PREFACE

The Electromagnetic Compatibility Analysis Center (ECAC) is a Department of Defense facility, established to provide advice and assistance on electromagnetic compatibility matters to the Secretary of Defense, the Joint Chiefs of Staff, the military departments and other DoD components. The Center, located at North Severn, Annapolis, Maryland 21402, is under executive control of the Assistant Secretary of Defense for Communication, Command, Control, and Intelligence and the Chairman, Joint Chiefs of Staff, or their designees, who jointly provide policy guidance, assign projects, and establish priorities. ECAC functions under the direction of the Secretary of the Air Force and the management and technical direction of the Center are provided by military and civil service personnel. The technical operations function is provide through an Air Force sponsored contract with the IIT Research Institute (IITRI).

This report was prepared for the Systems Research and Development Service of the Federal Aviation Administration in accordance with Interagency Agreement DOT-FA70WAI-175, as part of AF Project 649E under Contract F-19628-78-C-0006, by the staff of the IIT Research Institute at the Department of Defense Electromagnetic Compatibility Analysis Center.

To the extent possible, all abbreviations and symbols used in this report are taken from American Standard Y10.19 (1967) "Units Used in Electrical Science and Electrical Engineering" issued by the USA Standards Institute.

FEDERAL AVIATION ADMINISTRATION SYSTEMS RESEARCH AND DEVELOPMENT SERVICE SPECTRUM MANAGEMENT STAFF

STATEMENT OF MISSION

The mission of the Spectrum Management Staff is to assist the Department of State, Office of Telecommunications Policy, and the Federal Communications Commission in assuring the FAA's and the nation's aviation interests with sufficient protected electromagnetic telecommunications resources throughout the world to provide for the safe conduct of aeronautical flight by fostering effective and efficient use of a natural resource--the electromagnetic radio-frequency spectrum.

This objective is achieved through the following services:

- Planning and defending the acquisition and retention of sufficient radio-frequency spectrum to support the aeronautical interests of the nation, at home and abroad, and spectrum standardization for the world's aviation community.
- Providing research, analysis, engineering, and evaluation in the development of spectrum related policy, planning, standards, criteria, measurement equipment, and measurement techniques.
- Conducting electromagnetic compatibility analyses to determine intra/inter-system viability and design parameters, to assure certification of adequate spectrum to support system operational use and projected growth patterns, to defend the aeronautical services spectrum from encroachment by others, and to provide for the efficient use of the aeronautical spectrum.
- Developing automated frequency-selection computer programs/routines to provide frequency planning, frequency assignment, and spectrum analysis capabilities in the spectrum supporting the National Airspace System.
- Providing spectrum management consultation, assistance, and guidance to all aviation interests, users, and providers of equipment and services, both national and international.

A BRANCH - CONTRACTOR OF MALE

EXECUTIVE SUMMARY

The Federal Aviation Administration (FAA) is developing a precision approach-and-landing guidance system called the Time-Reference Scanning-Beam Microwave Landing System (MLS). The avionics for this system, which operates in the 5.0-5.25 GHz band, will be installed on many civilian and military aircraft by the 1980's. An analysis was performed to determine what, if any, equipments on existing aircraft would cause interference to (or receive interference from) the MLS.

Interactions were examined for nine aircraft specified by the FAA (McDonnell Douglas DC-10, DC-9, DC-8, the Boeing 747, 737, 727, 707, the Lockheed Tristar L-1011, and the T-39 Sabreliner) to determine the interference potential between the MLS and the weather radars, long-range radio altimeters, Doppler radars, DME or TACAN interrogators, and secondary-surveillance-radar interrogators and transponders.

In the initial phase of the analysis, an automated prediction model was employed. For each interaction, the interference power level at the receiver antenna was compared with a user-specified interference threshold, to determine whether the likelihood for interference exists. A potentially severe interference problem was predicted between the weather radars and the MLS, if the MLS horn antenna is mounted near the weather radar antenna on the aircraft nose bulkhead as planned.

If the existing C-band (5370-5430 MHz) weather radars are retained and the MLS antennas are to be installed on the nose of the aircraft, there is a high probability of interference to the MLS that will cause it to lose tracking ability. This interference potential could be reduced if the MLS antenna is located more rearward on the bottom of the airframe. Replacement of the onboard weather radar with one operating in another frequency band would also reduce the interference potential.

SECTION 1

INTRODUCTION

BACKGROUND

P & SPACE CONTRACTOR OF BUILD

The Federal Aviation Administration (FAA) is developing a precision approach and landing guidance system for future use. The Time Reference Scanning Beam (TRSB) system represents the United States proposed Microwave Landing System (MLS) candidate to the International Civil Aviation Organization (ICAO) as the international successor to ILS. The FAA has tasked the DoD Electromagnetic Compatibility Analysis Center (ECAC) to analyze the potential for intra-aircraft interference between the MLS and other on-board equipment for specified aircraft.¹

OBJECTIVE

The objective of this analysis was to determine the potential for interference between the proposed airborne MLS equipment and existing in-band and adjacent-band equipments operating on the same aircraft.

APPROACH

Nine aircraft types were specified by the FAA as representative of those aircraft that would be equipped with the MLS.

Equipment complements on board these representative aircraft were determined through a search of the ECAC data files for equipments that operate in the same frequency band as the MLS (5.0-5.25 GHz), in adjacent-frequency bands, or in harmonically related bands. The large number of nomenclatures thus located was reduced to a list of representative equipments having the widest selectivity and/or emission bandwidths and highest output powers in those frequency bands indicated.

Interference-signal power levels at each receiving antenna were predicted, based upon antenna location and system characteristics. Antenna gain and path loss along the airframe were included in the computations, along with the frequency-dependent factors of the emission spectrum and the receiver selectivity.

*

The interfering power levels were compared with a user-specified degradation threshold and potential problem cases were identified.

Where a receiver is tunable over a frequency range that overlaps the interfering transmitter operating frequency, calculations were made for the on-tune case. This assured consideration of the situation most likely to produce interference.

The initial estimates of coupled power density were confirmed with computations that included the effects of nearfield conditions present between the weather radar and MLS antenna.

Section 2

SECTION 2

ANALYSIS

BASIC MLS SYSTEM OPERATION

The Microwave Landing System is comprised of a ground-based angle-data transmitter, an airborne angle-data receiver/processor, and associated distance measuring equipment (DME). The antenna associated with the airborne MLS is located in the nose section of the aircraft. For *missed-approach* angle-data received signals, another antenna is located on the tail section of the aircraft.

The guidance information provided to the pilot by each system is the angular direction and magnitude of deviation between the position of an approaching aircraft and the desired runway-approach path.

With respect to each runway, there exists a volume of airspace in which the aircraft is to receive azimuth and elevation guidance signals with no interference from any source, including other landing systems. Figure 1 illustrates the coverage volume.² This volume is defined by an angle above and below the glidepath, and angle left and right of the runway center line, and some maximum range from the runway (20 nmi). The elevation coverage of not more than 20,000 feet is bound by the maximum elevation angle from the horizontal.

The desired path, called the glidepath, is normally defined by the extension of the runway axis at a constant vertical angle from the horizontal. The pilot receives elevation-deviation indications that tell him to fly down or fly up, depending on the instantaneous elevation relationship between the aircraft and the glidepath. Similarly, azimuthal deviation indications tell the pilot to fly left or fly right.

The MLS also provides missed-approach guidance. The missedapproach coverage volume is opposite in direction to that of the approach-coverage volume and is defined in exactly the same terms. Normally, it is not as large as the approach-coverage volume. Compatible operation is also required in missed-approach coverage volumes.

4: 100.1

the barrier " and an added the second and a

Section 2

DME provides the pilot with the slant range from the aircraft to the touchdown point on the runway. The DME system will utilize the standard, 2-way, airborne-interrogation and groundbased beacon-reply technique. The previously defined coverage volume is also required for compatible DME operation.

The frequency bands being considered for the MLS-DME are in the C-Band (5067.9-5187.6 MHz) and the L-Band (962-1215 MHz). This analysis, however, deals only with the 5000-5250 MHz (C-Band) MLS frequencies.

Frequencies of operation for the angle-data receiver and the DME transceiver are:

Angle-data receiver	5001.0-5060.7	MHz
DME ground-to-air	5067.9-5127.6	MHz
DME air-to-ground	5127.9-5187.6	MHz

Two C-Band frequency plans are being considered for the MLS: (1) the primary frequencies as listed above, and (2) an alternate plan, with frequencies translated up 30 MHz from the primary frequencies. This analysis deals with the primary frequencies, although the alternate frequencies are briefly discussed with respect to interference potential.

The proposed location of the MLS horn antenna is on or near the forward side of the bulkhead within the nose section of the aircraft. This antenna serves three functions: (1) to receive angle-data information, (2) to receive slant-range information, and (3) to transmit DME interrogator signals.

The MLS system has a missed-approach antenna located atop the vertical stabilizer of the aircraft. This antenna is vertically polarized (as are all MLS antennas) and was assumed to be a blade mounted vertically atop the stabilizer.

A conservative estimated value of 23 dB was used for the signal-to-interference threshold for the angle-data receiver throughout the model analysis. An estimated value of 3 dB was assumed for the signal-to-interference threshold for the MLS-DME. These are the same values that were employed in the MLS channel-assignment scheme.³

Section 2

ANALYSIS MODEL

An automated analysis model, AVPAK, is used for assessing the electromagnetic compatibility of equipment in an intraaircraft environment.⁴ The model compares the interference power levels at the receiving antennas with user-specified degradation thresholds for each receiver. Interference situations are handled from a worst-case point of view. Thus, if a receiver is tunable over a certain frequency range and the interfering transmitter operates (or could operate) at a frequency in that range, calculations are made for the on-tune interaction. Any other approach would overlook the situation most likely to produce interference.

The general equation for determining the interfering power at a potential victim receiver, in logarithmic form, is:

$$P_{R} = P_{T} + G_{T} + G_{R} - L_{p}$$
(1)

where

a state of the second of the s

 $P_{\rm p}$ = interfering power level at the receiver, dBm

 P_{T} = power of the interfering transmitter, dBm

 G_{T} = transmitter antenna gain, dBi

 G_p = receiver antenna gain, dBi

L_p = coupling loss between transmitting and receiving antennas, dB.

Allowing for the frequency-dependent rejection of the transmitter signal by the receiver, the effective input interfering signal level becomes:

$$I = P_{T} + G_{T} + G_{D} - L_{D} + FDR \qquad (2)$$

Section 2

where

I = effective input interfering signal, dBm

FDR = frequency-dependent rejection offered by the receiver to the interfering signal, dB.

Satisfactory performance will be obtained when the ratio of the desired signal, S, to an interfering signal, I, exceeds an acceptable threshold signal-to-interference ratio, $(S/I)_T$. Conversely, a degraded condition can be said to exist if

$$I > S - (S/I)_{T}$$

$$(3)$$

where

The state of the state of the

(S/I)_T = minimum value of S/I which ensures acceptable receiver performance, dB

I = received interference power, dBm

S = received desired signal, dBm.

Some of the signal-to-interference thresholds were obtained from References 4 and 5. For the remainder, conservative engineering estimates were used, based on known equipment characteristics.

If it is assumed that the desired signal is at the level of receiver sensitivity, R_S , the test for interference reduces to the following expression, which combines Expressions 2 and 3:

$$P_{T} + G_{T} + G_{p} - L_{p} + FDR > R_{c} - (S/I)_{T}$$
 (4)

When the number of equipments in the environment is large, many interactions can be eliminated from further consideration if

$$P_{T} + G_{T} + G_{D} - L_{D} + FDR \leq R_{C} - (S/I)_{T}$$
(4a)

Only those cases where Expression 4a is not satisfied need be of concern. By rearranging the inequality of Expression 4a, it becomes:

⁵Morgan, G., Avionics Interference Prediction Model, ESD-TR-70-286, ECAC, Annapolis, MD, December 1970.

Section 2

(4b)

(5)

$$(S/I)_T + P_T + G_T + G_R - L_P + FDR \leq R_S$$

This expression was used to evaluate each interaction in this analysis. (Note that values of frequency-dependent rejection and propagation path loss are determined by the model.)

Frequency-Dependent-Rejection Losses

The FDR term is composed of a bandwidth rejection factor plus whichever of the following four factors yields the most power in the receiver passband: adjacent-band spillover, image response, spurious responses, or harmonics at the receiver fundamental frequency. These components of frequency-dependent rejection are further explained below.

Bandwidth Rejection Factor. The bandwidth rejection factor (on-tune rejection) for pulsed equipment is defined as follows:

$$B = 20 \log \frac{B_R}{B_{IT}}, \text{ when } B_{IT} > B_R$$
$$= 0, \qquad \text{ when } B_{IT} \leq B_R$$

where

a set of any to appropriate of the set of a set

 B_R = the 3 dB bandwidth of the receiver B_{IT} = the 3 dB emission bandwidth.

Adjacent-Band Spillover. Adjacent-band spillover is that part of a transmitter's radiated energy that is present in the bandpass of a receiver that is operating in an adjacent frequency band. The magnitude of this energy decreases as the frequency difference between the transmitter and the receiver increases.

Transmitter Harmonics. The power level of a harmonic of a transmitter frequency as received by the victim receiver.

Image Response. The response level to the signal at the image frequency of the victim receiver.

Spurious Responses. The maximum spurious response level of the victim receiver.

AVPAK determines how many of the above factors apply to a particular interaction between a receiver and transmitter, and

which is the most significant in each case. The FDR term is then combined with the other terms in Expression 4b to determine if there is an interference possibility.

Propagation Path Loss, Lp

Propagation losses in AVPAK are computed for two types of losses. One is the knife-edge diffraction loss, where one antenna of a pair is forward of the nose bulkhead and the other is aft. The other type, curvature path loss, is used when both antennas are on the fuselage aft of the bulkhead. The loss over a curved surface, L_{pC} , is combined with the knife-edge diffraction loss if one antenna is forward of the nose bulkhead, to obtain the propagation path loss, L_p . Figure 5 illustrates these two basic

losses. Knife-edge diffraction geometry is represented by path A, where point a is the bulkhead obstruction, and a curved-surface path is represented by B.

Knife-Edge Diffraction. This loss, along a path between an antenna located on the fuselage and an antenna located on the forward side of the bulkhead, is calculated by AVPAK as follows (from Reference 4):

$$L_{K} = 10 \log\left(\frac{h^{2}f}{20d}\right)$$
(6)

where

The stand of the stand of the set

See 2

- L_{K} = the knife-edge diffraction loss due to the nose bulkhead, in dB
- h = the height of the obstruction above the endpoint to end-point straight-line path, in feet
- f = the transmitter frequency, in MHz
- d = the distance between the bulkhead and the nearer of the two antennas under consideration, in feet.

Curvature Path Loss. This loss between two isotropic radiators located on the fuselage of the aircraft is calculated by representing the fuselage either as a conical section or a cylindrical section, or a combination of both. Figure 5 displays both shapes. However, only the cylindrical section was used in this analysis, since no antennas of interest were located on the conical portion of any of the aircraft.

- A = Knife edge diffraction loss occurs along path A at point a

the state of the second of the second s

-

- Artes

State of

Figure 5. Sideview of a representative aircraft showing the conical and cylindrical body shapes as well as the loss types as calculated by AVPAK.

The curvature path losses along a conducting cylindrical surface can be calculated using the following equation:

$$L_{PC} = L_{PF} + 10 \log F(Y)$$
 (7)

where

24

-

L_{PC} = the path loss along a curved surface of the aircraft, dB

- L_{PF} = the path loss if the surface were flattened into a plane, dB
- F(Y) = the loss factor due to the curvature of the surface; (i.e., the curvature factor).

Parameter Y, for a cylindrical approximation of an aircraft is

$$Y = \frac{a \phi^2 k^{\frac{1}{2}}}{\left[(\Delta z)^2 + (a\phi)^2 \right]^{\frac{1}{4}}}$$
(8)

where

a = the radius of the cylinder, in feet

 $k = 2\pi/\lambda$ (λ is wavelength, in feet)

- Δz = the distance between the antennas along the central axis of the cylinder, in feet

Figure 6, a plot of F(Y) versus Y from Reference 4, is used by the model to evaluate curvature factor(s).

The path loss (L_{pF}) between the antennas on a flattened surface is calculated using the free-space spreading loss formula:

 $L_{DE} = 20 \log f + 20 \log D - 37.8$ (9)

where

f = the transmitter frequency, in MHz

D = $[(\Delta z)^2 + (a\phi)^2]^{\frac{1}{2}}$, the distance between antennas, along a cylindrical helical path, in feet.

16

The frequency-dependent-rejection losses and the propagation coupling losses in Expression 4b are calculated by the model. The other parameters, such as P_T , G_T , G_R , $(S/I)_T$ are necessary inputs to the model.

PARAMETERS DEFINITION

To utilize the Avionics Interference Prediction Model (AVPAK, Reference 4) for computations dealing with potential interference to the MLS system, the following information was required:

1. precise antenna location data for the aircraft being considered, and

2. the characteristics of the intra-aircraft equipment.

Antenna Locations

The an estimate the anti-sector of these to be the

Nine aircraft were selected for analysis for which precise antenna location information was available. This information included:

1. the station number of each location in inches, measured from forward to aft on the aircraft,

2. the equipment or equipment type associated with each antenna location, and

3. the angular position of each antenna with respect to the aircraft vertical center plane, with 0° at the top of the fuselage.

The aircraft with precisely known antenna location data were as follows:

McDonnell Douglas	DC-10
McDonnell Douglas	DC-9 series 10
McDonnell Douglas	DC-8 series 50
Boeing	747 basic design
Boeing	737 series 100/200
Boeing	727
Boeing	707
Lockheed	L-1011
North American Rockwell	T-39 Sabreliner, series 40 with special antenna locations provided by the FAA (Reference 5)

Precisely defined antenna locations were not provided for military aircraft. However, similarities may exist between many military aircraft and the aircraft included in the analysis. For

instance, the Boeing 747 is almost as large as the military C5A aircraft. Likewise, the T-39 Sabreliner is dimensionally similar to both the F-4 series and A-7 series of military aircraft. Al-though precise information on the antenna locations and equipment characteristics would be required for a definitive analysis of these military aircraft, the types of problems involved are similar.

Figure 7 illustrates the coordinate system for locating antennas and TABLE 3 lists the nine aircraft under consideration, along with certain physical dimensions. TABLE 4 lists the station number associated with each antenna, the equipment function type, the radius, and the angle (Θ) , for avionics equipment on board the nine aircraft analyzed.

Characteristics of Equipment

The ECAC Nominal Characteristics File and Organizational Platform Allowance File were searched for avionics equipment operating in the same band as the MLS, on adjacent frequencies, and on image-response and subharmonic frequencies.

The number of possible interferers was much too large to consider a one-to-one analysis of each possible interfering equipment. For this reason, the equipments were classified by frequency and/or function type and representative equipments were selected for analysis. Therefore, within each group, the equipments with the widest emission/selectivity bandwidths, highest output powers, and most-probable interference frequencies (i.e., co-channel, adjacent-channel, and harmonics of the MLS 5.0-5.25 GHz fundamental) were identified. Sixteen equipments were selected for analysis in five groups, as follows:

Function	Quantity
secondary surveillance radar (SSR)	2
distance measurement equipment (TACAN-DME)	2
long-range radio altimeter (LRRA)	7
weather radar (WEA RDR)	3
Doppler radar (D-RDR)	2

The reasons for the selection of these frequency/function type (F/FT) groups and the exclusion of other groups of equipments are indicated in the paragraphs following. The equipment characteristics applicable to this analysis are listed in TABLES 5, 6, and 7. A key to the abbreviations follows the tables.

the state of the s

F/FT Group 1, Secondary Surveillance Radar. In the near future, a secondary surveillance radar (SSR) interrogator, as part of a collision-avoidance system, will probably be standard equipment on many commercial aircraft. Many military aircraft already have an SSR interrogator as standard equipment. The fifth harmonic of the SSR interrogation frequency of 1030 MHz is nearly in-band with the MLS-DME ground-to-air (G/A) receiver (5067.9-5127.6 MHz) and may cause interference. However, two frequency plans are now being considered for the MLS. If the primary frequencies are translated up 30 MHz, the fifth harmonic (S150 MHz) of SSR interrogation frequency of 1030 MHz would occur within the MLS-DME G/A receiver frequency band. Therefore, if the translated frequency assignments are used, the only protection against possible interference would be the SSR's harmonic suppression capability.

The SSR transponder was not considered in this analysis, even though the receiver frequency of 1030 MHz falls on a subharmonic of the MLS-DME transmitter frequency (5127.9-5187.6 MHz), because of the large frequency-dependent rejection of approximately -138 dB between the receiver and transmitter. In addition, the SSR transmitter frequency of 1090 MHz does not have a harmonic relationship to the MLS 5.0-5.25 GHz frequency band.

F/FT Group 2, TACAN/DME. If the primary frequency plan is used (5001.0-5060.7 MHz for the MLS angle-data receiver, 5067.9-5127.6 MHz for the MLS-DME G/A receiver, and 5127.9-5187.6 MHz for the MLS-DME A/G transmitter), the only potential interference from equipment in the 962-1213 MHz band is the fifth harmonic of TACAN/DME air-to-ground channel number 1 (1025 MHz). The fifth harmonic (5125 MHz) falls within the MLS-DME G/A receive frequency range. For this frequency combination, the only protection against interference in an MLS-DME G/A receiver would be the harmonic suppression level of the TACAN/DME transmitter.

If the frequency plan is translated up 30 MHz, the tuning range of the MLS-DME G/A receiver would be 5097.0-5157.6 MHz. The first seven air-to-ground TACAN/DME channels (1025-1031 MHz) would then have fifth harmonics (5125-5155 MHz) in the tuning range of the MLS-DME G/A receiver.

While commercial aircraft do not use the military channels (1025-1031 MHz) for TACAN/DME, it is obvious that the military might experience problems if the translated frequency plan of MLS and TACAN/DME channels 1-7 are operated in the same environment.

"a a Want of " a wind with a " and a

Las and the

F/FT Group 3, Long-Range Altimeters. Long-range radio altimeters (LRRA) operate in a range from 4200 to 4400 MHz and merited examination because of the relative proximity to the MLS frequency band.

F/FT Group 4, Weather Radar. Two of the three weather radars examined operate at frequencies ranging from 5.37 to 5.43 GHz. These operating frequencies are near the frequency band of the MLS.

Thus, if it were desired to locate the MLS horn antenna within the nose section of the aircraft, the MLS might adversely affect the weather radar and vice versa. The computer model was used to determine potential problems between the MLS and the 5.3-5.4 GHz weather radars on all other aircraft. Since results indicated a problem, a more detailed analysis was undertaken and is described later.

The third weather radar examined operated in the frequency range of 9.337 to 9.414 GHz. This weather radar was not of major concern because of the frequency separation between it and the MLS. The weather radar receiver is isolated from the MLS-DME A/G transmitter by its waveguide cut-off frequency of 5.9 GHz. The MLS receiving function has some isolation from this weather radar, due in part to the large frequency-dependent rejection experienced by the interfering signals at the MLS receivers. Only one aircraft (the T-39 Sabreliner) had the 9.337-to-9.414 GHz weather radar.

F/FT Group 5, Doppler Radar. The representative Doppler radars (D-RDR) operate on two different frequencies: 8800 MHz and 13,200 MHz. Because the MLS transmitting equipment (MLS-DME A/G) transmits on 5127.9-5187.6 MHz, the Doppler radars operating on 8800 MHz and 13,200 MHz, respectively, are close to a harmonic of the MLS transmitting system. Therefore, these two Doppler radars merited examination; results of the examination are presented in TABLE 8.

INITIAL RESULTS

The model described earlier was used to assess the effects of the intra-aircraft environment on the MLS system. The results for implementation of the primary frequency plan are summarized in TABLE 8 for the nine selected aircraft types.

An example of how the results were obtained is given below as an aid to understanding the table. A particular segment of the AVPAK computer printout is given below for the DC-10 aircraft.

11 Mar 1

1. A. A.

Wants The Medicales of the burns

-

For this example, the Doppler radar transmitter operates at a frequency of 13,300 MHz and the MLS-DME G/A receiver operates over a range of frequencies from 5067.9 to 5127.6 MHz.

Transmitter	Receiver	S/I	٠	P _T	+	LF	+	G _T	+	GR	-	Lp	=	PI	<	$R_{\rm S}$
Doppler	MLS-DME-G/A	3.	+	30.	+	-108.	+	-20.	+	0.	-	116.	=	-211.	<	-93.

As previously stated in the subsection on model theory, values for S/I, P_T , G_T , G_R , and R_S are required inputs to the model. L_p and L_F (FDR) are calculated by the model and combined with S/I, P_T , G_T , and G_R to obtain an interference power, P_I . The P_I in this case is -211 dBm. When the receiver sensitivity, R_S (in this case -93 dBm), is subtracted, the result is negative ($P_I - R_S = -118$ dB), indicating that the interference power level does not exceed the sensitivity. Thus, a non-interference condition is predicted.

In examining the table, note that no interactions were predicted between the MLS and the long-range radio altimeters, SSR interrogators, or the Doppler radars.

Further examination of the table indicates that interactions were predicted between the MLS and the weather radars in all aircraft where the radar operates in the 5.3-5.4 GHz band. The table shows that the MLS angle-data receiver's antenna atop the vertical stabilizer would have a variety of interactions with the weather radar transmitters, depending on the relative distance between the vertical stabilizer and the nose section of the aircraft. In the case of the DME or TACAN/DME transmitter, marginal fifthharmonic interactions with the MLS-DME G/A receiver (nose) location were indicated.

If the alternate frequency plan is used, the results in TABLE 8 should be changed to reflect the following possible interactions:

1. The fifth harmonic of the secondary surveillance radar (SSR) interrogation frequency (1030 MHz) occurs in the translated frequency band of the MLS DME G/A receiver (5097.9-5157.6 MHz), which might result in potential interference to the system.

2. The TACAN/DME interrogator operation on the first seven 1-MHz channels (1025-1031 MHz) might cause harmonic interference to the MLS DME G/A receiver.

the state of additional states of the states

.

The physical dimensions and electrical properties of the C-747 aircraft are similar to those of the Military C-5A aircraft, and the A-7 and F-4 series of military aircraft are dimensionally similar to the T-39 Sabreliner. Therefore, the conclusions drawn for the 747 and the T-39 Sabreliner may be applicable to the indicated military aircraft, provided similar environment and equipment characteristics are used.

NEAR-FIELD CONDITION ANALYSIS

The initial part of the analysis identified those interactions where the MLS avionics may experience interference from other on-board equipments. The prominent interaction is between the weather radar transmitter and the MLS angle-data receiver. This part of the analysis addresses the effect of this interaction on MLS operation.

Received Power Calculation

Figure 8 illustrates the nose section of a Boeing 707, 727, or a 737 aircraft with the AVQ-10 weather radar antenna and the MLS antenna. The MLS horn antenna is in the near field of the weather radar antenna. The power density from the radar at the MLS antenna was calculated to be 62 dBm/m². This value was obtained using a technique suggested by Cherot⁶ and the AVQ-10 characteristics of TABLE 5.

The received power from the weather radar depends on the power density and effective area of the MLS antenna aperture. Gain of the MLS antenna at an off-axis angle of 38.5° (see Figure 8) was obtained from Figure 9. This plot is a vertical, free-space antenna pattern for a waveguide horn with a 6.75 dBi mainbeam gain.⁷ The value of gain chosen from this plot will be conservative for the more-directional 12-dBi-gain antenna assumed in this analysis.

The effective area, A, for the MLS antenna is:

 $A_{e} = G_{R(38.5^{\circ})} + 20 \log \lambda - 10 \log 4\pi$ = -34 dB-m² (10)

The received power entering the MLS receiver is then

$$P_{\rm R} = 62 \ dBm/m^2 + (-34) \ dB-m^2$$

= 28 \ dBm (11)

The frequency-dependent rejection (or OFR) provided at the second IF by the MLS receiver, in response to the weather radar transmitter, was calculated by an ECAC model to be 75 dB. Therefore, the predicted interference power received by the MLS is

$$P_{R(I)} = P_{R} - OFR$$
$$= -47 \text{ dBm}$$
(12)

Effect on MLS Performance

How the interfering power from the weather radar affects MLS performance depends on the desired signal level. The MLS approachcoverage volume extends a minimum of 20 nmi from the runway. The airborne angle-data processor must receive and track the groundtransmitted angle-guidance signal at any location within the coverage volume. The received power of the desired signal was calculated at ranges of 5, 10, 15, and 20 nmi from the ground transmitter using the following equation:

$$S = P_T + G_T + G_R - L_P - L_C$$
 (13)

where

S = desired signal from the transmitter site, dBm

- P_{T} = transmitter peak power from ground installation, 40 dBm
- G_{T} = transmitting antenna gain from ground installation, 19.6 dBi
- G_R = receiving antenna gain from airborne installation, 12 dBi

$$L_p$$

- f = frequency, MHz
- L_C = cable loss (5.4) + rain attenuation (2.8) + aircraft antenna-to-receiver loss (3.0) dB
- $L_{C} = 11.2 \text{ dB}.$

TABLE 9 shows the calculated desired signal level at the four ranges. The last item in the table is the signal-to-inter-ference ratio for the desired signal, S, and the interfering weather-radar signal, I.

Reference 3 states that typical C-Band radars operating in a collocated environment will cause the MLS to lose track or fail to acquire track if the interfering signal level is 10 dB greater than the MLS signal (i.e., $S/I \leq -10$ dB prevents tracking). Therefore, comparing this threshold with the calculated S/I values of TABLE 9 shows that the weather radar can prevent track at all distances within the MLS coverage volume. This will occur without, as well as with, losses caused by rainfall.

It is recognized that the effect of the weather radar on the MLS could be reduced by certain factors not considered in the analysis, such as cross-polarization and defocussing. The effect of these, however, will vary between aircraft and equipment types, and could best be determined through measurement.

SECTION 3

CONCLUSIONS

The major problem between MLS avionics and other avionics equipment on board aircraft is expected to be the interference between the C-Band (5370-5430 MHz) weather radar transmitter and the angle-data receiver of the MLS. Interference from the weather radar may prevent track acquisition or cause loss of track within the required coverage range of the MLS. It appears that during simultaneous operation of these equipments, additional isolation will be required between the MLS and C-Band weather radar antennas, or the MLS receiver and antenna will have to be redesigned for immunity to the weather radar.

Additional potential interference problems were identified. DME transceiver interaction with the weather radar receiver and vice versa will occur if the DME function is provided by C-Band equipment but not if provided by L-Band equipment (962-1215 MHz).

Indications are that, in the future, aircraft avionics on some commercial aircraft will include a secondary-surveillanceradar (SSR) interrogator (as presently employed by some military aircraft) that operates at 1030 MHz, and interference interactions from fifth-order harmonics may be experienced by the MLS if the MLS alternate frequency plan is implemented. For both primary and alternate frequency plans, if L-Band ranging is not implemented, the fifth-order harmonic of the TACAN/DME transmitters operating on channels 1 through 7 pose a potential interference threat to the G/A function of the MLS DME.
