1. BACKGROUND

The Coast Guard has developed a Task Bank of tasks performed by bridge, cargo, and engineering personnel of commercial vessels with a view towards using the data contained therein to develop licensing programs that insure the highest degree of safety in ship operation. Functional Job Analysis (FJA), a method developed by Sidney A. Fine, was used to produce the Task Bank of some 800 tasks.

FJA is both a conceptual system and a method of analysis. Central to the method of analysis is the role of language, since all data (whether obtained from observation, interview, or written material) is converted to language. Hence reliability is completely dependent on how the analytic information is expressed. Thus, FJA methodology is centered on controlling the language used to describe work. It does so by using the structure of the sentence as the vehicle for communicating the information (see Fig. 1), and by defining a vocabulary of functional activity (see Fig. 2). A task statement is formulated in response to five questions:

- Who? (Subject) The subject of a task statement is understood to be simply worker. The task statement does not define what kind of worker.
- Performs what action? (Action verb) A task statement requires a concrete, explicit action verb. Verbs which point to a process (such as develops, prepares, interviews, counsels, evaluates, and assesses) should be avoided or used only to designate broad processes, methods, or techniques which are then broken down into explicit action verbs.

The Task Bank was developed under contract DOT CG-4-903A by professional researchers at Operations Research, Inc., Silver Spring, Md. These workers had received one week's training in Functional Job Analysis from Dr. Fine after which they began an actual task analysis drawing on experience, existing literature, and observations in the field.

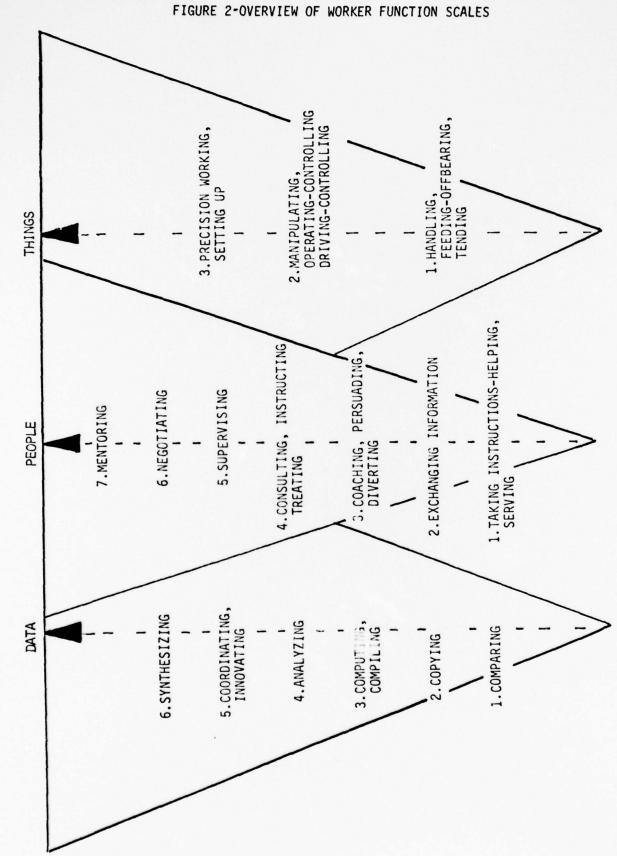

MODEL SENTENCE WORKSHEET FOR TASK STATEMENT

Task statement:	ment:				

FIGURE 1

SIDNEY A. FINE ASSOCIATES INC.

- To accomplish what immediate result? The purpose of the action performed must be explicit so that (1) its relation to the objective is clear and (2) performance standards for the worker can be set.
- With what tools, equipment, or work aids? A task statement should identify the tangible instruments a worker uses as he performs a task; for example, telephone, typewriter, pencil/paper, checklist, written guides, etc.
- Upon what instructions? A task statement should reflect the nature and source of the instruction the worker receives. It should indicate what in the task is prescribed by a superior and what is left to the worker's discretion or choice.

Tasks formulated in this manner and responsive to these questions provide the information necessary to consistently and reliably determine the complexity—el of difficulty) and orientation (worker involvement as a perso—the task and to develop performance standards and training content. Each of the elements of the task analysis reinforces the others. The interrelationships among the parts is illustrated by this paradigm:

In Order To Perform This Task - as described by the task statement and supported by the ratings - To These Standards, the Worker Needs This Training. (See Fig. 3).

The reliability of FJA task statements is determined by establishing agreement among analysts on the ratings made from seven Guttman type (ordinal) scales containing six to eight levels. The seven scales measure functional performance as such performance relates to Things, Data, People, Prescription/Discretion, Reasoning, Math and Language. In addition, an

Knowledge of work to be done.
Data People Things Data People Things W.F LEVEL SB 1A 1A 80% 10% 10% 30AL:	frames, and task assignments, considering individual capabilitinature of work, priorities, in order to plan re-delegation/reoriginal assignment cannot be met.		.All adjustments are clear and concise. Instructions are thorough and clear. Tasks are fairly distributed to workers. Completes task according to schedule. Numerical: Tasks are re-assigned X time prior to expected performance. Over period of time less than X number of complaints from office staff because of problems with work overload or poor understanding of expectations.

estimate of the Worker Function Orientation which measures the relative importance in the task of the performance standards relating to Things, Data, and People, is also made. (However, the Orientation assignment is not an important consideration in the usual reliability study.) Agreement is judged to be satisfactory when a minimum of 75% of the ratings (there are seven ratings per task) are the same or no more than one scale level different between independent ratings of individual FJA analysts. Significant differences between analysts or groups of analysts are evidence of an unreliable task statement indicating the need for further information, greater specificity, and improved clarity in the form of the task statement.

The reliability of the task statements is the most critical factor determining their value to the Coast Guard and to the industry. It is essential that a between-groups reliability study be completed before further use is made of FJA under contract CG-41-903A. That is, ratings assigned by FJA analysts knowledgeable of the specific content in the tasks must be compared to ratings determined by FJA analysts who are not familiar with the specific content of the tasks. This reliability data is necessary to evaluate the usefulness of FJA for future contract work and correct any deficiencies which may exist in the past and current application of FJA. Results from such a study may improve considerably the cost effectiveness and reliability of further research. In order to provide this data, Sidney A. Fine Associates, Inc. contracted to conduct a Reliability Study.

2. PROCEDURE

a) Reliability

The tasks in the Task Bank had been written and analyzed by FJA analysts who were knowledgeable about the specific content of the tasks. In the reliability study; the tasks were rerated by FJA analysts from Fine Associates who

has not been involved in the development of the Task Bank and who were not familiar with the specific nature of the work analyzed. The analysts studied some background material to acquaint them with the technical terminology employed by the Coast Guard. They were then provided with a complete set of the task bank of 822 tasks with all the ratings blanked out. Each of three raters was provided with a portion of the blanked task bank. At the end of pre-arranged periods of time (a week or ten days) the material was exchanged for another portion on which that rater had not yet worked. Therefore, two analysts independently rated each task in the Task Bank. These two ratings were compared and where disagreements occurred, a third analysts also rated the task. Differences in the ratings were resolved through a group discussion and by arriving at a consensus. Only then were the Associates' agreed on ratings for the seven scales compared and evaluated against the original ratings to calculate the reliability and to identify and determine the nature of any differences between them.

The seven ratings referred to are those which appear in Figure 3 on page 5 of this report. These seven ratings deal with the involvement of the task with Data, People and Things, the scale of Worker Instructions (the mix of prescription/discretion) and the General Educational Development represented by the Reasoning, Math and Language scales. They do not include the orientation ratings. The seven scales accurately measure the levels necessary to carry out the paradigm represented in Figure 3: To do this task to these standards, the worker needs this training. In assessing the reliability of the tasks, the same seven scale ratings assigned to a task should be assigned by an independent group of raters. A difference of only one level in any of the scales is not significant and therefore constitutes agreement.

The differences between the Associates ratings and the original raters

were of three sorts. The first related to the central focus of this study, namely differences in ratings. The second involved noting, in the process of reviewing the ratings, some departures from the principles and techniques of FJA Methodology. Finally, sometimes the information in the task "sentence", performance standards, and the training content was ambiguous or inconsistent, blurring the meaning/intent of the task. The latter two differences could occur even when ratings were the same as between the Associates and the original raters.

These three kinds of differences were dealt with as follows in making changes. Sometimes the Associates <u>new</u> ratings of the seven scales not only resulted in changes of two or more levels but also had the effect of creating differences in the orientation pattern, that is, the relative involvement with Things, Data, <u>and</u> People*. (These orientation changes were not part of the reliability count.) Such changes were discussed by the Associates and if the ambiguities were cleared up among them, the original ratings were accepted. In the other two instances apparent inconsistencies or ambiguities in the information or inadequate support for the ratings were noted and changes made.

There are some basic guidelines used in performing an FJA study. One key item to look for is a range of no more than one level difference between Data, Worker Instructions and Reasoning. These three items are very closely related and a rating of 4 on Data, 6 on Worker Instructions and 5 on Reasoning, for example, indicates that the original rater may not fully understand the principles of FJA.

^{*} Orientation categories are High, Medium and Low. High includes a range of 90% to 65%; Medium includes a range of 60% to 35%; Low includes a range of 30% to 5%.

^{1.} Fine, Sidney A., Ann M. Holt and Maret Hutchinson. <u>Functional Job Analysis:</u> How to Standardize Task Statements, the W. E. Upjohn Institute for Employment Research, October 1974, pp. 17, 26.

Another item to watch is a rating of 2 on the People scale. A 2 rating represents an exchange of information. If the task statement, performance standards and training content make no mention of any exchange of information between the worker and another person, a rating of 1A or 1B is correct.

Both of the above are worthy of mention here even though the difference between the original ratings and the new ratings may be only 1 level; the point is that some 1 level differences are a little more important than others. These are some of the items addressed in the report. However, a reliability of 98.1% was achieved based on only the 2-level differences. That is, differences in ratings of only one scale level or within the same orientation category which were consistent with the methodology of the task were accepted. (See Table 1, page 12.)

In examining the scale level differences we (the independent raters) must ask ourselves what it is about the task statement that caused us to rate it differently. This is where our group discussion comes in as outlined on page 7. Sometimes the group discussion elicits the realization that a word or phrase in the task statement was ambiguous or too general in nature which led to some disagreement on our part. If we are able to identify and clarify this ambiguity and agree that the original rating was reasonable, no changes were made. In some cases we made suggestions as to how to clarify the wording to more accurately match the rating. In other cases we may have felt that the rating was not accurate and needed to be changed.

The criterion of 75% reliability is basically founded on an examination of the seven scales; the general orientation assigned to the task by the raters is not rigidly scrutinized in a reliability study.

^{2.} Fine, Sidney A. Functional Job Analysis: A Desk Aid, the W. E. Upjohn Institute for Employment Research, April 1973, p. 6-8.

In initially assigning a percentage to reflect the overall orientation of the task, the general guidelines are reflected in the footnote on page 8 of the report. In checking the completed task bank, a slight shift in percentages which does not alter the basic assignment within the range of High, Medium or Low would be considered insignificant.

To summarize, according to the basic guidelines for establishing reliability, 98.1% of the ratings met the criterion of difference of no more than 1 level. This 98.1% should be compared to the established rule that 75% agreement means reliability has been achieved.

2) Additional Comments

After rating the tasks which were in disagreement (two levels different on any of the seven scales), the Associates also re-examined those tasks which contained one or more one-level differences. After some discussion during which the criticality of safety factors in the performance standards and training content was considered at length, it was decided to provide the Coast Guard with a much more detailed analysis applying harsher criteria. Some of the tasks with one level differences were then added to the original group of task statements which were "not in agreement". However, these are not included in the calculation of reliability.

All parts of the tasks, including the orientation, were examined in detail. By the time the task had been sifted through a second time, the Associates found they had pulled out a total of 188 of the 822 tasks which were found to have some type of problem which suggested changes or comments. These additional data are included in Tables 2 and 3 in Section 3, Results.

Appendices A-G* include all those tasks which required clarification, rewriting, or other changes. To facilitate the comparison of the differences

^{*} See Table of Contents, p. ii, for full titles of the appendices which were delivered in March 1977 to the Coast Guard.

between the original ratings and the Associate's ratings, only those tasks which have changes are included. Both sets of ratings appear on each task. Explanations of the differences as well as suggestions for clarification are included on a comment sheet which directly follows each task.

RESULTS

1) Reliability

As previously noted, satisfactory agreement-reliability-is achieved when at least 75% of the ratings of two independent groups of analysts are the same or no more than one scale level different. Since there are 822 tasks, the total number of ratings is 7 x 822 or 5754. Six hundred thirty four (634) tasks involving 4438 ratings were rated the same or only 1 level different; no changes were made on those tasks. One hundred seven (107) ratings were found to be in disagreement, out of a possible 5754. This yields a reliability of 98.1%.

2) Additional Comments

An additional 61 tasks were then pulled in accordance with the Associates'desire to make further constructive criticism. Of these tasks another 133 one-level rating changes were indicated (see Table 2). Suggestions for rewording also have been indicated to more clearly support the ratings. As noted, the Associates indicated suggested changes on a total of 188 task statements. Of these 188 tasks where changes were made (involving 1316 ratings) 1076 ratings were not changed. Thus, 4438 plus 1076 for a total of 5514 ratings remained unchanged. This is 95.8% of the total and represents the adjusted reliability based on scale rating changes including some 1-level changes.

The 188 tasks that the Associates suggest be changed involved 240 scale rating changes. These changes included some I level differences in ratings as noted in Section 2 above. These changes have been suggested when the original ratings were found to be inconsistent with the FJA methodology or the intent of the task. In addition, for about 36 of these 188 tasks there were major shifts in the orientation. On 19 tasks the original ratings were left unchanged but some verbal changes were made to suggest how the original ratings might be better supported. However, in accordance with standard procedures only those changes indicated in Table 1 need to be made. Tables 2 and 3 are additional recommendations which the Associates have made. We particularly recommend the changes indicated as "Major orientation shifts/ rewrite" appearing in Table 3.

Total other changes	9	26	26	31	8	14	10	124

^{*}These percentages reflect a hypothetical reliability based on two-level changes plus those one-level changes the Associates suggest be made in order to achieve PERFECT agreement on ratings.

While the level of agreement indicates the reliability of the task data, the study identified a number of trends which should be considered in evaluating the applicability of the Task Bank to meet specific needs. The comment sheet following each task statement in the appendices goes into detail.

Task Statement

Each task statement must include sufficient information to clearly portray the task as it is performed. Task statements should be written using clear action verbs to describe what the worker does. In reviewing the Task Bank, the Associates found that the worker actions were often described only by broad process verbs such as "tests" or "monitors" (see CO-III.D.3 and CO-II.C.5 following). In addition, some task statements tended to ignore two questions from the model sentence worksheet for task statements: "using what tools, equipment, and work aids?" and "upon what instructions?" (See Figure 1.) Answers to these questions would clarify the ambiguous verbs such as "tests" or "monitors" in terms of the level of complexity and the prescription/discretion mix required. For this study, it was possible to obtain this information from other elements of the task analysis - the performance standards and the training content. It should be stressed, however, that in order to communicate precisely about the work it is necessary to carefully read the entire task, considering the ratings, orientation assignments, performance standards and training content.

4) Worker Function Levels and Orientation

Most of the original ratings on the worker function scale level were in agreement with the Associates' ratings. However, it was noted that when the task statement referred specifically to emergency or safety procedures, the Data, Worker Instruction, and Reasoning Scale ratings tended to be higher than for a similar or comparable task. (See III.B.5 and III.B.10.) People level 2 with a 5% orientation was frequently used even though the task state-

ardous chemical liquid bulk cargo transfer operations s
t hazardous chemical l
GOAL: Conduc
111.B.10
TASK CODE:

Install necessary equipment for cargo transfer operations.

OBJECTIVE:

TASK: Connects cargo hose following standard operating procedure, using available tools and equipment, in order to

PERFORMANCE STANDARDS	TRAINING CONTENT
Descriptive:	Functional:
 Equipment 1s properly connected. 	 How to read instructions for setting up equipment.
 Arrangements completed thoroughly, according to instructions. 	• How to connect cargo hose equipment.
	Specific:
Numerical:	 Knowledge of standard operating procedures for
 Cargo hose connections are properly made in all 	connecting cargo hose (i.e., making allowance for
cases.	vessel movement, using properly gasketed flange joints
	and bolted tight with at least 3 bolts, properly
	supports hose, places pans or buckets under cargo hose
	connections aboard vessel, sets up shields around
	flanges of manifold connections to guard against
	cargo spray of certain chemicals such as acids).

Knowledge of specific cargo hose, cargo piping,

terminal piping, etc.

Knowledge of specific chemical cargo's hazards (acidity, etc.).

ment did not describe any "exchange of information" (see CO.1.A.2 and Nuke 2.1.1.). The 5% orientation correctly reflects the fact that there is no interpersonal involvement in this task.

The orientation assignments reflect the relative involvement expressed in proportions of 100% of the work with Data (information and ideas), People (interpersonal communication) and Things (physically handling tangibles). There was a tendency for the original orientation assignment to reflect less data involvement than described or indicated by the task statement, scale ratings, performance standards and/or training content (see III-E.8). The orientation assignments also tended to reflect a confusion between things which are physically handled, manipulated or operated and things which are a source of Data, e.g. data readouts or signals on computers or other electronic equipment.

Discrepancies of 1 level occurred frequently in the Language scale. While this is within the bounds of defined reliability, there appeared to be inconsistencies in the ratings by the original raters. The basis for the ratings appeared to be: a) procedural manuals such as the Operations and Safety Manual (see CO-III.A.1) and b) "prescribed" or "specified procedure". The original ratings were usually a level 4 or a level 3 but not consistently one or the other (see CO-I.B.14). On a fews tasks a level 2 was used for specified procedures (see CO-I.B.5). On some tasks a level 4 was assigned without firm support in the task statement (see CO-I.B.15). The Associates' ratings tended to be level 4 where specified procedures are cited. The Associates' consistencies and the original raters' inconsistencies produced many 1 level discrepancies. This was established

during review of the first 200 tasks and verified during subsequent rating. The inconsistencies can easily by cleared up by careful analysis of the basic reference materials.

The Math level produced some similar problems where only a careful study of the entire task produced any support for the original ratings (see CO-III.H.1).

5) Training Content

The training content portion of the task should contain only those items required to perform the particular task. The Associates felt that some tasks contained training content for the job as a whole, rather than for a specific task (see CO-II.C.4 and 1.4.5). This often occurs when task statements are written to cover the tasks entailed in a specific job. One possible result of this is selection of personnel who are over-qualified for the tasks at hand.

4. SUMMARY

The reliability of the ratings on the 822 tasks was very high. The Associates' impression was that most of the necessary data was available in the task analysis; the format, however, was not always consistent with the principles of FJA. If feasible, one of the original FJA analysts thoroughly familiar with the content could review the entire task bank for consistency, as it was obvious that different analysts were at work on specific sections. The Language inconsistency is a salient example. Many of the task statements can be polished by drawing on the performance standards and training content data to include a phrase or two for clarification. Suggestions along this line have been indicated on some of the comment sheets appended to the tasks in the March report. Because of the frequency of this occurrence and lack of knowledge of specific content the Associates did not feel it was within the scape of their contract to make these changes.

By going a step further, the Associates have identified some specific areas for improvement. However, again, the figure which should be compared are 98.1% reliability achieved versus a goal of 75%.

A detailed critique by the Associates is not usually given if there is reliability. In striving to meet the spirit and not just the letter of the study, the Associates have attempted to offer their suggestions for improvement. The overall work performed by the original raters was good. Our suggestions are aimed at moving closer to perfection since we recognize that safety is the most important factor in the tasks. This is the factor that caused us to go far beyond the normal work entailed in performing the reliability study.

5. TYPES OF CHANGES

The final section of this report consists entirely of a detailed list of the changes by task number.
