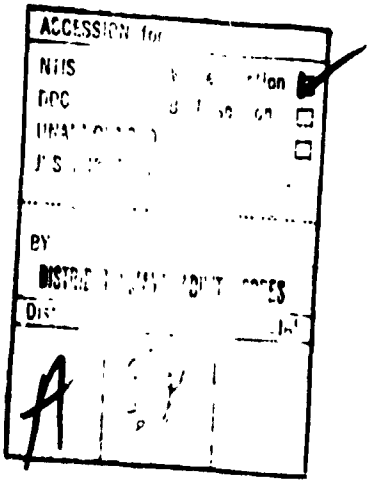
ABSTRACT

This final report describes the activities of ARINC Research Corporation pursuant to the development of a flight safety measurement and prediction capability for the U. S. Naval Safety Center.

The methodology developed encompassed functional analysis of the F-4J aircraft, assessment of the importance of safety-sensitive functional paths, and the construction and exercising of a mathematical model to arrive at a numerical measurement of the safety criticalities of aircraft equipments.

The results of this effort are presented in the text and appendices to this report.



FOREWORD

In 1965, ARINC Research Corporation began to explore the desirability and practicability of an objective quantification of flight safety. The investigation, which included a comprehensive review of current flight-safety activities, suggested the feasibility of developing a quantification technique.

An Air Force-funded study by ARINC Research in 1967 demonstrated the feasibility of a predictive technique based on system reliability characteristics. A methodology was developed for providing flight-safety indicators sensitive to changes in equipment malfunction rates, in their effects on the mission, and in unit or fleet operations. This methodology, in conjunction with accident data, permits timely predictions of accident potential, and can contribute to design evaluation and operational planning by providing a degree of safety assessment previously unavailable. The Air Force continued funding of this effort to develop the mathematical models for the F-106 aircraft.

In June 1968 the Naval Safety Center contracted with ARINC Research Corporation to extend this methodology to the F-4J aircraft.

The first months of this effort were devoted to data surveys, collection of flight data, acquisition of aircraft documentation, and formulation of criteria for adapting the Air Force mathematical model to the Navy application. Results of this initial effort appear in the first interim report under this contract.* The report also describes the techniques to be applied in identifying functional relationships and assessing safety sensitivity.

The second interim report,** describes the development of functional diagrams and safety sensitivity assessments for the F-4J aircraft. The functional diagrams and an example of safety sensitivity analyses are presented in the appendices.

CONTENTS

1. TECHNICAL APPROACH

1.1 GENERAL

The purpose of this program was to extend the previously developed flight-safety measurement and prediction methodology to Naval aircraft and data systems The analysis is designed to evaluate malfunction data with respect to the safety implications that are uniquely associated with each phase of the mission profile. Through this effort the safety criticality of malfunction occurrences can be quantified, thereby allowing correction of flight safety problems on a safety-priority basis.

At the outset of this study, ARINC Research conducted a functional criticality assessment of the F-4J aircraft. Criticality indices were developed which are sensitive to the flight phase in which the aircraft is operating, the degree of exposure to malfunctions in these phases, and the impact of this exposure on safety

Identification of the safety criticality of malfunction occurrences, when fully developed and implemented, can be used in the prevention of accidents. This can be achieved through problem identification based on data from all Navy and Marine aircraft.

The scope of this effort was limited to analysis of equipment functions and their relevance to flight safety. Flight safety problems such as pilot error, avoidance of air traffic, or enemy action can only be evaluated by this methodology to the extent that, should they cause loss of function (malfunction) of the aircraft equipment, the resulting degradation in safety can be assessed.

1.2 CONCEPTS

The mathematical model, and thus the safety methodology, is based on the premise that an aircraft is in a safe condition if it is operating within its prescribed performance limits. The model thus does not consider ejection capability, parachutes, life rafts, etc., which do not make an aircraft safer, per se, but provide for the survivability of the pilot when the aircraft is unsafe.

The elimination of personal injury and property damage is the objective of all safety efforts. However quantification of these factors is not suitable for predictive purposes, being of value primarily as an after-the-fact performance indicator The safety quantification methodology developed by ARINC Research does not use dollar risk as the quantification parameter because the magnitude of this value is influenced by factors not inherent to the aircraft system, but usually to location and happenstance. Therefore, this technique assumes that dollar-damage is an "effect" of being unsafe The parameter of safety quantified by this approach is a measure of how often the aircraft will be in a condition to cause damage (accident exposure).

The probability of an aircraft being in a condition to cause an accident can be expressed as the probability of an event multiplied by the conditional probability that the event will cause accident exposure. Stated in equation form,

$$P_{aj} = P_j \times P_{a/j}$$

where P_{aj} is the probability of an accident exposure due to event j;

P_j is the probability of occurrence of event j; and

$P_{a/j}$ is the probability of accident exposure given that event j has occurred (Sensitivity Factor).

In terms of malfunction contributions to accident exposure, P_j can be thought of as the probability of failure j, and $P_{a/j}$ as the probability that the occurrence of failure j will result in accident exposure. The probability of accident exposure, P_{aj}, is referred to as the Safety Criticality, and can serve as a parameter for ranking the safety significance of events.

The Sensitivity Factor ($P_{a/j}$) can be used to weight malfunction occurrence data to determine which malfunctions most degrade system safety. Sensitivity factors will often vary with mission phase, reflecting the change in malfunction importance with changes in the operating requirements associated with these phases.

The predictive ability of the flight-safety quantification technique is based on the identification of event-occurrence trends that indicate probable changes in accident rate.

1.3 APPLICATION

Under the present effort a criticality assessment model for the F-4J aircraft was developed. The resulting criticality indices are responsive to the flight phase in which the aircraft is operating, the exposure to malfunction in these phases, and the impact on safety of this exposure.

The identification of safety-problem criticality in operational aircraft provides the visibility necessary for arriving at decisions to mod or not-to-mod, optimizing of cost versus safety, and evaluation of the adequacy of corrective actions.

When included in routine periodic malfunction data processing programs, criticality trends can be identified and corrective actions implemented, thereby preventing the occurrence of accidents due to the identified cause.

This safety criticality assessment methodology could also be applied prior to an aircraft becoming operational. The assessment of safety sensitivity during the design phase of aircraft procurement can alert project management to potential trouble areas and functional weaknesses.

2. ANALYSIS

In this section is discussed the development of a capability for assessing problem criticality with respect to flight safety. The development comprises the six major tasks discussed in the following subsections.

2.1 DATA SOURCE SURVEY

A survey of available Navy data was made to determine its adequacy and applicability relative to a flight safety model, and any modifications necessary to the Air Force model to accommodate Navy data.

The Naval Safety Center's data bank was found to be adequately recording the malfunctions registered by the "3-M" data system, and the capability already exists within the Center for computing mean time between failure (MTBF) from 3-M failure information coupled with flight times reported on pilot debriefing forms (yellow sheets). As in the case of the Air Force math model (designed for application to the AFM 66-1 data system), the "When Discovered" codes used in the 3-M system are inadequate for describing the length of time an aircraft is exposed to malfunctions--a basic input to the safety-prediction math model.

An investigation was conducted to determine the impact on the predictive ability of the methodology if only total malfunctions versus total airframe hours were available. Data collected from the Aerospace Defense Command during the earlier Air Force study were examined from this standpoint. It was found that, due to a significant change in failure rate with flight time and mission phase, failure probabilities computed on the basis of a constant failure rate throughout the mission were unrealistic. It was therefore concluded that some form of data screening must be performed in order to provide accurate measurements of malfunction exposure.

Due to the magnitude of the effort required to collect all flight-phase information from all naval aircraft, it was decided to initiate an experimental data-collection and analysis program that would provide the data necessary to determine actual malfunction exposure with respect to the total number of failures experienced. The Naval Safety Center arranged for this data collection effort to be conducted at the VF-121 Squadron, Miramar Naval Air Station.

For this effort, ARINC Research compiled a manual for coding pilot-reported malfunction symptoms. The method of symptom coding is unique in its ability to allow machine processing of informal pilot "squawks." This Navy manual was adapted from that used by the Air Force Aerospace Defense Command in its Interceptor Sortie Evaluation Program, though extended to reflect the F4-B/J aircraft and naval mission requirements. Additionally, ARINC Research developed an experimental pilot debriefing questionnaire (Figure 1). These debriefings, held in the Maintenance Control Center following each sortie, provide first-hand (aircrew) information on any malfunction of the aircraft, detailed mission profile information for each flight, and the flight-purpose code.

This data-collection effort was begun in September 1968, and data were compiled from 1000 sorties flown by VF-121. Data received by ARINC Research from the squadron were reduced to computer-punchcard format for analysis of exposure indices.

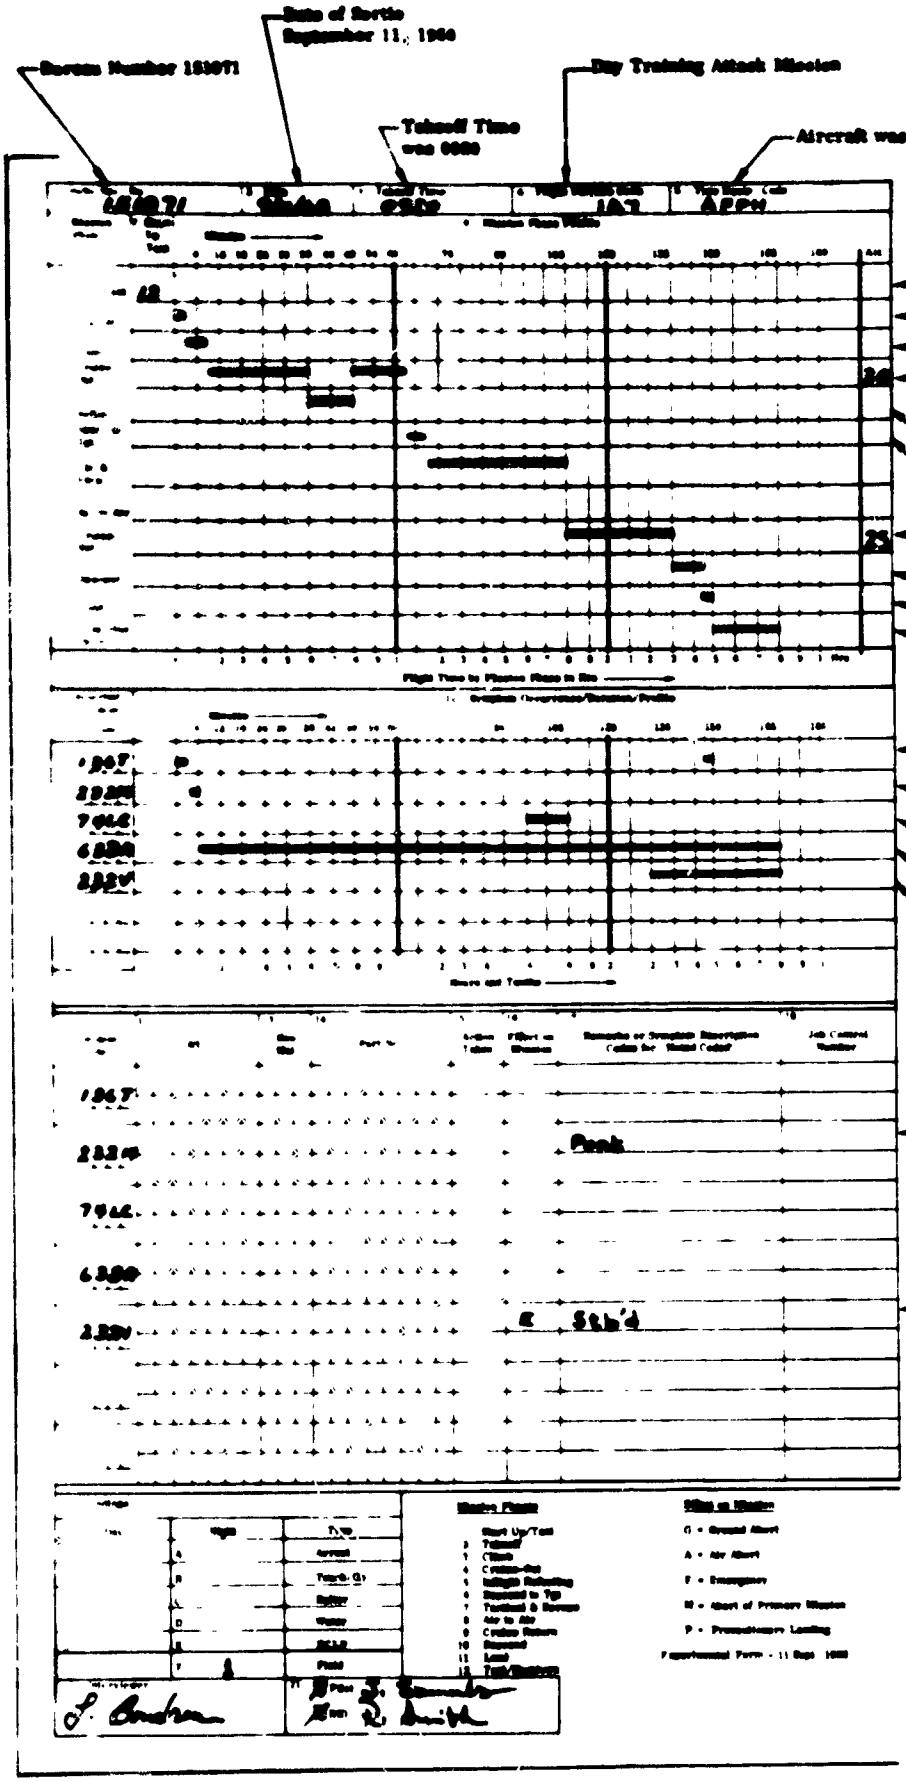

Figure 1. Sample Form

The information was then analyzed to determine the correlation between the number of failures reported and the actual exposure to failure during flight.

The Miramar data were first screened to eliminate CARQUAL and FCLP missions, thereby representing only missions in which mission phases are sequential and nonrepetitive. Naval Safety Center flight-time and 3M data for the Manual Flight Control System were compared with the corresponding VF-121 data and found to agree closely in both average flight time (within two minutes) and failure rate. Because of this good correlation, the method of assessing failure probability by mission phase was established as 1) computing the "average mission" failure probability

$$(P_F = 1 - e^{-\frac{\text{No. failures}}{\text{No. flights}}})^*$$

and then 2) determining the ratio of aircraft in a failed condition to the total aircraft in each flight phase. The ratio of the percent failed per phase to the mission failure probability was computed for each aircraft system for each mission phase. These values are listed in Table 1. In criticality computations utilizing 3M data, these values are used as weighting factors for mission-phase failure allocations. These allocations were used with the applicable safety sensitivity assessment to arrive at the mission phase criticality of malfunctions.

2.2 AIRCRAFT DESIGN DOCUMENTATION

The Naval Safety Center supplied ARINC Research with a complete set of Maintenance and Illustrated Parts Breakdown manuals for the F-4J aircraft. These documents served as the basis for functional analysis and the assessment of safety sensitivity. The adequacy of these documents is comparable to that of the equivalent documents on which the Air Force analysis was based.

A review was made of the documentation available at ARINC Research on the F-4C aircraft, as compiled under the IROS program for the Air Force. Diagrams constructed during this program identify the functional relationships of equipments required for mission success. With respect to a safety sensitivity assessment, however, the objective of the functional analysis must by definition be different; therefore this documentation was primarily of value in identifying Work Unit Codes for various aircraft equipments.

Due to the differences in the Navy/Air Force versions of the F-4, and the difference in the purpose of the two safety efforts, the functional analysis under the Navy contract did not utilize the Air Force F-4C documents. They were used only as a reference in cases where questions arose as to how the aircraft operates.

---

*This equation reflects the application of the traditional reliability equation, $R = e^{-\lambda t}$, modified to apply to only the average mission time ($\frac{\text{Total Time}}{\text{No. of Flights}}$). Because λ is equal to the number of equipment failures divided by the total flight time, the exponent becomes equal to the number of failures divided by the number of flights

**See footnote at bottom of Page 2-5.

2.3 MODEL DEVELOPMENT

At the outset of this program. it was anticipated that the existing Air Force flight safety model could be adapted in a limited-utility format for routinely processing Navy data to arrive at flight safety measurements. The initial idea was to use the total number of failures and the total flying hours to arrive at an average MTBF, and from this to compute the probability of failure. The latter quantity, together with the sensitivity estimate, would then provide a meaningful malfunction exposure and/or a cident exposure index. Upon investigation, however, the available information was found to be inadequate and inaccurate. Recognizing this factor, the Naval Safety Center agreed that, rather than have an early model with these properties, it would be far more desirable to embark upon an investigation to determine how best to arrive at an accurate model.

The first step in the subsequent activity was the initiation of a sample data collection program at Miramar. This effort resulted in obtaining actual equipment malfunction exposure measurements from which the basic factors affecting malfunction occurrence could be examined.

The construction of a safety analysis/criticality assessment model responsive to both the probability of failure and the significance (sensitivity) of each occurrence and be exercisable with 3M data was successfully completed. In equation form, the criticality of each Work Unit Code (WUC) is assessed as follows:

$$\overline{C} = \sum_{n=1}^{n=q} \left[\left(1 - \epsilon^{\frac{F}{f}} \right) m_n \, q \, S_n \right]$$

where: $\overline{C}$ = total criticality of the Work Unit Code

n = mission phase number*

m_n = failure probability correction factor computed from the VF-121 data (Table 1)

q = provisory factor discussed in Section 2.5

S_n = mission phase sensitivity of the failure

F = number of 3M reported failures

f = number of flights over which the 3M data was collected.

This equation, then, represents the probability that a piece of equipment will cause accident exposure in an aircraft flying an average mission profile (i.e., a mission made up of the nine mission phases is considered to be of about 100 minutes duration).

---

*Mission Phases are numbered as follows:

1 - Start and Taxi	4 - Cruise - Out	7 - Descent
2 - Takeoff	5 - Bombing, Air-to-Air, etc.	8 - Land
3 - Climb	6 - Cruise - Return	9 - Taxi-Shutdown

The criticality of each WUC is computed for each functional path that has a safety effect. The resulting quantity can then be applied to rank the WUC's in order of their safety criticality and therefore their current importance (on the basis of 3M data) with respect to flight safety.

2.4 FUNCTIONAL ANALYSIS

The first step in generating equipment criticality indices for pinpointing aircraft safety problems was to identify the primary functions of the F-4J aircraft. The aircraft was first subdivided into nine primary and two support functions, the latter functions being "Utilities" and "Pilot." Designated as primary functions were those generally common to all aircraft and for which the necessity is readily apparent in each flight phase. These primary functions, which can be identified independently of the equipment necessary to perform them, represent the tasks that the equipments perform. The support functions are more equipment-oriented. For example, under the primary function "External Environmental Control" the aircraft was divided into three functional groups: "Anti-Ice," "Lighting," and "Rain Clear." These groups were then further subdivided and charted into functional diagrams depicting 1) the various events necessary to achieve them, and 2) the inputs from other functions. In general, these diagrams are laid out showing, from left to right, the inputs, the function performed, the outputs, and the events achieved.

The next step was to identify the items of equipment required to accomplish each subfunction or function. Equipment identification is normally made at the WUC level, thereby identifying how a WUC contributes to the accomplishment of a function.

Each function of the aircraft carries an indentured "alpha" code indicating the primary safety sensitivity path, thus serving as an index for machine locating purposes. The diagram of Figure 2, for example, identifies the Aircraft Roll function as CC, which requires inputs from CCA-R and CCA-L, the right and left wing control surfaces, respectively. Because of the complexity of aircraft systems and the interdependency of one system on another, no consistent universal indenture system (from function to subfunction, etc.) is possible. One example of the problem, as can be seen in several of the diagrams in Appendix A, is the formation of functional loops. If all the diagrams applicable to an aircraft were combined, the total diagram would be so tangled with these loops that no meaningful analysis could be made. Accordingly, ARINC Research elected to follow the procedure of subdividing the aircraft into the nine primary and two support functions, identifying the input requirements for each and recording each functional relationship in a punchcard format. This procedure was followed down to the WUC level. A computer program was designed that could identify and document each functional path.

Performing the path identification/documentation task by computer proved to be not only useful but necessary. As an example, for a single WUC in the flight control system, the computer identified and documented 182 functional paths in which this item affected the aircraft. The human analyst could never be expected to keep track of 182 functional paths or be expected to assign a numerical sensitivity to each. The machine processing allows the human analyst to consider only one functional link at a time. The ability to be able to follow all of the functional interrelationships within the aircraft is necessary for meaningful assessment of the safety.

Figure 2

Appendix A to this report contains the functional relationship diagrams applicable to the F-4J aircraft. Most of these diagrams have been revised since the publication of the second interim report (ARINC Research Publication 753-01-2-968) in April 1969. Revisions were necessary to reflect more clearly and accurately the interrelationships of the functions.

Following each section of functional diagrams in the appendix is a listing of the functional and WUC relationship cards for that section. This listing identifies the equipment required to accomplish each subfunction, and the functions required to accomplish the next higher level function. The functional-link safety sensitivities are included in the individual cards and in the format of the printout.

2.5 SENSITIVITY ASSESSMENT

The process of assigning sensitivity values consists primarily of evaluating how much a particular function is needed for the next higher function. At the functional level immediately below a primary function, sensitivities are assigned for each mission phase. The assigned value is from zero to one, representing an estimate of the percentage of the time that the loss of the function would result in an accident (a condition in which the aircraft cannot be operated within its prescribed performance parameters). By performing this process at the functional level, the assignment of relative values across these major functions can be made uniformly, according to their relative importance.

Each link was thus assessed until the major functions of the aircraft were reached. At this point the sensitivity of these highest level functions were assessed independently for each of the significant mission phases for the aircraft. For instance, the landing lights have a safety significance of zero for all mission phases other than landing. Each sensitivity value was reviewed by a group of ARINC Research analysts at least three times to assure uniformity of criteria and standardization of numerical assignments. These sensitivity values were included in each functional relationship card.

Certain systems have a safety significance dependent on external influences, and for this situation Provisory Factors are identified. An example of this would be a windshield anti-ice system, which has a safety significance of close to one during landing under icing conditions but has a zero significance on a dry, warm day. In this example, the significance is identified as unity (worst case), and a Provisory Factor is assigned. By application of these factors (for instance, assigning a percentage of the time that icing conditions are present), relative equipment sensitivites can be tailored to the conditions of a particular flight or geographic area. The provisory factors used in the sensitivity assessment of the F-4J are listed, together with their code identifiers, in Table 2.

The sensitivity of each functional link, together with applicable Provisory Factors, are compiled in punchcard format, permitting sensitivity computations (the multiplying of all sensitivities from the equipment along each path up to the major function) to be performed by computer. This allows the sensitivity of WUC's to be assessed, regardless of the complexity associated with multiple and duplicate path relationships.

TABLE 2. PROVISORY FACTORS USED IN SAFETY SENSITIVITY ASSESSMENT OF F-4J AIRCRAFT

Code	Provisory or Conditional Factors
A	Ice
D	Night
E	IFR
F	Supersonic
G	Rain
K	Normal system failed
N	Drag chute failed
P	Carrier takeoff
Q	Carrier landing
S	Wheel brakes failed

The functional path identification/documentation program discussed in Section 2.4 multiplied the "link" sensitivities at each step in the path for each mission phase. A computer printout showing the path and sensitivity values for each WUC cannot be included in this report because of the bulk of such a printout. However, Figure 3 is a reproduction of a typical printout page.

The path and the path sensitivity information is stored on magnetic tape and is suitable for demand interrogation on specific paths, functions, or WUC items. These data are used, in the criticality computations discussed in Section 2.6. A copy of this tape is being furnished to the Naval Safety Center.

2.6 CRITICALITY MODEL EXERCISE

Criticality assessment consists of 1) selection of the mission of interest--in this case, the average mission; 2) selection of the Provisory Factors for the applicable conditions; 3) inclusion of failure probability numbers; and 4) computation of the product of equipment failure probability and safety sensitivity (as modified by the Provisory Factor) for each phase of the mission. The criticality identified is then proportional to the accident exposure being created by each piece of equipment on the aircraft.

A criticality computation program was developed which would accept 3M failure data (by WUC); compute the mission probability of failure,

$$(1 - e^{-\frac{F}{f}});$$

apply the mission phase weighting factor; and multiply this value by the mission phase sensitivity.

Figure 3. Example: Functional Path Sensitivity Printout

The mission phase criticalities are then summed over the mission to obtain the total mission criticality. Criticalities were computed for each WUC alpha designator (i.e., each individual component) by dividing the total number of failures by the number of alpha designators, thereby treating each as a separate item. The WUC criticality for those items where more than one item of that WUC is installed, is then the summation of the criticalities for each alpha designator applicable to that WUC.

The Naval Safety Center supplied the failure and flight data for the 12 months of May 1968 through April 1969, and a criticality model exercise was completed. Appendix B contains the results of this model exercise. The flow chart and program listing are contained in Appendix C. For purposes of this model exercise, all provisory factors were set to zero. Therefore the criticalities in Appendix B are representative of a "perfect" mission environment with field takeoff and landing and the presumption that emergency backup systems are available but not needed.

3. CONCLUSIONS

The use of the criticality computation model with the monthly 3M data processing will permit not only identification of the current month's critical problems, but also allow for the examination of undesirable safety trends.

Thus a capability has been developed for providing flight-safety indicators sensitive to changes, in equipment malfunction rates, in their effects on the mission, and in unit or fleet operations. This methodology, in conjunction with accident data, permits timely predictions of accident potential; and can contribute to design evaluation and operational planning by providing a degree of safety assessment previously unavailable.

APPENDIX A

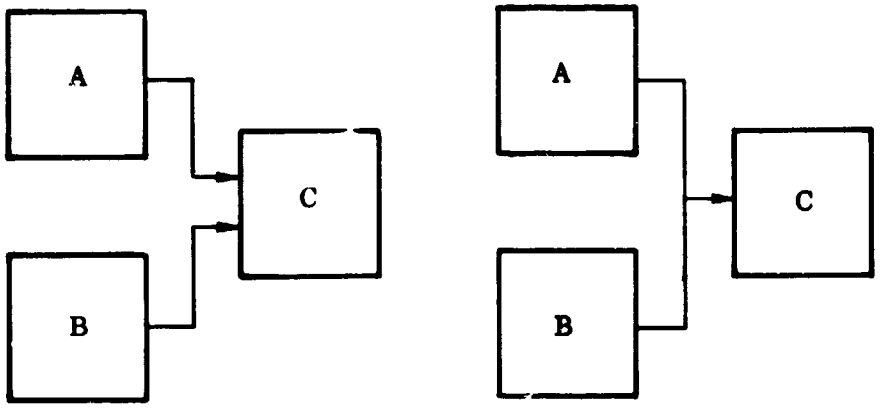
FUNCTIONAL ANALYSIS OF F-4J AIRCRAFT

A.1 GENERAL

This appendix contains the results of the functional analysis performed by ARINC Research for the F-4J aircraft. The tab locators identify nine primary and one secondary functional aircraft system (no diagram is included for the "Pilot"). The functional sections are lettered and the pages numbered according to function level. The title block on each functional diagram identifies the NAVAIR documents (including dates) used in construction of the functional diagram. In cases where the NAVAIR document described several configurations for aircraft block groups, the latest configuration was used for the diagram.

Wherever possible, diagrams are laid out with the inputs on the left side of the page and continuing through the sequence of events to the final function on the right side of the page. Unlike a reliability block diagram, in which blocks in series indicate a tying together physically of equipments, the series of blocks in these diagrams will indicate that if all of the input events to the left of a block occur, and the equipment unique to the functional block is operating, then that function will have been performed.

A form of shorthand logic symbology was used to depict the functional relationships, in which each input to a functional block which enters with a unique arrowhead can be considered AND functions, and inputs whose function lines are joined prior to the arrow entering the next functional block can be considered OR functions. Figure A-1 represents this relationship.



A and B are needed for C.

A or B is needed for C.

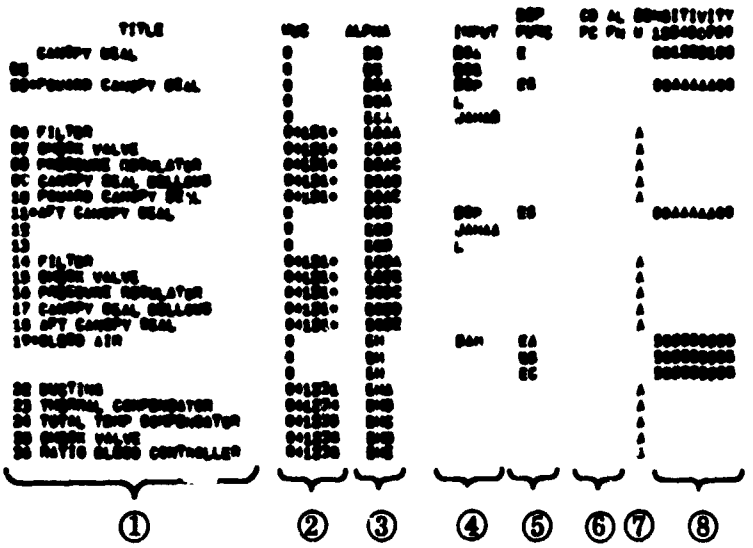
Figure A-1

A.2 ORGANIZATION

The functional description portion of this appendix is divided into ten sections. The first section describes the aircraft, in general. This diagram depicts the primary aircraft functions, together with the alpha designator assigned to each. For instance, the alpha designator "A" will prefix all functions and equipments associated with ground control of the aircraft, all of which will be found behind Tab A, Ground Control. On the tab sheet will be the functional breakdown of the primary function, together with a listing of the order in which the diagrams will appear. Following the diagrams in each section will be a computer listing of the function cards, showing inputs required and dependent functions; and of work unit codes, together with the function and in the functional chain to which the WUC operation contributes. The WUC's used to identify equipment types are as documented in NAVAIR 01-245FD-8, revised 1 June 1968.

If more than one piece of equipment with the same WUC is installed in the aircraft, each will be identified with a different alpha designator. If the same piece of equipment performs more than one function or operates in more than one functional branch, it would maintain only one alpha designator for all of the applications. This, therefore, provides a method for determining whether one piece of equipment has many effects, or whether many pieces of the same equipment are used in the aircraft, each providing one or many different effects.

The following page provides a guide for reading the printouts in this appendix.



① Function or Equipment Name

② Work Unit Code Number

③ "Alpha" Designator for WUC or Function (may be preceded by an R or L indicating right and left)

④ Functional "Inputs" Required

⑤ Dependent Functions of Function listed under "Alpha"

⑥ Conditional or Provisory Factor and Alpha Designator for alternate function if applicable

⑦ Sensitivity value for WUC with respect to function listed above it. (Values are A = 1.0, 9 = 0.90, 8 = 0.80, etc.)

⑧ Functional Sensitivity with respect to the listed dependent function by Mission Phase

APPENDIX B

EQUIPMENT SAFETY CRITICALITY PRINTOUT

This appendix contains the flight-safety criticality assessment for the F-4J aircraft.

These criticalities are based on the combined failure data for May 1968 through April 1969, the flight history for the same period, the sensitivity values for each Work Unit Code's functional path, and the weighting factors applicable to the distribution of system failure probability derived from the VF-121 data collection effort.

All conditional or provisory factors were set to zero for this model exercise. The criticalities therefore are based on VFR daylight mission with field takeoff and landing in which backup (emergency) systems are available but not needed. This appendix is divided into two sections, the first ranking WUC's by their criticality, and the second listing the same information but sorted according to WUC.

The format used in the printout shows the WUC on the left followed by the name, the criticality in each mission phase, and finally the total criticality.

In cases where there are more than one alpha designator (more than one part having the same WUC), the name is listed with the applicable alpha designator; its criticalities are shown for each mission phase; and the combined criticalities for all alphas having that WUC are shown on the line in which the WUC is listed.

Mission phases are numbered in accordance with the footnote on page 2-5 of the report.

APPENDIX C

COMPUTER PROGRAMS AND LISTINGS

This appendix presents the computer program listings for the six programs required for construction and exercise of the F-4J flight safety model.

The first program, "Navy Top-Down Path Generator" illustrates the path-identification and safety-sensitivity computation. Under each diagram is indicated the corresponding steps in the program listing.

The second program, "Criticality-Calculations", computes the path criticalities, then combines them for each Work Unit Code and mission phase. Inputs to this program are the path sensitivities from the first program, and Navy 3M data.

The other four programs are presented as lists because of their simplicity. These programs are:

a. "Top-Down Printout Routine" which prints out the results of the first program.

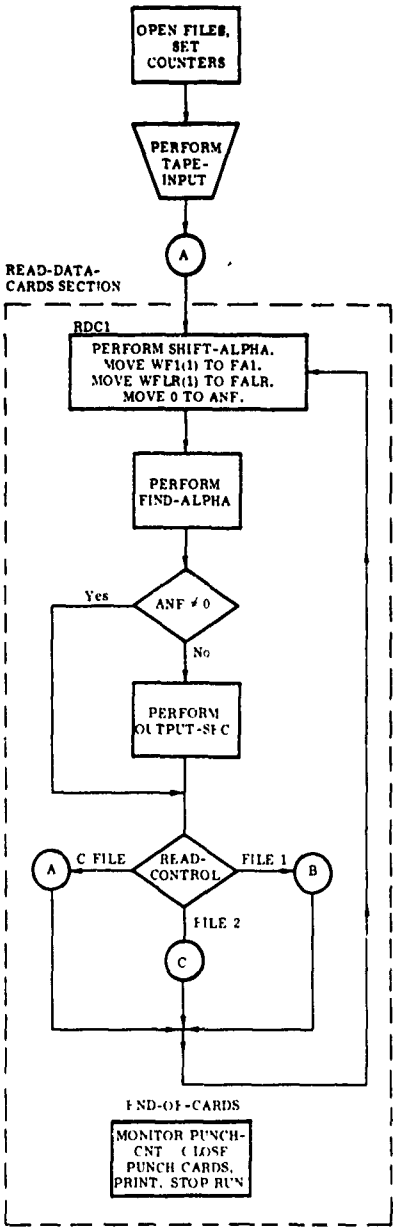
b. "Top-Down Tape Gen" which accepts the functional cards and produces a Dictonary Tape showing WUC, alpha's, and name; and a Dependent Function Array Tape containing sensitivity values for each functional link.

c. "Top-Down Tape Sort" which sorts the Dependent Function Array Tape by dependent function for use in the Top-Down Path Generator Program.

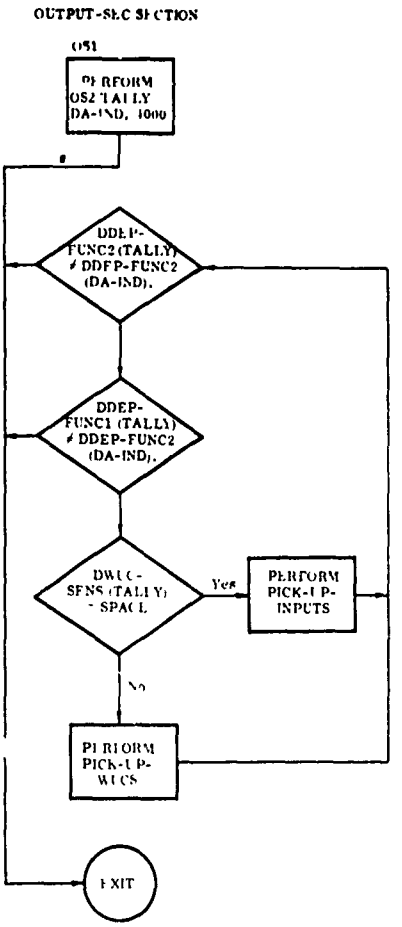
d. "Sort + Merge Path and Failure Data" which merges the path sensitivity information with the failure data applicable to each WUC for use in the Criticality Calculations Program.

NAVY TOP-DOWN PATH GENERATOR

(Listing Items 136-161)

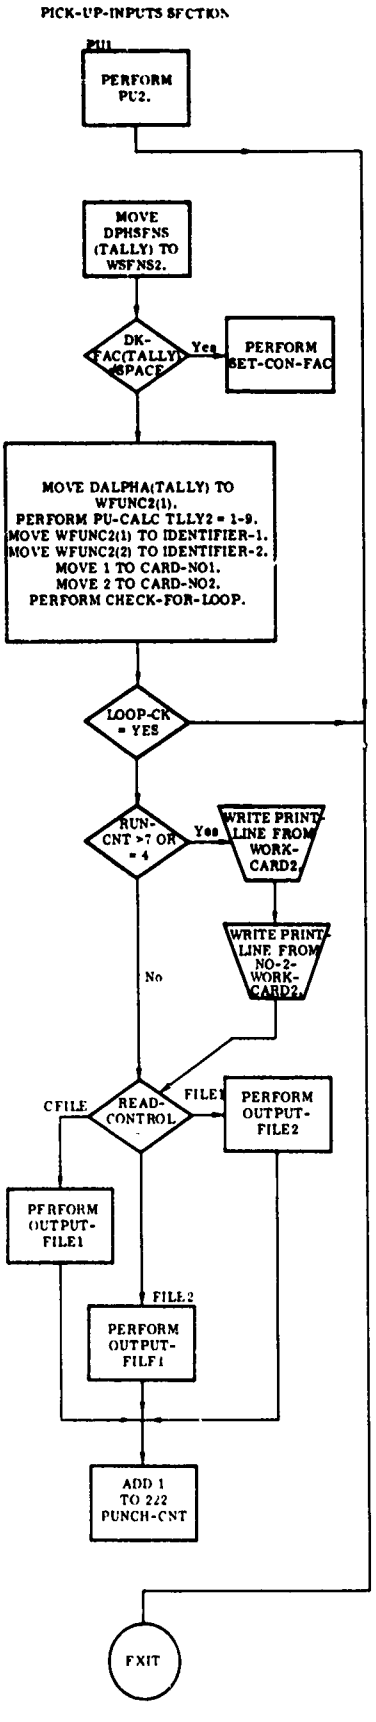


(Listing Items 168-180)

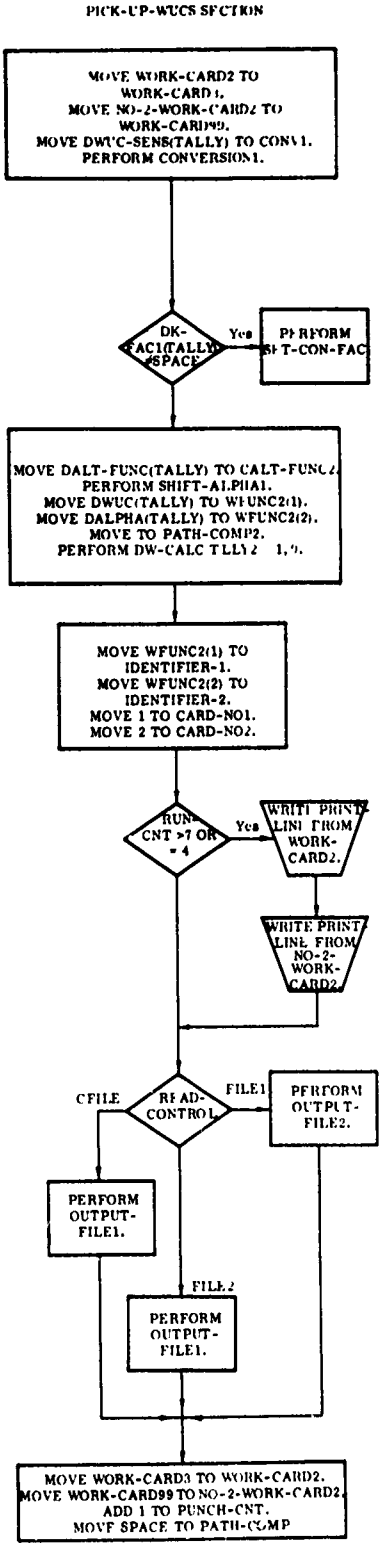


NAVY TOP-DOWN PATH GENERATOR

(Listing Items 236-282)

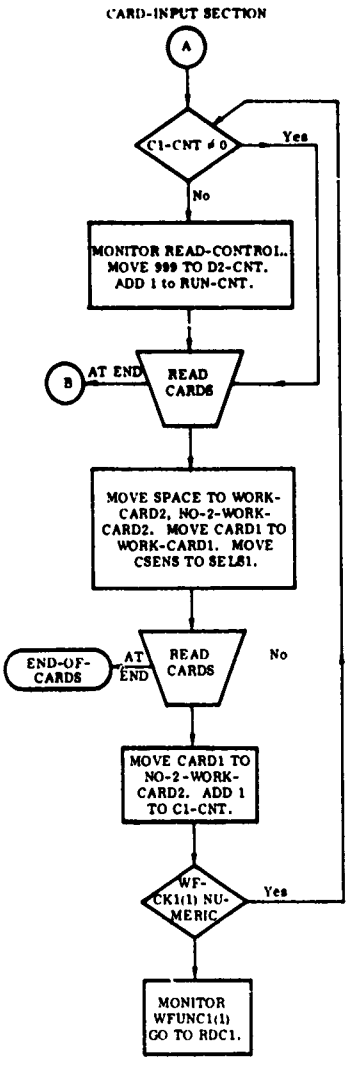


(Listing Items 289-316)

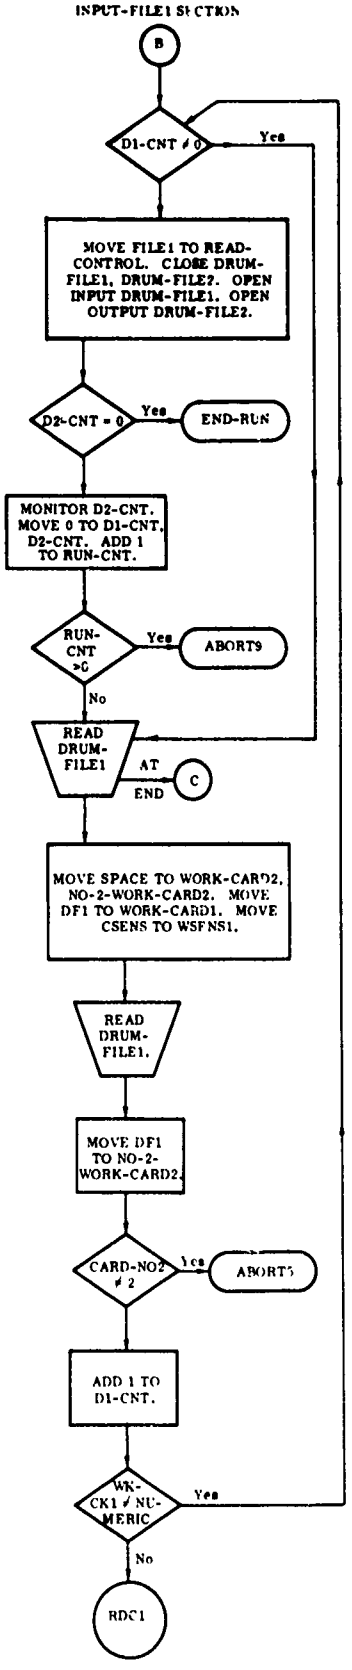


NAVY TOP-DOWN PATH GENERATOR

(Listing Items 343-361)



(Listing Items 362-386)



(Listing Items 386-397)
