, (over the range -110°C to +40°C) is determined. TCLE below glass point is not considered to be of value in stress analysis.

ANA does not show a significant change in glass point, but has a significant increase in TCLE above glass point (Figure 7-1).

Data on ANB lined cartons was limited but TCLE above Tg showed a significant increase (Figure 7-5).

ANT lined cartons show a significant decrease in glass point (Figure 7-6) and a significant increase in TCLE below Tg (Figure 7-7).

All ANB shows a significant decrease in glass point (Figure 7-8) and a significant decrease in TCLE below Tg (Figure 7-9).

It is apparent that there is much variation in the data but as the data base expands there should be greater consistency.

ANB 3066 PROPELLANT (ALL ANB) THERMAL COEFFICIENT OF LINEAR EXPANSION (BELOW GP)

SECTION VIII

CASE LINER BONDS

Cartons of propellant were lined with SD-851-2 liner/V-45 rubber. In the preparation of these cartons there are marked irregularities in the liner with the liner frequently penatrating up to 0.3" into the propellant. Moreover, some of these liners are pink with varing degrees of tackiness while others are buff colored and usually with little tackiness.

Two reports (MANCP Report Nr. 357(76) and ASPC Report 0162-06SAAS-15, Addendum 1, April 1976) detail a cooperative study on several cartons which had this problem. In this report ANB and ANT cartons of several ages have been combined to obtain time to failure (Table 8-1). The stress to cause failure at 100 minutes is well above the alert limit for storage for both constant load tensile and constant load shear. Plots are shown in Figures 8-1 thru 8-4. All show a significant decrease. It may be possible in the next report to do lot analyses to pinpoint those lots in which early failure may occur.

TABLE 8-1

APPENDIX

ANALYSIS OF COVARIANCE

The results of the analysis of covariance as described in Section III are summarized in Table A-A. The number in each block refer to the table number of each analysis. The tables show the specific F ratio and an associated degrees of freedom for each statistical test conducted.

20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

This report contains test results from testing of Minuteman III, Stage III propellant manufactured by Aerojet Solid Propulsion Company and Thiokol Corporation, Wasatch Division. These results are compared statistically with propellant of similar ages from Minuteman II Stage II.

Regressions are given for only statistically significant parameters from very low rate tensile, high rate biaxial tensile under pressure, stress relaxation and thermal coefficient of linear expansion tests. There are some significant regressions in each of these tests. (OVER)

DD FORM 1 JAN 73 1473 EDITION OF 1 NOV 65 IS OBSOLETE

Case liner bonds also show significant changes which are potentially life limiting.

Significant changes in other parameters may be the result of limited testing, both in numbers and ages.

Analysis of covariance for test data from lined and unlined cartons of Stage II and Stage III propellant and for the four tests listed above are given in the statistical appendix.
