ABSTRACT

This volume focuses primarily on detailed instructions for effectively using the File Structuring and File Revision Components. A brief introduction to these system components and a description of expected output are given.

This document supersedes CSM UM 15-74, Vol. II.

CSM UM 15-78, Volume II is part of the following additional NIPS 360 FPS documentation:

CSN UN 15-78	Vol I	- Introduction to File Concepts
	Vol III	- File Maintenance (FM)
	Vol IV	- Retrieval and Sort Processor (RASP)
	Vol V	- Output Processor (OP)
	Vol VI	- Terminal Processing (TP)
	Vol VII	- Utility Support (UT)
	Vol VIII	- Job Preparation Manual
	Vol IX	- Error Coles
TR 54-78		- Installation of NIPS 360 FFS
CSH GD 15-78		- General Description

Section 1

INT RODUCT ION

File Structuring (FS) is the initial phase in designing a new file. In structuring the file, the user determines the type of data which should be included in the file and the order of grouping. The structured data table is then referred to as a File Format Table (FFT). An FFT is generated for each file and is the basic outline used for performing file maintenance, output processing, and data retrieval.

FS can also be used to describe a non-NIPS data file. In this mode the user describes the contents of an existing file, including record control fields, record type fields and nonaccessible FILLER fields. The resulting FFT is used by the 20IP component for querying the non-NIPS file.

Section 2

FILE STRUCTURING COMPONENT

2.1 File Structuring Program

For input the File Stricturing program requires a deck of cards which contains the parameters defining the file format. These parameters are used to develop a table which provides the definition of the file format to the rest of the system. The File Format Table (FFT) contains not only the specifications of the internal format of the file, but also partial specifications of the external formats and the lata conversion required between the external and internal formats.

Briefly, the parameters in the input deck which define the file record format to PS include:

File ID (File Name)

Record ID (Record Control Group) fields or groups

Subroutines used for input and output conversion of field/group data

Subroutines applied to keyword fields to scan the transaction data.

Tables used for input and output conversion of field/group data

Tables applied to values within keyword fields to determine if the value is a keyword.

Edit control words for output of fields or groups Field names with sizes and modes (alphabetic or numeric)

Group names with list of all fields included within the group.

Labels for output.

Fields or groups to be used as file indexes.

Fields or variable sets to be used as keyword fields.

For a non-NIPS FS, the following parameters are included in the input deck:

Record format definition to assign a set sequence number.

Record type fields to contain the record format type code.

2.2 General File Concepts

Files have a definite structure or pattern called the file format. When data is grouped according to file format, each group contains a complete description of an activity, event, person, or thing. Each of these groups is called a file record. Thus, a Formatted File is an ordered collection of file records.

The file record is a collection of elements of data arranged in the pattern specified by the file format. The smallest unit of data is the field/record element. Each field has a defined length and contains only one specific type of data. If the data content of the field is fixed, the field is labeled a fixed field and will appear only once within the file record. In addition to fixed fields, a file may have periodic fields which may appear more than once within a file record.

Within the file record, 1 closer relationship can exist between some of the fields than exists between other fields. Fields are often reported, retrieved, and manipulated as a

unit called a group. Groups are collections of two or more fields within a file record and may be considered as a single data entity. The fields within the group do not lose their individual identities because of this grouping and may be treated like any other field. Groups are categorized is either periodic groups or fixed groups, depending upon the types of fields which are grouped. Fixed and periodic fields cannot be included within the same group.

Periodic fields may occur any number of times within a file record and the change of a value recorded in one field is usually accompanied by changes in periodic associated periodic fields. Periodic fields containing related information are grouped into units called subsets. when periodic data is added to a file record, it is usually idial is units of subsets rather than individual fields. This is not meant to imply that individual fields of an existing subset cannot be corrected or updated. It is the subset structure which is specified by the file format, while provision is made for the entry of as many identically structured subsets as are necessary. Periodic subsets having identical formats are grouped together into periodic sets. Thus, each periodic subset within a periodic set contains the same field in the same order, with only the data content of the fields varying. Periodic subsets of other formats are grouped into other sets. There is no limitation on the number of periodic subsets within a periodic set. However, the number of periodic sets per file record is limited to a maximum of 255.

The collection of all the fixed fields of a file record is called a fixed set. Since fixed fields are nonrepetitive within a file record, there is only one fixed set in any file record.

Dne additional type of data may be placed in a file record: commentary information. This unformatted data may be placed in a variable set, defined as a single field with an unrestricted length. This data may be accessed for retrieval by employing one of two capabilities. The first method is to use the CONTAINS operator at retrieval time. The second method is to use the Keyword Indexing capability. If neither of these methods is used, data from a variable

set may not be retrieved, but may be displayed along with other data elements of a file record during output processing.

An example of a file record is shown in figure 1. The format illustrated would correspond to a data file which was structured with a fixed set containing data element names PA through PN, one periodic set with element names 1A through 17, another periodic set with element names 2A through 2H, and a single variable set for remarks. A record control group, which contains data to identify each file record, must be defined as the first data element(s) of the fixed set. It appears in the graphic layout as the term RECORD ID. A data record will appear internally to the mattine as one or more logical records, each of which is prefixed with the contents of the record control group. This technique causes the association of many internal logical records to be classed as a single file record externally for the user. Specifically, an internal logical record is used to contain the data for a fixed set or a single subset of a periodic set. The portions of the file record labeled as RECORD ID also contain some system generated and maintained data elements used to differentiate the logical records among the periodic sets and the sequence numbers of subsets within a periodic set.

Figure 1. NIPS

NIPS 36C PPS PILE RECORD

6

A more detailed account of the format of a file record and a isscription of the file format table generated by the file structure appear in the appendix of the Introduction to File Concepts (Volume I).

Data is stored in the system data files in several different formats or modes. Although it is possible to use the system without full understanding of the intricacies of data mode, system efficiency can be improved by correct spacification and usage. Four specific modes of data storage are used by the system: Alphameric, Decimal, Binary and Coordinate. The user explicitly controls these modes when using alphameric or coordinate forms. However, in the case of numeric data, the system effectively controls the mode and the user assigns the mode implicitly. An overall generic tern, NUMER, is used in the system and implies numeric data. This term is described in the following sections of this volume and is used only by the File structuring component. Note that neither binary nor decimal may be specified directly by the user except for subroutine attributes. The system assigns one of two modes to every numeric (NUMER) field; the binary mode is provided automatically except in the following cases:

- a. When the field defined by the NUMER mode statement is a part of the record or subset control group (record key or identifier), the mode of the field becomes decimal.
- b. When the field defined by the NUMER mode statement is included within the range of a GROUP statement definition, the mode of the field is set to decimal.

During most of the system processing, the analyst need consider only alphameric, coordinate, and numeric (binary or decimal) modes. In some instances, however, he is required to directly reference the internal system mode in precise terms, and must specify alphameric, coordinate, binary, or decimal. In all cases where mode is not explicitly stated by the analyst, the system will provide the automatic conversion necessary to "match" or adjust modes correctly. Only in cases such as the specification of subroutine

attributes is the analyst required to use one of the four specific modes rather than the three generic classes of data.

The types of mode specification required are specifically discussed on a statement-by-statement basis throughout the remainder of this volume. This preliminary discussion is intended only to acquaint the user with the general concepts involved in internal data formats.

2.3 General File Structure Statements

The user submits as input to the file structure component a deck of statements defining the format for his file.

The subsections which follow will discuss in general terms the statements used by the file structure language. Section 2.4 will then define the exact format and syntax required.

2.3.1 File Identification

The first statement in the file structure source deck defines the file name. The data file name must be unique and conform to name conventions described in Volume I, Introduction to File Concepts section 2.6.3 NIPS 360 FFS Language contents.

2.3.2 Subroutine/Table Identification

Fach subroutine or table used for data value conversion is identified by a subroutine or table statement. Furthermore, a subroutine or table statement must be used to describe each subroutine or table to be used by any Secondary Indexing function. The operator may be either the term SUB or TAB. The optional use of either operator is to aid the user in distinguishing between his conversion subroutines and tables. The following parameters must appear in the statement:

State of the second sec

Subroutine/Table Name - Identifies a module on the system library for data conversion.

Use Function - Identifies the conversion of input or output data. If this SUB/TAB statement describes a subroutine or table to be used by a Secondary Indexing function, then either CONVERT or ANALYZE must appear here as the Use Function. This entry describes the function of the subroutine or table for Secondary Indexing purposes only. A detailed description of these functions is found in Volume IV, Retrieval and Sort Processor.

Size of Input Data - Indicates the length in bytes of the data to be converted.

Size of Output Data - Indicates the length in bytes of the converted data.

Mode of Input Data - Identifies the mode of the data to be converted.

Mode of Output Data - Identifies the mode of the converted data.

The mode specification for data elements is stated in exact terms:

- a. ALPHA mode is used to reference data which is represented in EBCDIC notation form. Elements in a file record defined as ALPHA mode are of this characteristic.
- BINARY mode is used to reference data contained in a binary word (32 bits of numerical significance).
 Elements in a file record defined as NUMER mode (and not included within a group definition) are of this characteristic.
- c. COORD mode is used to reference any data element with a system internal coordinate format. Elements in a file record defined as COORD are of this characteristic.

9

3. DECIMAL mode is used to reference any data element defined with a NUMER mode and included within a group definition.

A maximum of 50 subroutines/tables may be defined for a file during file structuring.

2.3.2.1 Subroutine/Table Identification for Keyword Usage

When subroutines or tables are applied against keyword fields they perform a different function (see SUB Statement for Keyword Usage for details) but the same basic rules apply. The following parameters appear on the statement:

Subroutine/Table Name - Ilentifies a module on the system library.

Use Functions - Identifies one of three functions. STOP indicates a table containing all words that are to be eliminated from keyword processing. DICTIONARY indicates a table containing all allowable keywords for the field. SCAN indicates a user provided subroutine that is to extract keyword candidates from a transaction record. For a detailed description of these tables see Volume I, File Concepts, Keyword Indexing Capability section.

2.3.3 Edit Mask Identification

Each user-edit mask must be defined by an edit statement. The operator for this statement is the term EDIT. The following parameters are required:

> Edit Mask Name - A user-supplied name to identify the edit mask when used as a parameter in a field or group statement. The name must be unique for the file and follow the system names rules.

and the second sec

Edit Mask - The actual edit mask to be used during output conversion. The following limitations are imposed:

Up to 50 efit masks may be defined per file.

Each edit mask may be up to 69 characters in length.

The sum of edit mask lengths for a single file must not exceed 1,000 characters.

The rules for writing an edit mask are specified in the Introduction to File Concepts.

2.3.4 File Classification

The user may identify the file classification at file structuring time. The operator for this statement is the term CLASS. This single parameter may be up to 32 characters in length. If this statement is not present, the file structured with no classification, i.e., the classification is set to blanks.

The statement types SUB, TAB, EDIT, and CLASS may appear in any order as long as they come after the file identification statement and before any FIELD definition statement.

2.3.5 Field Definition

The field statement defines the characteristics of each data element in the data file record. The user writes the statements, defining in sequence the entries of the fixed set, Periodic Set One, Periodic Set Two, etc. The following rules apply:

a. The fields containing the file record control data must be defined first.

- b. All fields in each set must be defined together; for example, all fields for the fixed set must be defined in a sequence of statements.
- c. If a periodic set has fields to be used for subset control (standard language capability), these fields must be defined first in that periodic set.
- d. If a variable length field is defined for a set (standard language capability), it must be defined by the last statement for that set.
- e. When defining periodic sets, set numbers must be specified. For example, a record with three periodic sets must be assigned the numbers 1, 2, and 3, in this order.
- f. Record control and subset control fields should be defined as ALPHA mode.
- g. Up to and including a maximum of 100 fields may be defined for each set of the user's file record.
- h. The maximum number of characters in a set may be determined by referring to Volume I, Introduction to File Concepts, Appendix A.2, Data File Records. By knowing the size of the record control field and largest subset control field, the user can add up the system overhead bytes and the user-defined control fields to determine the maximum number of noncontrol characters in a set.

The following terms are used to describe parameters in the FIELD statement:

- a. <u>Field Name</u> User-assigned name to the field which will be used to access specific record data. The name must be unique within the file and follow the same conventions of length and character mode as the file name.
- b. <u>Field Size</u> Size in bytes for the data item as it appears in the data record (after input conversion,

if used). For numeric fields, which are stored as binary words (four bytes), the external form length is used.

- c. <u>Set Number</u> Number defining the set to which the field will belong.
 - d. <u>Field Mode</u> Term defining the mode of the field (e.g., ALPHA, NUMER, or COORD).
 - e. <u>Input Conversion Routine Name</u> Name of the subroutine or table which was earlier described with a Sub/Tab statement.
 - f. <u>Output Conversion Routine Name</u> Name of the subroutine/ table which was earlier described with a Sub/Tab statement.
 - g. <u>Bdit Name</u> Name of the edit mask defined by an edit statement.
 - h. <u>Field Label</u> Label of up to 69 characters which nay be assigned to the field in lieu of the actual field name when using QUIP.

2.3.6 Group Definition

The group statement relefines a sequence of adjacent fields/groups with a new name which may be used as a data reference. This group statement is a powerful logical operator which allows the manipulation of larger segments of related data, thus increasing machine efficiency. The following conventions and rules must be followed:

- a. In the statement string, the group statement must immediately follow those statements which define data elements including those within the group.
- b. All elements (fields or groups) defined within a group must be adjacent to one another; none may be omitted. Control fields and noncontrol fields may not be part of the same group.

- c. All items appearing in a group definition must belong to the same set of the data record.
- d. Definition of a group including other groups within its range is permitted. The number of levels or "nesting" permitted is unlimited.

as an example of these rules, consider the following form t and the pseudo FS statements which define the format. Note the nesting which may be done and the sequence in which the field and group statements appear.

FA FB FC FD FE FF FG FH

STATEMENT LIST

Itan_Nama	Operator	Operand List
PA	FIELD	
FB	FIELD	
PC	FIELD	
GA	GROUP	FB,FC
GB	GROUP	FA. GA
FD	FIELD	
FE	FIELD	
FP	FIELD	
GC	GROUP	FD. FE. FF
FG	FIELD	
GD	GROUP	GC.FG
PH .	FIELD	
GE	GROU P	FD, FE, FF, FG, FH (OT GD, FH)

14

The following format depicts a desired structure. The statement source includes intentional errors illustrating common rule violations.

				Set	For	mat
	GA			3 B		
FI	PR	FC	PD	PE	PP	FG

STATESENT LIST

Ites_Name	Operator	Operand List
PA	FIELD	
FB	FIELD	and the second of the second s
FC	FIELD	
GA	GROU P	FA, FC (1)
FD	FIELD	
FE	FIELD	1
FF	FIELD	
FG	FIELD	
GB	GROUP	FE,FP (2)

(1) This statement is invalid because the group definition omits field FB.

(2) This statement is invalid because the group definition does not immediately follow the items that it relefines. This statement should precede the field statement for FG.

The mode of the fields/groups included within a group definition must be considered. Some combinations are invalid, while others cause the system to redesignate an element's mode. Fable 1 shows the possible combinations of mode grouping and the results.

Table 1. Mode Grouping and Results

User-Defined <u>Group Mode</u>	Case	Results
ALPHA Group	Contains all ALPHA defined fields	Hode remains the same
	Contains ALPHA and NUMER fields	NUMER fields change to decimal mode; group remains ALPHA
	Contains all NUMER defined fields	All fields change to decimal mode, group remains ALPHA
	Contains any COORD defined fields	Rejected!
NUMEF Group	Contains all ALPHA fields	Rejected!
	Contains ALPHA and NUMER fields	Rejected!
	Contains any COORD defined field	Rejected!
10010 163 13 3563 88572	Contains all NUMER defined fields	All fields and groups change to decimal mode
C))RF Group	Contains all COORD defined fields	Mode remains the same
	Contains any ALPHA or NUMER defined fields	Rejected!

16

100.00

The following terms are used to describe parameters in a GROUP statement:

- a. <u>Group Name</u> User-assigned name which must be unique to the file.
- b. <u>Field/Group List</u> A list, in sequence, of all the fields/groups to be defined within the new group.
- c. <u>Group Mode</u> Term designating the mode of the group.
- d. <u>Input Conversion Routine Name</u> Name of a subroutine or table which was described in a Sub/Tab statement.
- e. <u>Jutput Conversion Routine Name</u> Name of a subroutine or table which was described in a Sub/Tab statement.
- f. <u>Group Editing</u> Mane of the edit mask defined by an edit statement.
- g. <u>Group Label</u> Label of up to 69 characters which may be assigned to the group in lieu of the actual group name during a QUIP run.

The user may optionally use the group statements to provide additional names for single elements in the data record. A group statement referencing a single field in its operand string will provide a limited synonym capability.

2.3.7 Index Definition

The INDEX statement defines an element of the data file, either a field or group, to be used as a file index. File indexing concepts are discussed in Introduction to File Concepts, Volume I.

Any field or group that is defined by a field or group statement, except variable-langth fields and not exceeding

30 bytes in length, may be designated as a file index. One exception to this rule exists, however. If the field specified is a record control field, and the length is the same as the record control field, the attempt to specify that field as an index will be rejected. Cross-indexing a file by Record ID is redundant and would be inefficient.

Indexes may be fixed or periodic. There is no maximum or minimum number of indexes. Indexing is an optional capability, and any or all non-wariable-length fields or groups may be specified.

The following terms are used to describe parameters in the INDEX statement:

- a. <u>Field Name</u> The user-assigned name of the field or group which will access specific record data. The field or group must be defined by a valid FIELD or GROUP statement. An index field or group cannot exceed 30 bytes in length.
- b. <u>Index Operation</u> (ADD or DELETE) Default is ADD. DELETE is used to eliminate an existing index. It is for use by the Index Specification function performed by the Utility, UTMDISPC.
- C. <u>Conversion Subroutine</u> (Optional) This is the name of a user-provided subroutine to convert data from data file form to index form. This subroutine nust have been identified by a SUB/TAB statement during the run in which the index is being specified, and it must have been defined as a CONVERT subroutine or table. If no subroutine is specified, the values for the index field will be in their internal data file format.
- d. <u>Analyzer Subroutine</u> (Optional) This is the name of a user-provided subroutine used to analyze and determine the qualification value(s) for any FUNCTION operator in which the indexed field/group is a parameter. It must have been defined as an ANALYZE subroutine or table on a SUB/TAB statement.

2.3.7.1 Index Definition for Keyword Fields

This format of the INDEX statement defines a field or variable set that is to become a Kayword Indexing Pield. For a detailed description of Keyword Indexing see Introduction to File Concepts, Volume I.

Any variable field, variable set, or fixed periodic alpha field that has been defined for the file may be specified as a keyword field, the only restriction being that a field may not be defined for both secondary and keyword indexing.

The following terms are used to describe parameters in the INDEX statement defining a keyword field:

- a. <u>Field Name</u> The user-assigned name of the field or variable set that will access specific record data. The field or set must be defined by a value FIELD or VSET statement.
- b. <u>Index Operation</u> (ADD or DELETE) Default is ADD. DELETE is used to eliminate an existing index and is used only by the Index Specification function performed by the Utility, UTNDXSPC.
- c. <u>KEINORD</u> Designation of this statement as one that defines a keyword field rather than the standard Secondary Index Field.
 - NOTE: For a DELETE operation on a keyword field, the KEYWORD parameter is optional. The ielete operation will occur regardless.
- d. Hyphen Designation The user can control processing of the hyphen by the system's scan routine. A hyphen is always treated as a word separator if it follows a word separator character. If it is followed by a text character, one of four options can be applied. TEXT is the default option which means the hyphen is to be treated and

19

retained as part of the value. The other options are DROP, RETAIN, and SEPARATE.

DROP

- The hyphen is either superfluous or it is a word separator, depending upon its context with respect to adjacent characters. It is superfluous if: (1) text characters immediately precede and follow it, or (2) it is immediately preceded by a text character and followed by one or more blank characters and a text character. In this case, blanks are considered to be superfluous. If neither of these cases apply, the hyphen is treated as a word separator. In any case, the hyphen is dropped.
- RETAIN The hyphen is subject to the same rules as the DROP option, except that in the two cases where it is considered superfluous it is retained in the value as a text character.
- SEPARATE- The hyphen is always treated as a word separator.
- e. <u>Stop Table</u> (Optional) This is the name of the user provided table that is to be applied against the values in this field. If a value is found in the table, it is to be eliminated from any further consideration as a keyword. If a value is not present in the table, or if no table were specified, the value becomes a keyword candidate. This table must have been identified by a SUB/TAB statement and have been defined as a STOP table.
- f. <u>Dictionary</u> (Optional) This is the name of the user provided table containing all nonliteral values from this field that may become keywords. This table must have been identified by a SUB/TAB statement and have been defined as a DICTIONARY. If no dictionary is specified, all values in the field, unless some were eliminated by a Stop Table,

become keywords. Literal words always become keywords.

9. Scan Subroutine - (Optional) This is the name of the user provided subroutine that is to be invoked to process the keyword field. This subroutine must have been identified by a SUB/TAB statement and have been identified as a SCAN subroutine. If no subroutine is specified, the system's scan routine will determine what qualifies as a value for keyword selection. See Volume I; File Concepts, User Scan Subroutine section, for a generalized description of the system scan routine.

2.3.8 Variable Set Definition

The VSET statement defines a variable set containing a single field which may be used to store commentary data in textual form. There is no practical limit to the amount of data which may be placed in this set.

The statement operator is the term VSET. The parameters used are as follows:

- a. <u>Variable Set Name</u> User-assigned name unique for the file. Name conventions defined in Volume I, Introduction to File Concepts, apply.
- b. <u>Display Size</u> Value expressing the size of data to be printed per line during QUIP component processing.
 - c. <u>Variable Set Label</u> Label of up to 69 characters may be used in lieu of the name during QUIP processing.

The variable set statement(s) should appear in the source dack after all field and group statements. Since no operand is used to designate a set number, the file structure component will automatically assign the next set available. For example, if the last periodic set defined by

the user through field and group statements was 18, the first variable set would become set number 19.

2.3.9 End-of-Job Statement

The end-of-job statement appears last in the sourcestatement deck. It signifies the completion of file definition. It contains the operator term BWDFS and has no parameters.

2.3.10 User Connentary Statement

If the user desires commentary remarks on the source listing, this capability is provided by the NOTE statement. It may appear anywhere between the file definition and endof-job statement. There is no limit on the number of WOTE statements which may appear in a run.

2.4 FS Language

2.4.1 Introduction

The standard FS language discussed in this section allows the user to define additional capabilities not offered with the compatible WIPS 1410 FFS language. Among these are:

- a. A maximum of 255 periodic sets may be defined for a file record.
- b. More than one variable set may be defined. (The sum of the number of periodic and variable sets may be up to 255.)
- c. A variable length field may be defined for each set to hold commentary data.
- d. A subset control group may be defined. One or more fields specified at the beginning of a periodic set

can be flagged for direct subset identification in place of sequence numbers.

- e. A total of 100 fields or groups may be defined for each set.
- f. A maximum of 99 fields may be defined as a group.
- g. A maximum of 50 groups may be defined in a set.
 - h. The record control group may be as large as 244 characters.
 - i. The number of subsets per set is a variable and is a function of the available computer core storage and the processing function requested. No theoretical limit is established and the practical limit is large in comparison to previous systems.
 - j. Pields and groups may be specified as file indexes. Any field not variable in length and not systemgenerated may be specified as a secondary index. Any fixed-alpha field, variable field, or variable set may be specified as a keyword index. Any fixed-alpha field, variable field, or variable set may be specified as a keyword index. No fixed field may be both a secondary and keyword index. There may be as many indexes as there are userdefined fields in the data file.

2.4.2 Language Conventions

The standard language is free format as described by the general language description and detailed in Volume I, Introduction to File Concepts. Text strings are considered to be serial strings of words/characters without regard to cari (record) boundaries and may be initiated in any character position. Words may not be split between cards (records); however, any number of commas/blanks may be used to separate words. The source language may be in either card or sequential data set form. Only the first 71 characters of each record are used. However, sequence

information may be provided in characters 73 through 80 and will be checked by the module. If the sequence field indicates a break in sequence, an advisory message will be issued; however, structuring will still be performed. The EBCDIC collating sequence is used for performing the sequence check; all cards of the input stream including and following the STRUCTURE card will be tested. If sequence checking is not desired, the first card of the input should contain blanks in the sequence field.

The input stream is made up of a series of statements. By definition, each statement is a series of words or terms initiated by an operator and terminated by a period. The sequence of the statements is subject to general rules which are provided in the following sections. Each statement type is discussed in the sequence of its occurrence in the input stream.

2.4.3 Language Statements

2.4.3.1 STRUCTURE Statement

This statement uses the operator STRUCTURE followed by the data file name. This statement must occur first in the input deck. It is used to establish the name of the file. File names conform to standard system naming rules as defined in Volume I, Introduction to File Concepts.

Example:

STRUCTURE SOFTEST.

2.4.3.2 SUB Statement

The operator SUB may be used interchangeably with the term SUBROUTINE. The parameters which follow the operator must be in the following sequence:

- <u>Subroutine Name</u> Any unique name identifying a user subroutine; follows general system-naming conventions.
- b. <u>Function</u> May be input or output, specifying the use of the subroutine for either input conversion or output conversion. If this is a subroutine for a Secondary Indexing function, CONVERT or ANALYZE nust appear instead of INPUT or DUTPUT. If the subroutine is to be used for ANALYZE functions, the following length and mode entries are not needed. For all other functions (input, output, and convert), the entries must be present.
- c. <u>Input Length</u> Decimal integer, specifying the length of the input data field to be processed by the subroutime.
- d. <u>Output Length</u> Decimal integer, specifying the length of the data string which will be output by the subroutine.
 - e. <u>Input Mode</u> May be ALPHA, DECIMAL, COORD, or BIMARY indicating alphameric (EBCDIC), numeric, coordinate, or binary modes of operation. This parameter identifies the mode of the input to the subroutine, regardless of the function for which the subroutine is used. See subsection 2.3.2 of this volume.
 - f. <u>Jutput Hode</u> Same is previous paragraph, where the mode specified applies to the form of output from the subroutine, regardless of the function for which the subroutine is used.

Examples:

SUB SUBNAME INPUT 7 7 ALPHA ALPHA.

This example indicates a subroutine named SUBNAME which is to be used for input data conversion. The length of the argument furnished to the subroutine is to be seven characters and the output function provided by the

subroutine is seven characters. The mode of the input to the subroutine is alphameric as is its output mode.

SUBROUTINE CONVERT OUTPUT 4 21 COORD ALPHA.

This example indicates a subroutine named CONVERT which is used for output conversion. It expects an input argument of four characters (bytes) and will provide an output function of 21 alphameric characters. The mode of the input argument is the special system mode of coordinates, discussed under the FIELD statement.

SUB SUBO1 CONVERT 17 2 ALPHA DECIMAL

This example indicates a subroutine named SUB01 to be used to convert data in an index field from its file format to the format it will follow in the Index Data Set associated with the data file. It expects an input argument of 17 characters, alphameric mode, and will provide an output of two decimal characters.

SUBROUTINE SUBO2 ANALYZE

This example indicates a subroutine named SUB02 to be used to analyze the parameter list of the FUNCTION operator to determine index usage and to provide a list of values for index qualification.

2.4.3.2.1 SUB Statement for Keyword Usage

The SUB statement, when used to define subroutines or tables applicable to keyword indexing, has the following parameters following the operator:

- a. <u>Subroutine Name</u> Any unique name identifying a user subroutine; follows general system-naming conventions.
- <u>Function</u> Identifies the function of the specified subroutine.

An account that the the said

STOP: - Indicates a table containing the words that are to be eliminated from any further keyword processing.

DICTIONARY - May also be specified as DICT. This parameter indicates a table containing all values that are acceptable as keywords for the fild.

SCAN - Indicates this user-provided subroutine, rather than the System Scan routine, is to be indexed to process and extract keyword candidates from the keyword field in the transaction record.

Examples:	TAB	STOPNAM	STOP
	TAB	DICTNAM	DICTIONARY
	SUB	SCANNAM	SCAN

2.4.3.3 TAB Statement

Use of this statement is the same as for the SUB statement. The term TABLE may also be used.

2.4.3.4 EDIT Statement

This operator identifies an edit mask provided by the user. The format of the statement is the operator followed by a unique name (within this file and follows the general system name rules) and the user-supplied edit mask. The mask is delineated by single quotation marks (5-8 punch), and may contain any valid edit mask characters as defined for the NIPS 1410 FFS system with the exception of the floating dollar sign option, the debit option, the minus sign left option, and the asterisk protection option. An example of this statement is:

EDIT EDNAME '0.'.

This statement identifies the indicated edit mask and gives it the user-name EDNAME. For coding rules concerning
creation of edit masks, see Volume I, Introduction to File Concepts.

2.4.3.5 CLASS Statement

The operator CLASS for this statement may be substituted by the term CLASSIFICATION. The classification label follows and is enclosed within single quotation marks. Classification labels may not exceed 32 characters.

Fxample:

CLASSIFICATION 'TOP SECRET'.

2.4.3.5 FIELD Statement

The following parameters are used with the FIELD operator. Where sequence is critical, appropriate notation is made. When the presence or absence of the operand is optional, the word "Optional" appears in parenthesis in the heading for the description.

- a. <u>Field Name</u> Immediately follows the operator; must be a unique name (for the file) that follows the general system name rules: the length cannot exceed seven characters.
- b. <u>Field Length</u> Refers to the EBCDIC length of the data field. Where NUMER mode is specified, the actual field length may differ from the specified field length; however, this adjustment is internal to the system and does not affect the specification in the FIELD statement. Typically, this length is the length expected in the input transaction or the length to be produced by the system for output purposes. The entry is coded as a numeric integer, not to exceed three characters in length. Highorder zeros may or may not be included.
- c. <u>Set/Function Identifier</u> Indicates in which set the field is to be structured. May be the single

The second s

alphabetic character X or C, indicating fixed field or record control field respectively, or may be a numeric integer not over three characters in length or greater than 255 in value, specifying the periodic set to which the field is to be assigned. May also contain a single alphabetic character prefix to indicate the following capabilities:

- "Cn", where "n" is any integer not greater than 255. Specifies a subset control field for the "nth" periodic set. This capability is to be used when the analyst desires the subset control field to be a data field of the set, rather than using the system-supplied "PSSQ" number for subset control.
- > "Vn", where "n" is subject to the rules specified above. This form indicates the analyst desires the field to be defined as a variable field. "n" again specifies the periodic set in which this field is to be structured.
- đ. **<u>Field Mode Identifier (Optional)</u> - Sequence of this** and all following FIELD statement operands is not critical. Mode specification is optional. If not provided, the system will assume ALPHA mode, and issue an advisory message. The allowable modes are ALPHA, NUMER, and COORD. ALPHA indicates that the data field content is to be alphameric (EBCDIC) information and that arithmetic operations against this field will not be performed. NUMER indicates that the data field content is to be considered numeric data. COORD specifies the special system form for geographic coordinates. This data is maintained by the system in internal format for processing by geographic retrieval techniques and should be used only when such usage is expected. Note that automatic conversion of input and output is provided by the system when this mode is specified. Allowable input formats to this field are latitude and longitude as a single field or as separate fields defined as a group. Output formats

produced by the system conversion routines are also provided. Note that field lengths of 5, 6, 7, 8, 11, and 15 characters are permissible when this mode is specified. All others will cause error indications and the structuring process to be voided.

- E. Input Subroutine Specification (Optional) -Subroutine or table name required for automatic conversion of this data entry should be included in the operand string. Note that this name must be included in a subroutine or table statement, as previously discussed in sections referring to SUB statements and TAB statements. The function (input or output) specified in the subroutine or table statement is assumed and cannot be overridden.
- f. <u>Output Subroutine Specification (Optional)</u> -- Same as input subroutine specification above.
- g. <u>Edit Mask Specification (Optional)</u> Follows the same rule as the subroutine specification. The name provided for the edit mask must be defined on an edit statement, as previously discussed in the section under EDIT statement; this will cause the mask to be associated with the field for output editing. Note that both output subroutine processing and editing may be specified.
- h. <u>Jutput Title/Label (Optional)</u> The user may include an output title or label to be associated with the field when it is output under the QUIP component. Failure to include this operand will cause the QUIP component to use the field name for a title. When the label is to be included in the FFT, it is specified by delineating the desired "literal" with single guotation marks (5-8 punch).

Examples of FIELD statements:

FIELD CPLDONE 5 X ALPHA INSUB OUTSUB EDIT1 "CONTROL FIELD ONE".

Carponent front and Tank

This example indicates that the field CFLDONE is to be five characters in length and a part of the fixed set to contain alphameric data, to be processed on input by the SUB named INSUB (assumes the existence of SUB statement), to be processed on output by the subroutine OUTSUB (same assumption), to be edited on output by the edit mask specified by the name BDIT1, and to include the output title or label CONTROL FIELD ONE. Note that the sequence of operands after the set identifier (X) is not critical.

FIELD MAJEOPT 7 3 ALPHA.

This example identifies a request for a field named MAJEQPT which is to be seven characters long, to be contained in the third periodic set, and to be alphameric information. No conversion or editing has been requested, and no output label was provided. Note that the sequence of all of the terms in this example is critical. Actually, ALPHA is excepted from this statement and, if used, the mode must not precede the set identifier.

2.4.3.7 GROUP Statement

The format of the GROUP statement follows a pattern similar to that established by the FIELD statement. Following the GROUP operator, the user-supplied name must be found. Standard system naming rules apply to the group name. The names of each of the fields/groups which are to be included in this group definition must follow the group name. Beyond this point in the operand string, the GROUP statement's format and sequence rules are exactly the same as those for the FIELD statement beginning with the rules for mode identification of the FIELD statement description.

2.4.3.8 INDEX Statement

The first entry must be INDEX. Following this, the user-supplied name must appear. This name must be defined as a field or group by an appropriate control statement. Standard system naming rules, of course, apply. Note: No

field or group longer than 30 bytes may be specified as an INDEX.

The following parameters apply to the INDEX statement. All operands are optional. Default parameters are noted.

- a. <u>Index Operand</u> ADD or DELETE; default is ADD. DELETE is used to delete an existing index during a UTNDX3PC run. It is of no consequence during FS.
- b. <u>Pile to Index Conversion</u> <u>Subroutine</u> <u>Specification</u> (Optional) - The subroutine or table that will be invoked for automatic conversion from data file format to Index Data Set format. This name must be specified as a conversion routine in a SUB or TAB statement as described in section 2.4.3.2. If no subroutine is specifiel, values will be carried in their internal data file format.
- c. Index Analysis Subroutine Specification (Optional) - The subroutine required to analyze and determine the qualification values for any PUNCTION operator in which the indexed field or group is a parameter. This name must be specified as an analyzer subroutine in a SUB or TAB statement as described in section 2.4.3.2. If no subroutine is specified, when the field is used in a FUNCTION operator clause, the clause will be bypassed by Index Processing.

Example of the INDEX statement:

INDEX CNTRY ADD

This example indicates that the field CNTRY will be issignated as a file index. No subroutine will be used to convert data from the file format to a separate index format. Further, no analysis of a FUNCTION operator parameter list in which this field appears will be performed by Index Processing.

2.4.3.8.1 INDEX Statement for Keyword Fields

The first entry must be INDEX. Pollowing this the usersupplied name must appear. This name must be defined as a field or variable set by the appropriate control statement. Standard system naming rules apply. A field may not be lefined as both a keyword and secondary index.

The following parameters apply to the INDEX statement.

- a. <u>Inder Operand</u> (ADD or DELETE) Default is ADD. DELETE is used to eliminate an existing index and is used only by the index specification function performed by the stility UTNDXSPC.
- b. <u>KEYWORD</u> Designation of this statement as one that defines a keyword field rather than the standard secondary index field. This parameter is mandatory for an ADD operation, but optional for a DELETE operation as the field has already been designated as a keyword field.
- C. Hyphen Designation The user can control processing of the hyphen by the system scan routine. A hyphen is always treated as a word separator if it follows a word separator character. If it is followed by a text character, one of four options can be applied. TEXT is the default option which means the hyphen is to be treated and retained as part of the value. The other options are DROP, RETAIN and SEPARATE.

DROP

- The hyphen is either superfluous or it is a word separator, depending upon its context with respect to adjacent characters. It is superfluous if: (1) text characters immediately precede and follow it, or (2) it is immediately preceded by a text character. In this case, blanks are considered to be superfluous. If neither of these cases apply, the hyphen is treated as a word

separator. In any case, the hyphen is dropped.

RETAIN - The hyphen is subject to the same rules as the DROP option, except that in the two cases where it is considered superfluous it is retained in the value as a text character.

SEPARATE- The hyphen is always treated as a word separator.

- d. <u>Stop Table</u> (Optional) This is the name of the user provided table that is to be applied against the values in this field. If a value is found in the table, it is to be eliminated from any further consideration as a keyword. If a value is not present in the table, or if no table were specified, the value becomes a keyword candidate. This table must have been identified by a SUB/TAB statement and have been defined as a STOP table.
- Dictionary (Optional) This is the name of the user provided table containing all nonliteral values from this field that may become keywords. This table must have been identified by a SUB/TAB statement and have been defined as a DICTIONARY. If no dictionary is specified, all values in the field, unless some were eliminated by a Stop Word Table, become keywords. Literal words always become keywords.
- f. <u>Scan Subroutine</u> (Optional) This is the name of the user provided subroutine that is to be invoked to process the keyword field. This subroutine must have been identified as a SCAN subroutine. If no subroutine is specified, the system's scan routine will select the keyword candidates from the field.

Example:

INDEX VSET1 ADD KEYWORD TAB1 TAB2.

This example indicates the field name VSET1, which has already been defined as a variable set, is to be a keyword initx. When processing this field in the transaction record, TAB1, defined as a stop word table and TAB2, defined as a dictionary are to be used to determine what values are to become keywords.

2.4.3.9 VSET Statement

The VSET statement defines a variable set for the user's lata file. More than one variable set may be defined with a VSET statement supplied for each one.

The operator for the statement is the term VSET which appears first. The following parameters are used:

- a. <u>Variable Set Name</u> Must immediately follow the operator and is unique for the file.
- b. <u>Variable Set Display Size</u> Decimal number stating the width of the variable set to be printed per line during QUIP processing.
- c. <u>Variable Set Label (Optional)</u> Label of up to 69 characters in length may be associated with the variable set, and must be enclosed within single quote marks.

2.4.3.1) NOTE Statement

This statement provides the capability to have explanatory comments about the source deck recorded on the printout produced by PS. The NOTE operator must occur first in the statement. The information following will be printed on the source printout produced by PS. No periods may be included within the body of the NOTE statement, since such in occurrence would signify the end of the note. Other than

this restriction, all other valid EBCDIC characters may be used. The NOTE statement may occur anywhere in the input stream after the structure statement and is not subject to the sequencing rules already specified or those discussed in the following section.

2.4.3.11 END Statement

The last statement in the PS source deck uses the single term END or ENDPS to signify the last user-supplied statement.

2.5 File Structuring for a Non-NIPS File

FS can be used to create an FFT which describes all the usable data elements of a non-NIPS data file. This description includes the definition of various record formats, record type fields used to identify the different record formats, record ID fields, and FILLER fields to account for elements within a record format to be ignored.

2.5.1 General Considerations

In describing a non-NIPS file via PS, the file must conform to various constraints and restrictions. These deal with general file organization, logical record size, record type fields, record ID fields, complete format description and data content.

2.5.1.1 File Organization

To be described by FS, a non-NIPS file must contain either fixed length or variable length records. Fixed length records can be up to 996 bytes in length. Variable length records can be up to 1,000 bytes, but the first four bytes must contain the length of the record. The records in the file may be either blocked or unblocked.

2.5.1.2 Record Formats

The records within a non-NIPS file may have many different formats. Up to 256 different formats may be contained with a single file. Each format must be identified by a single record type field. This field must be present in all records, have the same location in all records, and have the same length in all records (up to 10 bytes).

of the possible 256 different record formats, one must be identified as a nonrepeating (fixed) format. This format will be treated like the fixed set in a NIPS record and it must be present for each unique record ID. Only one occurrence of the nonrepeating format is permitted within a record ID. All other formats are considered to be repeating formats and will be treated as periodic sets in a NIPS record. Their presence is optional within a record ID.

When describing the format of a record type, each byte in the record must be included in a field definition. These include data fields which are not relevant to query requirements and various system fields such as the record length field. Fields which are to be ignored can be lesignated by the special, repeatable field name FILLER. FILLER fields cannot be referenced beyond definition.

2.5.1.3 Record ID Fields

Each record must have record identification data which is contained in one or more user designated fields. These fields need not be contiguous; but each field must be present in each record. The field positions may differ between record types, but the field size and its relative position in the record ID must not differ. The length of the record ID cannot exceed 256 bytes.

2.5.1.4 Data Field Restrictions

Data fields will be processed as either alphabetic, numeric, or coordinate; however, numeric and coordinate mode

fields must adhere to certain restrictions. To be processed as numeric, a data field must be either a binary fullword or a zoned decimal field. All other numeric data fields (nonfullword binary, floating point, and packed decimal) must be defined as alpha and have an associated subroutine to provide output translation.

Data fields which are defined as coordinate must conform to the standard NIPS coordinate lata field format. The data must be in binary word format, a fullword each for latitude and longitude, and must be translatable by the NIPS coordinate subroutines into a standard external 11 or 15 character geographic coordinate. Otherwise, the field must be defined as alpha.

A single variable length data field may be defined for each record type provided the field is the last field in the record type. Also the record type must include a fullword binary field containing the length of the variable field.

2.5.2 Language Statements

2.5.2.1 STRUCTURE Statement

The SIRUCTURE statement, in addition to defining the file name, will initiate creation of a non-NIPS PFT, when the keyword NONIPS follows the file name. The file name must still conform to all standard NIPS conventions.

Fxample:

STRUCTURE NNTEST NONNIPS.

2.5.2.2 DEFINE Statement

The DEFINE is used to lefine the beginning of a new record type and must preceed all FIELD/GROUP statements for the record type. The parameters which follow the operator must be in the following sequence:

- a. <u>Record type sequence number</u> Either an "Y" for the first record type defined or a one-up sequence number for each additional record type (1 through 255). An "X" denotes that the record type is nonrepeating. The nonrepeating record type must be the first record type defined.
- b. <u>Record type code</u> The value with a record which will uniquely identify the record type. The code may be from 1 through 10 characters in length and may be expressed in either character or hexadecimal representation. For character representation, the code is entered as alphanumeric characters, enclosed in single guotes if any special characters are used. Embedded single guotes are not permitted. For hexadecimal representation, the code is entered in hexadecimal notation, enclosed in single guotes, and preceded with an X. The code, in hexadecimal, may represent a maximum of 10 bytes.

Brample using character representation:

DEFINE X ABC9. DEFINE 1 '71+Z'.

Example using hexadecimal representation:

DEFINE 2 X'F1E4FF40'.

NOTE: The DEFINE statement is not permitted when structuring a standard NIPS PPT.

2.5.2.3 FIELD Statement

The FIELD statement is used to describe each field in the non-WIPS file. The following parameters are used following the FIELD operator:

a. <u>Field Mane (required)</u> - Innediately follows the operator. Any mane conforming to the standard NIPS

naming conventions can be used with the following restrictions:

- 1. FILLER is the name used to account for unneeded or unused bytes within a record type.
- 2. VSZn is the name used to reference a binary fullword field which contains the length value for the variable field in the record type. In the name VSZn, "n" is omitted when referenced in the nonrepeating record type and "n" is the record type sequence number when referenced in a repeating record type.
- 3. When the name is applied to a record ID field, the name must be duplicated for the redefinition of the field in each record type. When the name is applied to the record type field, the name maybe duplicated for each record type. In this case, any reference in QUIP to the field name will apply to the fixed record type only.
- b. <u>Field Length (requirel)</u> The length of the field with the following considerations:
 - Record ID fields The length must be the same for all occurrences of the same record ID field name.
- Record type field The length can be a maximum of ten bytes and must remain constant for each redefinition of the field. The length must be sufficient to contain the record type code entered on the preceding DEFINE statement.
- 3. NUMER fields The length is the number of positions to be output. The internal length is assumed to be four bytes an a full word boundary unless the field is contained in a group; then the internal length is the same is the output length.

4.

- COORD fields The output length of the coordinate field. Acceptable lengths are 5,6,7,8,11 and 15. The internal length is assumed to be four bytes if the output length is less than 11 or eight bytes if the output length is greater than 8. Internal, the field is assumed to be on a full word boundary.
- 5. ALPHA, DECML and FILLER fields The length is the number of bytes contained in the field in the file.
- c. Set/Function Identifiers (required) The set sequence number from the preseeding DEFINE statement or one of the following codes for special functional use:
 - "Cn" is used to identify the field as a portion of the record ID. The "n" is a 1- to 3-digit number denoting the fields relative position in the ID. When used on a redefinition of a record ID field, the "Cn" value must be the same as on the original definition.
 - "T" is used to identify the field as the record type field. This field will contain the record type code as specified on the preceding DEFINE statement.
 - 3. "Vn" is used to identify the field as a variable field. The "n" is the set sequence number from the preceding DEFINE statement. A field identified as a variable field must have an associated "VSZn" field and must be the last field defined in the record type description.
- <u>Field Mode Identifier (Optional)</u> If specified, this is the mode of the field. Valid entries are:
 - 1. ALPHA, used to identify the field as containing either alphanumeric data or

nonstandard numeric data. Nonstandard numeric data includes packed decimal fields and binary fields which are not fullwords. No arithmetic operations are permitted against ALPHA fields. ALPHA is the only valid mode for record ID and record type fields.

- 2. NUMER, used to identify the fields as containing standard numeric data. The data will be assumed to be fullword binary unless the field is contained in a group, in which case it will be assumed to be zoned decimal (EBCDIC).
- 3. DECML, used to identify the field as containing zoned decimal numeric data. This mode is not permitted when executing a standard NIPS File Structure.
- 4. COORD, used to identify the field as containing coordinate data in the standard internal NIPS binary word format.
 - <u>Other Operands</u> Additional operands which may be specified are:
 - 1. Input Subroutine Specification
 - 2. Output Subroutine Specification
 - 3. Edit Mask Specification
- 4. Output Title/Label

The uses of these operands is the same as when specified for a standard NIPS PS and are described in section 2.4.3.6.

2.5.2.4 GROUP Statement

The GROUP statement is used to identify a sequence of adjacent field/groups to be collectively referenced via a new name. The rules which apply to defining a group for standard NIPS files also apply for non-NIPS files as described in sections 2.3.6 and 2.4.3.7.

When defining a group for a non-NIPS file, the group cannot contain any FILLER fields, nor can it be named FILLER. Additionally, no fullword binary fields can be included in a group.

2.5.2.5 Other PS Statements

The INDEX and VSET statements are not allowed for non-NIPS files. The SUB, TAB, EDIT, CLASS, NOTE and END statements are used in the same manner as for standard NIPS files.

Section 3

OUTPUT

Output from the file structuring program consists of a listing of the input deck with messages noting any diagnosed errors. Some messages are only advisory, but most of them relate to errors which prevent the structuring of the PFT. If the PFT is successfully structured, it is printed out immediately following the deck listing and the individual records which make up the PFT are written on the direct access device saved for file generation. The newly structured PFT can be contained in an Indexed Sequential Access Method (ISAM) or a Virtual Storage Access Method (VSAM) data set as detailed in Volume VIII, Job Preparation Manual. At that time the actual data records are created and will reside with the PFT on the same volume. During file structuring, the user has the option of specifying a file block size greater than 1,004. If he does not specify a block size, file structuring will use the standard 1,004 size. Details for block size specifications can be found in Volume VIII, Job Preparation Manual.

3.1 Error and Exception Detection

Some errors are abortive in constructing an FFT, while others are merely advisory in nature. All errors are listed on the system output device as they are discovered in each input card submitted. At the end of a job, the FFT is constructed if no abortive errors were found during the processing of the input deck.

3.2 Operation for the File Structure Component

This subsection contains a brief flowchart of the operations performed by PFTs during execution.

3.3 Sample File Structure Job

Contained in this subsection is a listing of both the OS job control language statements and the file structure source lack (standard language) used to structure the sample file presented in Volume I, Introduction to File Concepts.

Section 4

FILE REVISION

File Revision (FR) revises the format in which data is stored in an FFS data file. FR provides the restructuring of an existing data file, allowing the insertion or removal of fields or sets of data and also allowing for a new optional file block size.

File Revision will compare the PFT describing the file in its current format with the FFT describing the file in its revised format. FR will then generate PM logic statements which will be used by PM for copying selected lata elements into the new format.

FR will process data on a field basis only. It will permit the addition, deletion, and limited relocation of fields as well as changes to their storage mode, size, and name. Storage mode (alphabetic, zoned decimal, binary, coordinate) changes are permitted with two exceptions. FR will not allow a binary or zoned decimal field to be changed to a coordinate field, nor will it allow a coordinate field to be changed to a binary or zoned decimal field. Field sizes must conform to File Structuring rules. Alphameric field size changes result in truncation or blank padding on the right. Zoned decimal field changes in truncation or zero fill on the left. Specification of numeric (binary) field size changes affect only the external representation of the field.

Periodic sets may be deleted or relocated. They may also be added, but no data will be included, as a direct result of FR, in either new sets or fields. FR will permit fields from any set in the old file to be split into several sets in the new file. It will not permit fields from multiple sets in the old file to be merged into one set in

the new file. There is no way for FR to logically connect the subsets of two existing sets.

FR will permit the addition of major or subset control fields. Major or subset control fields may be deleted as long as the <u>retained</u> control fields (i.e., the control fields common to both the old and new files) provide a unique key for each record. Control fields may be added and deleted within the same FR run if the retained control fields provide unique keys. If the retained control fields will not provide unique keys, two FR runs must be made: the first to add the additional fields, and the second to delete unwanted control fields. If two FR runs are made, none of the control fields from the first file will be retained in the final file.

The revised file will contain only the PPF, the logic statements for the report 'PR', and the data records. Before the user processes his new file, he must review and molify, as required, his old logic statements, queries, RITs, tables, and subroutines to ensure compatibility with his new file design. The logic statements must be recompiled and added to the logic statement library (report 'PR' should be deleted). Other materials must be recompiled, as required, and placed on the appropriate library.

4.1 FR Description

The user structures an PFT describing the file in its revised format. He then executes the procedure XFR, ifentifying both old and new files, field name changes, and the FR output and processing options. This procedure causes execution of the control program FR. This program calls the routines to process the user's control deck, the old FFT, and the new FFT; it also produces the logic statements that may be compiled and executed through linkage to the File Haintemance (FH) component.

After identifying and processing the control options, PR will develop a name change table from the remaining input

parameters. Another table will be developed from the field description records in the revised FFT.

Having accomplished this initialization, File Revision will read the current FFT and generate, for each set type, an FMS logic statement. Any Secondary Indexing Specification must be provided by the user when the new FFT is structured. The data required to generate indexing information will be provided by FM.

FR will build a data set containing FMS control records and the generated logic statements. The data set or selected portions of it may be punched and/or printed. The user may use the FR-generated logic statements, with or without modification, in subsequent independent FM executions.

Additionally, FR will print an FFT comparison. This comparison will indicate the field name, size, storage mode, and set number for each field in both the current and revised files. It will also annotate all changes with the appropriate remarks.

At the successful completion of FR, FH will be executed to compile the generated logic statements for report 'FR' and will execute them to generate the revised file. The old file data records provide the transactions to the FH generation phase.

4.2 Processing Flow

Figure 3 illustrates the processing flow of the File Revision process.

100

.

4.2.1 Details of Processing

This section describes the major functions performed by each pass of the File Revision process.

FR - FR Supervisor.

Links FP subroutine PRSUP.

Tests and links to PM component dependent on results from PR execution.

FRSUP - FR Subroutine Caller.

Reads File Revision specifications.

Stores FR run options.

Calls all PR subroutines.

Regains control after each subroutine and prints error messages as appropriate.

FRKWIP - FR card scanner.

Isolates and interprets PR parameters.

Builds table 1 of identifiable keyword parameters.

Builds table 2 of name change specifications and unitentified keyword parameters.

FRINIT - FR Initializer.

Reads the PFT for the new file.

Builds table 3 of new FFT field information.

Builds table 4 of new FFT control field locations.

FRGEN1 - PR work record builder.

Combines old and new specifications for related data fields.

Builds 28-character records containing field name, size, set, and storage mode.

Writes these records on to the file 'FRWK1', which is then sorted by old set number, new set number, and old field location within set.

FRGFN2 - FR Generator.

Reads the sorted work file 'FRWK2'.

Generates TDD control card images to describe the old data file which is to be used by FM as a data source.

Generates POOL control card images to perform the required movement of data from the old to the new file.

Outputs TDD cards and POOL statements on separate data sets, for use by 'FROUT'.

Prints an analysis of the FR action to be performed with each field.

FROUT -

- FR output subroutine.

Combines PMS and library action control card images with the TDD and POOL generated by 'PRGEN2'.

Writes out data sets containing control card information to perform logic statement compilation, library action, and file generation.

Prints and/or punches the generated logic statements as required.

Returns control to FRSUP which will in turn pass control to the supervisor, PR, to link and execute the File Maintenance (FM) component.

4.3 FR Input

The following paragraphs describe input data sets and control cards.

4. 4.1 Old Data File

The old 360 FPS data file (the file to be revised) may be either a SAM, an ISAM or a VSAM data file. The file organization is identified by using the 'SAM', 'ISAM' or 'VSOLDf' parameters on the KPR execute card.

As the old data file is used as the transaction source to the generate phase of PM, an additional parameter 'TRANTYP' must be used to identify the file organization. This parameter must equal SAM if the old data file is SAM, or VSAM if the old data file is VSAM. If old data file is ISAM, the TRANTYP parameter will default to ISAM.

4.3.2 New File Format Table

Before running File Revision, the new PFT must be structured and must reside on direct access storage as either an ISAM or VSAM data set. The new PFT is sequential organization. The new PFT is identified by using the 'NEWFFT' parameter on the XFR execute card for an ISAM FFT or the 'VSDSN' parameter for a VSAM PFT. The PFT name need not be the same as the old file name.

4.3.3 Card Input

File Revision control cards are free format and, with the exception of the field name change cards, use keywords to identify parameters. Since the field name change information is not identified by keywords, all of the field name change information must follow the keyword-identified information in the user's input deck. Furthermore, no extraneous information, such as comments, may be punched on any of the user's control cards, since FR will interpret this information as field name change information.

The sequence of keyword-identified information will be: KEYWORD, VALUE, KEYWORD, VALUE, etc., with no fixed format or parameter sequence requirement. The user may enter multiple parameters after a single keyword if the parameter list is enclosed in parentheses. Any number of blanks may separate keywords and values from their connecting equal sign; e.g., KEYWORD ## VALUE. Any number of blanks and/or commas may separate keyword/value pairs; e.g., PILE = TESTA,NEWFILE = TESTB PRINT = ALL.

Special characters other than the comma, equal sign and parenthesis are not valid in File Revision control statements.

Processing options such as PUNCH, PRINT, etc., and file name identifiers are keywords. All other words found in the keyword positions are assumed to be old field names, and the words following them are assumed to be the new names.

valid input parameters are listed in the following paragraphs.

<u>OLDFILE</u> or <u>FLLE</u> specifies the name of the data file to be converted. This parameter is required.

<u>NEWFILE</u> identifies the revised file name. If the file name does not change, this parameter is unnecessary. If this parameter is not specified, the old file name will be used as the file name for the revised file.

The <u>PRINT</u> parameter is optional. <u>PRINT</u> causes the printing of the generated logic statements. It may be followed by the word <u>ALL</u> to cause the printing of all the statements or by the desired set numbers. If the set numbers are used and more than one set is desired, they must be enclosed in parentheses and separated by commas; e.g.,

$$PRINT = (1, 4, 7, 23)$$

The <u>PUNCH</u> parameter is optional. <u>PUNCH</u> causes the punching of the generated logic statements. The operands which may be used are the same as those for the <u>PRINT</u> parameter.

<u>NOGO</u> is an optional parameter followed by PM, indicating that the File Revision job should terminate just before execution of File Maintenance.

Field name changes are input in the form -

old-field-name = new-field-name

and must follow all keyword-identified parameters.

4.4 FR Jutput

The following paragraphs describe the output of File Revision.

4.4.1 Revised File

If no errors are detected by the PR program (and the user has not selected the NOGO=PM option), a revised file will be produced. This file will always be a sequential file, and unless the user specifies the device type by using the 'NEWUSAM' parameter on his execute card, it will reside on the device type specified by the default parameters in the PMSAMOUT DD statement. The new file will consist of the PFT, the logic statements that were created by PR to create the file, and the data records. The old logic statements will not be carried over to the new file. The file name

will either be the same as the old file, or the same as the user specified in his PR control deck, using the 'NEWFILE' parameter. The new file will be cataloged. If the old file was sequentially organized and its name was used for the new file, it will be uncataloged. Otherwise, the old file will remain cataloged. The block size of the new file will be the same as the old file unless the user specifies a new block size using the ESZNEWF symbolic parameter of the XFR procedure.

4.4.2 Index Data Set

If indexes were specified for the revised data file, an Index Data Set will be created. The parameters necessary for creating this data set must be provided by symbolic parameters of the XFR procedure.

4.4.3 Printer Output

FR produces three types of printer output.

The first list consists of a print-back of the user's control deck, with appropriate error comments.

The second printer output consists of a comparison of the old and new PFTs, with field changes indicated and any illegal field changes noted.

The third printer output consists of a list of the generated logic statements that the user requested to be printed by using the PRENT parameter in his control deck. One logic statement will be created for each old set, provided all the fields in a given set were not deleted. They will be printed in set sequence.

Pollowing the FR printouts, the normal FM printouts will appear, showing the compiled logic statements, transaction processing errors which would indicate deletion of a set, and confirmation messages.
FILE STRUCTURING (FS)

4.4.4 Punched Output

FR will punch the generated logic statements for the sets requested in the PUNCH parameter.

4.5 FR Examples

The following examples illustrate typical uses of File Revision.

4.5.1 Sample Revision with Two Name Changes

FILE = TESTA, NEWPILE = TESTB PUNCH=(4, 7, 9) PRINT=ALL

ARRTIM = ATA, NUMBR = FLTNBR

The current file name is TESTA, and the revised file is to be TESTB. The user specifies that the logic statements and FM control records, which are generated for current file set numbers 4, 7 and 9, are to be punched. All the generated logic statements are to be printed. The names of the two current file fields ARRTIM and MUMBR are to be changes to ATA and FLTNBR in the revised file.

4.5.2 File Structure, Revision, and Maintenance

An illustrative example of a file revision run can be found in Vol. VIII, Job Preparation Manual.

4.5 File Revision, Special Considerations

File Revision typically involves adding or deleting of data fields and/or periodic sets. It may also involve changes in mode, size, or location of data fields. These actions will, in many cases, change the relative location of data elements within a set. Although some existing

FILE STRUCTURING (FS)

retrievals and report instruction tables may still be valid, it is recommended that the user recompile them and store them on the appropriate library to preclude production of erroneous output. File Maintenance logic statements <u>must</u> be recompiled and stored on the revised file. This will preclude inadvertent destruction or degradation of the revised file.

In order to revise a segmented SAM data file, a definite process must be followed. Each segment of a segmented data file must be revised in chronological order based on Record ID's. If the Record control field changes, the order should be based on the new Record control fields expected. In general, revising the Record control fields is not advised.

The first step should be creation of the FFT. The execution of FR should be done with the NOGO option allowing storage of the FR logic statements. The third step would involve a SAM segment generation run with a segment control record to define the segment boundary for the first segment. The FFT and Logic statements on the ISAM or VSAM FFT must be used for each generation of a segment. Each segment generation must include a segment control card.
