An Assessment of the Available Evidence on the Returns to Military Training

Eva Norrblom

A report prepared for
DEFENSE ADVANCED RESEARCH PROJECTS AGENCY

The research described in this report was sponsored by the Defense Advanced Research Projects Agency under Contract No. DAHC15-73-C-0181.

Reports of The Rand Corporation do not necessarily reflect the opinions or policies of the sponsors of Rand research.

PREFACE

This report was prepared as part of Rand's DoD Training and Manpower Management Program, sponsored by the Human Resources Research Office of the Defense Advanced Research Projects Agency (ARPA). With manpower issues assuming an ever greater importance in defense planning and budgeting, the purpose of this research program is to develop broad strategies and specific solutions for dealing with present and future military manpower problems. This includes the development of new research methodologies for examining broad classes of manpower problems, as well as specific problem-oriented research. In addition to analyzing current and future manpower issues, it is hoped that this research program will contribute to a better general understanding of the manpower problems confronting the Department of Defense.

This report documents part of the preliminary work undertaken for a Rand study of the economic returns to separatees from military vocational training.* A review of the relevant literature is considered an integral part of the larger study, because it provides insights into reasons for the failure of previous studies to fully evaluate and test the hypothesis that military vocational training affects the civilian opportunities of separatees.

The issue of the economic effects of military training has application in a variety of policy areas. The most obvious area is that of military manpower management. An estimation of the civilian wage offers available to potential reenlistees provides evidence on the earnings alternatives against which the services must compete. Moreover, information on the transferability of military training to the civilian sector may aid employers in assessing the capabilities of individuals with military-acquired skills. If the value of military training in the civilian sector can be measured, civilian employers and educational institutions may more readily recognize the formal and informal training gained

* Eva M. Norrblom, *The Returns to Military and Civilian Training*, R-1900-ARPA, The Rand Corporation, July 1976.

during a tour of military duty. The information provided by this study may, therefore, increase the degree of use of future military skills in the civilian sector. An increased understanding of the impact of military training on later employment in the civilian sector may also be useful in coordinating and assessing civilian and military training programs.

Finally, by providing first-term enlistees with military vocational training, the Department of Defense may be transferring real resources to the civilian sector. This study offers evidence that, if separatees use their service-acquired skills, the military's loss is partly compensated by a positive externality accruing to society. This benefit to society may be offset, however, by the additional payments imposed on taxpayers for the cost of military training.

SUMMARY

A limited number of studies have evaluated the potential benefits accruing to individuals from military training when they separate from active duty. Most of the available studies indicate that training in the military does not have a positive effect on the post-service civilian opportunities of veterans. This conclusion is reached despite evidence that more than three-fourths of the job specialties available to enlistees have direct civilian counterparts.*

The available studies interested in the effect military training has on the post-service opportunities of separatees focus on two issues. The first is the extent to which individuals utilize military-acquired skills in civilian jobs. Two very simple methodologies have generally been used in the attempt to determine the degree to which military skills are transferable to the civilian sector. These include evaluating the opinions of separatees about the degree to which they use military skills in civilian jobs or cross-tabulating the military occupational codes with the civilian occupational codes of individuals. No theoretical models of occupational choice or statistical tests of significance for the association between the military occupations and post-service occupations of individuals are provided by these studies. Moreover, since the findings of these studies vary significantly depending on the occupational groups examined, the method used to group civilian and military occupations, and the period in which the selected sample of individuals served their tours of duty, existing studies do not offer much in the way of conclusive evidence on the degree to which

*Harold F. Clark and Harold S. Sloan, *Classrooms in the Military*, Bureau of Publications, Teachers College, Columbia University, New York, 1964, pp. 103-107. Clark and Sloan indicate that 85 percent of all enlisted personnel job specialties have direct civilian counterparts and 60 percent of all military education and training is applicable directly to civilian life. Additionally, approximately 50 percent of all enlisted job specialties are classed as skilled. See also Paul A. Weinstein, "Occupational Crossover and Universal Military Training," in Sol Tax (ed.), *The Draft, A Handbook for Facts and Alternatives*, University of Chicago Press, Chicago, 1967, p. 28.

military-acquired skills are used in the civilian sector. The only conclusion forthcoming from these studies is that separatees in the more technical military specialties have a higher probability of continuing to work in the same occupations when they enter the civilian labor force than separatees in the less technical military specialties.

The second issue addressed by these studies is the economic effect of military training. These studies evaluate the economic effect of military training on the civilian earnings of separatees by developing and estimating empirical models. Of the existing studies concerned with the economic effect of military training on the post-service opportunities of separatees, none have fully addressed the issue of the economic returns to military training that accrue to individuals who enter civilian occupations related to their military-acquired skills, compared to individuals who do not. Moreover, owing mainly to insufficient data, previous studies have not been able to observe the effect of formal and informal military vocational training while concurrently controlling for the effects of other factors that may influence their conclusions--such as skills acquired in the civilian sector that may be substitutes for or complements to military training. In the same context, when the military experience of individuals is viewed, in total, as simply the length of time spent in training, no consideration is given to the type of skills acquired or the intensity of formal compared to informal military training.

I. INTRODUCTION

This report reviews the available literature on the benefits from military vocational training accruing to enlistees when they separate from the service. The study is part of a larger effort conducted at Rand that focuses on the economic effects of military training on the post-service opportunities of enlistees. A review of the literature is considered to be an integral part of the larger effort, because it provides information on the extent to which the relevant hypotheses have been addressed. This literature review also compares and synthesizes the methods and assumptions employed by previous studies concerned with the returns to separatees from vocational training acquired in the military.

The available studies of the effect of military service on the civilian opportunities of separatees may be categorized into two distinct theoretical frameworks including that of occupational choice and human capital theory. Of the studies that focus, at least partially, on the occupational choice of separatees, none go beyond calculating a simple distribution across occupations to indicate the percentage of separatees who enter civilian occupations related to their military jobs. No attempt is made by these studies to develop a theoretical model of occupational choice. On the other hand, studies of the effects of military training on the civilian earnings of individuals are based on a theoretical model generally referred to as the human capital approach. The human capital approach provides theoretical and empirical models in which investments in training are a central explanatory factor leading to the observed inequality of labor income. Training raises productivity and is acquired by individuals who expect the returns to training to compensate for the costs of training. If military training does affect the productivity of individuals, wages will depend, in part, on the type and amount of military training individuals have acquired. Consequently, the observed wages of individuals are used to determine

whether investments in various types and amounts of training yield private returns to recipients.*

To allow a comparison across studies concerned with each of the above two issues, the simple question of transferability and the economic returns to training, this literature review is divided into sections according to the issues addressed and the methodologies used. There are essentially three methodologies that have been used by existing studies to assess the economic effect of military service. Studies interested in determining the extent to which separatees are able to use their military-acquired skills in post-service jobs use either the opinions of separatees obtained through surveys or cross-tabulations of the military-acquired skills of separatees with their chosen civilian occupations. These studies are discussed in Sec. III. The third method, employing multiple regression analysis or, on a less sophisticated level, comparing the mean earnings of various groups, is generally used to determine if military training has a positive effect on the civilian wages of veterans. These studies are discussed in Sec. IV. Finally, Sec. V presents one important facet of Rand research on this subject in more detail.

* Although wages may reflect, in part, a credential effect, arguments against established labor theory have been debated extensively without offering sufficient supporting evidence. For a discussion of the credential effect, refer to Taubman and Wales.

II. OVERVIEW

A description of the data sources, the methodologies, and the principal findings of the relevant studies is presented in Table 1.* As discussed above, these studies generally rely on three principal methodologies to evaluate the effects of military training on the civilian opportunities of veterans.

Eight of the thirteen available studies use the opinions of separatees to some extent in formulating their conclusions. These studies include the ones by the U.S. Senate Committee on Armed Forces, Richardson (1966), Sharp and Biderman, Nathan Associates, Thorndike and Hagen (1957), McCall and Wallace, Weinstein et al., and Freeman. The first three of these studies are primarily concerned with the vocational readjustment problem faced by separatees. The emphasis is on the *general* transferability of the military experience of individuals to the civilian labor market rather than on the transference of specific military skills to related civilian jobs. In all three of these studies, half or more of the technically trained separatees felt their military backgrounds helped them qualify for civilian jobs. These studies also indicate that separatees trained in military skills that have civilian counterparts have less difficulty in securing employment in the civilian sector.

The next three studies, using opinion survey data, present evidence on the extent to which separatees enter civilian occupations directly related to their military-acquired skills. Using a sample of military-trained medical care specialists, Nathan Associates found that one-fifth of the sample respondents entered related civilian occupations. Similarly, Thorndike and Hagen (1957) found that approximately one-fifth to two-fifths of the separatees with training in the more technical military specialties entered related civilian occupations. In contrast, a much

* A number of the studies to be discussed are interested in both the use of military skills in the post-service period and the effect of military training on earnings. The available studies are therefore included in each of the relevant sections below.

Table 1

SUMMARY TABLE OF DATA USED IN PREVIOUS STUDIES.

Study	Data Source and Sample Size	Branch of Service	Length of Service	Timing of Survey After Separation Date	Period of Service
Sharp and Biderman	1965 ^a survey: Pre-retirement (2094); 1st post-retirement (346); 2d post-retirement (1665) 1963 DoD survey (11,985)	Retirees: Army Air Force Navy	20 years or more	6 mo to 1 year	Pre-WWII
Cutright	Selective Service 1% sample of April 1953 linked with SSA ^b data (5972 whites and 1650 blacks).	Veterans (primarily inductees)	2 years	3-4 years and 9-10 years	Korean War
Freeman	1966 Department of Labor's National Longitudinal Survey (Parnes tape) of men aged 45-59 (1760).	Army veterans	Not specified	Not specified	Pre-WWII and WWII
Hanushek	DoD Post-Service Information File of 180,000 civilian-employed separatees.	Army veterans (primarily inductees)	2 years	10 mo	1966-1967
Kassing	Selective Service 1% sample of April 1953 linked with SSA data (8104). Data from the study by Weinstein et al. (item #9 in this table) (2313 Army and 1084 veterans).	All veterans	One term	3-4 years and 9-10 years	Korean War
McCall and Wallace	1966 survey of civilian-employed separatees (505).	Air Force electronic specialists	One term	2 years	1958-1972
Mason (1970)	1964 Current Population Survey; and CPS and DoD Survey (3045 veterans and 6548 nonveterans).	Veterans (enlistees)	Not specified	Variable	Post-WWII
Nathan Associates	Telephone interviews (100 Army, 106 Navy, and 100 Air Force veterans).	Enlistees: Army Air Force Navy	One term	2-3 years	Early 1960s.
Weinstein et al.	Service records and telephone interviews with civilian-employed standby reservists (2313 Army and 1084 Navy veterans).	Army and Navy veterans	One term	2-4 years	Late 1950s and early 1960s
Richardson (1967)	Interviews (412).	Air Force veterans (enlistees)	One term	2 years or less	Early 1960s
Thorndike and Hagen (1957)	Interviews and mail questionnaires (3005).	Air Force veterans (enlistees)	One term	1 year or more	Korean War
U.S. Senate Committee on Armed Forces	DoD mail questionnaires (3168).	Air Force officers on the retiree roles in 1961	20 years or more	1-6 years	Late 1930s and early 1940s
Winkler and Thompson	DoD Post-Service Information File of 1968-1970 separatees (85,409).	Air Force veterans (enlistees)	One term	1-1/2 years or less	1964-1966

NOTE: Footnotes appear at the end of the table.

Table 1 (cont.)

Study	Primary Purpose of the Study	Method Used to Analyze the Effects of Military Training	Conclusions on the Economic Effects of Military Training
Sharp and Biderman	Analyze the vocational readjustment problems of military retirees entering the civilian sector.	Opinions of retirees and cross-tabulations of military and civilian occupations. Civilian occupations are classified by industrial codes. Military occupations are classified by 1-digit DoD codes.	1/3 to 1/2 of the separatees were working in civilian jobs comparable to their military specialty. Separatees with training in military specialties with civilian counterparts have fewer problems securing post-service jobs. Educational achievement and personality-type qualifications are the most important factors in the occupational adjustment of separatees.
Cutright	Analyze the determinants of earnings and changes in earnings and measure the effect of military service on post-service earnings.	A comparison of veterans and nonveterans. Two data points are also used to determine if the effect of military training changes over time. Occupational groups are not considered separately.	The earnings of veterans are not higher than the earnings of comparable nonveterans.
Freeman	Analyze the effect of military and civilian occupational training and job experience on civilian earnings.	Opinions of separatees and regression analysis using earnings data. Civilian occupations are defined by broad industrial codes and Army specialties are aggregated without regard to type or intensity of training.	Military training does not have a significant effect on earnings. Roughly 2/3 of those working use their civilian institutional training in their civilian job, whereas only 1/3 of the veterans use their Army training.
Hanushek	Analyze the differential in earnings across geographical labor markets.	Regression analysis using earnings data. Civilian occupations are defined by 1-digit DOT ^c codes and military occupations by 1-digit DoD codes.	Military service does not have a significant effect on the earnings of veterans.
Kassing	Assess the available evidence on the benefits from military vocational training and determine if veterans fare better than nonveterans.	Regression analysis using earnings data. Separatees from 9 major military occupational groups are compared with infantrymen. Veterans are also compared with nonveterans.	Military vocational training does not result in a higher wage for veterans with technical training compared to those without technical training. The earnings of veterans are not higher than the earnings of comparable nonveterans.
McCall and Wallace	Analyze the responsiveness of reenlistment rates to changes in remuneration and the transferability of Air Force training to the civilian sector.	Opinions of Air Force trained electronic specialists and regression analysis using earnings data. Veterans who use their military training in their civilian jobs are compared with veterans who do not.	2/3 of the civilian-employed Air Force separatees use their military skills in their civilian jobs. Veterans who use their military training receive higher post-service wages than separatees who do not use their military training.
Mason (1970)	Analyze the effect of military vocational training on the socioeconomic status of veterans.	Cross-tabulations of military and civilian occupations and regression analysis. The comparability of military and civilian skills is defined by ratings of the socioeconomic standing of broad military and civilian occupational groups. Veterans are compared with nonveterans.	Military service does affect socioeconomic status but this effect operates through an increased educational level of veterans. Lower status men use their military training to a greater extent in their post-service jobs.

Table 1 (cont.)

Study	Primary Purpose of the Study	Method Used to Analyze the Effects of Military Training	Conclusions on the Economic Effects of Military Training
Nathan Associates	Analyze the transferability of military-acquired medical skills to the civilian sector.	Opinions of military-trained medical specialists and comparisons of earnings data. Veterans who use their military training in their civilian jobs are compared with veterans who do not.	Separatees who use their military-acquired medical training earn more than separatees who enter unrelated post-service occupations. 1/5 of separatees entered civilian jobs comparable to their military occupation. The nontransference of military skills is due primarily to the lack of recognition of military medical skills by the civilian sector.
Weinstein et al.	Analyze the benefits from military vocational training.	Opinions of separatees, cross-tabulations of military and civilian occupations and regression analysis using earnings data. Separatees are classified into 9 major military groups and are compared with infantrymen.	1/6 of the Army and 1/4 of the Navy separatees use their military training in their civilian jobs. Military vocational training is not a significant determinant of the post-service wages of separatees.
Richardson (1967)	Analyze the vocational readjustment problems of veterans entering the civilian sector.	Opinions of separatees and cross-tabulations of military and civilian occupations. Civilian occupations are classified by a 1-digit DOT code. Military specialties are divided into 2 major groups and are also presented by 2-digit Air Force Specialty Codes.	1/2 of the separatees use their military training in their civilian job. Although enlistees with certain types of training are able to use their military-acquired skills in the civilian sector, there is no strong relationship between Air Force training received and the post-service job chosen by separatees.
Thorndike and Hagen (1957)	Analyze the reasons for low retention rates in high-skill groups.	Opinions of separatees and cross-tabulations of military and civilian occupations. Civilian occupations are coded by the 1948 DOT classifications and military specialties by 2-digit Air Force Specialty Codes.	Depending on the military specialty, 1/3 to 1/5 of the separatees reported they entered civilian jobs related to their Air Force training.
U.S. Senate Committee on Armed Forces	Analyze the reasons retirees have problems securing jobs in the civilian sector.	Opinions of separatees. Responses are presented by 11 military skill groups.	The military-to-civilian transfer problem is not so much a result of unmarketable skills but rather one of relating the skills gained in the military to civilian counterparts.
Winkler and Thompson	Analyze the extent of utilization of military skills in the civilian sector.	Cross-tabulations of military and civilian occupations. Civilian occupations are classified by 2-digit and 3-digit DOT codes and military skills by 5-digit Air Force Specialty Codes.	Military skills are transferable to the civilian sector, especially if they are associated with a high degree of technical training. Up to 4/5 of the separatees from more technical military specialties entered related post-service occupations.

^a Bureau of Social Science Research.

^b Social Security Administration.

^c Dictionary of Occupational Titles.

higher percentage of skill use of Air Force-trained electronic specialists is reported by McCall and Wallace. Approximately two-thirds of those who left the Air Force and entered civilian jobs use their Air Force training.

In the process of analyzing the economic returns to training, Weinstein et al. and Freeman also discuss the extent of skill use reported by individuals in their samples. Both studies report that, on the average, one-fifth to one-third of the separatees with training use their military-acquired skills in their post-service jobs. In addition, Weinstein et al. indicate that a larger percentage of separatees from the more technical military specialties enter related post-service occupations.

The second method, which is used by the remaining five out of the thirteen studies evaluating the transferability of military skills, is to cross-tabulate the military specialties of separatees with their civilian occupations. By such cross-tabulating, Winkler and Thompson find from their sample that military training is transferable to the civilian sector. They conclude, as do many of the above studies, that use of military skills is higher for separatees trained in the more technical military specialties. Across military occupational groups the percentage of skill utilization ranges from approximately 8 percent to 80 percent. The other four studies cross-tabulating military and civilian occupational codes categorize occupational groups on a highly aggregated basis (Massell and Nelson, Richardson (1966), Sharp and Biderman, and Thorndike and Hagen (1957)). As a consequence, it is difficult to observe whether separatees with more technical training have a greater tendency to use their military-acquired skills in post-service jobs. In general, these studies find that less than one-third of the separatees enter civilian occupations related to their military specialties.

In addition, eight of the above studies go beyond the issue of skill utilization to evaluate the economic effects of military training using statistical techniques. Of these studies, six conclude that military vocational training does not have a positive effect on the post-service wages of separatees. Freeman, for example, finds that although

civilian vocational training has a positive effect on earnings, military vocational training does not. Weinstein et al. also conclude that veterans do not receive a positive economic return from military vocational training. Mason (1970), Hanushek, Cutright, and Kassing reach similar conclusions. Classifying military and civilian occupations by rankings of socioeconomic status, Mason (1970) finds that the military occupations and lengths of service of veterans do not have a positive association with civilian earnings. Similarly, Cutright and Kassing find that veterans are not better off than nonveterans as a result of having acquired military occupational training. In comparison, McCall and Wallace and Nathan Associates indicate that *separatees who enter military-related civilian occupations* earn more, on the average, than separatees who did not acquire military skills related to their post-service occupations.

The conclusions reached in the above studies depend on the samples selected and the manner in which the data available to each study are evaluated or analyzed. Sections III and IV present a detailed discussion of previous studies of the effect of military vocational training on the post-service opportunities of separatees. The sections are organized on the basis of the methods and samples used by each study.

III. STUDIES OF THE TRANSFERABILITY OF MILITARY SKILLS

Studies that depend of the opinions of veterans or on cross-tabulations of military and civilian occupational codes to evaluate the extent to which military skills are transferable to the civilian sector use samples of separatees or retirees from the Army, Navy, or Air Force. The following discussion outlines, in detail, the samples and conclusions offered by these studies.

STUDIES USING OPINION SURVEY DATA

Studies of Army and Navy Separatees

Two of the existing studies use survey data from interviews with separatees (Weinstein et al. and Freeman). The major concern of the effort by Weinstein et al. is the effect of military vocational training on the earnings opportunities of enlistees when they separate from military service. The sample used consists of civilian-employed standby reservists who separated from active duty between 1960 and 1965 after one term of service. Data were taken from Army and Navy service records and telephone interviews for which response rates of 41 percent for the Army and 28 percent for the Navy were obtained. Veterans who served less than two years of active duty were excluded from the sample.

Separatees were asked if they looked for and accepted jobs similar to their military training. One-third of the Army and one-half of the Navy separatees who looked for related civilian jobs actually entered civilian occupations in which they could use their military-acquired skills (see Table 2a). Approximately one-sixth of the Army sample and more than one-fourth of the Navy sample use their military training. Of these separatees approximately one-half of the Army veterans and three-fourths of the Navy veterans reported their military experience helped them obtain a pay advantage or a better job position in the civilian sector (See Table 2b). For skills that require the most intensive amount of training almost one-half of the separatees entered civilian occupations connected with their military-acquired skills.

Freeman's study focuses primarily on the returns to formal training. He draws on the data available from the U.S. Department of Commerce, *National Longitudinal Survey*, for men aged 14-24 and 45-59. Interviewees were asked if they use their formal civilian or military vocational training in their jobs. While two-thirds of the working nonveterans reported they use their civilian institutional training, slightly more than one-third of those with Army training indicated their military skills are used in their civilian jobs. In this sample, however,

^aBased on less than 8 observations.

veterans in the older age group received their military training during World War II, when many of the military skills did not have direct civilian counterparts and a large percentage of military men were trained for combat. In addition, a large percentage of the younger males probably consists of veterans from the infantry who did not receive military training in skills with civilian counterparts. Since information on

the type or amount of military training acquired by each individual in the sample is not available, the percentage of separatees who utilize civilian-related military skills may be underestimated.

Studies of Air Force Separatees

Three studies of Air Force separatees who left the military after one term of duty are available. Thorndike and Hagen (1957) address the issue of benefits from military vocational training in the context of the civilian competition the Air Force must face for its technicians. They are primarily interested in dealing with the problem of low retention rates in high skill groups. As in the above two studies using Army and Navy data, the value of military training to separatees is evaluated by interviewing veterans.

Thorndike and Hagen's sample consists of 3005 Air Force enlistees from six selected military specialties. The separatees interviewed began their tours of duty around the time of the Korean War and had been out of the service for approximately one year at the time they were interviewed. A response rate of 65 percent was obtained for Thorndike and Hagen's survey. According to the survey responses, a large percentage of the separatees did not attempt to find civilian jobs related to their military specialties. Many felt related jobs were not available or they did not like their Air Force specialty and returned to pre-service jobs.

Only one-sixth of the sample in Thorndike and Hagen's study accepted related civilian jobs upon separation from the service (see Table 3). In higher-skilled areas approximately one-fifth to one-third of the separatees found civilian occupations comparable to their military jobs. In the sample surveyed by McCall and Wallace, a significantly higher percentage of the separatees entered related civilian occupations. Although McCall and Wallace deal primarily with the responsiveness of reenlistment rates to changes in remuneration, they also attempt to measure the degree to which Air Force training is transferable to the civilian sector by asking interviewees if their Air Force experience is used in their civilian jobs. Their survey of 505 Air Force electronic specialists who left the service in 1962 and who were

SOURCE: Thorndike and Hagen (1957), Table 34, p. 54.

employed in 1964 received a response rate of 60 percent. Approximately two-thirds of the interviewed Air Force-trained electronics specialists use their Air Force training. Contrary to Thorndike and Hagen, McCall and Wallace conclude that military training *is* transferable to the civilian sector. Since the military and civilian occupational structures have been shown by Wool (1959), Biderman and Sharp, and others to be converging over time, McCall and Wallace's sample of 1962 Air Force separatees may be more indicative of the current opportunities available to separatees than the sample of early 1950 Air Force veterans in Thorndike and Hagen's study.* Wool (1959), for example, reports that from the end of World War II to 1960 the percentage of individuals employed in military combat specialties without civilian counterparts decreased by approximately 57 percent (Table 4).†

* Also see Wool (1969).

† The returns to military training may increase if military and civilian occupational structures do continue to converge over time.

NOTE: Excludes trainees and other personnel not identified by occupation.

Another Air Force study by Richardson (1966) is concerned with the vocational readjustment problems of military separatees entering the civilian sector. The data used by Richardson are provided by interviews with Air Force officers and enlistees who separated from the military in 1965 and 1966. The response rate for the survey is 62 percent. Approximately one-half of the enlistees who separated from active duty after one term of service reported they use their military training a great deal in their civilian jobs (see Table 5). As with the study by Weinstein et al., Richardson found that veterans from military specialties requiring more training tend to make greater use of their military-acquired skills.

Over one-fourth of the enlisted separatees in Richardson's sample felt that their military training helped their performance in their

If so, studies using longitudinal data should explicitly consider the period in which individuals in the selected samples served their tours of military duty.

NOTE: The sample consists of 418 separatees.

post-service jobs and also aided them in securing those jobs. Of course, to judge the value of military training in securing civilian jobs, employers would also have to be contacted. Military training in a skill, for example, may make a potential employer more willing to hire a veteran if it is thought that the necessary on-the-job training would be less extensive.

Although peripheral to the studies of first-term enlistees, additional information, at least for the purpose of comparison, may be obtained from two available studies that focus on military careerists. The studies by Sharp and Biderman and by the U.S. Senate Committee on Armed Forces examine the vocational readjustment problems of military retirees when they enter the civilian sector. Sharp and Biderman's survey of May 1961 Army, Navy, and Air Force retirees with 20 or more years of active duty yielded a response rate of over 60 percent. Information from a second survey of retirees conducted by the Department of Defense is also used in Biderman and Sharp's study. Over one-half of the respondents from the two surveys reported that they use their military skills in the civilian sector to a greater extent or at least as much as they did in their military jobs (see Table 6). One-half of the job holders in the sample of retirees felt their military backgrounds helped them qualify for their civilian jobs.

^cExcludes (40) no answers.

The study by the Senate Committee on Armed Forces is concerned with the general transferability of military skills to the civilian sector rather than with the employment opportunities of retirees with specific occupational skills. A mail questionnaire was sent to all Air Force officers on the retiree rolls in March and April of 1961 who left the service between 1955 and 1960. The 3,168 responses received indicate a response rate of 74 percent. More than one-third of the sample used by the Senate Committee on Armed Forces reported their military backgrounds improved their performance in their civilian jobs. The military-to-civilian transfer problem was found to be not so much a result of unmarketable skills but rather one of retirees' matching up civilian job descriptions with their military skills and providing potential employers with this information.

Summary of Conclusions Based on Interviews With Separates

Studies that use opinion survey data to determine the degree of military skill use in the civilian sector indicate that the percentage of separates who use their military skills in their civilian jobs ranges

from approximately one-sixth to three-fourths of the sample respondents. Moreover, skill utilization tends to be higher for military specialties that are associated with more extensive amounts of technical training.

The studies discussed above may be subject to severe limitations. Any evidence presented implying that military training has a positive effect on the post-service opportunities of separatees is based on the subjective evaluations of veterans questioned. If interviewees separated from the military because of their distaste for military service, their responses to the survey may be biased.* Moreover, the gains from military training may be so subtle that some separatees cannot recognize the effect military training has on their post-service opportunities.

Four of the studies reviewed use data on separatees who received their military training during World War II or the Korean War when military training was more oriented toward combat skills. Since draftees are legally entitled to return to their pre-service jobs after completing their tours of duty, the data may indicate a larger percentage of separatees do not enter service-related jobs, if inductees are included in the sample. The study by Weinstein et al., for example, found that one-half of the Army separatees but only one-sixth of the Navy separatees returned to their pre-service jobs. Since the Army sample is composed of about three-fourths inductees or draft-induced enlistees, the percentage of skill utilization for Army separatees with formal military vocational training that could potentially be used in civilian jobs may be underestimated in the studies by Weinstein et al. and Freeman. The failure of separatees to enter civilian jobs in which they can use their military-acquired skills could also be a consequence of enlistees not being assigned to their preferred military specialty.†

* For careerists, a bias in the opposite direction may be present.

† Harding and Richards. Assignment to a preferred military specialty may not occur if: (1) physical, mental, and educational requirements are not met, (2) quotas for the preferred areas of training and duty have been filled, (3) the enlistee is well-qualified for an area in which the service has an insufficient supply of manpower, and (4) the enlistee does not have enough information about each military specialty.

As an alternative to the use of survey opinions, some studies use occupational codes to tabulate the degree to which veterans use their military-acquired skills. The conclusions reached by these studies are reported in the next subsection.

STUDIES USING CROSS-TABULATIONS OF OCCUPATIONAL CODES

A second technique used to determine the extent to which military skills are transferable to the civilian sector is to compare the military specialty of separatees with their current civilian occupation. Cross-tabulations of civilian and military occupational codes indicate that skill utilization ranges from approximately 8 to 100 percent, depending on the amount of technical training associated with an occupation.

Studies of Separatees Using Detailed Occupational Groups

Winkler and Thompson have provided the most detailed and extensive cross-tabulations of the relationship of civilian and military jobs. The comparability of military and civilian occupations and the extent to which military skills are used in the civilian sector are evaluated by using two-digit and three-digit DOT codes and five-digit Air Force Specialty Codes (see Table 7).^{*} Occupational codes are grouped together on the basis of job characteristics. The data used are extracted from the Post-Service Information File. The selected sample includes Air Force enlistees who left the service between 1968 and 1970 after serving one term of military duty.

Winkler and Thompson indicate that in two-thirds of the Air Force specialties, more than one-fourth of the respondents use their military skills in their civilian occupations. Thirteen of the thirty-three

* U.S. Department of Labor (1965). Of the currently available classifications of occupations, DOT codes appear to be the most useful for the issues addressed here. The DOT was constructed from a sample of 4000 jobs in 1956 by the Bureau of Employment Security. The first digit of the DOT code signifies the major occupational group, the second indicates the function of the group, and the third digit a more detailed subject matter. For example, DOT 720 is defined as:

- 7 = benchwork occupations
- 2 = occupations in assembly and repair of electrical equipment
- 0 = occupations in assembly and repair of radio and television receiving sets and phonographs.

career fields with a variable reenlistment bonus (VRB) level of four have utilization rates ranging from 50 percent to 100 percent (see Table 8).^{*} For the remainder of these career fields, approximately one-third of the separatees entered related civilian occupations. Thus Winkler and Thompson conclude that military skills are transferable to the civilian sector, especially if they are associated with a high degree of technical training.

Studies of Separatees Using Broad Occupational Groups

The other studies that use DOT codes to classify the relationship between military and civilian occupations cross-tabulate occupations by much broader groups. Using data obtained from the Post-Service Information File and the End-of-Service File (tape), which include separatees who served one term of active duty and who separated from the military in 1971, Massell and Nelson cross-tabulate the civilian occupations of separatees with their military specialties (Table 9). In contrast to Winkler and Thompson, Massell and Nelson report that the use of military-acquired skills is not significantly high. Of the military specialties included in their analysis, mechanics have the highest probability of entering related civilian occupations, with approximately 25 percent of the separatees employed in comparable post-service jobs. In comparison with Winkler and Thompson, Massell and Nelson use primarily one-digit DOT codes. Consequently, within any one group, the skills are more mixed as to job content. That is, one-digit DOT codes include a greater diversity of skills than two-digit and three-digit DOT codes. The professional group, DOT 0 and DOT 1, for example, includes such diverse occupations as engineers, physicians, artists, pilots, and teachers. The cross-tabulations presented in the studies by Richardson and by Sharp and Biderman, which are discussed above, illustrate the difficulty encountered in determining if individuals entered civilian occupations comparable to their military specialties in

^{*} A variable reenlistment bonus of four indicates that the military specialty requires an extensive amount of technical training and that the military services are faced with a shortage of trained manpower in the skill area.

studies that use one-digit DOT codes (Tables 10 and 11).^{*} As an alternative to one-digit DOT codes, Winkler and Thompson evaluate two-digit and three-digit occupational codes to aggregate individuals on the basis of the type of skills required for each category. (Tables 8 and 9 versus Tables 10 and 11). In this way they are able to facilitate their evaluation of the extent to which military skills are transferable to the civilian sector.

SUMMARY

With the exception of the studies by McCall and Wallace and by Winkler and Thompson, the general conclusion forthcoming from the available studies is that military training is not transferable to the civilian sector. However, since the findings offered by the above studies vary depending on the occupational groups examined, the method used to group civilian and military occupations, and the period in which the selected sample of individuals served their tours of duty, conclusive evidence on the association between the military occupations and post-service occupations of individuals is not provided. The only conclusion offered consistently by all of the above studies is that separatees in the more technical military specialties have a higher probability of continuing to work in the same occupation when they enter the civilian labor force than separatees in the less technical military specialties.

In examining the transferability issue, existing studies do not formulate a model of occupational choice. Consequently, none of the available studies takes into consideration the influence of such factors as prior civilian training on a separatee's choice of a post-service occupation. As an alternative approach to that of occupational choice, some studies focus on the effects of military training on the post-service earnings of individuals. These studies are evaluated next.

^{*} It is not only difficult to assess the comparability of military and civilian groupings but, since different studies use alternative methods of aggregating occupational groups and varying levels of aggregation, it is difficult to compare the findings on the transferability of military skills across studies.

IV. STUDIES USING STATISTICAL TECHNIQUES TO DETERMINE
IF SEPARATEES RECEIVE ECONOMIC RETURNS
TO MILITARY TRAINING

INTRODUCTION

The economic effect of military training has been evaluated by existing studies using two basically different data bases. First, the earnings of separatees with military vocational training are compared to the earnings of similar veterans from the infantry. Second, the earnings of veterans and comparable nonveterans are evaluated to determine if the loss of civilian work experience is compensated for by military-acquired training. Using these two approaches, previous studies have analyzed the extent to which separatees receive a positive economic return from military vocational training.

If investment in military vocational training increase the productivity of veterans who are employed in civilian occupations, it will also have a positive effect on the earnings of these individuals, as is supported by human capital theory. Therefore, post-service earnings are used in these studies to measure the economic benefits provided to separatees from military vocational training. These studies evaluate the economic returns to military training using multiple regression analysis to standardize or control for the influence of other factors that affect productivity and thereby earnings.

STUDIES THAT COMPARE DIFFERENT COHORTS OF VETERANS

Weinstein et al. focus on the economic effect of military vocational training on the post-service earnings of veterans. Army and Navy separatees were asked if they used their military training in their post-service occupations in the three years following the separation of veterans in the sample from active duty.

Weinstein et al. find that individuals who use their military training earn significantly more than those who do not. This seems to support the hypothesis that separatees who use their military training in their civilian jobs receive a positive return to military vocational training. However, Weinstein et al. also find that separatees with both

pre-military and military training related to their post-service jobs tend to have lower earnings than separatees with related pre-military training who were not in similar military specialties. This implies that military vocational training has a negative effect on the post-service earnings of veterans. Since separatees who enter post-service occupations related to their military training have a greater probability of doing so if they have been employed in related pre-service civilian jobs, Weinstein et al. are led to conclude that where income is affected it is due to the pre-military work experience acquired by separatees rather than to their military training.

Although the opportunity cost of changing occupations is higher for individuals with both pre-service and service training in the same occupation, this does not provide substantive evidence that separatees benefit from civilian training but not military training. Weinstein et al. do not attempt to statistically control for pre-service civilian training while concurrently evaluating the economic effect of military vocational training. As a consequence of the manner in which the empirical study is structured, their report does not offer conclusive evidence on the economic effect of military training. In addition, they make no attempt to formulate a statistical test of the returns to additional amounts of formal and informal military and civilian training that is used in post-service occupations.

Using the same data as Weinstein et al., Kassing also evaluates the earnings of vocationally trained Army separatees and compares them with the earnings of infantrymen. Kassing concludes, as do Weinstein et al., that vocationally trained separatees do not receive higher earnings than ex-infantrymen who did not undergo military training transferable to the civilian sector.

A third study that offers some evidence on the effects of military vocational training is made available by Freeman. Using data on white Army veterans who served in the pre-World War II and World War II periods, Freeman finds that although most types of formal civilian occupational training have a positive effect on earnings, training received in the Army does not. Freeman's concern is with the very broad and general effects on earnings from formal vocational training acquired

by individuals in various institutions. Consequently, he aggregates training in different occupational groups and does not distinguish between different amounts or types of military training. In addition, no distinction is made between individuals who use their training in their current occupations and those who do not.

Hanushek focuses on differentials in earnings across geographical labor markets. Using the Post-Service File, data on 180,000 separatees who left the Army during FY 1969 after two years or less of active duty are obtained ten months after they separated. Hanushek indicates that the military occupation of an individual does not have a significant impact on earnings.* He suggests this result is probably due to the low level of military training acquired by individuals in his sample. Since the sample consists of separatees who served only two years or less of active duty, they are less likely to have had extensive technical training. In addition, Hanushek does not distinguish between individuals who use their training in their current occupations and those who do not. He also assumes that individuals within the same one-digit DoD code receive equal amounts of formal military training.

Mason's (1970) analysis of the May 1964 Current Population Survey of men under 35 years of age indicates that the military occupation and length of service of individuals do not have a positive effect on the income of separatees when they enter the civilian labor market. His sample consists of 1,454 veterans who are employed full-time and not enrolled in school. Since Mason is interested in the effect military service has on the socioeconomic status of veterans, occupations are classified into ten major census groups by socioeconomic rankings. The comparability of civilian occupations and military skills is determined by these rankings of general occupational socioeconomic standing. He concludes that military training does not result in a positive economic return to veterans. In fact, Mason concludes that there is a negative return to military training. He attributes this result to the fact

* It should be noted that the timing of the surveys relative to the separation date of individuals may affect the conclusions of the available studies interested in the effects of military service on the post-service opportunities of separatees.

that the military experience of an individual takes away from the time that could be spent obtaining civilian labor force experience.

Neither Mason nor the above studies differentiate between individuals who use their military-acquired skills in their current occupations and those who do not. McCall and Wallace indicate that the earnings of separatees are positively and significantly associated with whether or not they use their Air Force training. Using a sample of Air Force-trained electronic specialists, McCall and Wallace find that the civilian earnings of separatees in their sample are significantly higher for those who enter related civilian occupations.

STUDIES THAT COMPARE VETERANS WITH NONVETERANS

Kassing attempts to evaluate the returns to military vocational training by comparing veterans with nonveterans who are employed in the civilian sector. Kassing uses a subsample of 8,104 veterans from the one percent sample of 1953 Selective Service System Records and data from the Social Security Administration. The sample consists of separatees who served one term of active duty during the Korean War. Data were obtained for individuals three to four years after and also nine to ten years after their separation dates.

Kassing finds that military service does not result in a significant wage differential as a consequence of military vocational training. However, he makes no distinction between the type of military training, the current occupation, or the relationship of the military training to the current occupation of individuals in the sample. Moreover, in comparing veterans with nonveterans, infantrymen who did not receive vocational training are included in the veteran sample.

Drawing from the same data sources used by Kassing, Cutright's sample includes only those veterans who served two years in the military during the 1949-1953 period. As in Kassing's study, data were also taken three to four years after and nine to ten years after the date of separation of veterans. The sample consists of 5,972 whites and 1,650 blacks. Cutright is interested in evaluating the factors that affect earnings. He is particularly concerned with the impact of general military service on the civilian earnings of separatees and

how the effect of military service on earnings changes over time. Since he is not interested in the different effects of military service that result from acquiring various types of military training, the data are not disaggregated by occupational groups. By comparing the earnings of veterans with similar nonveterans as Kassing does, Cutright also concludes that the positive effects of military training do not overcome the negative effects that result from being out of the civilian labor market.

SUMMARY

A number of considerations must be dealt with in evaluating the extent to which previous studies have presented conclusive evidence on the economic effects of military training on the civilian earnings of veterans. One important aspect that must be taken into account in evaluating the conclusions reached by various studies is related to the data bases used. Hanushek's sample, for example, consists of separatees who have had only two years or less of active duty. They are, therefore, less likely to have had any extensive amount of technical training in the military. Other studies use samples that consist of a large percentage of separatees who were inducted into the service during or prior to the Korean War.* During this time, intensive military training in civilian-related skills may have been less prevalent than during peacetime periods.

Second, the earnings of former military personnel may depend on the type and amount of military training received and the relationship of this training to the current occupation of individuals. Moreover, the return to training may differ across occupational groups. The return to training for any one specific military specialty may not be discernible if all military-trained separatees are aggregated and assumed to be homogeneous.

Of the studies that distinguish between various types of training or amounts of military training, none have effectively considered the

* For a comparison of the characteristics of the samples used by each of the studies discussed above, see Table 1.

return to training for separatees who use their military-acquired skills in the civilian sector compared to the return for those who do not. As a consequence of insufficient data on the type and amount of pre-service training, which may affect the conclusions of studies based on empirical tests of the economic effect of military training, previous studies have not been able to offer conclusive evidence on the economic returns to specific types and amounts of military training.

V. ON-GOING RESEARCH ON THE RETURNS TO MILITARY TRAINING

The available theoretical evidence suggests that the wages of individuals reflect their productivity. Changes in productivity resulting from military training may therefore be measured by comparing the wage differentials of different cohorts of individuals. Given the absence of detailed data on the work histories of nonveterans, comparisons of different cohorts of veterans can be used to measure the effect of military training on productivity. Separates from military specialties related to their current civilian occupations, for example, could be compared to individuals in the same occupation who did not acquire related military training.

None of the available studies have fully addressed the issue of the potential economic returns to military training that accrue to individuals who use military-acquired skills in post-service occupations. Moreover, previous studies have not been able to observe the effect of formal and informal military vocational training while concurrently controlling for other factors that may influence their conclusions--such as skills acquired in the civilian sector, which may be substitutes or complements for military training. In the same context, when the military experience of individuals is viewed, in total, as the length of time spent in active duty, no consideration is given to the extent of formal compared to informal military training acquired by individuals. Instead, a distinction needs to be made between the amount of time spent in formal military training, the amount of time spent working in the military, and the type of military and job experience acquired. That is, it is likely that enlistees who served in the military as cooks, for example, have different opportunities than comparable individuals who served their tours of duty in more technical military specialties.

Two of these studies evaluate the economic effects of military vocational training by using infantrymen as a control group under the assumption that infantrymen do not receive military training that can potentially be used in the civilian sector. These studies do not

consider the possibility that training in other military specialties besides the infantry may not have civilian counterparts. Moreover, since infantrymen constitute a disproportionate percentage of draftees, they may be an inadequate control group for evaluating the economic effects of specific types of military training. As an alternative, a companion Rand study (Norrblom, 1976) uses earnings data for selected civilian occupations to compare separatees who acquired military vocational training and use it in their current occupations with those who did not receive related military training.

Many issues on the effects of military training remain to be evaluated. Without these additional considerations, the available evidence is not sufficient to support any firm conclusions on the economic effect of military vocational training. These considerations include the returns to specific types of military training, the returns to military training for separatees who use their military-acquired skills in their post-service occupations compared to those who do not, the returns to formal as compared to informal military training, and the consideration of military training as a complement to or substitute for civilian training. These issues are addressed in the companion report cited above.
