DISTRIBUTION STATEMENT A Approved for public release; Distribution Unlimited Robert Clifford Hilb, son of Theodore Robert and Marjory (Hayes) Hilb, was born April 21, 1948, in Plainfield, New Jersey. He attended Westfield Public Schools and graduated from Westfield Senior High School, Westfield, New Jersey in 1966. In June, 1966, he entered the United States Air Force Academy and received the degee of Bachelor of Science in Engineering Sciences (Astronautics and Computer Science) and a commission as a Second Lieutenant in the United States Air Force in June, 1970. After of a number assignments in the U. S. Air Force, he was sent by the Air Force Institute of Technology to the Graduate School, Auburn University. He married Barbara, daughter of Earl Easten and Louise (Currier) Hawkins in June, 1970.

THESIS ABSTRACT A PRE-PROCESSOR FOR A STRUCTURED VERSION OF COBOL

Robert Clifford Hilb

Master of Science, March 17, 1977 (B.S., U.S. Air Force Academy, 1970)

77 Typed Pages

Directed by Bruce E. Herring

A version of COBOL that permits structured programming was designed. It was implemented using a pre-processor that outputs standard COBOL. The pre-processor will indiscriminately run programs that are either structured or nonstructured, or with very limited restrictions, programs with a mixture of both. A structured IF was included as a modification of the COBOL IF. In line looping was created with a redefinition of the PERFORM, maintaining all of its capabilities and adding a DO UNTIL. The PERFORM was also modified to allow a CASE construct. All new structures are completely nestable.

I. INTRODUCTION

Structured Programming is one of the generally accepted methods of reducing software costs, both of acquisition and maintenance, while improving program quality. Until very recently the high cost of hardware relative to software resulted in the development of software that minimized the need for and, as a result, the cost of hardware. Today the situation is reversed and in the future it is predicted to

even more one-sided. With the concentration on co-technology development, the size and cost of computer hardware has made a quantum jump downward while the available core has increased almost as much. At the same time, the size and complexity of problems that can be programmed have greatly increased. Almost everyone in the computer field, especially those in management who have seen their budgets and cost estimates for software development and maintenance soar out of sight, have realized something must be done.

According to McGowan (1975), in 1975 the U.S. Air Force estimated that 65% of its computer costs went towards software and by 1985 95% will. He estimated that overall 10 billion dollars was spent on software in 1975. Gansler

(1976) stated that U. S. Air Force avionics software development costs were \$75 per instruction while maintenance of the same software was close to \$4000 per instruction. A method that has been shown by Baker (1972a) to not only reduce initial development costs but more importantly to reduce the time and cost of debugging and increase maintainablity is top down structured programming. It was Dijkstra (1968) who first formalized structured programming into a programming discipline. However, it is a method of programming that was probably unconsciously used by the best ALGOL programmers for years.

When PL/I, SIMSCRIPT and other second generation languages were developed¹, the facilities for structured programming were included, again unconsciously since the tenants of structured programming had not been formulated at the time. Of the three early languages, ALGOL had the only real facility for structured programming. Unfortunately, due to its poor implementation and the opposition and competition from a major U. S. producer of hardware and software, it was and is the least used of the three. Most programming is still done in FORTRAN or COBOL. These were languages that were originally designed to run very quickly

¹For the purposes of this thesis, FORTRAN, ALGOL, and COBOL are defined as first generation languages and the other major languages that were developed, or else redeveloped, like SIMSCRIPT was, from the mid 60's on, as second generation languages.

in small computers. They were and still are seriously lacking in ease of designability and maintainability, and as a result often have poor reliability. Due to its widespread use in academia and utter incompatability to the methods of structured programming, many changes for FORTRAN have been recommended. Some have been implemented in both preprocessors and, for some vendors, in compilers.

COBOL has been a different story. According to Yourdon (1975c), little has been done for COBOL because of disdain for it by the academic community and the lack of research that is done by the business community in language design. However, recently there has been widespread support for changes to COBOL. In April of 1975 a conference was held by the Programming Language Committee of CODAYSL1, the Symposium on Structured Programming in COBOL-Future and Present. Many proposals were put forth by the participants, ranging from not changing COBOL at all (a minute minority) to changing it so much that it would resemble PL/I. By the end of the conference it was generally agreed that some changes were needed, although no agreement was reached on exactly what changes should be made. The changes are not close to happening. One participant, Edward Yourdon (1975b) predicted that it would be 1978 or 1979, at the earliest,

¹CODOSYL, the <u>CO</u>nference <u>On DA</u>ta <u>SY</u>stems <u>L</u>anguage, is the body which governs the specification of the COBOL language.

before any changes would be reflected in any new versions of COBOL.

Statement of the Problem

The purpose of this study was to design a structured version of COBOL and implement it using a pre-processor. Structured programming in PL/I was used to design and implement the pre-processor. The considerations used to design the structures were: (1) as much as possible redefinitions of existing COBOL structures were used, (2) any new verbs or structures were patterned after existing COBOL structures, and (3) all existing programs could be run against the preprocessor with no changes.

Rather than drastically change the COBOL language, which would, most likely, produce resistance from experienced programmers, a gradual change would allow a more orderly transition to a fully structured COBOL. The changes made here are an addition to, rather than a change to, COBOL. This will allow the training of new programmers in structured programming while slowly transitioning the old programmers. All of the basic structured programming structures are included in this version of COBOL. As a future proposal other refinements can be added. Of course, too drastic a change to COBOL would result in a language so similiar to PL/I that PL/I could be used instead. However, due to the large investment in existing COBOL programs, it will not be economically feasible, at the present, and prob-

ably not for the forseeable future, to replace COBOL. Therefore, not only is a version of COBOL needed that will allow structured programming, but also one that will run all existing COBOL programs. When maintenance is done on existing programs the new structures should be able to be intermixed with the old. No distinction should be necessary between old and new programs; they should all run under the same job control language including the pre-processor. The route taken in this study is, then, to extend the meaning of certain COBOL verbs, while keeping all previous meanings, and adding some minor terminators and optional modifiers for clarity.

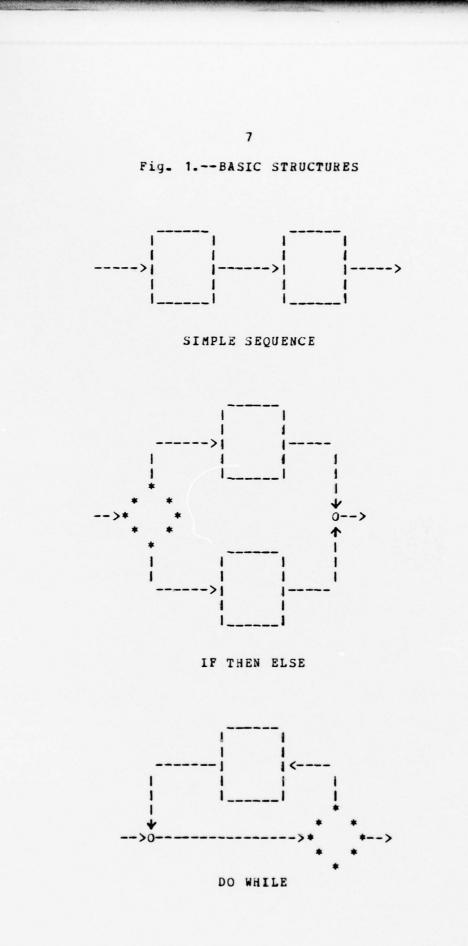

Literature Search

Many books and papers have been written on structured programming. In fact, it is probably the favorite subject of both programming theoriticians and practitioners at the present time. COBOL has been used almost strictly by the business community. Until recently this has resulted in the absence of research on the subject as cited before in Yourdon (1975c). The theoretical foundations for structured programming in any language were laid in 1966.

Bohm and Jacopini (1966) showed that any program with one entry and one exit (that is, an algorithmic solution to a problem as almost all programs are) could be programmed with only the following three logic structures: simple sequence, conditional branch to two choices (IF THEN ELSE),

and iteration (DO WHILE) (Fig. 1). Put more simply, any program, no matter what its complexity, can be written with a combination of these three structures. Dijkstra (1968) took their basic theory and developed a practical programming methodology.

The Structured Programming presented by Dijkstra includes using only the above three structures. Any program can be developed by the appropriate nesting of these structures. The flow of program control must include single entrance and exit with no branching out of the flow allowed. Most practitioners advocate the black box or modular concept (McGowan, 1975), where each module, subroutine, function, etc. is a small easily understood section of code. Many recommend that the size be one page or less. This allows for both easy debugging and maintenance. The concept is also fundamental for top down programming. This also eliminates the forward and backward referencing of either the basic or conditional GO TO. Dijkstra (1972) maintains, and it seems obvious, that any type of branching out of the logic flow not only causes the logic of the programming to be hard to follow but is also a chief cause of error. To add to both the understandability and readability of programs, both indentation and documentation are also required. For example,

```
PERFORM Z100 UNTIL A.
  z100-
      IF B THEN
      IF D THEN E
      ELSE F
      ELSE G.
is much harder to follow than
      PERFORM UNTIL A.
           IF B THEN
                IF D THEN
                      E
                 ELSE
                      F
                 END-IF
           ELSE
                G
           END-IF
```

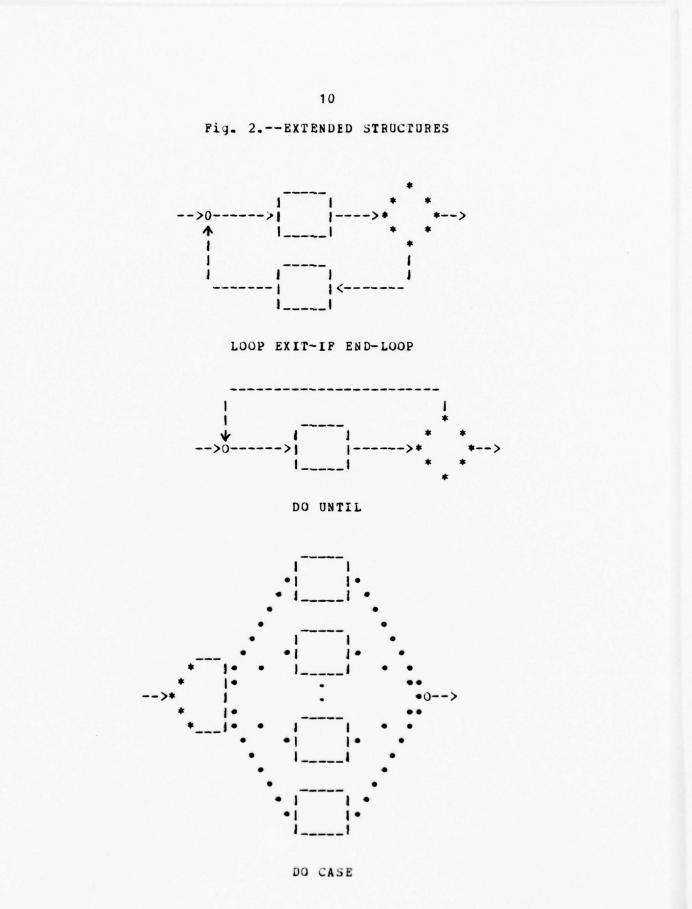

END-PERFORM.

Of course for anyone else to understand, check, or change a program, it is much easier if, at the beginning of each section, is written what the programmer thinks the section will accomplish.

It has also generally been accepted (Yourdon, 1975a and McGowan, 1975) that extension to the three basic structures be allowed. These include DO CASE, DO UNTIL, and LOOP EXIT-

IF END-LOOP (Fig. 2). These do not affect the underlying principles of structured programming and will allow more efficient coding. Although anything can be programmed using the three basic structures, limiting programming to just the three sometimes results in awkward, inefficient, and hard-to-understand code, this is just the opposite of the purpose for structured programming. Extensions to the basic structures are sometimes necessary to avoid the "turing tarpit" (Couperus, 1975), where everything is possible but nothing is easy. Some authors still feel there should only be a limited number of structures and constructs (Yourdon, 1975c). However, one of the main tenants of structured programming is that it allows for better debugging and maintenance because it results in understandability and simplicity. What is simpler than having one construct that does what its name implies, yet replaces a group of complicated code (as many of the advanced constructs in PL/I do)?

Besides a method for coding, top down structured programming is also an overall programming strategy. Most programming has been traditionally done with a bottom up approach where the lowest level programs, subroutines, or subsystems were designed, coded, and tested first. These programs needed driver programs to test them and for integration testing with parts that other programmers had written. Problems often occurred during integration because of inconsistent data definitions and interfaces (McHenry,

1973). The whole system was sometimes delayed while important segments were reworked to allow proper interfacing. The top down approach, as the name implies, is just the opposite.

Top down programming follows the natural systems approach (Yourdon, 1975a and McGowan, 1975). The system is broken down into a tree structure (Fig. 3). First the

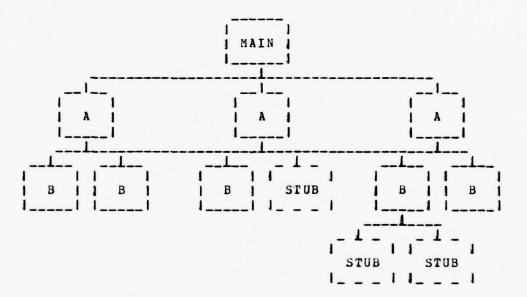

Fig. 3.--TOP DOWN DESIGN

major functions are identified (A). From there the next level down is identified, lesser functions (B) derived from those above it. At the same time the interfaces and data definitions are defined. During this development all undefined or uncoded segments or branches of the tree are

replaced with a dummy stub. For example, if the interface is in the form of a procedure, when the procedure is called, a message or a dummy value is returned. This allows the system to be continually tested as the development proceeds. Since many errors occur in the interfacing, they are removed early in the development since they will be the most tested part of the system. Each time the system is tested all that was completed before is tested again. This is compared to the traditional bottom up method, where the overall system is not tested until the end of the development, and at that point it may be difficult to pinpoint where the problem is.

The method was first used in the now famous New York Times project (Baker, 1972a and 1972b). The project involved the automation of the New York Times morgue. It was to take the newspaper's clipping file and, via a thesauras and abstracts, have an on-line capability of search and retrieval, with the added capability to retrieve the original article on microfiche and display it at the remote on-line terminal. The final system required more than 83,000 source lines of code. It took 132 man-months of effort. Using normal projections and the generally accepted figure of five lines of code per man-day, the project under old methods would have taken over 500 man-months. To add to this was the fact that the system had an historic low error rate, with most of these errors, as could be expected using top

down design, in the lowest level and least tested code. But these also turned out to be the easiest to fix with no error taking more than one day to correct. Equally impressive results were obtained in a second project, the mission simulation of Skylab for NASA.

Structured COBOL

All of the above literature were on the general topic of structured programming and did not address the problem of structured programming in COBOL, except for McGowan (1973) and Yourdon (1975a). They, together with McClure (1975) and numerous other authors in journals and recent publications, included small sections on how to simulate structured COBOL for those constructs in COBOL which hinder or prevent structured programming from being attained. In most cases, the authors recommend that COBOL be changed, although few give specifics on how it should be changed. Some, such as Kauffman (1975), recommend that a pre-processor be written and used until the official language changes are made and incorporated into compilers. All of the serious proposals for changes to COBOL, in regard to structured programming, were presented at the 1975 CODASYL conference.

Although some authors added a few of their own specific examples of COBOL code that hindered structured programming, almost unanimous agreement was shown for four serious shortcomings of COBOL. These are: (1) there is insufficient blocking capability, which partly results in the next

two shortcomings, (2) the IF THEN ELSE can not be fully nested and as a result does some unexpected things, (3) there is not a method for performing in-line loops, and, (4) there are no capabilities for the DO UNTIL and CASE structures. Although there was agreement on the main problems, there was none in the proposed solutions to each of the above problems. Many solutions did not fit the criteria that were previously established. Others were contradictory to what the majority felt were needed. A fourth consideration for designing the language was thus added to the original three. The structures should be those that are likely to be adopted in the official COBOL language, therefore allowing as much compatibility as possible for the future. The following articles were considered, along with those previously mentioned, when this structured version of COBOL was designed.

Benning and Nead (1975) made the broadest proposal. They proposed to use labeled BEGINS and ENDS to designate blocks in all structures. This would solve the problem of both the IF THEN ELSE and the in-line PERFORM, in the inline PERFORM using PERFORM block... with the BEGIN-END forming the block. They also recommended a CASE structure entirely independent of the PERFORM. They suggested allowing arguments for the PERFORM and changing the AT END to an IF statement.

Couperus (1975) only suggested adding a CASE statement by allowing subscripted labels. Then either the GO TO or the PERFORM could be used to operate on the subscripted label.

Goquen (1975) recommended local terminators to solve the blocking problem. They would include the END-IF, END-PERFORM, END-KEY, END-ON, and END-AT. The END-IF would solve the problem of the nested IF THEN ELSE. She, as did Benning and Nead, suggested an in-line PERFORM, but used the END-PERFORM to delimit it. She recommended retaining the UNTIL and adding a WHILE, which would be its exact opposite, and appears a little superfluous. These two would form the DO WHILE structure. To have a DO UNTIL structure, she would add a REPEAT UNTIL at the end of the PERFORM loop. To add a CASE structure, the GO TO DEPENDING ON and the PERFORM were combined into a PERFORM DEPENDING ON... with the target a group of subscripted CASE's. The AT END, ONSIZE ERROR, and INVALID KEY would be changed by having local terminators END-AT, END-ON, and END-KEY. One final change would be making EXIT a return from anywhere in a paragraph being PERFORMed.

Hide and Croes (1975) made some PL/I type suggested changes. To solve the blocking problem, they proposed local terminators, CLOSE-IF, CLOSE-WHILE, CLOSE-LOOP, and CLOSE-PROCEDURE. Along with the CLOSE-IF, they would add an ELSEIF to solve the nested IF problem, however there does

not seem to be much advantage to adding another reserved word. In fact, they did not really specify what would be the difference between their new ELSEIF and the normal ELSE IF. It just seems harder to read. Rather than allowing an in-line PERFORM, they would add a myriad of other constructs, WHILE, REPEAT UNTIL, LOOP, DO, and PROCEDURE, each as a stand alone verb with their own individual local terminators.

Hicks (1975), as with most, would use local terminators to obtain blocking. His choice of terminators was quite unique, however. He would reverse the normal IF THEN ELSE and have IF ELSE THEN. The conditional and true part would fall between the IF and ELSE and the false part between the ELSE and THEN, with normal program flow continuing after the THEN. He would also allow the ELSEIF that Hide and Croes suggested. Instead of changing the PERFORM, he would have a general loop with the exit allowed anywhere in it. It would take the form of LOOP ... EXIT ... REPEAT. The EXIT with a conditional could be moved anywhere in the loop, so that to obtain a DO WHILE construct the EXIT would be at the top, a DO UNTIL construct would have the exit at the bottom. This seems to be a very flexible idea.

McComas (1975) would prefer blocking like Bening and Nead suggested, the BEGIN and END. However, he would not label them. He would eliminate the PERFORM altogether. He would replace the call function of it with internal proce-

dures and the expansion of CALL to include internal procedures. The looping function of PERFORM would be replaced with DO, redefining UNTIL and adding WHILE, CASE, and TIMES. To add one more PL/I type change, he would do away with the A-margin and require labels to be followed by a colon.

McGuinness (1975) would have local terminators also. The END-IF would terminate the IF and allow for complete nesting. An in-line PERFORM would be allowed with END-PERFORM terminating it. The AT END, INVALID KEY, and ONSIZE ERROR would all be changed to implied IF statements. That is, there would be an assumed IF in front of each one. This would allow the use of ELSE and END-IF after them.

Orr and Neely (1975) also recommended the local terminators END-IF and END-PERFORM to solve the blocking, nested IF, and in-line PERFORM problems. They would make CASE a seperate verb and would have it in the form CASE SE-LECTION ... END-SELECTION. They would also like to see a feature for in-line expansion added to the COBOL language.

II. LANGUAGE DESIGN

The primary considerations for the proposed change to COBOL have been given earlier. To review the criteria, (1) as much as possible redefinitions of existing COBOL structures would be used, (2) any new verbs or structures would be patterned after existing COBOL structures, (3) all existing programs could be run against the pre-processor with no changes, and (4) the structures should be those that are likely to be adopted in the official language. A careful analysis of the problems in COBOL already presented show that the blocking problem is throughout COBOL. However, as far as structured programming is concerned, in any language, the critical structures are the IF THEN ELSE and looping. Although some of the suggestions were for a general block structure, such as the BEGIN-END, this would be a drastic change to COBOL, and except for the just mentioned two structures, the Paragraph and Section constructs already constitute at least a type of blocking. Thus local terminators were used in this design. The two selected were END-IF and END-PERFORM. The use of the END was because of the precedent in COBOL of the END DECLARATIVES. The naming of particular ENDs was used to allow better distinction of

which block was ending and to avoid ambiguity. The use of the hyphen was to avoid a possible problem when, as often occurs, the IF THEN ELSE is not followed by a period. The addition of the second IF or PERFORM, could result in an END IF IF or END PERFORM PERFORM situation, which would tend to be forgotten or to be confusing. The use of these two local terminators also solves the problems of the nested IF THEN ELSE and in-line loops. To add a DO UNTIL and CASE constructs without adding whole new constructs and local terminators, additions to the PERFORM verb were made. As it turns out, then, all changes could be made using criterion one and it was not necessary to use criterion two. Criteria three and four are discused under the individual redefinitions.

IF_THEN_ELSE

The easiest redefinition to make was in solving the nested IF THEN ELSE problem. As can be seen in the Structured COBOL section of this thesis, the great majority of authors favored adding a local terminator to close the IF THEN ELSE; specificially END-IF was favored. Thus criterion four was complied with. As can be seen from the redefinition and as explained below, criterion three was also satisfied.

FORMAT
[statement-1] {statement-2}
IF condition [THEN] { } ELSE { }
[NEXT SENTENCE] {NEXT SENTENCE}
[END-IF]

The restrictions that make it possible to run all old programs against the pre-processor follow. All of those that are listed in the present official COBOL language. If the optional END-IF is used, THEN becomes mandatory. Any type sentence is allowed in either the true part, between the THEN and ELSE, or the false part, between the ELSE and the END-IF. Complete nesting of IF statements can occur in either part. Of course, no periods are allowed as this would terminate the IF statement as in official COBOL. Thus all criteria for design have been met.

In-Line Looping

Although there was not as great a majority of authors who preferred the in-line PERFORM for the generalized solution to the in-line looping problem, there were a significant number who did. Also there was no consensus of those who preferred the in-line PERFORM on what form the changes should take. Therefore the simplest and most straightforward change was accomplished. To be consistent with the IF,

the END-PERFORM, as stated before, was used as the local terminator. All looping was accomplished by redefining the PERFORM formats. There are four PERFORM formats in official COBOL and the changes in all of them will be explained individually. The first format has no applicability to looping and a redefinition is really meaningless. However, for consistency, the following redefinition is made.

FORMAT 1 PERFORM [procedure-name-1 THRU procedure-name-2] [sentences END-PERFORM]

The following restrictions are added to those in official COBOL. Procedure-name-1 becomes optional; however either it or the END-PERFORM, but not both, must be present. Logically, THRU procedure-name-2 can only be used if procedure-name-1 is used. This restriction also applies to the other formats. The pre-processor will correctly process Format 1, but the result, when using it as a structured PER-FORM, would be the same as a simple sequence of the same sentences, paragraphs, or sections.

The same general changes are made for the other formats but the changes become more meaningful. Format 2 becomes as follows.

FORMAT 2 PERFORM [procedure-name-1 THRU procedure-name-2] {integer-1 } { J TIMES [sentences END-PERFORM] { identifier-1}

The only change is the addition of the in-line capability. As above THRU procedure-name-2 is only allowed when procedure-name-1 is used and when procedure-name-1 is used nothing is allowed after TIMES.

Format 3 has added to it the capability for the DO UNFIL. When UNTIL is used in COBOL, the structure that results is actually a DO WHILE since the condition is checked before entering the loop. Since the object was to minimize the changes to COBOL and a redefinition of UNTIL would both tend to confuse and would create problems in running old programs, the problem occurred about which word to use to implement the DO UNITL. The problem has been discussed before. Tompkins (1975) points out while and until do not, by any stretch of the imagination, connotate "zero-or-more" or "one-or-more". In fact, in any literal interpretation, they are logical opposites. He suggests that they should be used as inverses and that a new looping structure of REPEAT WHILE and REPEAT UNTIL be used as the "one-or-more", with the DO being the "zero-or-more". This

would be fine for a language like PL/I where a DO construct is already present. However, since this type of change is not wanted for COBOL, the word BEFORE was chosen as having the closest meaning to imply "one-or-more". Format 3 thus becomes,

FORMAT 3 PERFORM [procedure-name-1 THRU procedure-name-2] {UNTIL } { condition-1 [sentences END-PERFORM] {BEFORE}

with no other restrictions or changes execpt for those in the previous two formats. Format 4 has no changes except for the addition of the in-line capability. It also has no additional restrictions or changes as shown below:

FORMAT 4 PERFORM [procedure-name-1 THRU procedure-name-2] . [sentences END-PERFORM]

The capability that was to be added to the perform verb was the CASE construct. It did not easily fit into any of the other formats, so an additional format, Format 5, was added. For the authors that did suggest adding a CASE construct there was no agreement on either the form of the CASE statement or the label targets. Thus the simplest form was chosen, again in the hope that this would result in compatability with any official changes. In this case, this was the closest to compliance to criterion four that could be obtained. The resulting format is as follows.

FORMAT 5 PERFORM CASE identifier-1(arithmetic-expression) identifier-1(1) [statements identifier-1(2) statements . identifier-1(n) statements] END-PERFORM

The subscripted identifier-1 must have consecutive subscripts from 1 to N, where N is greater than or equal to 1. The statements after the subscripted identifier-1 are optional. As a result a statement may have more then one subscript identifying it, allowing more flexibility. This is limited by the fact that the subscripts must be consecutive. Periods are optional after the arithmetic expression, after each subscripted identifier, at the end of each statement, and at the end of the construct, after END-PERFORM.

There are a few other restrictions on all of the above new constructs and redefinitions that are a result of implementation by a pre-processor. The first was mentioned for some of the individual redefinitions but applies throughout. The restriction in COBOL that no periods appear in an IF statement or else the IF statement is terminated applies equally for any of the structured constructs. This should not affect any programs and should not in any way hinder the use of any of the structured constructs. All will work with no periods in them. Programmers must be aware that when they are programming in an IF statement, that they use no period until after the END-IF. A second restriction is that no labels starting with Z are allowed. These are reserved for the pre-processor. The following reserved words are also added: END-IF, END-PERFORM, BEFORE, and CASE. The only other restriction is that a structured PERFORM not be used in a non-structured IF statement. This restriction should not matter to programmers writing a new program, since they should be using either all structured or all nonstructured programming. It might affect a programmer doing maintenance on an old program. Any time a structured PER-FORM is added to an old program, the programmer must insure that it is not within an IF statement or else the IF statement must also be re-written. The reason for this restriction is the pre-processor will sometimes add periods when processing a structured PERFORM. These periods are taken

care of when the structured IF is processed, so they do not affect the structured IF. The removal of these restrictions and further additions to COBOL are discussed in the conclusion of this thesis.

III. PRE-PROCESSOR IMPLEMENTATION

This chapter describes the PL/I program (Appendix A) that implements the pre-processor. PL/I was used for two reasons: one, it is a language designed for character manipulation while COBOL is not, and, two, it is a language that can be programmed using structured programming and thus would be a good example to show structured programming methods. Top down design was also used to design the program. Many changes were made between the original top down design and the final design that corresponds to the final program.

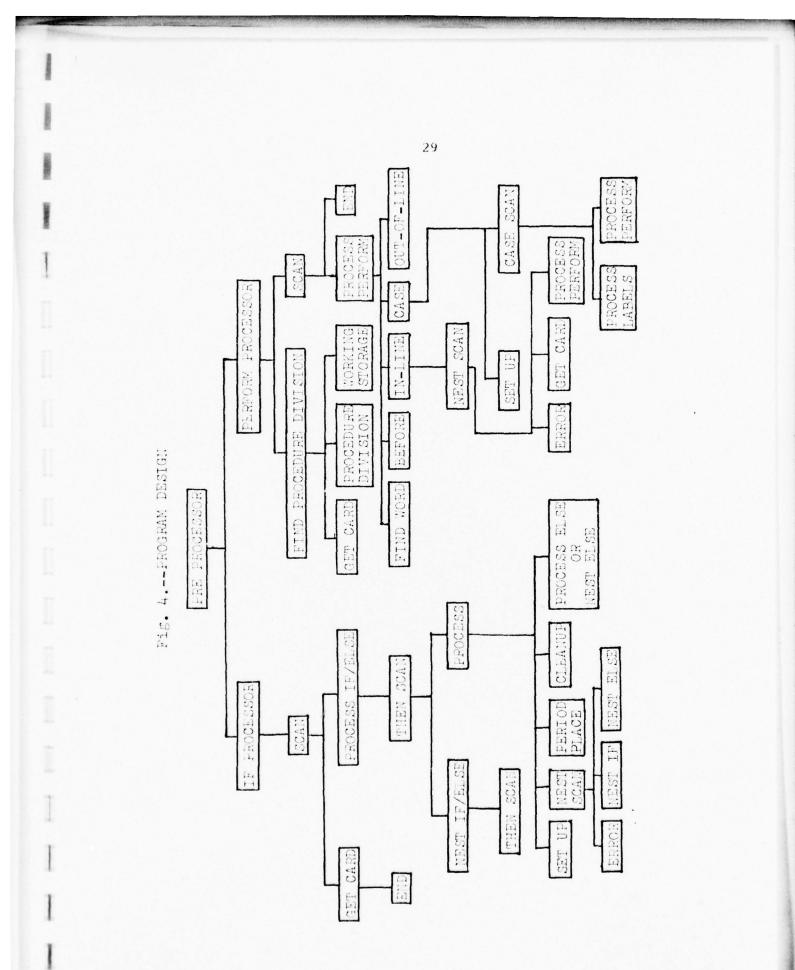

The major reason that the top down design had to be completely reworked was a result of the same problem that caused the previouly discussed restrictions. The problem is that no periods are allowed in the IF statement. This meant that in the processing of the structured IF's and PERFORMS, when nesting occurred some way had to be found, in rewriting the mixture of the two, to have no periods, yet to still have proper blocking. The only fairly simple method that was found involved taking the original design, which intermixed the processing, and separating it into two job steps. Thus in essence two programs were written. This is

shown in Fig. 4 where an immediate breaking into two separate parts at the top of the design tree occurs. The rest of the design can be seen in Fig. 4 and the two separate job steps are explained below.

IF Processing

The first job step scans the source program for IF statements. It prints out the source listing as it scans, if requested. Each IF statement is checked. If it is a structured IF then it is processed, if not it is ignored. The general scheme is that statements between the THEN and ELSE and the ELSE and END-IF are moved to a paragraph at the end of the source program and are replaced with a PERFORM of that paragraph. Nesting can occur as many times as necessary. After this job step, all structured IF statements end up in the form: IF condition PERFORM label-Zn THRU label-Zn+1 ELSE PERFORM label-Zm THRU label-Zm+1. Since all other statements, including structured PERFORM statements, are in the PERFORMed paragraphs at the end of the source program, they can be processed in a second job step regardless of periods.

The only executable statement in the main program of the first job step is a call of SCAN. This initiates all other execution through calls on procedures. At the beginning of each procedure there is a small paragraph that explains what each procedure does. The three main procedures are called PROCESS_IF, NEST_SCAN, and NEST_IF. The

PROCESS IF is called from the main scan any time an IF is encountered. Unless it has already been determined that the present statement is a structured IF, by the presence of a THEN in the same line, the source program is searched for a THEN or an ELSE. An IF statement that has a THEN in it is processed the same whether it is actually a structured IF or not. When an ELSE is found first, it means that the present statement is not a structured IF so a return without processing is made. The IF is transformed into the form given above and then NEST_SCAN is called to build the paragraph. NEST SCAN builds the paragraph until either another IF is encountered or else an ELSE, END-IF, or period is encountered. If any of the latter three is found, then a return is made to PROCESS_IF, where the completion of processing is done. If an ELSE has been returned, it will be necessary to build another paragraph so PROCESS_IF is called again.

If, back in NEST_SCAN, an IF had been found, a different processing path must be taken. In this case since a paragraph is being built at the end of the source program, it is necessary to have a procedure which will consecutively build new paragraphs at the end of the string that is being built; this is NEST_IF. Its operation is almost exactly like that of PROCESS_IF except instead of building the IF-PERFORM in the middle of the source program, it does all its operations at the end of the source program. It also turns out that for simplicity and for core size savings, it is

better to dump each paragraph as it is completed, so that some paragraphs will end up ahead of the paragraphs from which they are performed. This only occurs at the end of the original program, however, and does not affect anything except readability.

PERFORM Processing

The second job step takes the output from the first job step and scans it for structured PERFORMS, processing them as encountered. Since all of the structured PERFORMS have already been removed from the structured IFs and are not allowed in the unstructured IFs, it is a simple matter to change all of the in-line PERFORMS into a PERFORM of a paragraph. The paragraph is inserted immediately after the PERFORM, using a GO TO to remove the paragraph from the stream of the program. All of the PERFORMS except for the CASE are transformed into the following form.

PERFORM Zn THRU Zn+1 conditions.

GO TO Zn+1.

Zn.

sentences.

Zn+1.

The only additional processing required is for the PERFORM BEFORE. In this case an additional simple PERFORM on the paragraph is added. This insures at least one execution of the paragraph. A large part of the job step is used to keep the labels straight in nesting situations. Another large part of the job step is used in the processing of the PERFORM CASE. To implement the CASE, the GO TO DEPENDING ON was used. However, the target of a GO TO DEPENDING ON is very limited; only an identifier of four digits or less with a limited USAGE is allowed. To add the flexibility that is allowed by the definition of the PERFORM CASE given in the last chapter, the pre-processor adds an identifier, named CASE, in the working storage section. The target for the CASE, an arithmetic statement, is assigned to the variable CASE in a COMPUTE statement. The form that the processed CASE takes is as follows:

COMPUTE CASE = (arithmetic statement).

GO TO Zn.

case-label-1.

statements. GO TO Zn+1. case-label-2.

case-label-n.

statements.

GO TO Zn+1.

Zn.

GO TO case-label-1, case-label-2,

case-label-n, DEPENDING ON CASE.

Zn+1.

The liberal use of GO TOS in the processing of the PER-FORMS does not result in a structured product. However, this output is invisible to the programmer. It does have the advantage of putting the processed code in the position corresponding to its position in the input, thus allowing for easier debugging. As in the first job step, all procedures have an explanation of what they do at their beginning in the program listing. PROCESS_PERFORM and NEST_SCAN have about the same purposes as the corresponding procedures in the first job step. They are not as complicated and there is no need for a procedure corresponding to NEST_IF, since there is no need to distinguish between any nested PERFORMS as they all will be put in-line in the source program.

Appendix B is a COBOL program that is written using the structures defined here. Appendix C is the same program after it has been processed. Appendix D is a user's manual for the pre-processor.

IV. CONCLUSIONS AND RECOMMENDATIONS

These changes to COBOL need to be adopted into the official COBOL language and implemented into the COBOL compilers as soon as possible. The advantages of structured programming that have been given here and shown to work in some of the projects listed, prove that there are definite cost savings and increased reliability resulting from its use. The longer the delay, the more unstructured programs will be written which will have to be maintained in the future. The major obstacle seems to be the disagreement on exactly what changes need to be made. As seen in the 1975 conference, in many cases there is wide disagreement on which structures are needed and how they should be implemented. The changes suggested here are a minimum that will allow good structured COBOL to be written. They also have the advantage of offering the least change to, and are the closest to keeping, the traditional COBOL. Thus they have the best chance of being accepted. Any change to a language should be evolutionary, both because of the investment in programs and to keep the retraining and transitioning as simple as possible. If any drastic or revolutionary changes to a language are needed, it is probably best to go to a

completely new language, thereby making a clean break with old methods and any bad habits that may have evolved.

The advantages of implementing these changes in a compiler as soon as possible are twofold; it will increase coding efficiency and it will remove those restrictions that had to be made because of the pre-processor. Since the local terminator is present in the IF, it should be possible to implement the compiler with no restrictions on the use of periods in the IF THEN ELSE. This will allow better readability and make the program easier to follow, a definite goal of structured programming.

The only other constructs whose value would make them candidates for implementation in the near future would be allowing an exit in the middle of a loop as suggested by Hicks (1975) and explained in the first chapter, and adding local terminators for the AT END, ONSIZE ERROR, and INVALID KEY as suggested by Goguen (1975). Of the two, the first would probably have the most usage and therefore should be implemented first.

This study has examined structured programming and its possible use in COBOL. Recommendations for changes to COBOL to allow structured programming have been made and implemented in a pre-processor. They definitely need to be accepted and implemented into the official language. Until this is done, the pre-processor can be used to attain structured programming in COBOL.

CARDS HERE

The job control language given here will have to be modified

depending on the particular COBOL and PL/I procedures that are available and the requirements that they entail. If it is not desirable to maintain the capability to print out the source listing of the pre-processor, it would be much more efficient to compile and link-edit both job steps and make the whole pre-processor a cataloged procedure with the output options as parameters to the procedure.
