# 1. Introduction

The National Software Works (NSW) system development activities which we report for this guarter clearly indicate the substantial progress in the overall NSW effort. For the first time since the start of the project, a major portion of our activities have been diverted from developing a demonstrable minimum NSW logical functionality to tasks associated with providing an operational entity. The increased concern for both the reliability of the system, and for its overall performance under realistic conditions are a direct result of the maturing of the system functionality to a point where an operational NSW could be feasible. The extensive discussions of system performance and reliability in this progress report reflect this subtle change in project direction. Although there are still many problems yet to be attacked, the fact that the system has developed to the point where reliability and performance are important is indeed encouraging.

In the following sections we discuss the major accomplishments of this quarter. As usual, the bulk of the effort surrounds two major Tool Bearing Host (TBH) components, MSG and the Foreman. In addition to performance and reliability related developments, we also report on maintenance activities and some increased functionality in these components. Other activities reported include the distribution of additional NSW

-1-

A State

and and

documentation, and our participation in various meetings held with a number of groups to further the goals of the NSW project.

an it may

Bolt Beranek and Newman Inc.

# 2. TENEX MSG Related Activities

During this quarter, the major part of our MSG related effort was spent in gathering and interpreting performance data for the TENEX MSG component itself, and for obtaining initial performance measures for the other NSW components as seen from within MSG. This work is discussed in detail in Section 2.2 and Appendix A. We have also released a sequence of new versions of the TENEX MSG component. These releases incorporate added functionality and provide solutions to problems that arose out of the increased use of MSG for NSW development activities. The nature of the changes are detailed in Section 2.1.

Another important part of this quarter's effort was the development and distribution of a TENEX MSG User Manual. This document (BBN Report No. 3540) describes from a user's point of view the TENEX implementation of MSG. It is intended as a reference for programmers who use MSG and as a guide for those responsible for the operation of systems, such as NSW, which use MSG. The user guide is the TENEX-specific companion document to the MSG design specification ("MSG: The Interprocess Communication Facility for the NSW," BBN Report No. 3483). The manual contains sections describing the MSG supported process interface (programmers guide) and descriptions of the various ways to define and run MSG configurations. Additionally, there is a section describing the use of the MSG process monitoring and

-3-

### Bolt Beranek and Newman Inc.

control functions, as well as an appendix enumerating the assigned error code values. The TENEX MSG User Manual is an important reference document for all MSG related activities, and will certainly contribute to the self-sufficiency of the various contractors using MSG. We intend to periodically update the manual in order to keep abreast of MSG implementation changes and the pending conversion of MSG for TOPS-20.

2.1 MSG Implementation Developments

There were a number of releases of new versions of TENEX MSG to the NSW project community during this reporting period. Since the communication subsystem is an integral part of almost all NSW component testing, we are especially sensitive to the need for prompt attention to any MSG software problems which arise from operational use. In an effort to expedite overall system testing, we will most often try to correct MSG bugs immediately as they are reported to us. When problems require more than a simple on-line modification, we usually immediately begin the process of releasing a new version of the software incorporating the more extensive changes necessary to correct the problem. In addition to the maintenance related changes, there were two other substantial modifications incorporated into MSG this guarter. These changes accommodate added functionality regarding the use of MSG by network dispatched NSW FE processes, and a substantial reorganization of the parts of MSG which handle direct connections.

-4-

ST & Ston Wilson

Bolt Beranek and Newman Inc.

The MSG job to handle network dispatched NSW FE processes is a little different from most other NSW MSG jobs. The job hierarchy for these FE jobs includes a Dispatcher related root node (responsible for managing the ARPANET Telnet connection to the user terminal) which is superior to the MSG task controlling process, which is superior to the FE process(es). The root node is tasked with ensuring the integrity of the job within the TENEX operating system, while the MSG process maintains the integrity of the MSG operation relative to the other co-located MSG jobs. It is the responsibility of the FE process to cooperate with other network-wide NSW components to ensure the integrity of the NSW system as a whole.

For an FE process to complete a normal termination, (e.g., after a user NSW LOGOUT), the FE must execute its termination and cleanup routines before relinquishing control. Likewise, the MSG process, upon detecting the termination of the FE, does its cleanup before it signals the root node to proceed with the job cleanup and deallocation. All of the preceding is the usual order of occurrence. However, there are circumstances in which the signalling is initially reversed. In particular, it is the root node that detects a break in the job's Telnet connection. This signal is then passed to the MSG process which until recently would immediately proceed with its termination sequence. However, new requirements for NSW functional behavior now give FE

-5-

#### Bolt Beranek and Newman Inc.

processes a role in handling these conditions and mandate that the FE proceed with an "autologout" scenario with other NSW components. The autologout is used to properly save some of the user's context and to adjust system status tables so the user can continue at a later time. In order to carry out its protocol obligations when the user connection has failed, the FE must be informed of the failure and allowed sufficient time and resources to complete its operations. Accordingly, we have added such a capability to the TENEX MSG. Now, whenever an MSG for dispatched FE jobs is signalled about a broken Telnet connection, MSG, in turn, signals the FE process via a channel previously set up by the FE. MSG then allows the FE to complete its cleanup before proceeding with the job deallocation sequence.

An extensive effort was also made this quarter to improve the code for handling direct ARPANET connections within MSG. Because of the asynchronous, multi-step procedures required for both opening and closing ARPANET connections, the MSG code to handle these functions is complex. It is implemented as a finite state machine, but this simple model of operation becomes somewhat obscured by the requirement for a large number of possible states along with a large number of possible transitions. Due to its complexity and its inherent asynchronous nature, extensive testing and debugging is very difficult. Because of this, many of the problems with direct connections

-6-

Bolt Beranek and Newman Inc.

have come to light only after substantial field use of MSG. The types of failures reported, as well as the opportunity to "catch" and examine transient failures as they occurred in actual use, led to an increased understanding of the measures which were necessary to prevent certain error producing situations from occurring and in successfully dealing with others when they do occur. The effort expended in modifying the direct connection handling in MSG should make subsequent releases of MSG much more reliable and well behaved in this area.

2.2 MSG Performance Measurements

As reported last quarter, we have developed and installed an instrumentation package for the TENEX MSG component. The data which is collected can be used to measure the overall performance of the MSG component in delivering messages, sending alarms, and setting up network connections. In addition, by recording selected process parameters whenever a process interacts with MSG, measurements can be obtained to estimate certain aspects of NSW component behavior in carrying out the various NSW protocol scenarios. We have now performed a number of experiments to obtain both types of performance data and have written a fairly extensive report summarizing our findings. The purpose of the measurement experiments was to gain a quantitative understanding of the operation of the NSW system in order to identify performance bottlenecks and to determine ways to improve NSW

-7-

## Bolt Beranek and Newman Inc.

performance. Part of our objective was also to develop support software and methodologies to be used for subsequent, more detailed measurements.

Two distinct sets of measurements were taken. The first class of measurements were for MSG operations, and measured the elapsed real time for performing these operations under various conditions. The second class of measurements were for the various higher level NSW components, (e.g., Front End, Works Manager, etc.), and measured the CPU requirements for each under the various NSW functional operations, (e.g., RUNTOOL, OPEN-FILE, etc.). The performance measurement summary, including sections on the measurement methodology as well as the observed results, is included in as Appendix A of this progress report.

## 2.3 An MSG Performance Experiment

In an effort to improve MSG's response characteristics, we have experimented with a change in the layout of MSG internal data structures. The thought behind the experiment was to see if a different layout might minimize the number of data pages that need to be accessed in completing an operation. This, in turn, might minimize the number of page faults, which might then contribute to decreasing the delay associated with the various MSG operations.

-8-

Bolt Beranek and Newman Inc.

Currently, most MSG data structures, (i.e., tables for message block entries, connection blocks, etc.) are organized as a series of parallel tables. That is, each data field of a given n-word entry is retrievable as the same index (i) into each of n different single dimension arrays. Put another way, the data structure representing the ith item is the composite of the ith entry for each of the n parallel tables. We call this a horizontal data structure. We can contrast this to another organization technique in which the n-words of each entry are stored in consecutive locations, with the i+lst item in its entirety following the ith. We call this a vertical data structure. While both organizations accommodate the same data, one or the other may be more appropriate depending upon the access patterns to the data. For example, if we are primarily dealing only with a specific field of an entry in conjunction with the same field of other entries, then a horizontal table might be appropriate. If, on the other hand, accessing one data field of an entry normally also means an immediate reference to the other fields of the same entry, then a vertical structure might be more appropriate.

At the outset in coding the MSG component, we developed and utilized a series of macro functions which are used to define and access internal data structures. Because of this, it was a relatively easy task to convert to an alternative table

-9-

Bolt Beranek and Newman Inc.

organization. We performed the experimental conversion and ran a number of tests. The results were that by utilizing a vertical table organization we were able to achieve about a 20-25% improvement in the "paging" characteristics of MSG over using a horizontal structure. The improvement relates to the measurement of the working set size, the number of page faults, and the average CPU time per page fault to do equivalent tasks under roughly similar conditions. However, we also found that despite the improved locality of reference exhibited by MSG, the delay associated with the various MSG operations did not improve. Thus, we conclude that MSG performance is not currently being limited by its paging behavior. Other experimentation is continuing.

 $\square$ 

# 3. TENEX Foreman Related Activities

This quarter there were a number of new releases of the TENEX Foreman component. These releases corrected various problems that arose in testing and component integration by other contractors, as well as from limited use by outside organizations such as the system development group at NELC. In addition, there were major implementation efforts in the areas of reliability and instrumentation. A few new features have also been added to the Foreman, and another tool (the text formatting program MRUNOFF) has successfully been added to the available NSW repertoire. These developments are elaborated further in the following subsections.

3.1 Implementation to Support the Interim Reliability Plan

Last quarter we reported on the design effort to incorporate NSW file system reliability concepts into the existing NSW component structure (see BBN Report No. 3736, Section 3.1). This quarter we can report that the so called "interim reliability plan" has been finalized, and also that its implementation for the TENEX Foreman component is complete. As we have previously noted, the plan is an attempt to provide roughly the same degree of safety regarding losing files and completed user work as could be expected by a user dealing directly with the tool bearing host operating system. The problem addressed by the reliability plan

-11-

# Bolt Beranek and Newman Inc.

is brought about by one of the primary design goals of NSW. That is, the user must not deal directly with any of the constituent TBH operating systems. Rather, in order to incorporate a single, uniform view of the entire system, the user is permitted to interact only with NSW which intercedes on his behalf with the local operating system. Thus, we require mechanisms within NSW itself to assure adequate safety in handling the NSW file catalog and the files themselves whether they currently reside in the tool workspace or in the NSW file space.

The interim reliability plan requires each Foreman, during a tool session, maintain a local name dictionary (LND) on a non-volatile storage medium to allow file retrieval in the event of a system failure. The LND is a temporary local file directory that contains such information as the user's name for an NSW file, and the local host name for the image of that file. The LND for a normally terminating tool session is not discarded until the WM "guarantees" the acceptance and "permanent" recording of the appropriate workspace files. Any session which does not terminate normally (that is, with the successful completion of file delivery and cleanup operations) has its LND automatically saved. Saved LNDs are subsequently reported to the WM so that workspace files which have not yet been incorporated into the NSW file system can later be retrieved by the affected user.

-12-

Π

Bolt Beranek and Newman Inc.

The TENEX Foreman has been extensively modified to implement these reliability related concepts, as well as to incorporate the spirit of these changes in other reliability related areas not specifically addressed by the interim plan. On TENEX, the LND is maintained as part of the TENEX file system to ensure its existence across system restarts. Convenient access to the LND data base is achieved by "mapping" the LND file pages into the virtual address space of the appropriate Foreman process. When a tool session is begun, the Foreman selects a workspace from the pool of available directories for handling the file storage requirements for the session. The LND is itself a file resident in the workspace while it is active.

Most error conditions detected by the Foreman during a tool session (e.g., message timeouts) cause the tool session to be saved. In addition, the FE can request that the Foreman save a tool session in the event that the FE loses contact with its user (see also the discussion of autologout in Section 2.1 of this report). Tool sessions which abruptly come to a halt because of a host system "crash" are automatically saved when the NSW is next restarted on the effected TBH. The implementation of the saving, reporting and rerunning of the tool sessions is centered around two shared Foreman data bases. (Each TENEX TBH has its own private copy of the data bases, which are accessible to all Foremen on the TBH.) One data base describes the state of all

-13-

### Bolt Beranek and Newman Inc.

accessible NSW workspaces (i.e., the workspace list) and the other companion data base contains the state of all saved tool sessions (i.e., the rerun list). Saved tool sessions are currently maintained in the workspace in which they were originally run. This means that part of the procedure for saving a tool session is ensuring that the workspace which supported the session is not placed back into the pool of available spaces when the Foreman is deallocated. This allows another Foreman at some subsequent time to complete ("rerun") the session merely by connecting to the appropriate workspace which already has the appropriate LND and supporting files. However, it also means that the workspace is not available for running other tools while the session is still saved. For the initial implementation we evaluated this as an acceptable tradeoff.

Whenever a tool session is saved, the appropriate workspace data base entry is marked as containing a saved session (to prevent it from bing reused) and a rerun list entry for the session is created. The rerun list entry will be used to coordinate the activities which are appropriate for saved tool sessions (e.g., reporting them to the WM, rerunning). The creation of the rerun list entry along with the appropriate exchanges with the WM to report the saved session can be initiated in two different ways. If the Foreman process controlling a tool is alerted to or detects some error condition,

-14-

Π

Bolt Beranek and Newman Inc.

it adjusts the data bases to reflect the new status and then immediately tries to report the saved session. For those cases in which the tool Foreman does not retain control (e.g., system or Foreman crash), a special Foreman process will save and report all previously unreported sessions as a group, when the TBH software is next reinitialized. After a saved tool session is properly recorded in the FM data base and reported to the WM, it can at any time be rerun. The rerun request is a generic message to a Foreman which then searches the rerun list for the saved session. After a successful search, the Foreman can locate and access the saved LND and its associated files and properly terminate the session.

We have completed the initial implementation in accordance with the specifications set forth in the interim reliability plan. We have also tested these changes in stand alone fashion to the degree possible without having the supporting matched components. Other contractors are now finishing the implementation of their component responsibilities under the plan, and we are beginning to mount a large scale system integration effort for all of the updated components.

3.2 Foreman Instrumentation

Another major implementation effort undertaken this quarter was in the area of instrumentation for the Foreman. We have

-15-

#### Bolt Beranek and Newman Inc.

designed and implemented a package handling three different types of instrumentation needs within the Foreman. The overall approach is to use probes inserted throughout the Foreman corresponding to specific events. Each time a probe is executed, selected information is placed in a core buffer marking the event, time of occurrence, and other raw data relating to the nature of the event. Immediately before asking to be deallocated, the individual Foreman process dumps the contents of the event recording buffer along with appropriate header information into a common file shared with other Foreman processes. These files can then be processed off-line. This approach has been taken to minimize the overhead for handling the instrumentation while processing user demands.

There are three basic uses for the probes, with use each being configured differently. One probe type is used for recording message traffic both to and from the Foreman process. This is very helpful when attempting to reconstruct the sequence of events leading to a particular internal process state. It has also proven useful in pinpointing the origin of protocol violations in transmitted messages.

A feature of the FM instrumentation package is the ability to have the entries being recorded in the "core buffer" converted to text and displayed on the job controlling terminal as they are recorded. This is quite useful as an on-line testing and

-16-

Sister may

and and the second

#### Bolt Beranek and Newman Inc.

debugging aid, although it can introduce substantial delay in servicing messages and would invalidate most performance measurement recording. Certain probes are inserted mostly for their tracing effect to be used in an on-line terminal environment.

A second type of probe is used to report unusual events and error conditions occurring in an unattended system. One mode of FM operation is to have an individual process halt on detecting an inconsistent situation. This is useful in trying to uncover the problem but is not feasible unless the system is monitored by someone thoroughly familiar with the operation of the FM. Since this is not normally the case, we usually have the FM set up to clean up as best it can on error conditions, then try to gracefully terminate its operation. The trouble here is that the cause of the error often goes undetected. To remedy this, we have utilized special probes which try to capture some of the relevant state of the FM when an error condition is detected. These probes insert data into the log file which can be used off-line to not only detect the occurrence and frequency of failures, but also to attempt to reconstruct their cause. We have already discovered and fixed a number of FM bugs which came to our attention days after the errors actually occurred in NSW configurations managed by other contractors.

-17-

a to show without

Bolt Beranek and Newman Inc.

The third type of probe is used to obtain performance measurements. These probes record process characteristics such as CPU time used and connect time, along with more global characteristics such as system and group load averages. Measurement probes are generally used in pairs to obtain time intervals (CPU time and/or real time) for certain events. To gain experience with the measurement technique and in trying to formulate a measurement methodology, we will experiment with measuring both internal FM performance for selected large grain events (e.g., BEGINTOOL) and external NSW performance in handling FM related functions (e.g., time to complete an Open-file request).

The probe handling software is currently undergoing checkout. When complete, a new FM will be distributed with probes in place to automatically record error conditions and performance data.

3.3 Other Implementation Developments

A number of operational problems were corrected this quarter through a series of FM system component releases to the NSW community. The most notable fix corrects the problems associated with race conditions arising out of "simultaneous" FE and FM instigation of similar functions in trying to terminate the tool. On certain occasions, these races caused some files to be

-18-

Bolt Beranek and Newman Inc.

delivered twice when a user tried to terminate a tool both from within the tool and also via the NSW command language. A similar problem caused occasional abort commands to be ignored when received after a tool had begun its termination sequence. To correct these problems we have transformed the existing tool status descriptor into a multiple component state variable with finer grain states which can now adequately depict all of the various combinations of legal termination sequences. The message handling code is now integrated with the complete tool status variable to achieve a proper functionality.

New releases of the Foreman also now support the STOP-TOOL and START-TOOL (SUSPEND, RESUME) features as described in the Foreman Specification document. In theory, a user can now instruct his FE, via the NSW command language, to suspend an active tool, and later to resume its execution. In practice, the NSW FE has not implemented the support for these functions so they are not as yet part of the primitive tool control set.

-19-

Bolt Beranek and Newman Inc.

BBN Report No. 3751

## 4. Documentation and Meetings

This quarter we have issued an update to the Tool Builder's Guide manual (Massachusetts Computer Associates, Document CADD-7702-1811, BBN Report No. 3308. This update reflects the wide ranging changes in the NSW over the last year. The description of both NSW characteristics relating to the tool interface and the operational procedures for inserting a tool in NSW have been revised to reflect the current system release. Also in the documentation area, we have issued an updated Appendix to the Foreman specification document detailing the messages and patterns of use for implementing the interim reliability scenarios. In a break with the past, all messages dealing with the reliability constructs for all components are now compiled within a single document.

There were a number of inter-contractor meetings this period to define and then to coordinate the implementation of the interim reliability measures. We have also worked closely with personnel from Massachusetts Computer Associates in designing the NSW measures to be adopted within the context of a larger, more extensive reliability plan. Toward that end, we were meeting on a weekly basis to discuss these technical issues.

Finally, at the request of the ARPA office, we met with Professor Howard Morgan of the University of Pennsylvania. We

-20-

Π

Π

discussed the possible use of the MSG facility for supporting a data base alerting service which he is currently working on. MSG's message oriented communication approach seems well suited to this type of data base processing system, and we expect the dialog to continue.

BBN Report No. 3751

#### 1. Introduction.

This report summarizes a set of performance measurements made on the NSW system. The purpose of these measurements and ones to follow is to gain a quantitative understanding of the operation of the NSW system. With this understanding, it should be possible to identify performance bottlenecks and to determine how to improve NSW performance.

The measurements reported here should be regarded as the first set of a series of measurements to be performed on NSW. These measurements were largely exploratory in nature. The primary objectives were twofold: to derive a general quantitative feeling for NSW operation in order to identify aspects of system operation to be more thoroughly measured; and, to develop software and methodologies to be used for subsequent, more detailed measurements.

Two distinct classes of measurements were performed. The first class of measurements were for MSG, the NSW interprocess communication facility. The delay (elapsed real time) incurred to perform various MSG primitives was measured both for intra-host and inter-host operation. These measurements are reported in Section 2. The second class of measurements were for the various NSW components (e.g., Front End, Works Manager, File Package, Foremen). The CPU time required by each of the components to perform its part of an operation was measured for various operations (e.g., RUNTOOL, OPEN, DELETE, etc.). These measurements are reported in Section 3.

Note that in one case (for MSG) we have measured delay and in the other case (for NSW components) we have measured CPU requirements. For these preliminary measurements these different properties for the two cases were chosen because we believed them to be both the easiest to measure and the most interesting in each case. Subsequent experiments will be made to measure MSG CPU requirements and NSW component delays for various scenarios.

As noted above, the measurements reported here are preliminary. In this report we have refrained, as much as possible, from interpreting the measurement data. We have, however, tried in a few cases to make comments of an explanatory nature. We believe that these measurements are likely to raise more questions than they answer. We believe that this is good and that the answers to these questions will come both from more comprehensive and directed measurements and from re-examination of component implementatons and inter-component protocols. We expect to work closely with other NSW project personnel to develop a plan for additional performance measurements and subsequent performance improvement efforts.

and President &

2. Measurements of MSG.

2.1 Measurement Method.

A series of experiments were run to measure delays incurred performing various MSG primitive operations. The measurements were made using two processes, called M1 and M2, which cooperate to exchange messages, send alarms, and open and close connections. Round-trip delays are directly measured from which one-way delays can be derived.

Using Ml and M2, measurements can be made for the SendGeneric, SendSpecific, SendAlarm, OpenConn and CloseConn primitives. The SendGeneric experiment measures the elapsed time for Ml to send a generic message of N bytes to M2 and to receive a reply (specific) message of N bytes from M2. The SendSpecific experiment is similar with the exception that the message from Ml is a specific message. The SendAlarm experiment measures the elapsed time for Ml to send M2 an alarm and to receive a reply alarm from M2. For the connection experiments, Ml and M2 establish a connection of a given type, exchange some data, and then close the connection. The delay to open the connection and the delay to close the connection are measured.

The M1 process accepts a specification of the measurements to be made from a user, ininteracts with the M2 process to inform it of the measurements to be made, and then cooperates with the M2 process to perform the measurements. As an example, consider an experiment to measure SendSpecific delays by sending 1000 400-byte messages. First, Ml would send M2 a (generically addressed) message specifying that 1000 400-byte messages were to be exchanged. Next, Ml would measure the delay incurred in sending a 400-byte message to M2 and receiving a 400-byte reply message from M2. After 1000 repetitions of the above message exchange, M2 would terminate and M1 would produce a summary of the experiment. The summary includes: the average, maximum and minimum measured delays; histograms of measured delays; and histograms of system and group load averages which are measured by M1 each time an MSG primitive is executed. Appendix 1 is a summary produced for a typical experiment.

A detailed specification of the Ml and M2 processes given in a stylized programming language appears in Appendix 2. We recommend that Ml and M2 processes be implemented for all MSG hosts so that MSG performance measurements can be made for all combinations of MSG host types.

### 2.3 Comments.

- All measurements were made under very light TENEX loads. Consequently, we believe that the "Min" figures approximate lower bounds on delays for the operations measured (for the current TENEX MSG inplementation).
- 2. Intra-host message delays are independent of message length. This is to be expected since intra-host messages are handled by TENEX page mapping operations which are independent of the size of the messages within a page. Inter-host message delays, in general, increase with message size as might be expected since the message must be sent as a stream of bytes across the network.
- 3. The SendGeneric measurements were made for an M2 process that executes a StopMe primitive after its SendSpecific reply to M1. The "termination specification" for M2 was "RESTARTPROC" (see TENEX MSG User Manual). Subsequent measurements should be made to determine how, if at all, delay depends upon the termination specification for M2. In addition, measurements in which M2 executes a new ReceiveGeneric rather than a StopMe should be compared with the above measurements.
- 4. We can not explain the large maximum delays for some experiments. For example, we believe that the response of the TENEX scheduler to transient load variations does not adequately account for the single delay of 13.057 seconds for the 400-byte intra-host SendGenerics (without which the average delay would be 8% less). The cause of these gross delays should be investigated.

-27-

3. Measurement of TENEX NSW Components.

3.1 Measurement Method.

A series of experiments were conducted to measure the CPU time required by NSW components to perform standard NSW operations. The measurements were made using the event logging capability of MSG which, when enabled, logs the occurrence of various "interesting" events. Appendix 3 contains a small portion from the MSG event log for one of the experiments along with a description of the various log entries.

The general experimental procedure was fairly simple. An NSW configuration was initialized with MSG event logging enabled and standard scenarios for user sessions were used to exercise the system. With a knowledge of the user scenarios and the underlying inter-component protocols, the resulting MSG event log was analyzed to determine component CPU times for the various NSW operations. All experiments were performed with only a single NSW user.

In general, these measurements reflect internal component CPU requirements exclusive of CPU requirements of MSG to support inter-component communication. For "servers" (e.g. Works Manager processes), the CPU quantity is generally measured from receipt of a request to completion of the request. For requesting components, CPU time is generally measured from initiation of a request until the request is satisfied; this measurement would, of course, include any activity by the component to participate in the protocol scenario, if any, associated with the request.

3.2 Measurement Data

The measurements were made on the BBNB TENEX for an NSW system usually used for debugging purposes. This was strictly a single host system; there were no inter-host interactions.

The following "certification" data serves to identify the components measured in these experiments:

Works Manager: CERTIFICATION: BOLDUC, bbnb, < WMSRC>WM.SAV;107, 4-Feb-77 12:04:42

TENEX File Package: CERTIFICATION: R. FANEUF, BBNB, <FANEUF>FLPKG.SAV;32, 11-Feb-77 10:57:36

and the wing of

TENEX Front End: CERTIFICATION: bearisto,bbnb,<BEARISTO>FE.SAV;92, 7-Feb-77 13:51:55

TENEX Foreman: CERTIFICATION: MASSEY, BBNB, < BBN-NSWTST>FOREMAN.SAV;1300, 8-Mar-77 16:14:00

Measurements were made for the RUNTOOL, TOOLHALT, OPEN, DELIVER, and DELETE operations. These operations were chosen as representative of NSW operations. Unless otherwse noted, all measurements were made under light TENEX loads.

#### RUNTOOL:

Protocol Scenario:

1.	SendGeneric	FE ·	->	WM	
2.	SendGeneric	WM ·	->	FM	
3.	SendSpecific	FM ·	->	WM	
4.	SendSpecific	FM ·	->	FE	
5.	OpenConn	FM ·	->	FE	
6.	OpenConn	FE -	->	FM	
7.	SendSpecific	WM	->	FE	

CPU quantities measured (ms):

- FE: Time from execution of SendGeneric (1) to execution of ReceiveSpecific following (7).
- WMT: Time from receipt of generic message (1) to execution of ReceiveGeneric following (7).
- WM1: Time from receipt of generic message (1) to execution of SendGeneric (2).
- WM2: Time from receipt of specific message (3) to execution of SendSpecific (7). (Note: WM1+WM2 will be somewhat less than WMT due to WM processing subsequent to SendSpecific (7)).
- FM: Time from receipt of generic message (1) to completion of OpenConn (5).

#### DELIVER

Protocol Scenario:

L.	SendGeneric	$FM \rightarrow WM$	
2.	SendGeneric	WM -> FLP	KG
3.	SendSpecific	FLPKG ->	MM
1.	SendSpecific	WM -> FM	

Note: DELIVER, like OPEN, involves a local file copy. For DELIVER, the copy is from tool workspace into NSW file space. As in the OPEN measurement, the file in question was very short and the file name always unabiguously specified. In addition, all of the DELIVER operations created new files rather than replaced existing ones.

CPU quantities measured (ms): WMT: Time from receipt of generic message (1) to execution of ReceiveGeneric following (4).

WM1: Time from receipt of geneic message (1) to execution of SendGeneric (2).

WM2: Time from receipt of specific message (3) to execution of SendSpecific (4).

FLPKG: Time from receipt of generic message (2) to execution of ReceiveGeneric after (3).

TOTAL: WMT+FLPKG

#### 3.3 Comments.

- For all the above measurements, the WM message-loging feature was enabled. Disabling WM message-logging can be expected to reduce WM CPU figures somewhat.
- WM CPU figures have been broken down further than those for other components for two reasons:
  - The WM role in all scenarios above generally consists of clearly identifiable sub-roles;
  - b. We were somewhat surprised by the extensive WM CPU requirements and thought it would be useful to have a more detailed breakdown of those requirements.
- 3. To put the above figures into perspective, consider the OPEN scenario which (exclusive of MSG CPU requirements) requires 7.5 seconds of CPU time to open a short file. Roughly speaking, this means that a TENEX dedicated to NSW would be able to satisfy between 7 and 8 such file open requests in a minute, assuming the dedicated TENEX was involved in no other NSW activity.
- 4. The large variance in FE and FM CPU requirements in RUNTOOL and TOOLHALT requires further investigation.
- 5. On the surface of it, OPEN and DELIVER appear to be similar operations, differing primarily in the direction of the file movement between NSW filespace and tool workspace. It is, therefore, somewhat surprising that WM and FLPKG CPU times are not approximately the same for these operations. Investigation of the operation of these components with respect to OPEN and DELIVER seems to be indicated.

```
Appendix 2 - Specification of Ml and M2.
```

//Specification of M1 and M2 processes which cooperate to
//perform end-to-end MSG measurements.

```
//Ml is the driving process for end-to-end MSG measurements.
//It begins by determining the parameters to be used for
//the measurement run. These parameters include:
// HOST = host where M2 runs.
// SGMCNT = Number of times to repeat:
11
        M1:
                                   M2:
11
        SendGenericMessage
                               ->
                                   ReceiveGenericMessage
        ReceiveSpecificMessage <- SendSpecificMessage
11
// SGMSIZ = Size of message in bytes for above measurement.
// SSMCNT = Number of times to repeat:
11
        M1:
                                     M2:
11
        SendSpecificMessage
                                -> ReceiveSpecificMessage
11
        ReceiveSpecificMessage <- SendSpecificMessage
// SSMSIZ = Size of message in bytes for above measurement.
// SALCNT = Number of times to repeat:
11
        M1:
                       M2:
11
        SendAlarm ->
11
                   <-
                       SendAlarm
// OPBCNT = Number of times to repeat connection open measurement
11
   for binary send (M1) to binary receive (M2) - 8 bit bytes.
// OPPCNT = Number of times to repeat connection open measurement
11
   for binary pair - 8 bit bytes.
// OPTCNT = Number of times to repeat connection open measurement
// for User TELNET (M1) to Server TELNET (M2).
// The connnection open measurement is:
11
        M1:
                             M2:
11
        OpenConn
                         <->
                              Openconn
        Send 100 bytes
11
                          ->
        CloseConn
                         <-> CloseConn
11

S. S. Ston Wildy and

Each log entry has the same first line:

TimeSinceStartup Job MSG Process Delta (RUP,LOG,Status) MSGReal

Total Job CPU time. Job: MSG: Total CPU time for MSG fork. Total CPU time for top fork of involved process (if any) Process: Delta: Job-MSG-Process RUP: Total CPU time used in routines that manage Recent User Primitives. LOG: Total CPU time used in routines that do event logging. Total CPU time used in status reporting routines (S). Status: MSG-RUP-LOG-Status: CPU time used by MSG fork for MSG MSGReal: functions.

The rest of the lines depend upon the type of event being logged. Job and Process Creations and Terminations should be self explanitory except that "All Forks CPU" is an estimate of total CPU time used by all forks of the process based on taking the total Job CPU time minus the MSG fork CPU time.

For user primitives the next line is:

JCB ProcessName (DeltaCPU in DeltaTime)

DeltaCPU: MSG CPU time used since primitive was issued. DeltaTime: MSG real time since primitive was issued.

The succeeding lines should be self explanitory.

For Completed PEs the second line is the same as for User Primitives except that the Deltas are since the last receipt of an intra-Host MSG-MSG signal; they are thus not always of relevance. The other lines are self explanitory except that "Delay" is the real time delay from when the message (or alarm or connection) control block was created until it was delivered.
