ACKNOWLEDGMENT

This final report is prepared for the Office of Naval Research, Arlington, Virginia under Contract N00014-76-C-1022. This work was performed between July 23, 1976 and January 31, 1977. The technical monitor at ONR is Dr. Stuart Brodsky. Dr. H. L. Stalford, who managed the project, and Dr. Chan Park are the project engineers.

The authors wish to thank their colleague Dr. Harold Schneider for stimulating discussions on aspects of quadratic spline functions.

CHAPTER I

INTRODUCTION

1.1 Contents and Organization of Report

Chaper I contains the study objectives and a discussion of the applicability of the newly developed Optimal Spline Method to ship classification and to the system identification of aircraft nonlinear aerodynamic flight regimes. Summarized in Chapters II and III are its successful application to ship classification work and to an on going aircraft identification study[†]. A detailed mathematical development of the Optimal Spline Method is derived in Chapters IV-X. Chapter IV contains a mathematical description of the problem investigated in the study. Six different cases of the problem are discussed in Section 4.4. The Optimal Spline Method is derived in Chapter V as a solution to the posed problem of Chapter IV. The analytical expressions for the quantities of Case 1 (i.e. the case applicable to aircraft system identification) are derived in Chapters VI and VII. The analytical expressions for the ship classification case (i.e. Case 2) are derived in Chapter VIII. Cases 3-6 are treated in Chapter IX. The procedure that determines the starting estimates of the knots and their locations is described in Chapter X. Chapter XI gives the conclusions.

Pristance in Rolly Pill and

[†]Study to Develop and Apply Nonlinear State Estimation and Parameter Identification Techniques to the High Angle of Attack/Sideslip Flight Regime of Conventional Aircraft and to the Hover and Low-Speed Flight Regimes of V/STOL Aircraft. 1.2 Study Objectives

in the same a section the case

A nonlinear function can be chopped into subarcs having small nonlinearities which can be adequately represented by simple spline functions. The domain of a subarc is called a spline region and a point joining one spline region with an adjacent one is called a knot. The piecewise combination of the simple spline functions that fit the subarcs is a spline representation of the nonlinear function. Spline representations can closely approximate the nonlinearities of any function. The goodness of fit depends on the number of spline regions and on the location of the knots. The first objective of this study is to derive an automated method that minimizes the number of spline regions and optimizes the locations of the knots to provide an adequate fit of a given nonlinear function. This has been accomplished by the development of the Optimal Spline Method discussed herein. The second objective is to apply the derived automated method to two important applications. This objective has been accomplished by the successful application of the Optimal Spline Method to ship classification and to system identification of aircraft nonlinear aerodynamic flight regimes.

1.3 Applicability of the Optimal Spline Method to Ship Classification

A major technological area challenging our U.S. Fleet is the over-the-horizon detection, classification and targeting of surface ships. The introduction of weapons like the HARPOON, the TOMAHAWK, and the ALCM have brought about new requirements in ocean surveillance. Active and passive sensors are required to provide beyond the horizon knowledge of all vessels under all weather and communication conditions. A large gap in surveillance capability currently exists in bad weather for non-communicating targets. The high range resolution radar system is a candidate having great potential to fill this gap. Current technology allows the existence of radar systems capable of obtaining surface ship signatures (stern-bow profiles) having classification potential^[1]. Accordingly, identifying a ship signature is largely a software problem. This report provides a very important contribution to this area by presenting a <u>new technique</u> - an <u>Optimal Spline Method</u> - which <u>generates</u> the independent features of a ship signature for <u>classification purposes</u>.

The integrated signal returns of a high range resolution radar system provide data from which the radar cross-section per range cell of a ship can be estimated. Radar cross-section is a measure of the amount of a ship's superstructure contained in a range cell. Consequently, a graph of the radar cross-sections per range cell drawn over a ship's length (i.e., a stern-bow profile) provides a means for classifying ships. The stern-bow profiles are the signatures for ship classification. The separate superstructure masses provide peaks in the profile while the absence of superstructure appears as valleys. An automated technique is needed for determining the number of separate superstructure masses, their separation from each other, their locations and their extended widths. These are the independent features of a ship's stern-bow radar cross-section profile. The Optimal Spline Method is an automated technique that fulfills this need.

Stern-bow profiles of ships lend themselves well to quadratic spline representations. Quadratic spline functions have the flexibility to fit any ship's stern-bow profile and, most importantly, they have coefficients that represent the independent features. These functions are mathematically described in Section 4.2. The spline coefficients provide the features for pattern recognition, and they are equal to the number of spline regions.

The problem of identifying a pattern increases exponentially with the number of features. Each set of data contains a fixed number of independent features. If too many spline regions are used the independent features are distributed into a higher number of spline coefficients. In this case the set of spline coefficients form a dependent set of features, making the classification problem unnecessarily complex. An independent set of features can be determined by minimizing the number of spline regions. This can be accomplished by optimizing on the locations of the spline regions for each fixed number of knots and by minimizing the number of knots. This is precisely what the Optimal Spline Method accomplishes.

1.4 <u>Applicability of the Optimal Spline Method to Aircraft System</u> Identification

The inability of empirical and theoretical techniques to accurately predict the nonlinear aerodynamics of the high angle of attack/sideslip domain for conventional aircraft and the propulsion induced aerodynamics on V/STOL aircraft has spurred interest in extracting these effects from actual flight data. Efforts to develop suitable nonlinear state estimation and parameter identification techniques for application to the high angle of attack/sideslip flight regime of conventional aircraft have been underway for several years. Dynamics Research Corporation (DRC) has developed a unique proprietary approach to nonlinear state estimation and parameter identification called the Estimation-Before-Modeling (EBM) identification method which determines state-dependent aerodynamic models for the forces and the moments acting on CTOL and V/STOL aircraft in any flight regime. DRC is currently under contract to the Naval Air Development Center to model a conventional aircraft and a V/STOL aircraft using the EBM identification method.

and normal concretes all care

The EBM identification method covers two phases -- state estimation followed by model structure and parameter determination. During the state estimation phase noisy flight records are processed by a unique proprietary DRC estimation approach which uses quadratic spline functions in generating optimal, smoothed time histories of all aircraft states, forces and moments. Various applications of spline functions are given in References [2-12]. Quadratic spline functions are used in DRC's approach to model the unknown time histories of the forces and of the moments. Each quadratic spline function is a function of parameters called knots as well as a function of time. The location of the knots influence the performance of the estimation unless a sufficiently large number of knots are used in the modeling of each force time history and of each moment There is a limit, however, to the practical number of knots time history. that can be used in a computer program. That is, the number of simultaneous equations that must be solved in the estimation process grows at the rate of one parameter per knot per quadratic spline function. Since there are 6 quadratic spline functions - one for each of three forces and one for each of three moments - the number grows at the rate of 6 per knot. For the case of 10 knots per quadratic spline function there is a total of 87 simultaneous equations; the additional 27 simultaneous equations are due to parameters other than those related to knots. The computations and the storage requirement of the estimation process grows exponentially with the number of knots. Consequently, it is advantageous to use as few knots as possible while maintaining an excellent estimation performance. This advantage is realizable by optimally selecting the knot locations. The Optimal Spline Method is an automated technique that performs an optimization of the knot locations and as a result better models of the force and moment time histories are obtained. leading to improved system identification of aircraft.

5

2. mint how in a second fill was

The Optimal Spline Method is being utilized in a study to develop and apply nonlinear state estimation and parameter identification techniques to high angle of attack/sideslip flight regimes of conventional aircraft and to hover and low-speed flight regimes of V/STOL aircraft. The results [13] of one phase of that study will be presented at the 4th AIAA AFM Meeting in August 8-10, 1977.

CHAPTER II

RESULTS OF AN APPLICATION OF THE OPTIMAL SPLINE METHOD TO SHIP CLASSIFICATION

In Figure 2-1 it is shown how the Optimal Spline Method fits into DRC's approach to ship classification. Note that it is the final block in the feature selection process. Specifically, it extracts the important features of the IRFP stern-bow profile. The IRFP stern-bow profiles are generated by the Image Reconstruction From Projections (IRFP) Method which reconstructs stern-bow images using high range resolution radar data. Before presenting the results of an application of the Optimal Spline Method to ship classification it is necessary to discuss the background of IRFP stern-bow profiles.

A test bed high range resolution radar system having a resolution of 50 feet was used in a Naval Research Laboratory Measurement Program sponsored by the Navy Space Project Office (PME-106) of the Naval Electronic Systems Command to generate profile data of fifteen ship types. Examples of the radar data collected on passes over each of three ship types are shown in the top three plots (1st, 2nd and 3rd projections) of Figures 2-2 through 2-5. The IRFP method which was applied to the top three plots generated the bottom plot called the reconstructed image of the stern-bow profile (i.e., IRFP stern-bow profile). On Run No. 38/Pass No. 8 of the U.S.S. BARNEY the upper three profiles of Figure 2-2 were taken at the aspects (measured clockwise from the ship's bow) 202°, 165° and 135°, respectively. Note the measured radar cross-sections 362, 5540, and 2061 square meters taken at the first, second and third projections, respectively. The projected length of the ship at each projection is noted also. The horizontal axis of each plot denotes the number of range cells (50 feet per range cell) measured from the stern to the bow along the projection. The vertical axis denotes the radar cross-section of the ship's portion contained in the range cell.

10 00.

The bottom profile is the output of the IRFP method resulting from the input of the upper three profiles. This is the reconstructed image of the U.S.S. BARNEY. The left end of the profile represents the stern and the right end the bow. The IRFP results of another pass over the U.S.S. BARNEY are given in Figure 2-3. A broadside drawing of the U.S.S. BARNEY (DDG-6) is given in Figure 2-6. Note the similarity between the IRFP stern-bow profiles of Figures 2-2 and 2-3 and the superstructure of the U.S.S. BARNEY in Figure 2-6. The IRFP results of a pass over the U.S.S. Dahlgren and of a pass over a Danish tanker (the ESSO DENMARK) are given in Figures 2-4 and 2-5, respectively. A drawing of the U.S.S. DAHLGREN is presented in Figure 2-7. A picture of the ESSO DENMARK is shown in Figure 2-8. In all passes the upper three profiles have been normalized to a total cross-section of the projection that lies between the cross-section of the other two projections. The IRFP profile has been normalized to this same crosssection.

The results of the application of the Optimal Spline Method to the IRFP stern-bow profiles of Run 38/Pass 8, Run 40/Pass 6, Run 32/Pass 1 and Run 44/Pass 1 are contained in Figures 2-9 through 2-12, respectively. In this application the radar cross-section is normalized to unity. The coefficient of the optimal spline function for each spline region is symbolized by the notation "PBAR". Optimally placed knots are denoted by the notation "OPTIMAL". For example, in Figure 2-9 the value of r_1 , (i.e., the first component of the p vector Equation(4.16)) for the first spline region [0.0, 0.72] is equal to 0.19; the first knot is optimally located at 0.72. The second knot is optimally placed at 2.75. Since each range cell represents 50 feet along the ship's length and since the stern starts at zero it follows that the first knot falls at 0.72 x 50 feet = 36 feet from the stern, the second at 138 feet, etc.

The number of knots, an output of the Optimal Spline Method, is five for both U.S.S. BARNEY passes - Figures 2-9 and 2-10. Note that eight knots were calculated for the U.S.S. DAHLGREN and seven for the ESSO DENMARK - Figures 2-11 and 2-12, respectively. The knot locations and the optimal spline coefficient values are tabulated in Tables 2-1 and 2-2.

Analyzing the first two columns of Table 2-1 and the first two columns of Table 2-2 we see that for both U.S.S. BARNEY passes the knot locations and the coefficient values are in good agreement. Looking at the third column of Table 2-2 we observe that the coefficients for the U.S.S. DAHLGREN differ from those of the U.S.S. BARNEY in sign as well as in magnitude. These differences together with the difference of 5 knots for the U.S.S. BARNEY versus 8 knots for the U.S.S. DAHLGREN make it easy to distinguish these two ship types.

It is also easy to distinguish between the ESSO DENMARK and the U.S.S. BARNEY because (1) there are five knots for the U.S.S. BARNEY and seven for the ESSO DENMARK, (2) their knot locations differ considerably and (3) their optimal spline coefficients differ greatly in magnitude for some of the spline regions.

Furthermore, it is easy to distinguish between the ESSO DENMARK and the U.S.S. DAHLGREN because (1) their coefficients differ in sign and (2) they have differences in knot locations.

Optimally locating the knots has two advantages. The first is the extraction of the independent features for classification purposes. The second is the reduction of the least-squares error. In Table 2-3 is presented a comparison of the least-squares error between optimally located knots and equally spaced knots. The least-squares error of Run No. 38/

CHAPTER III

RESULTS OF AN APPLICATION OF THE OPTIMAL SPLINE METHOD TO AIRCRAFT SYSTEM IDENTIFICATION

Aerodynamic derivatives are highly dependent on the angle of attack variable α and the sideslip angle variable β . Thus, these angles are important state variables in the state-dependent modeling of the forces and the moments that act on an aircraft. Presented in Figures 3-1 and 3-2 are applications of the Optimal Spline Method to angle of attack and sideslip angle flight test data of a light jet trainer aircraft. The Optimal Spline Method calculated twelve knots for the angle of attack data and optimally located them as shown in Figure 3-1. It calculated eight for the sideslip angle and optimally located them as shown in Figure 3-2. The first knot denoted by "OPTIMAL" for the sideslip angle is optimally placed at 4.62 seconds; the spline coefficient which is denoted by "PBAR" is 0.02 for the first spline region, 0.30 for the second spline region, etc.

Equally spaced knots have been used to fit the same angle of attack and sideslip angle data. The result of using twelve equally spaced knots on the angle of attack data is shown in Figure 3-3. The fit is not adequate at the times 3.5, 5.5, 7.5, 9.3, 10.7, 13.7, and 14.7. At each of these times the smooth curve falls outside the statistical limits of the noise. Shown in Figure 3-4 is the result of the use of eight equally spaced knots for the sideslip data. An unsatisfactory fit is even more pronounced here than it is in Figure 3-3. Consequently, equally space knots provide unsatisfactory smoothing unless an abundance of them are used. The Optimal Spline Method provides an adequate fit with a reduced number of knots by optimally locating them so that the resulting smooth curve can stay in phase with the data.

CHAPTER IV

MATHEMATICAL DESCRIPTION OF PROBLEM

4.1 Time Function Representations

The problem being investigated deals with the representation of a time function by the superposition of a family of simple functions which are easy to define, generate and implement. In particular, it is sought to minimize the number of parameters in such representations, while maintaining a required degree of accuracy.

Let f(t) denote a square integrable time function defined over a time interval $[T_o, T_f]$. Let d(t) be a measured time history of f(t):

$$d(t) = f(t) + \eta \tag{4.1}$$

where η is a stationary Gaussian process with variance σ^2 .

Let { $\alpha_n(t)$: n = 1, 2, --- } denote the family of simple square integrable functions to be used in the superposition. Since only a finite number of terms, N, is possible for a practical realization of f(t), it is necessary to choose coefficients q_1 , q_2 , ---, q_N so as to render a minimum to the criterion:

$$E = \int_{T_{o}}^{T_{f}} \left[d(t) - \sum_{n=1}^{N} q_{n} \alpha_{n}(t) \right]^{2} dt \qquad (4.2)$$

For the case of a complete orthonormal function series (e.g., Fourier, Walsh, Haar) the minimum is attained by making

$$\mathbf{a}_{n} = \int_{0}^{T} \mathbf{f} \quad d(t) \, \boldsymbol{\alpha}_{n}(t) \, dt \qquad (4.3)$$

and the error E monotonically decreases to the variance σ^2 as N becomes very large.

The advantage of using orthogonal series is the ease with which the optimum q_n 's of (4.2) are computable, i.e., using Equation (4.3). Frequently, a large value of N is needed in order that the error E is sufficiently close to σ^2 . Large values of N are disadvantageous in some applications (e.g., ship classification and aircraft system identification). There are nonorthogonal function series that provide excellent fits and use only small values of N.

One such nonorthogonal series is composed of quadratic spline functions. Before introducing these functions the solution of (4.2) will be derived for nonorthogonal series. Define[†] the row vector q^{T} as

$$\underline{\mathbf{q}}^{\mathrm{T}} = (\mathbf{q}_{1}, \mathbf{q}_{2}, \dots, \mathbf{q}_{n})$$
(4.4)

the row vector $\underline{\alpha}^{\mathrm{T}}(t)$ as

$$\underline{\alpha}^{\mathrm{T}}(t) = (\alpha_{1}(t), \alpha_{2}(t), \dots, \alpha_{n}(t))$$
(4.5)

[†]The superscript T denotes transpose.

and the matrix B whose i^{th} row and j^{th} column element b_{ij} is given by

$$b_{ij} = \int_{-T_0}^{T_f} \alpha_i(t) \alpha_j(t) dt \qquad (4.6)$$

The solution of (4.2) is given by

$$\mathbf{q} = \mathbf{B}^{-1} \int_{T_o}^{T_f} \mathbf{d}(t) \, \underline{\boldsymbol{\alpha}}(t) \, \mathrm{dt}$$
 (4.7)

For the case that B is the identity matrix this solution reduces to (4.3).

4.2 QUADRATIC SPLINE FUNCTIONS

Consider the following general 2nd order nonlinear differential equation

$$\dot{r}(t) = f(t, r(t), \dot{r}(t))$$
 (4.8)

where r and f are scalars and where f is a continuously differentiable function. Integrating both sides of this equation twice with respect to time over the interval $[T_0, t]$ gives

$$r(t) = r(T_0) + r(T_0) (t - T_0) + \int_{T_0}^{t} \int_{T_0}^{\tau} f(s, r(s), r(s)) ds d\tau$$
 (4.9)

The double integral can be rewrittn as

$$\int_{T_{O}}^{t} \int_{T_{O}}^{t} \delta (s, \tau) f(s, r(s), r(s)) ds d\tau$$

where

$$\delta(\mathbf{s}, \tau) = \begin{cases} 1 & \mathbf{s} \leq \tau \\ 0 & \mathbf{s} > \tau \end{cases}$$
(4.10)

Interchanging the order of integration and carrying out the integration results in

$$\int_{T_o}^t (t - s) f(s, r(s), \dot{r}(s)) ds$$

Consequently r(t) can be rewritten as

$$\mathbf{r}(t) = \mathbf{r}_{0} + \dot{\mathbf{r}}_{0} (t - T_{0}) + \int_{T_{0}}^{t} (t - s) f(s, \mathbf{r}(s), \dot{\mathbf{r}}(s)) ds$$
 (4.11)

where $r_0 \stackrel{\Delta}{=} r(T_0)$ and $\dot{r}_0 \stackrel{\Delta}{=} \dot{r}(T_0)$. This equation is the integral equivalent of the differential equation. The integral term is evaluated as follows: The total time domain of interest $[T_0, T_f]$ is divided into a number of subregions $[T_{j-1}, T_j]$, j = 1, 2, ---, m+1 called "splines". The points $T_1, T_2, ---, T_m$ are called knots. Here, $T_{m+1} = T_f$. The integral can be written equivalently as a sum of integrals over each spline region, i.e.,

$$r(t) = r_{0} + \dot{r}_{0} (t - T_{0}) + \sum_{k=1}^{j-1} \int_{T_{k-1}}^{T_{k}} (t - s) f(s, \dot{r}(s)) ds + \int_{T_{j-1}}^{t} (t - s) f(s, r(s), \dot{r}(s)) ds$$
(4.12)

where $t \in [T_{j-1}, T_j]$, j = 1, 2, ---, m+1. By choosing sufficiently many splines we can model f (s, r(s), $\dot{r}(s)$) as a constant \dot{r}_j over each spline region $[T_{j-1}, T_j]$, j = 1, 2, ---, m+1. With this approximation r(t) becomes

$$\mathbf{r}(t) = \mathbf{r}_{0} + \dot{\mathbf{r}}_{0} (t - T_{0}) + \sum_{k=1}^{j-1} (T_{k} - T_{k-1}) (t - \frac{T_{k-1} + T_{k}}{2}) \ddot{\mathbf{r}}_{k} + \frac{(t - T_{j-1})^{2}}{2} \ddot{\mathbf{r}}_{j}$$
(4.13)

HARMEN STRATERS

where te $[T_{j-1}, T_j]$. This is the quadratic spline function. The family of such functions is generated by letting the knots and the parameters $r_0, r_0, r_1, \dots, r_m$ vary over their regions of definition. In vector form the quadratic spline function can be written as

$$\mathbf{r}(t) = \underline{\mathbf{a}}^{\mathrm{T}}(t; \underline{\mathrm{T}}) \cdot \underline{\mathbf{p}}$$
(4.14)

where the knot vector \underline{T} is given by

$$\underline{T} = (T_1, T_2, \dots, T_m),$$
 (4.15)

where

the norm of state the case

$$\underline{\mathbf{p}} = (\mathbf{r}_1, \dots, \mathbf{r}_{m+1}, \mathbf{r}_0, \mathbf{r}_0)$$
(4.16)

$$\underline{\mathbf{a}}^{\mathrm{T}}(\mathsf{t};\underline{\mathrm{T}}) = (\mathbf{a}_{1}(\mathsf{t};\underline{\mathrm{T}}), \mathbf{a}_{2}(\mathsf{t};\underline{\mathrm{T}}), \dots, \mathbf{a}_{m+3}(\mathsf{t},\underline{\mathrm{T}})) \qquad (4.17)$$

$$a_{m+2}(t; \underline{T}) = 1$$
 (4.18)

$$a_{m+3}(t; \underline{T}) = t - T_0$$
 (4.19)

and where, for j = 1, 2, ..., m+1,

$$a_{j}(t; \underline{T}) = \begin{cases} 0 & T_{o} \leq t \leq T_{j-1} \\ \frac{(t - T_{j-1})^{2}}{2} & T_{j-1} \leq t \leq T_{j} \\ (T_{j} - T_{j-1})(t - \frac{T_{j-1} + T_{j}}{2})(t \geq T_{j}) \end{cases} (4.20)$$

In an application to ship classification the function r represents the radar cross-section per unit range resolution (i.e., density) along the length of the ship from the stern to the bow. Since this density is zero at the beginning of the stern and at the end of the bow the constraints

$$r_0 = 0$$
 (4.21)

$$r(T_{m+1}) = 0 (4.22)$$

must necessarily be invoked. The coefficients r_j , j = 1, 2, ..., m+1 provide a composite picture of the ship's superstructure.

To put the quadratic spline function in the notation of Section 4.1 let the vector \underline{T} be fixed and define

$$\alpha_{i}(t) = a_{i}(t; \underline{T}) \quad j = 1, 2, ---, N$$
 (4.23)

where N = m+3. The vector g corresponds to the vector p.

4.3 A GENERAL TIME FUNCTION OPTIMIZATION PROBLEM

The quadratic spline functions introduced in the previous subsections provide a family of simple functions for the representation of a time function. The quadratic spline functions form a nonorthogonal function series that quadratically depend on a parameter set <u>T</u> of knots. In general, then, a family of simple functions for time function representation will depend on a set of parameters such as <u>T</u> and the dependence will be possibly nonlinear. Consequently a general time function

PARTICIPAL OF MANY PARTIES

optimization problem has the error criterion

$$E(\underline{q}, \underline{T}) = \int_{T_{O}}^{T_{f}} \left[d(t) - \underline{\alpha}^{T}(t; \underline{T}) \cdot \underline{q}\right]^{2} dt \qquad (4.24)$$

where

$$\underline{q}^{T} = (q_{1}, q_{2}, \dots, q_{N})$$
 (4.25)

$$\underline{\alpha}^{\mathrm{T}}(\mathrm{t};\underline{\mathrm{T}}) = (\alpha, (\mathrm{t};\underline{\mathrm{T}}), \alpha_{2}(\mathrm{t};\underline{\mathrm{T}}), \ldots, \alpha_{N}(\mathrm{t};\underline{\mathrm{T}})) \qquad (4.26)$$

and where the (m+1) dimensional vector \underline{T} denote the set of parameters on which the simple functions α_i (t; \underline{T}), i = 1, 2, ---, N, depend. In the case of quadratic splines the vector \underline{T} represents the set of knots.

Since the argument \underline{q} occurs linearly inside the square brackets the error criterion $E(\underline{q}, \underline{T})$ can be minimized with respect to \underline{q} , holding \underline{T} fixed, to give an analytical expression for \underline{q} as a function of \underline{T} . Equation (4.24) can be rewritten as

$$E(\underline{q}, \underline{T}) = \int_{T_{o}}^{T_{f}} [d^{2}(t) - d(t) \underline{\alpha}^{T}(t, \underline{T}) \cdot \underline{q}] dt$$
$$- \int_{T_{o}}^{T_{f}} [d(t) - \underline{\alpha}^{T}(t; \underline{T}) \cdot \underline{q}] \alpha^{T}(t; \underline{T}) \cdot \underline{q} dt \qquad (4.27)$$

Minimizing E (q, \underline{T}) with respect to q gives

$$\int_{T_0}^{T_f} [d(t) - \underline{\alpha}^T (t; \underline{T}) \cdot \underline{q} \alpha_j (t; \underline{T}) dt = 0, j = 1, 2, \dots, N \quad (4.28)$$

Or, equivalently, in matrix form

Development in a structure and

$$B(\underline{T}) \stackrel{\wedge}{\underline{q}} (\underline{T}) = \underline{\gamma} (\underline{T}) \qquad (4.29)$$

where $\stackrel{\wedge}{q}(\underline{T})$ denotes the optimum \underline{q} , the vector

$$\underline{\gamma}(\underline{T}) = (\gamma, (\underline{T}), \gamma_2(\underline{T}), \dots, \gamma_N(\underline{T}))$$
(4.30)

has components

$$\gamma_{j}(\underline{T}) = \int_{T_{O}}^{T_{f}} d(t) \alpha_{j}(t; \underline{T}) dt, j = 1, 2, ---, N \qquad (4.31)$$

and the matrix B (T) has elements

$$p_{ij}(\underline{T}) = \int_{T_0}^{T_f} \alpha_i(t; \underline{T}) \alpha_j(t; \underline{T}) dt, i, j = 1, 2, \dots, N \quad (4.32)$$

Substituting the optimum $\frac{\Lambda}{q}$ (T) into (4.27) gives

$$E\left(\stackrel{\wedge}{\underline{q}}(\underline{T}), \underline{T}\right) = \int_{T_{O}}^{T_{f}} d^{2}(t) dt - \int_{T_{O}}^{T} d(t) \underline{\alpha}^{T}(t, \underline{T}) \cdot \stackrel{\wedge}{\underline{q}}(\underline{T}) dt \quad (4.33)$$

since the second integral of (4.27) is zero by way of (4.28).

Using the definition of γ (T) we can rewrite (4.33) as

$$E\left(\underline{q}\left(\underline{T}\right), \underline{T}\right) = \int_{T}^{T} d^{2}(t) dt - \underline{\gamma}^{T}\left(\underline{T}\right) \cdot \underline{q}\left(\underline{T}\right) \qquad (4.34)$$

Since the first term is independent of \underline{T} it will have no bearing on the generation of the optimum $\stackrel{\wedge}{\underline{T}}$. Consequently, we redefine the error criterion E as

$$E(\underline{T}) = \chi^{T}(\underline{T}) B^{-1}(\underline{T}) \chi(\underline{T})$$
(4.35)

which is the last term of (4.34).

Our objective is to maximize (4.35) with respect to the knot vector \underline{T} in the presence of the constraints

$$T_{i-1} \leq T_i, i = 1, 2, ---, m+1$$
 (4.36)

where $T_{m+1} = T_f$.

FARME S ANTERS

4.4 VARIOUS CASES OF THE QUADRATIC SPLINE OPTIMIZATION PROBLEM

The quadratic spline function r(t) is given by (4.14). In some problems the values of $r(T_0)$ and $r(T_f)$ are known a priori and in other problems the values of $r(T_0)$ and $\dot{r}(T_0)$ are known a priori. When this is the case such knowledge reduces the dimension of the coefficient vector \underline{q} . The following cases cover a spectrum of applications.

Case 1. No knowledge about r(t) is known a priori. In this case

$$\underline{\alpha} (t; \underline{T}) = \underline{a} (t; \underline{T}) \qquad (4.37)$$

$$\underline{\mathbf{q}} = \underline{\mathbf{p}} \tag{4.38}$$

<u>Case 2</u>. The values of $r(T_0)$ and $r(T_f)$ are known a priori:

$$r(T_0) = c_1$$
 (4.39)

$$r(T_f) = c_2$$
 (4.40)

For this case it is convenient to redefine the data d(t) as

$$\widetilde{d}(t) = d(t) - c_1 - (c_2 - c_1) \frac{(t - T_1)}{(T_f - T_0)}$$
 4.41)

and to define

$$\underline{q}^{T} = (\dot{r}_{1}, \dot{r}_{2}, \dots, \dot{r}_{m+1})$$
 (4.42)

and $\underline{\alpha}$ (t; T) with the components

$$\alpha_{j}(t; \underline{T}) = a_{j}(t; \underline{T}) - a_{j}(T_{f}; \underline{T}) \frac{(t - T_{o})}{(T_{f} - T_{o})}$$
(4.43)

for j = 1, 2, ---, m+1. This case with $c_1 = c_2 = 0$ applies to the ship classification application.

<u>Case 3</u>. The values $r(T_0)$ and $r(T_0)$ are known a priori:

$$r(T_0) = c_1$$
 (4.44)

$$\dot{r}(T_0) = c_3$$
 (4.45)

The data is redefined as

1

$$\widetilde{d}(t) = d(t) - c_1 - c_3 (t - T_0)$$
 (4.46)

In this case the vector function $\underline{\alpha}$ (t; T) and the coefficient vector \underline{q} are given by

$$\underline{\boldsymbol{\alpha}}^{\mathrm{T}}(\mathsf{t};\underline{\mathrm{T}}) = (\mathsf{a}_{1}(\mathsf{t};\underline{\mathrm{T}}), \mathsf{a}_{2}(\mathsf{t};\underline{\mathrm{T}}), \dots, \mathsf{a}_{m+1}(\mathsf{t};\underline{\mathrm{T}})) \qquad (4.47)$$

$$\underline{q}^{T} = (\dot{r}_{1}, \dot{r}_{2}, \dots, \dot{r}_{m+1})$$
 (4.48)

<u>Case 4</u>. The value of $r(T_0)$ is given a priori:

$$r(T_0) = c_1$$
 (4.49)

The data d(t) is redefined as

$$d(t) = d(t) - c_1$$
(4.50)

The vector function $\underline{\alpha}$ (t, \underline{T}) and the coefficient vector \underline{q} are defined as

$$\underline{\alpha}^{T}(t; \underline{T}) = (a_{1}(t; \underline{T}), a_{2}(t; \underline{T}), \dots, a_{m+1}(t; \underline{T}), a_{m+3}(t; \underline{T}) \quad (4.51)$$

$$\underline{q}^{T} = (\mathbf{\dot{r}}_{1}, \mathbf{\dot{r}}_{2}, \dots, \mathbf{\dot{r}}_{m+1}, \mathbf{\dot{r}}_{0}) \quad (4.52)$$

<u>Case 5</u>. The value of $r(T_0)$ and $r(T_f)$ are given a priori:

$$r(T_0) = c_3$$
 (4.53)

$$r(T_f) = c_2$$
 (4.54)

The data d(t) is redefined as

1

and multiply and any in a new site in

$$\tilde{d}(t) = d(t) - c_2 - c_3 (t - T_f)$$
 (4.55)

The vector function $\underline{\alpha}$ (t, \underline{T}) has components

$$\alpha_{j}(t; \underline{T}) = a_{j}(t; \underline{T}) - a_{j}(T_{f}; \underline{T})$$
(4.56)

for j = 1, 2, ---, m+1. The coefficient vector \underline{q} is defined as

$$\underline{q}^{T} = (\dot{r}_{1}, \dot{r}_{2}, \dots, \dot{r}_{m+1})$$
 (4.57)

<u>Case 6</u>. The value of $\dot{r}(T_0)$ is given a priori

 $r(T_0) = c_3$

The data d(t) is redefined as

1

entrone president

$$\widetilde{d}(t) = d(t) - c_3(t - T_0)$$

The vector function $\underline{\alpha}$ (t, \underline{T}) and the coefficient vector \underline{q} are defined as

$$\underline{\alpha}^{\mathrm{T}}(\mathrm{t}; \underline{\mathrm{T}}) = (\mathrm{a}_{1}(\mathrm{t}; \underline{\mathrm{T}}), \dots, \mathrm{a}_{\mathrm{m+2}}(\mathrm{t}; \underline{\mathrm{T}}))$$

$$\underline{q}^{\mathrm{T}} = (\mathbf{r}_{1}, \mathbf{r}_{2}, \dots, \mathbf{r}_{\mathrm{m+1}}, \mathbf{r}_{0})$$

CHAPTER V

SOLUTION TO POSED PROBLEM - AN OPTIMAL SPLINE METHOD

The problem is to maximize $E(\underline{T})$ of (4.35) with respect to the knot vector \underline{T} . Several gradient methods are available for carrying out the optimization: steepest descent, Newton-Raphson, Newton, Gauss-Newton, Fletcher-Powell and Davidon. Newton's method is appealing because of its quadratic convergence properties. It can be implemented since the Hessian matrix is analytically computable.

The derivative
$$\frac{\partial E(\underline{T})}{\partial \underline{T}}$$
 has a Taylor series expansion
 $\frac{\partial E(\underline{T}^{b})}{\partial \underline{T}} = \frac{\partial E(\underline{T}^{a})}{\partial \underline{T}} + \frac{\partial^{2} E(\underline{T}^{a})}{\partial \underline{T}^{2}} (\underline{T}^{b} - \underline{T}^{a})$

+ higher order terms (5.1)

If $E(\underline{T})$ has a maximum at $\underline{T} = \underline{T}^{b}$ then

I sin now go a work the case

$$\frac{\partial E(\underline{T}^{b})}{\partial T} = 0$$
 (5.2)

In addition, if the higher order terms are sufficiently small compared to the other terms of (5.1) then \underline{T}^{b} can be approximated by

$$\underline{\mathbf{T}}^{\mathrm{b}} = \underline{\mathbf{T}}^{\mathrm{a}} - \left[\frac{\partial^{2} \mathbf{E}(\underline{\mathbf{T}}^{\mathrm{a}})}{\partial \underline{\mathbf{T}}^{2}}\right]^{-1} \qquad \frac{\partial \mathbf{E}(\underline{\mathbf{T}}^{\mathrm{a}})}{\partial \mathbf{T}} \qquad (5.3)$$

Sufficient conditions for the existence of a local maximum value of $E(\underline{T})$ at $\underline{T} = \underline{T}^{b}$ are given in [14, 15] and are that (5.2) is satisfied and that

$$D_i \ge 0, i = 2, 4, 6, ---$$
 (5.4)

$$D_i < 0, i = 1, 3, 5, ---$$
 (5.5)

where

$$D_{i} = \begin{cases} E_{11} & E_{12} & \cdots & E_{1i} \\ E_{21} & E_{22} & \cdots & E_{21} \\ & & & & \\ E_{i1} & E_{i2} & \cdots & E_{ii} \end{cases}$$

$$E_{nk} = \frac{\partial^{2} E(\underline{T}^{b})}{\partial T_{n} \partial T_{k}} , n, k = 1, 2, \dots, i \qquad (5.7)$$

Since the higher order terms are seldom zero the optimal value \underline{T} is obtained through convergence. That is, if $\underline{T}^{a} = \underline{T}^{k}$ represents the solution of (5.3) for the kth iteration and if $\underline{T}^{b} = \underline{T}^{k+1}$ represents the solution of (5.3) for the (k+1)th iteration then

$$\frac{\hat{T}}{\underline{T}} = \lim_{k \to \infty} \lim_{\infty} \frac{T^{k+1}}{(5.8)}$$

Since

$$\stackrel{\wedge}{\underline{q}}(\underline{T}) = B^{-1}(\underline{T}) \underline{\gamma}(\underline{T})$$
(5.9)

we can rewrite E(T) in the following forms

$$E(\underline{T}) = \underline{q}^{T}(\underline{T}) \underline{\gamma} (\underline{T})$$

$$= \underline{\gamma}^{T}(\underline{T}) \underline{q} (\underline{T})$$
(5.10)
(5.11)

In much of the following development the argument \underline{T} will be left out of the various functions such as E, $\stackrel{\wedge}{q}$, $\underline{\gamma}$, B and their derivatives.

The vector
$$\frac{\partial E}{\partial T}$$
 has components $\frac{\partial E}{\partial T_1}$, $\frac{\partial E}{\partial T_2}$, \dots , $\frac{\partial E}{\partial T_m}$

These components are given by, k = 1, 2, ---, m,

$$\frac{\partial E}{\partial T_{k}} = 2 \frac{A}{q} \frac{\partial \gamma}{\partial T_{k}} - \frac{A}{q} \frac{\partial B}{\partial T_{k}} \frac{A}{q}$$
(5.12)

which is obtained by use of the identify

$$\frac{\partial B^{-1}}{\partial T_k} = -B^{-1} \frac{\partial B}{\partial T_k} B^{-1}$$
(5.13)

The elements of the matrix $\frac{\partial^2 E}{\partial T^2}$ are

given by, k, n = 1, 2, ---, m,

Sector File and

$$\frac{\partial^{2}E}{\partial T_{k}\partial T_{n}} = 2 \left\{ \frac{\partial \underline{\gamma}^{T}}{\partial T_{n}} B^{-1} \frac{\partial \underline{\gamma}}{T_{k}} + \underline{q}^{T} \frac{\partial^{2} \underline{\gamma}}{\partial T_{k}\partial T_{n}} \right.$$
$$- \frac{AT}{\underline{q}} \frac{\partial B}{\partial T_{n}} B^{-1} \frac{\partial \underline{\gamma}}{\partial T_{k}} - \underline{q}^{T} \frac{\partial B}{\partial T_{k}} B^{-1} \frac{\partial \underline{\gamma}}{\partial T_{n}}$$
$$+ \frac{AT}{\underline{q}} \frac{\partial B}{\partial T_{k}} B^{-1} \frac{\partial B}{\partial T_{k}} B^{-1} \frac{\partial \underline{\gamma}}{\partial T_{n}} \left. (5.14) \right]$$

Consequently, in order to solve (5.3) we need the following computed for k, n = 1, 2, ---, m:

$$\chi, B, B^{-1}, \frac{\Delta}{q}$$

$$\frac{\partial \chi}{\partial T_{k}}, \frac{\partial B}{\partial T_{k}}$$

$$\frac{\partial^{2} \chi}{\partial T_{k} \partial T_{n}}, \frac{\partial^{2} B}{\partial T_{k} \partial T_{n}}$$

7

And and St. Halto P. G. H.

Expressions for the above quantities can be derived for each case discussed in Section 4.4. These expressions are derived for Case 1 in Chapters VI and VII.

CHAPTER VI

ANALYTICAL EXPRESSIONS FOR THE QUANTITIES OF CASE 1

6.1 The B Matrix

The elements of the symmetric matrix B are given by

$$b_{ji} = \int_{T_0}^{T_f} a_j(t) a_i(t) dt$$

for j, i = 1, 2, -----, m+3 where the a's are defined by (4.18) - (4.20). The argument \underline{T} has been dropped.

For i = 1, 2, ---, m+1, define

$$Z_i = T_i - T_{i-1}$$
 (6.1)
 $S_i = T_f - T_i$ (6.2)

For i = 1, 2, ---- , m+1 the following equations can be derived:

$$b_{ii} = \frac{Z_i^5}{20} + \frac{Z_i^4}{4} S_i + \frac{Z_i^3}{2} S_i^2 + \frac{Z_i^2}{3} S_i^3$$
(6.3)

For i = 1, 2, --- , m the following equation holds:

$$b_{i(i+1)} = Z_{i} Z_{i+1} \left\{ \frac{Z_{i+1}^{2}}{12} \left[\frac{Z_{i+1}}{2} + Z_{i} \right] + \frac{S_{i}^{3}}{3} + \frac{S_{i}}{4} \left[Z_{i} S_{i+1} - Z_{i+1} S_{i} \right] \right\}$$
(6.4)

The following equation has been derived for i = 1, 2, --, m-1;

j = i + 2, ---, m + 1:

I

1

France presentition

$$b_{ij} = \frac{Z_i Z_j}{2} \{ (S_i + \frac{Z_i}{2}) [S_j (S_j + Z_j) + \frac{Z_j^2}{3}] + \frac{(S_j^2 - 1 + Z_j^2)}{3} (S_j - \frac{Z_j}{2}) - \frac{5}{12} Z_j^3 \}$$
(6.5)

Equations (6.6) and 6.7) hold for i = 1, 2, ---, m+1.

$$b_{i(m+2)} = \frac{Z_i^3}{6} + \frac{Z_i^2}{2} S_i + \frac{Z_i}{2} S_i^2$$
 (6.6)

6.6 The γ Vector

Break more providently can

The elements of $\underline{\gamma}$ are given by

$$\gamma_j = \int_{T_0}^{T_f} d(t) a_j(t) dt$$
 (6.51)

for $j = 1, 2, \dots, m+3$. Since the data d(t) is given in discrete form rather than continuously we write the discrete form of (6.51) as

$$\gamma_{j} = \frac{T_{f} - T_{o}}{I} \sum_{i=1}^{L} d_{i} a_{j} (t_{i})$$
(6.52)

where I is the number of data points and where

$$d_i = d(t_i), i = 1, 2, ---, I$$
 (6.53)

$$\mathbf{t}_{\mathbf{i}+\mathbf{j}} = \mathbf{t}_{\mathbf{j}} + \Delta \mathbf{t} \tag{6.54}$$

$$\Delta t = \frac{T_f - T_o}{I}$$
(6.55)

$$t_1 = T_0 + \frac{\Delta t}{2}$$
 (6.56)

$$t_{I} = T_{f} - \frac{\Delta t}{2}$$
(6.57)

For j = 1, 2, ---, m define the integer J(j) so that it satisfies the inequalities

$$t_{J(j)} \leq T_j < t_{J(j)+1}$$
 (6.58)

Consequently, γ_1 is given by

$$\gamma_{1} = \frac{(T_{f} - T_{o})}{I} \left\{ \begin{array}{c} J(1) \\ \Sigma \\ i=1 \end{array} d_{i} \frac{(t_{i} - T_{o})^{2}}{2} + \\ Z_{1} \\ \sum_{i=J(1)+1}^{L} d_{i}t_{i} + Z_{1} \frac{(Z_{1} - T_{1})}{2} \\ i=J(1)+1 \end{array} \right\} (6.59)$$

For j = 2, 3, ---, m, γ_j is given by

$$\gamma_{j} = \frac{(T_{f} - T_{o})}{I} \{ \begin{array}{c} J(j) \\ \Sigma \\ i=J(j-1)+1 \end{array} d_{i} \quad \frac{(t_{i} - T_{j-1})^{2}}{2} + \\ Z_{j} \quad \begin{array}{c} I \\ \Sigma \\ i=J(j)+1 \end{array} d_{i}t_{i} + Z_{j} \left(\begin{array}{c} Z_{j} \\ 2 \end{array} - T_{j} \right) \quad \begin{array}{c} I \\ \Sigma \\ i=J(j)+1 \end{array} d_{i} \} \quad (6.60)$$

Furthermore, γ_{m+1} is given by

m pracoverse.

$$\gamma_{m+1} = \frac{(T_f - T_o)}{I} = \frac{\Sigma}{i=J(m)+1} d_i = \frac{(t_i - T_m)^2}{2}$$
 (6.61)

and, γ_{m+2} and γ_{m+3} have the equations

$$\gamma_{m+2} = \frac{(T_f - T_o)}{I} \qquad \begin{array}{c} I \\ \Sigma \\ i=1 \end{array} \qquad (6.62)$$

$$\gamma_{m+3} = \frac{(T_f - T_o)}{I} = \frac{I}{\sum_{i=1}^{\Sigma} d_i (t_i - T_o)}$$
 (6.63)

6.7 The
$$\frac{\circ \underline{\gamma}}{\partial T_k}$$
 Vector for k = 1, 2, ---, m

The elements of $\frac{\partial \gamma}{\partial T_k}$ are denoted by

$$\frac{\partial \gamma_j}{\partial T_k} = \gamma_j, k \qquad (6.64)$$

From (6.59) - (6.61) we derive

1

at count and been go and the top and

$$\gamma_{j, k} = 0 \quad j = 1, 2, \dots, k-1$$
 (6.65)

$$\gamma_{k, k} = \frac{(T_{f} - T_{o})}{I} \sum_{\substack{i=J(k)+1}}^{I} d_{i} (t_{i} - T_{k})$$
 (6.66)

$$\gamma(k+1), k = -\gamma_{k, k}$$
(6.67)

$$\gamma_{j, k} = 0 \quad j = k+2, \dots, m+3$$

$$\frac{\partial^2 \gamma}{\partial T_k \partial T_n}$$
 Vector for n=1, 2, ---, m; k=n, n+1, ---, m

The elements of $\frac{\partial^2 \gamma}{\partial T_k \partial T_n}$ are denoted by

$$\frac{\partial^2 \gamma_j}{\partial T_k \partial T_n} = \gamma_j, \ kn \tag{6.69}$$

For $k \neq n$ we note that

$$\gamma_{j, kn} = 0, j = 1, 2, ---, m+3$$
 (6.70)

For k = n we can check that

- Produce grandstilling

$$\gamma_{j, nn} = 0 \text{ unless } j = n \text{ or } n+1$$
 (6.71)

$$\gamma_{n, nn} = - \frac{(T_f - T_o)}{I} \sum_{\substack{i=J(n)+1}}^{I} d_i$$
 (6.72)

$$\gamma_{(n+1), nn} = -\gamma_{n, nn} \tag{6.73}$$

CHAPTER VII

ANALYTICAL EXPRESSIONS FOR
$$\frac{\partial E}{\partial T_k}$$
 and $\frac{\partial^2 E}{\partial T_k \partial T_n}$

In Section 6.7 it is shown that the vector $\frac{\partial \gamma}{\partial T_k}$ has at most two nonzero components. In Section 6.2 it is shown that the matrix $\frac{\partial B}{\partial T_k}$ has at most two nonzero rows and two nonzero columns. The sparseness of the nonzero elements in these vectors and matrices greatly facilitates the calculations of $\frac{\partial E}{\partial T_k}$ and $\frac{\partial^2 E}{\partial T_k \partial T_n}$. The formulas for these derivatives are given in this section.

It is convenient to make the following definitions for n = 1, 2, ---, m; k = 1, 2, ---, m:

$$A_{n} = \sum_{j=1}^{m+3} b_{jn, n} q_{j} - (q_{n} - q_{n+1}) b_{nn, n}$$
(7.1)

$$C_{n} = \sum_{i=1}^{m+3} b_{in, nn} q_{i} - (q_{n} - q_{n+1}) b_{nn, nn}$$
(7.2)

$$f_{nk} = h_{nk} - h_{n(k+1)} + h_{(n+1)(k+1)}$$
 (7.3)

$$F_{nk} = \sum_{i=1}^{m+3} \sum_{j=1}^{m+3} b_{in, n} b_{jk, k} h_{ij}$$
(7.4)

$$G_{nk} = \sum_{i=1}^{m+3} b_{in, n} (h_{ik} - h_{i(k+1)})$$
(7.5)

where the matrix H is given by

Visit town in a second the on

$$H = B^{-1}$$
 (7.6)

with elements h_{ij} , i, j = 1, 2, ---, m+3.

Note that

and a second second

$$b_{kk, k} + b_{(k+1)(k+1), k} = -2 b_{k(k+1), k}$$
 (7.7)

$$b_{nn, nn} + b_{(n+1)(n+1), nn} = -2 b_{n(n+1), nn}$$
 (7.8)

The following analytical expressions have been derived, having made use of (7.7) and (7.8):

$$\stackrel{\wedge}{\underline{q}}^{\mathrm{T}} = \stackrel{\partial \gamma}{\underline{\partial T}_{k}} = (q_{k} - q_{k+1}) \gamma_{k, k}$$
(7.9)

$$\stackrel{\wedge T}{=} \frac{\partial B}{\partial T_k} \stackrel{\wedge}{=} 2(q_k - q_{k+1}) A_k + (q_k - q_{k+1})^2 b_{kk, k}$$
(7.10)

$$\frac{\partial E}{\partial T_{k}} = 2 (q_{k} - q_{k+1}) (\gamma_{k, k} - A_{k}) - (q_{k} - q_{k+1})^{2} b_{kk, k}$$
(7.11)

$$\frac{q^{T}}{q} \frac{\partial^{2} \gamma}{\partial T_{k} \partial T_{n}} = 0 \text{ for } k \neq n$$
(7.12)

$$\frac{q^{T}}{\partial T_{n}^{2}} = \gamma_{n, nn} (q_{n} - q_{n+1})$$
(7.13)

$$\frac{\partial \gamma^{T}}{\partial T_{n}} B^{-1} \frac{\partial \gamma}{\partial T_{k}} = \gamma_{n, n} \gamma_{k, k} f_{nk}$$
(7.14)

$$\stackrel{\text{AT}}{=} \frac{\partial B}{\partial T_k} = B^{-1} \frac{\partial \gamma}{\partial T_k} = \gamma_{k, k} [(q_n - q_{n+1}) G_{nk} + f_{nk} A_n]$$
(7.15)

$$\frac{\stackrel{\wedge}{\mathbf{T}}}{\underline{\mathbf{q}}} \frac{\partial \mathbf{B}}{\partial \mathbf{T}_{k}} = \frac{\mathbf{a} \mathbf{T}_{k}}{\frac{\partial \mathbf{T}_{n}}{\partial \mathbf{T}_{n}}} = \gamma_{n, n} \left[(\mathbf{q}_{k} - \mathbf{q}_{k+1}) \mathbf{G}_{kn} + \mathbf{f}_{nk} \mathbf{A}_{k} \right]$$
(7.16)

For n = 1, 2, ---, m-1 and k = n+1, n+2, ---, m it can be shown that (7.17) holds:

$$\stackrel{\wedge T}{=} \frac{\partial^2 B}{\partial T_k \partial T_n} \stackrel{\wedge}{=} 2 b_{nk, kn} (q_n - q_{n+1}) (q_k - q_{k+1})$$
(7.17)

For n = k it can be verified that (7.18) holds:

$$\frac{\Delta T}{\underline{q}} \frac{\partial^2 B}{\partial T_n^2} \frac{\Delta}{\underline{q}} = 2(q_n - q_{n+1}) C_n$$
(7.18)

$$\frac{A^{T}}{q} \frac{\partial B}{\partial T_{n}} = B^{-1} \frac{\partial B}{\partial T_{k}} \frac{A}{q} = A_{n} A_{k} f_{nk} + (q_{n} - q_{n+1}) A_{k} G_{nk} + (q_{k} - q_{k+1}) A_{n} G_{kn} + (q_{n} - q_{n+1}) (q_{k} - q_{k+1}) F_{nk}$$
(7.19)

Consequently, it follows from (7.12), (7.14) - (7.17) and (7.19) that the following Equation (7.20) holds for k = n and Equation (7.21) holds for $k \neq n$:

$$\frac{\partial^{2} E}{\partial T_{n}^{2}} = 2 \{ f_{nn} (A_{n} - \gamma_{n, n})^{2} + (q_{n} - q_{n+1}) [\gamma_{n, nn} - C_{n} + (q_{n} - q_{n+1}) F_{nn} + 2 G_{nn} (A_{n} - \gamma_{n, n})] \}$$
(7.20)

$$\frac{\delta^{2} E}{\delta^{T}_{k\delta} T_{n}} = 2 \{ f_{nk} (A_{n} - \gamma_{n, n}) (A_{k} - \gamma_{k, k}) + (q_{n} - q_{n+1}) (q_{k} - q_{k+1}) (F_{nk} - b_{nk, kn}) + (q_{k} - q_{k+1}) G_{kn} (A_{n} - \gamma_{n, n}) + (q_{n} - q_{n+1}) G_{nk} (A_{k} - \gamma_{k, k}) \}$$
(7.21)

 (8.24)

$$\beta_{(n+2)(n+1)}, (n+1)n = \beta_{n(n+1)}, (n+1)n$$
 (8.25)

$$\beta_{(n+2)(n+2), (n+1)n} = 0 \tag{8.26}$$

8.5 The
$$\frac{\partial^2 B}{\partial T_k \partial T_n}$$
 Matrix for k = n+2, ---, m; n = 1, 2, ---, m-2.

The elements of
$$\frac{\partial^2 B}{\partial T_k \partial T_n}$$
 are denoted by
 $\frac{\partial^2 \beta_{ij, kn}}{\partial T_k \partial T_n} = \beta_{ij, kn}$
(8.27)

Since B is symmetric we consider only those elements β_{ij} with $i \leq j$.

$$\beta_{ij, kn} = 0$$
 unless $i = n \text{ or } n+1 \text{ and } j = k \text{ or } k+1$ (8.28)

$$\beta_{nk, nk} = b_{nk, nk} - \frac{S_k b_{(m+3)n, n}}{(T_f - T_o)} +$$

$$S_n \left[\frac{S_k b_{(m+3)(m+3)}}{(T_f - T_o)^2} - \frac{b_{(m+3)k, k}}{(T_f - T_o)} \right] \quad (8.29)$$

8.6 The § Vector

The elements of $\underline{\mathbf{\delta}}$ are given by

$$\delta_{j} = \int_{T_{O}}^{T} f d(t) \alpha_{j}(t) dt \qquad (8.30)$$

for j = 1, 2, ---, m+1. Making use of (4.43) we obtain

$$\delta_{j} = \gamma_{j} - \frac{a_{j}\gamma_{m+3}}{(T_{f} - T_{o})}$$
, $j = 1, 2, ---, m+1$ (8.31)

8.7 The
$$\frac{\partial \mathbf{\hat{0}}}{\partial T_k}$$
 Vector for k = 1, 2, ---, m.

The elements of $\frac{\partial \underline{\delta}}{\partial T_k}$ are denoted by

$$\frac{\partial \delta_j}{\partial T_k} = \delta_{j, k}$$
(8.32)

It can be shown that

$$\boldsymbol{\delta}_{j, k} = 0 \quad j = 1, 2, \dots, k-1, k+2, \dots, m+1$$
 (8.33)

65

The Equations (8.34) and (8.35) hold for j = 1, 2, --, m:

$$\delta_{j, j} = \gamma_{j, j} - \frac{S_j}{(T_f - T_o)} \alpha_{m+3}$$
(8.34)

$$\delta_{(j+1), j} = -\delta_{j, j}$$
 (8.35)

8.8 The
$$\frac{\partial^2 \mathbf{\delta}}{\partial T_k \partial T_n}$$
 Vector for n = 1, 2, ---, m; k = n, n+1, ---, m.

The elements of $\frac{\partial^2 \underline{\delta}}{\partial T_k \partial T_n}$ are denoted by

$$\frac{\partial^2 \boldsymbol{\delta}_j}{\partial T_k \partial T_n} = \boldsymbol{\delta}_{j, kn}$$
(8.36)

For $k \neq n$ we note that

1

Friday & Alberty

$$\delta_{j, kn} = 0$$
, $j = 1, 2, ---, m+1$ (8.37)

For k = n we can verify that

$$\delta_{j, nn} = 0$$
 unless $j = n \text{ or } n+1$ (8.38)

$$\delta_{n, nn} = \gamma_{n, nn} + \frac{\gamma_{m+3}}{(T_f - T_o)}$$
 (8.39)

$$\delta_{(n+1), nn} = -\delta_{n, nn}$$
 (8.40)

The analytical expression of $\frac{\partial E}{\partial T_k}$ and $\frac{\partial^2 E}{\partial T_k \partial T_n}$ for Case 2 have the same form as given in Chapter VII. It is only necessary to substitute $\underline{\delta}$ for $\underline{\gamma}$ and $\underline{\beta}$ for b. It is important to modify the data d(t) according to Equation (4.41) before computing the vector $\underline{\delta}$ and its derivatives of Section 6.6 - 6.8 for their use in Sections 8.6 - 8.8.

I shall be mar and the self can

CHAPTER IX

ANALYTICAL EXPRESSIONS FOR THE QUANTITIES OF CASES 3-6.

The analytical expressions for Cases 3 and 4 are the same as for Case 1; the only differences are (1) the dimension of the vectors \underline{q} and $\underline{\alpha}$ and (2) the summations of Equations (7.1, 7.2, 7.4 and 7.5) are carried out over the dimension of \underline{q} . Case 6 is similar.

9.1 The B Matrix for Case 5

The elements of the symmetric matrix B are given by

$$\beta_{ij} = b_{ij} - a_j b_{(m+2)i} - a_i b_{(m+2)j} + a_i a_j b_{(m+2)} (m+2)$$
 (9.1)

where the a_i 's are defined by (8.3) and the b's are given in Section 6.1. Comparing (9.1) with (8.2) we note that the analytical expressions of B and its derivatives have the same form as in Case 2; it is only necessary to make the following substitutions together with their partial derivatives:

substitute
$$b_{(m+2)}(m+2) = \frac{\text{for } b_{(m+3)}(m+3)}{(T_f - T_o)^2}$$
 (9.2)
substitute $b_{j(m+2)} = \frac{\text{for } b_{j(m+3)}}{(T_f - T_o)}$.

9.2 The <u>8</u> Vector for Case 5

The elements of $\underline{\kappa}$ are given by

$$\kappa_{j} = \gamma_{j} - \alpha_{j} \gamma_{m+2}, \quad j = 1, 2, ---, m+1$$
 (9.4)

Consequently, in view of Equation (8.31) the analytical expressions for $\underline{\Lambda}$ and its derivatives in Case 5 have the same form as Case 2; it is only necessary to make the following substitution together with its derivatives:

substitute
$$\gamma_{m+2}$$
 for $\frac{\gamma_{m+3}}{(T_f - T_o)}$ (9.5)

It is necessary to modify the data d(t) according to Equations (4.46, 4.50 and 4.55) before computing the $\underline{\gamma}$ and its derivatives of Sections 6.6 - 6.8 for their use in Cases 3-5.

CHAPTER X

PROCEDURE FOR STARTING ESTIMATES OF KNOTS

In this section we describe a method for generating a starting estimate for the minimum number of knots and starting estimates for the knot values.

10.1 A Procedure for Estimating the Minimum Number of Knots

Let M be an integer and let the knots \widetilde{T}_i , i = 1, 2, ---, M be equally spaced across the time interval $[T_0, T_f]$. Equation (4.29) or (5.9) can be solved for the values of q_i , i = 1, 2, ---, M+3. The error $E(\underline{q}, \underline{\widetilde{T}})$ can be computed using Equation (4.24). If the error falls outside a required degree of accuracy then the value of M is increased until the computed error lies within a required degree of accuracy. When this is the case the spline coefficients q_i , i = 1, 2, ---, M+1 are sequentially grouped in order, timewise, according to positive or negative values. For example, if q_1 is positive, q_2 , q_3 and q_4 negative and q_5 and q_6 positive with q_7 negative then q_1 forms the first group, q_2 , q_3 , and q_4 the second group and q_5 and q_6 the third groups, etc. A single spline region is designated to span each group of positive values. The same is true for each series of negative values. The number of groups determine the starting estimate for the minimum number of knots. Let m+1 represent the number of such groups.

10.2 A Starting Estimates Procedure for the Knot Locations

The times separating the above groups provide excellent starting estimates for the knot locations. For example, the times

$$t_{2} = \widetilde{T}_{4}$$

$$t_{3} = \widetilde{T}_{6}$$

$$\vdots$$

$$t_{m} = \widetilde{T}_{i}, \text{ for some } j$$

 $t_1 = \widetilde{T}_1$

can be used as excellent starting estimates for the sequence of knots $T_1, T_2, T_3, \ldots, T_m$ that are used in the Optimal Spline Method of Chapters VI-IX.

With reference to Equation (4.1) let σ^2 denote the variance of the data to be splined. In the system identification of aircraft the following procedure works well for estimating the minimum of knots and for providing starting estimates of the knot locations. The knots are recursively located so that the RMS value between the data and the spline fit is approximately equal to σ over each spline region. This is accomplished by placing the first knot so that the first spline region is the maximum of all spline intervals that have an associated RMS less or equal to σ . Each succeeding knot is similarly placed.

ristron is not a loss

CHAPTER XI

CONCLUSIONS

An automated technique called the Optimal Spline Method has been developed for application to problems having high nonlinearities. Its application to ship classification and to aircraft system identification has solved a major problem in each of those technological areas. These are: (a) the development of a technique to determine independent features for classification of ship types and (b) the development of a method that minimizes the number of parameters that are necessary for optimal estimation of force and moment time histories in aircraft system identification.

The Optimal Spline Method in ship classification applications determines the number of separate superstructure masses, their separation from each other, their locations and their extended widths. These independent features correspond directly to optimal spline coefficients of the method. The results contained in Chapter II show that ships of like type have similar optimal spline coefficients and ships of different types exhibit large differences in their optimal spline coefficients. In particular, it is shown that the optimal spline coefficients provide a clear destinction between a DLG class and a DDG class.

In aircraft system identification applications the use of the Optimal Spline Method has two advantages. They are: (a) the computions and the storage requirement of the estimation process can be significantly reduced without a decrease in estimation performance and (b) an increase in estimation and, therefore, in identification performances can be achieved under the constraint of a fixed number of spline parameters. Advantage (b) is demonstrated by the results contained in Figures 3-1 through 3-4. Figure 3-4 shows the results of using eight equally spaced knots. The increase in performance due to the application of the Optimal Spline Method is shown in Figure 3-2. Advantage (a) is indirectly demonstrated by the results contained in Figures 3-1 through 3-4. In Figure 3-2 the third and fourth knots are separated by 0.82 seconds. In order to obtain equivalent performance through the use of equally spaced knots it is necessary to space them at approximately 0.82 seconds. This spacing increases the number of knots from eight to more than sixteen. The computations and the storage requirement increase exponentially with the number of knots.
