RATIONAL SYNTHESIS OF UNIDIMENSIONAL MIXED VALENCE SOLIDS. STRUCTURE-OXIDATION STATE-CHARGE TRANSPORT RELATIONSHIPS IN IODINATED NICKEL AND PALLADIUM BISBENZOQUINONEDIOXIMATES.

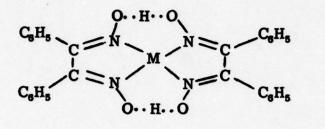

by Leo D. Brown, <sup>1a</sup> Davida Webster Kalina, <sup>1a</sup> Malcolm S. McClure, <sup>1b</sup> Steven Schultz, <sup>1c</sup> Stanley L. Ruby, <sup>1c</sup> James A. Ibers, \*<sup>1a</sup> Carl R. Kannewurf, \*<sup>1b</sup> and Tobin J. Marks\*<sup>1a, 2</sup>

## ABSTRACT

This paper presents a detailed study of crystal structure, stoichiometry, oxidation state, and electron transport in the materials Ni(bqd)<sub>2</sub>, Pd(bqd)<sub>2</sub>, Ni(bqd)<sub>2</sub>I<sub>0,02</sub>, Ni(bqd)<sub>2</sub>I<sub>0,5</sub>. S, and Pd(bqd)<sub>2</sub>I<sub>0,5</sub>. S, where bqd = <u>o</u>-benzoquinonedioximato and S = an aromatic solvent. The compound Pd(bqd)<sub>2</sub>I<sub>0,50</sub>. 0.52 <u>o</u>dichlorobenzene has been shown by single crystal X-ray diffraction to crystallize in the tetragonal space group  $D_{4h}^2$ -P4/mcc, with four formula units in a cell of dimensions <u>a</u> = 16.048(7) and <u>c</u> = 6.367(3)Å. Fullmatrix least-squares refinement gave a final value of the conventional R index (on F) of 0.052 for 1278 reflections having  $F_0^2 > 3_{\text{C}}$  ( $F_0^2$ ). The crystal structure consists of stacked Pd(bqd)<sub>2</sub> units, each staggered by 65° with respect to its nearest neighbors, and disordered chains of iodine atoms extending in the <u>c</u>-direction. The solvent molecules are disordered throughout tunnels which extend parallel to <u>c</u>. The Pd-Pd distance is 3. 184(3)Å, Pd-N = 1. 996(7)Å, and the Pd(bqd)<sub>2</sub> units are rigorously planar. Resonance Raman studies ( $v_0 = 4880-6471$ Å) of Pd(bqd)<sub>2</sub>I<sub>0, 50</sub>. S and Ni(bqd)<sub>2</sub>I<sub>0, 5</sub>. S indicate that the predominant form of

the iodine present is  $I_3^{-1}$  ( $v_{fundamental} = 107 \text{ cm}^{-1}$ ), hence that the formal oxidation state of the M (bqd)<sub>2</sub> units is +0. 17(2). Iodine - 129 Mössbauer studies are also consistent with the I<sub>3</sub> formulation. Optical spectra of these complexes exhibit a strong, broad transition at 600 nm which is largely, if not exclusively, due to the polyiodide chains. Crystallization of Ni(bqd)<sub>2</sub> from benzene containing traces of iodine produces the new orthorhombic phase Ni(bqd)<sub>2</sub>I<sub>0,02</sub>. Single crystal x-ray studies have shown it to crystallize in the space group  $D_{2b}^{26}$  - Ibam with four formula units in a unit cell of dimensions  $\underline{a} = 16.438(2)$ ,  $\underline{b} = 14.759(4)$ , and  $\underline{c} = 6.360(2)$  Å. Full-matrix least-squares refinement gave a final value of the conventional R index (on F) of 0.11 for 1026 reflections having  $F_0^2 > 3_{\sigma}$  ( $F_0^2$ ). The structure contains rigorously planar Ni(bqd)<sub>2</sub> units stacked along the c axis with each molecule staggered by 68° with respect to its nearest neighbors. The Ni-Ni distance is 3. 180(2)Å, and Ni-N = 1.88(10)Å. Structural relationships are discussed for all M (bqd)<sub>2</sub> and M (bqd)<sub>2</sub>I, compounds; partial oxidation results in a small contraction of the interplanar spacings of 0.019Å(Pd) - 0.027Å(Ni). Single

crystal electrical conductivity measurements (dc and 100 Hz ac) in the stacking direction show an increase in conductivity upon partial oxidation of > 10<sup>3</sup> (Ni) and > 10<sup>4</sup> (Pd). Maximum conductivities at 300° K are Ni(bqd)<sub>2</sub>I<sub>0.50</sub><sup>-</sup> 0.24 toluene =  $1.1 \times 10^{-5} (\Omega - cm)^{-1}$  and Pd(bqd)<sub>2</sub>I<sub>0.5</sub>  $\cdot$  0.52 <u>o</u>-dichlorobenzene =  $8.1 \times 10^{-3} (\Omega - cm)^{-1}$ . Variable temperature studies show that the electrical conductivity follows, over the entire range investigated, an exponential temperature dependence with a single activation energy:  $0.54 \pm 0.08$  eV(Ni) and  $0.22 \pm 0.03$  eV(Pd). In an accompanying article<sup>3</sup> we discuss the properties of stacked, partially oxidized bisdiphenylglyoximates of nickel and palladium,  $M(dpg)_2I, A$ .

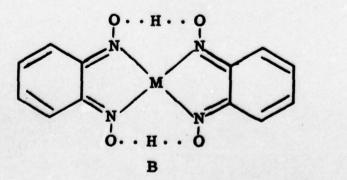

A

I

M = Ni, Pd

It was found that the iodine in these materials was present predominantly if not exclusively as  $I_5^-$ , hence that the  $M(dpg)_2$  units possess formal fractional oxidation states, representable approximately as  $[M(dpg)_2]_5^+I_5^-$ . Though the iodine oxidation produces a  $10^7-10^8$  increase in dc electrical conductivity, the facility of electron transport in these materials is still less than that of  $K_2Pt(CN)_4Br_{0.3} \cdot 3H_2O^4$  and several other classes of partially oxidized metallomacrocycles that we have recently synthesized. <sup>5</sup> It was thus of interest to explore the effect of chemical functionalization on the metal bisgly oximate core. A means to decrease stacking distances and to elaborate conjugation was evident in the planar nickel and palladium complexes of benzoquinonedioxime,  $M(bqd)_2$ , <u>B</u>.<sup>6</sup> The

M = Ni, Pd

earlier work of Keller and co-workers<sup>7,8</sup> established the existence of quasione-dimensional materials of reported stoichiometry  $M(bqd)_2 I_{0.5}$ , M=Ni, Pd. The nickel complex was reported to possess a tetragonal (P4/mcc) crystal structure with stacks of partially staggered Ni(bqd)<sub>2</sub> units (Ni-Ni = 3.153(3)Å) and disordered chains of iodine-containing species running parallel to the <u>c</u> direction.<sup>8</sup> It was proposed that iodine was present as  $I_5^-$ , though this conclusion could not be derived from the Bragg diffraction pattern. The crystal structure of the uniodinated precursor, Ni(bqd)<sub>2</sub>, was found to be monoclinic (P2<sub>1</sub>/n) by Leichert and Weiss<sup>9</sup> and to consist of canted bis(benzoquinonedioximato)nickel units. In contrast, the structure of Pd(bqd)<sub>2</sub> is orthorhombic (Imcb) with stacked Pd(bqd)<sub>2</sub> moieties extending along the <u>c</u> axis.

Though the aforementioned work provided an important initial glimpse of the range of bisbenzoquinonedioximate structures and compositions obtainable, several important questions remained unanswered. First, the nature of the iodine in the  $M(bqd)I_{0.5}$  species was undetermined. Thus, it was impossible to say with certainty whether the iodinated nickel and palladium bisbenzoquinonedioximates were actually mixed valence (partially oxidized) materials. Second, the available structural data did not provide a clear picture as to what geometrical changes, if any, (e.g., in the metal-metal stacking distances) accompanied iodination. The canted

78 10 03 045

monoclinic Ni(bqd)2 and stacked tetragonal Ni(bqd)2I0.5 structures could not be meaningfully compared in the sense that the stacked Ni(dpg)2 and Ni(dog) I structures could.<sup>3</sup> In addition, structural data on Pd(bqd)<sub>2</sub>I<sub>0.5</sub> were not available for comparison with the existing orthorhombic Pd(bqd)<sub>2</sub> structure. Finally, little was known about the charge transport properties of  $M(bqd)_2 I_{0.5}$  single crystals vis -à-vis those of  $M(bqd)_2$ .<sup>11</sup> In a preliminary communication<sup>12</sup> we reported a resonance Raman and iodine-129 Mössbauer study of Ni(bqd) $_{2}I_{0.5}$  which showed the iodine to be present predominantly as  $I_3$ , hence that the charge distribution could be represented by formal fractional oxidation states as depicted by  $[Ni(bqd)_2]_s^{\dagger}I_s^{-}$ . Independent of this work, analysis<sup>13</sup> of the diffuse X-ray scattering pattern arising from the disordered iodine chain structure in Ni(bqd)<sub>2</sub>I<sub>0.5</sub> reached exactly the same conclusion concerning the form of the iodine:  $I_3$ . In this paper we present a full exposition of our chemical, spectral, structural, and charge transport investigations within the nickel and palladium bisbenzoquinonedioximate series. This discussion includes a reformulation of the actual composition of the M(bqd)<sub>2</sub>I<sub>0.5</sub> materials, the structural characterization of Pd(bqd)<sub>2</sub>I<sub>0.5</sub>. 0.52 o-dichlorobenzene, the synthesis and structure elucidation of a new. orthorhombic Ni(bqd)<sub>2</sub>I<sub>0.02</sub> compound, comments on M (bqd)<sub>2</sub>I<sub>y</sub> optical spectra, <sup>14</sup> and a comparison of the geometrical, partial oxidation state, and charge transport characteristics in all of the aforementioned materials.

## EXPERIMENTAL

4

All solvents and chemicals were reagent grade. Benzene, toluene, and hexane were freshly distilled from sodium-potassium alloy under nitrogen; o-dichlorobenzene was dried over Davison 4A molecular steves. The ligand o-benzoquinonedioxime (bqdH) was synthesized by the reduction of o-dinitrosobenzene with sodium borohydride as described elsewhere.<sup>15</sup> Elemental analyses were by Ms. H. Beck, Northwestern Analytical Services Laboratory, Micro-Tech Laboratories, Galbraith Laboratories, or Alfred Bernhardt Microanalytical Laboratories. Analysis of Ni and I by neutron activation was performed by General Activation Analysis, Inc. Mass spectra were recorded on a Hewlett-Packard 5930 instrument by Dr. D. Hung. Iodinated materials were routinely stored at -20° C.

<u>Bis(benzoquinonedioximato)nickel(II), Ni(bqd)</u><sub>2</sub>. This complex was prepared by the room temperature reaction of NiCl<sub>2</sub>  $\cdot$  6H<sub>2</sub>O with bqdH in ethanol-water. The reaction is complete within 0.5 hr. The crude, dark-brown Ni(bqd)<sub>2</sub> was collected by suction filtration, washed with distilled water, washed with methanol, and then dried for several hours at 110°C. The crude product was finally Soxhlet extracted (twice) with benzene to yield a dark-brown, microcrystalline solid. Yields of Ni(bqd)<sub>2</sub> from this procedure were typically about 80%. Large crystals (elongated platelets) for transport studies were grown by very slow cooling of hot toluene solutions. <u>Anal.</u> Calcd for C<sub>12</sub>H<sub>10</sub>N<sub>4</sub>O<sub>4</sub>Ni: C, 43.28; H, 3.03; N, 16.83. Found: C, 43.21; H, 2.96; N, 16.74.

Infrared data (Nujol mull, cm<sup>-1</sup>): 3090w, 1600s, 1500s, 1265s, 1140m, 1080s, 950s(br), 820w, 740vs, 610m.

<u>Bis (benzoquinonedioximato)palladium(II)</u>,  $Pd(bqd)_2$ . The procedure for the synthesis and purification of this compound was analogous to that described above for Ni(bqd)<sub>2</sub> except that the  $PdCl_2$  starting material was solubilized by treatment with a small amount of hydrochloric acid. The final product,  $Pd(bqd)_2$ , is a dark-green microcrystalline solid. Larger crystals can be grown by slow cooling of hot toluene solutions.

<u>Anal.</u> Calcd. for  $C_{12}H_{10}N_4O_4Pd$ : C, 37.86; H, 2.65; N, 14.72. Found: C, 37.78; H, 2.60; N, 14.68.

Infrared data(Nujol mull, cm<sup>-1</sup>): 1600s, 1520vw, 1490s, 1415s, 1355s, 1285vs, 1185m, 1165m, 1130w, 1060vs, 965w, 880m, 790m, 740s, 730s, 615m.

<u>Bis (benzoquinonedioximato)palladium  $\cdot 0.50$  indine  $\cdot 0.52$  <u>o</u>-dichlorobenzene, Pd(bqd)<sub>2</sub>I<sub>0,50</sub>  $\cdot$  0.52 <u>o</u>-C<sub>8</sub>H<sub>4</sub>Cl<sub>2</sub>. Solutions of Pd(bqd)<sub>2</sub> in <u>o</u>dichlorobenzene (4.5 x 10<sup>-3</sup>M) were heated to 90°C and were then made 4.0 x 10<sup>-2</sup>M in triply sublimed iodine. The resulting mixture was next filtered while hot, and the filtrate rewarmed to 90°C. The hot solution was then sllowed to cool to ambient temperature over a period of 3-5 days. At this time the cooled solution was suction-filtered, and the solid product was washed repeatedly with cold hexane, and then dried in air. Dark, needle-like crystals of the desired product possessed a golden luster and were typically 3-15 mm. in length. These crystals were mechanically separated from the noncrystalline and microcrystalline material. The yield of golden</u>

the state of the second party

crystals obtained in this manner was ca. 40%. On the basis of the elemental analysis, the stoichiometry  $Pd(bqd)_2I_{0.5} \cdot 0.52 \ one{0.52} - C_8H_4Cl_2$  is assigned.

<u>Anal.</u> Calcd. for  $C_{15, 12}H_{12, 08}N_4O_4PdI_{0, 5}Cl_{1, 04}$ : C, 34.91; H, 2.34; N, 10.78; I, 12.13; Cl, 7.06. Found: C, 34.56; H, 2.34; N, 10.82; I, 12.19; Cl, 7.09. Analyses (C, H, N, Bernhardt) on each of three single crystals weighing 0.372 mg., 0.500 mg., and 0.675 mg., indicated an average incorporation of <u>o</u>-dichlorobenzene corresponding to:  $Pd(C_8H_5N_2O_2)_2PdI_{0, 52}(2)$  $(o-C_8H_5Cl_2)_{0, 41(2)}$ .

Mass spectra of the above crystals (10 or 70 eV ionizing voltage) recorded with source and probe temperatures of  $200^{\circ}$  C and  $100^{\circ}$  C, respectively, revealed the parent ions and fragmentation patterns characteristic of iodine and <u>o</u>-dichlorobenzene.

Infrared data (Nujol mull, cm<sup>-1</sup>): 1600s, 1520vw, 1490s, 1415s, 1355s, 1280vs, 1185m, 1160m, 1130w, 1065vs, 970w, 880w, 790w, 740s, 730s, 615m.

When the above synthetic procedure was carried out with increased iodine concentrations (4.9, 5.9, 6.9,  $7.9 \times 10^{-2}$ M) the yield of golden crystals decreased and the appearance of a dark, shiny, rather flaky material was noted. By elemental analysis it appears to be Pd(bqd)<sub>2</sub>I<sub>x</sub> x = 1.5 - 2.0.

<u>Bis (benz oquinonedioximato)nickel  $\cdot$  0.52 iodine  $\cdot$  0.32 toluene,</u> <u>Ni(bqd)<sub>2</sub>I<sub>0,52</sub>  $\cdot$  0.32 C<sub>7</sub>H<sub>8</sub>.</u> Solutions of Ni(bqd)<sub>2</sub> (6.0 x 10<sup>-3</sup>M) and triply sublimed iodine (4.0 x 10<sup>-2</sup> - 4.4 x 10<sup>-2</sup>M) in toluene at 90°C were treated in a manner analogous to the previously described procedure involving  $Pd(bqd)_2$  in <u>o</u>-dichlorobenzene. Large needle-like crystals exhibiting a golden luster could be isolated from the toluene solutions in ca. 20% yield.

<u>Anal</u>. Calcd. for C<sub>14.24</sub> H<sub>12.56</sub>N<sub>4</sub>O<sub>4</sub>NiL<sub>0.52</sub>: C, 39.92; H, 2.96; N, 13.08; I, 15.40. Found: C, 37.60; H, 2.74; N, 13.07; I, 15.49.

The mass spectrum of the above crystals (10 or 70 eV, 200° C source, 100° C probe) exhibited a pattern characteristic of iodine and 16b toluene.

Infrared data(Nujol mull, cm<sup>-1</sup>): 3090w, 1600s, 1500s, 1265s, 1160m, 1080vs, 980w(br), 830m, 740vs, 615m.

<u>Bis(benzoquinonedioximato)nickel  $\cdot$  0.0177 iodine, Ni(bqd)<sub>2</sub>I<sub>0.0177</sub>. A solution of Ni(bqd)<sub>2</sub> (6.2 x 10<sup>-3</sup>M) and triply sublimed iodine (1.4 x 10<sup>-2</sup>M) in benzene was heated to 78°C, filtered while hot, and the filtrate allowed to cool slowly to ambient temperature. The resulting dark crystals were collected by suction filtration, washed repeatedly with hexane, and dried in air. The crystals of this material are dark needles, exhibiting no golden luster. The C, H, N elemental analysis is experimentally indistinguishable from Ni(bqd)<sub>2</sub>.</u>

Anal. Calc. for  $C_{12}H_{10}N_4O_4NiI_{0.0177}$ : C, 43.00; H, 3.01; N, 16.72. Found: C, 43.45; H, 3.25; N, 16.23. Calcd for  $C_{12}H_{10}N_4O_4Ni$ : C, 43.28; H, 3.03; N, 16.83.

A determination of the ratio of nickel to iodine in a single crystal (the X-ray data crystal) by neutron activation analysis gave Ni : I =

the second and a second proved

## 1.00:0.0177(73).

Infrared data (Nujol mull, cm<sup>-1</sup>): 3090w, 1600s, 1500s, 1265s, 1140m, 1080s, 950s(br), 820w, 740vs, 610m.

# Spectral Measurements

Infrared, resonance Raman, and electronic spectra were recorded in the same manner and with the same apparatus as described previously.<sup>3</sup> Iodine Mössbauer Studies

The apparatus and data acquisition/analysis procedures employed were as described previously.<sup>3</sup> Samples were prepared by weighing ca. 70 mg. of Ni(bqd)<sub>2</sub> into a small vial, adding the desired amount of  $^{129}I_2^{3}$  in 1-2 ml. of benzene or <u>o</u>-dichlorobenzene, capping the vial, heating the mixture to ca. 80° C, and then allowing it to cool slowly overnight. The solid product was next collected by centrifugation, washed several times with 162 ml. of hexane, and was then dried under a stream of dry nitrogen. Several samples were prepared which elemental analysis showed to have a Ni:I ratio greater than 1.0.

# Single Crystal Electron Transport Measurements

The procedures and apparatus for four-probe conductivity measurements were those described for the M(dpg)<sub>2</sub>I work.<sup>3</sup> Contact materials were colloidal graphite suspended in 1,3-butylene glycol or Demetron M8001 cold-setting conductive gold contact paint. Results with these two contact preparations were indistinguishable. Typical crystalline samples of the bisbenzoquinonedioxmates were approximately tetragonal needles with

lengths of 2.0-4.0 mm. and widths of 0.1-0.3 mm. All measurements were conducted with current flow along the needle axis, i.e., along the molecular stacking direction. Variable temperature studies employed measurements taken with both increasing and decreasing temperature to check for possible hysteresis; none was observed. Room temperature conductivity measurements were always made after high temperature studies to ascertain if sample decomposition was taking place.

# X-Ray Diffraction Study of Ni(bqd)<sub>2</sub>I<sub>0 02</sub>

Preliminary film data were consistent with Laue symmetry mmm. Systematic extinctions are indicative of space groups Ibam or Iba2. Based on the setting angles of 14 manually centered reflections ( $40 \le 2_{\theta} \le 60^{\circ}$ , CuK<sub>Q</sub>) the cell constants presented in Table I were obtained. Data were collected at room temperature on a Picker FACS-1 diffractometer using methods general in this laboratory. Important features of the data collection are summarized in Table I.

The structure was solved and refined in a facile manner, using procedures and computer programs described before. <sup>17</sup> The centrosymmetric space group Ibam was assumed on the basis of excellent agreement among Friedel pairs. The positions of the atoms of the Ni(bqd)<sub>2</sub> species were obvious from a three-dimensional, origin-removed, sharpened Patterson function. Included in the final cycle of least-squares refinement were the contributions from hydrogen atoms on the carbon atoms. The positions of these hydrogen atoms were calculated, assuming C-H = 0.95 Å. The hydrogen atom position in the 0(1)-H-O(2) hydrogen bond

where the second design prove

was not included. This final refinement converged to R indices and an error in an observation of unit weight given in Table I.

Examination of the final agreement between  $|F_0|$  and  $|F_c|$  reveals some disturbing features: (1) The highest residual peak of  $1.36 \text{ e/A}^3$  is located at  $\frac{1}{2}00$ , but there is a general level of density along the  $\frac{1}{2}0z$  line; (2) There are some outstanding differences between  $|F_0|$  and  $|F_c|$  especially for hk0 reflections (e.g., 510: 8.7, 25.0; 330: 12.3, 1.9 e). On the bais of the neutron activation analysis of the data crystal (see above) there appears to be approximately 0.02 iodine atoms per nickel atom in the material. Presumably, the iodine atoms are positioned along the  $\frac{1}{2}$  or row, since there are large channels there that could accommodate iodine. Although a number of attempts were made to approximate the iodine scattering, none was especially successful. However these calculations did establish that the overall structural parameters of the Ni(bqd), portion of the structure are insensitive to models for the iodine scattering. Ultimately we chose as the final model one that ignores the presence of iodine. Table II presents the final paramters from this model. Table III presents the final listing of  $10|F_0|$  vs  $10|F_c|$  for those reflections used in the refinement.<sup>18</sup>

# X-ray Diffraction Study of Pd(bqd), In 50 0. 52 CaH4 Cla

Preliminary film data indicated Laue symmetry 4/mmm and systematic extinctions are consistent with space groups P4/mcc and P4cc. The cell constants (Table I) were obtained from the setting angles of 15 reflections manually centered on a FACS-1 diffractometer ( $30 < 20 < 40^\circ$ , MoKa<sub>1</sub>). Other

The second and the second provide second

features of the crystal and data collection are given in Table I.

The structure was solved and refined as described above. Examination of Friedel pairs strongly suggested that the centrosymmetric space group P4/mcc is the correct one. The Pd(bqd)I<sub>x</sub> portion of the structure was located from a Patterson function and subsequent difference Fourier maps. In the final refinement of this portion of the structure variable occupancy of the iodine atom was included. The resultant formula was Pd(bqd)<sub>2</sub>I<sub>0.444</sub> and the final values of R, wR, and an error in an observation of unit weight were 0.070, 0.102, and 3.63 e<sup>-</sup>. Again there were some individual examples of poor agreement betwe en  $|F_0|$  and  $|F_c|$ , in this instance not restricted primarily to the hk0 reflections. A difference Fourier map showed as its main features a peak of height 1.28 e/A<sup>3</sup> at approximately 0.06, 0.13, 0.15 and a ring of electron density about x = 0, y = 0 in the  $z = \frac{1}{4}$  plane.

At this point it was discovered (see above) that the crystals of this compound contain varying amounts of <u>o</u>-dichlorobenzene, the average amount being 0.52 solvent molecule/palladium atom. Consequently, a number of attempts were made to account for the residual electron density as arising from a variable amount of <u>o</u>-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> in the 0,0, z channel. Because of the 4-fold symmetry imposed on this channel and the fact that the solvent molecule does not intrinsically possess such symmetry, the disordering of the solvent is considerable. Although a calculation of the contributions of a C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> rotor, constrained to lie in the  $z = \frac{1}{4}$  plane, led

to some improvement between  $|F_0|$  and  $|F_c|$ , this model did not account for the main residual peak. Ultimately, a Cl atom was placed at the position of this residual peak and in subsequent cycles the occupancy and isotropic thermal parameter of this Cl atom were varied, along with the other variables of the Pd(bqd)<sub>2</sub>I<sub>x</sub> portion. This refinement ultimately converged to the formula  $Pd(bqd)_2I_{0,48} \cdot 0.91$  o-dichlorobenzene and agreement indices present in Table I. Because of correlation between occupancy and thermal parameter of the CI atom and because of the very approximate nature of the model for solvent scattering, the ratio of solvent to Pd(bqd)<sub>2</sub>I derived from these data is very uncertain. We will henceforth refer to this compound, based upon the elemental analysis (vide supra), as  $Pd(bqd)_2I_{0.50} \cdot 0.52$ o-dichlorbenzene. Placement of a Cl atom at this position is made chemically reasonable by the resultant Cl... Cl distance of 3.05Å, a value to be expected in  $O-C_{g}H_{4}Cl_{2}$ . The improvement in agreement indices is considerable as is more importantly, the removal of outstanding, individual discrepancies between  $|F_0|$  and  $|F_c|$ . Table IV presents the final parameters from this model. Table V gives a listing of 10  $|F_0|$  vs 10  $F_c$  for the reflections used in the refinement. 18

and the second second property

#### **RESULTS AND DISCUSSION**

(1)

#### Chemistry and Stoichiometry

The slow crystallization of Ni(bqd)<sub>2</sub> and Pd(bqd)<sub>2</sub> from certain hot aromatic solvents in the presence of an approximately 10-fold molar excess of  $I_2$  produces iodinated crystalline materials with a golden luster (eq. (1)). In the case of Pd(bqd)<sub>2</sub>, iodination in <u>o</u>-dichlorobenzene

 $M(bqd)_2 + I_2 + S \implies M(bqd)_2 \cdot xI \cdot nS$ 

M = Ni, Pd S = aromatic solvent

yields a crystalline compound of approximate composition  $Pd(bqd)_2I_{0.50}$ 0.52 <u>o</u>-C<sub>8</sub>H<sub>4</sub>Cl<sub>2</sub>. The presence of the solvent could be demonstrated by elemental analysis and mass spectrometry (see Experimental Section). In our hands, Ni(bqd)<sub>2</sub> was too soluble in <u>o</u>-dichlorobenzene to give good yields of a crystalline iodination product. However in toluene,golden lustrous crystals of approximate composition Ni(bqd)<sub>2</sub>I<sub>0.52</sub> · 0.32 toluene could be isolated. The solvent incorporation was again assigned by elemental analysis and mass spectrometry. For Pd(bqd)<sub>2</sub>, the solubility in hot toluene was too small to allow isolation of crystalline iodinated materials in sufficient quantities for complete characterization. The above formulations differ from previous iodination studies on the nickel and palladium bisbenzoquinonedioximates where solvent incorporation (<u>o</u>dichlorobenzene) was apparently not detected. <sup>7,8,13</sup> In our experiments, iodination of Pd(bqd)<sub>2</sub> in o-dichlorobenzene with a greater than 10-fold

The shirt a set where it does provide it

excess of iodine produced a dark flaky solid which analyzed approximately as  $Pd(bqd)_{2}I_{\chi}$ , x = 1.5-2.0. Iodination of  $Ni(bqd)_{2}$  in hot benzene with a two-fold excess of iodine yielded a dark (not golden) crystalline material which contained liftle or no iodine according to standard elemental analyses. For the crystal of this material chosen for X-ray diffraction studies (vide infra), neutron activation analysis revealed a nickel/iodine ratio consistent with the stoichiometry  $Ni(bqd)_{2}I_{0.0B}$ . Thus, our chemical results indicate that the  $M(bqd)_{2}I_{\chi}$  stoichiometry has considerably greater variability than previously thought, both in terms of halogen content and in terms of the tendency for solvent incorporation. It will be seen that both characteristics are understandable in terms of the crystal structures of these materials.

### **Resonance Raman and Iodine-129 Mössbauer Measurements**

Raman spectra of the  $M(bqd)_{2I_X}$  nS materials are presented in Figure 1; data are set out in Table VI. As was discussed in depth for the  $M(dpg)_{2I}$ studies, <sup>3</sup> different polyiodide species give rise to characteristic, resonantenhanced Raman scattering spectra. <sup>5a, 19</sup> Spectra of Ni(bqd)<sub>2</sub>I<sub>0,52</sub>  $\cdot$  0. 32 toluene and Pd(bqd)<sub>2</sub>I<sub>0,50</sub>  $\cdot$  0. 52 <u>o</u>-dichlorobenzene are essentially identical; a strong emission is observed at 107 cm<sup>-1</sup> and an overtone at 215 cm<sup>-1</sup>. These bands are absent in the uniodinated materials. Such a Raman scattering pattern is characteristic of I<sub>3</sub><sup>-</sup>, the 107 cm<sup>-1</sup> vibration corresponding to the totally symmetric I-I-I stretch. <sup>5a, 19, 20</sup>

There is no evidence for free  $I_2$ , weakly coordinated  $I_2$ , or any more than trace amounts of  $I_5^-$  in these spectra. As was discussed in the  $M(dpg)_2I$ work, such species are readily detected in resonance Raman spectra.<sup>3, 5a,19</sup> Unlike the diphenylglyoximate systems, no scattering from the  $M(bqd)_2$ units could be discerned in the iodinated materials. In the iodine-rich compounds of stoichiometry  $Pd(bqd)_2I_x$ , x = 1.5-2.0, strong scattering at ca. 180 cm<sup>-1</sup> was observed, indicative of weakly coordinated  $I_2$ , as found in the structures and spectra<sup>5a, 19</sup> of materials containing  $I_2$ and  $I_3^-$  units in close proximity (e. g. (phenacetin)<sub>2</sub>H<sup>+</sup> $I_3^- \cdot I_2^{-3, 21a}$ ,  $(Cs^+)_2(I_3^-)_2 \cdot I_2, {}^{5a, 19, 21b} (C_2H_5)_4N^+ J_3^- \cdot 2I_2^{-5a, 19, 21c})$ . In the iodine-poor material, Ni(bqd)<sub>2</sub> $I_{0, 018}$ , no Raman scattering attributable to a polyiodide species could be observed.

In an effort to explore the possibility that Raman-inactive I was present in the iodinated  $M(bqd)_2$  materials, iodine -129 Mössbauer<sup>22</sup> studies<sup>3, 5a</sup> were undertaken.<sup>12</sup> In a cubic or approximately cubic environment, I gives a characteristic singlet ( $\delta = -0.51 \text{ mm/sec}$ ,  $e^2qQ=0$ )<sup>22</sup> in the iodine Mössbauer spectrum. Because of the expense of iodine -129 and the very large excesses of iodine necessary to prepare practical quantities of Ni(bqd)<sub>2</sub>I<sub>0.52</sub>·0.32 toluene or Pd(bqd)<sub>2</sub>I<sub>6.80</sub>·0.52 <u>o</u>-dichlorobenzene as crystalline samples, it was necessary to study polycrystalline powders. Several iodinated nickel specimens were prepared by stirring Ni(bqd)<sub>2</sub> compounds with a stoichiometric amount of <sup>200</sup>I<sub>2</sub> in benzene or <u>o</u>-dichlorobenzene, then removing the supernatant and washing the solid product with pentane (see Experimental Section for details). The Raman spectra of these samples exhibited the characteristic L fundamental at

the second stand and strate provides

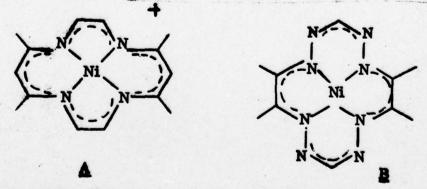

ca. 108 cm<sup>-1</sup> and no evidence of appreciable  $L_5^-$  or  $L_2$ . Elemental analysis showed a Ni:I ratio greater than 1.0. The Mössbauer spectra of these materials were somewhat broader than normal, <sup>3</sup> apparently reflecting macroscopic or microscopic sample inhomogeneity arising from the preparative procedure. For this reason the derived polyiodide spectral parameters are not as accurate as in the  $M(dpg)_2I$  studies, <sup>3</sup> and exhaustive data refinement was not carried out. Most important, however, is the information these Mössbauer data provide on the possible presence of I<sup>-</sup> or, also, free  $L_2$  ( $\delta \approx + 0.98$  mm/sec,  $e^2qQ \approx -1586$  MHz).<sup>22</sup> A conservative estimate of the amount of I<sup>-</sup> which could be present is ca. 3 mole %; for free  $L_2$ , this number is ca. 5 mole%.

As already noted, a diffuse X-ray scattering study<sup>13</sup> of Ni(bqd)<sub>2</sub>I<sub>0.5</sub> concluded that the form of the iodine present was  $I_3$  in agreement with our spectral results. We find that the diffuse scattering pattern exhibited by Pd(bqd)<sub>2</sub>I<sub>0.50</sub>  $\cdot$  0.52 <u>0</u>-C<sub>5</sub>H<sub>4</sub>Cl<sub>2</sub>(<u>vide infra</u>)is identical to that of Ni(bqd)<sub>2</sub>I<sub>0.50</sub>,<sup>13</sup> indicating that an identical form of iodine is present, namely  $I_3$ .

# Ni(bqd) I. oz Crystal Structure

The crystal structure of Ni(bqd)<sub>2</sub>I<sub>0,02</sub> is composed of individual Ni(bqd)<sub>2</sub> units which exhibit no unusual non-bonded contacts. The Ni(bqd)<sub>2</sub> units are stacked along the crystallographic <u>c</u>-axis, such that the coordination planes of the Ni atoms are perpendicular to the stacking direction. A view of the unit cell is presented in Figure 2. Each Ni(bqd)<sub>2</sub> moiety is staggered by approximately 68° with respect to its nearest neighbors along the stacking axis. <sup>23</sup> The iodine atoms, whose presence was established by neutron activation analysis of the crystal used in the X-ray diffraction experiment, are presumed, based upon analogous structures, to be positioned in the channels<sup>3,5a,7,8,13</sup> along  $\frac{1}{2}$ , 0, z, which exhibit residual electron density.

The Ni atoms in Ni(bqd)<sub>2</sub>I<sub>0.02</sub> occupy the 4c special positions in the orthorhombic space group Ibam; thus, all Ni atoms are equally spaced along the stacking axis by c/2 (3.180(2)Å). This Ni-Ni distance can be compared with values of 3.856(2)Å for Ni(bqd)<sub>2</sub> (a monoclinic, slipped-stack structure)<sup>9</sup> and 3.153(3)Å for Ni(bqd)<sub>2</sub>I<sub>0.50</sub>.<sup>8</sup> Partial oxidation typically results in a contraction in the metal-metal distance as illustrated by the nickel metallomacrocycles Ni(dpg)<sub>2</sub> and Ni(dpg)<sub>2</sub>I (3.547Å vs. 3.271(1)Å,<sup>3</sup> as well as NiPc<sup>24</sup> and NiPcI,<sup>5a, e, f</sup> Pc = phthalocyanine (4.79Å for a slipped-stack structure vs. 3.244(3)Å). Nickel-nickel separations for stacked, unoxidized glyoximate systems are as short as 3.24Å in Ni(CHD)<sub>2</sub>,<sup>25</sup> CHD = 1,2-cyclohexanedionedioximato and 3.25Å in Ni(dmg)<sub>2</sub>,<sup>26</sup> dmg = dimethylglyoximato. The shortest Ni-Ni distances are found in the dimeric, eclipsed face-to-face structures of nickel macrocyclic compounds <u>A</u> (Ni-Ni = 3.063(1)Å)<sup>27</sup> and <u>B</u>(Ni-Ni=2.788(2)Å.

In these complexes the nickel atoms are displaced slightly out of the ligand planes (as defined by the four coordinated nitrogen atoms) toward each other. Thus, the interplanar spacings are estimated to be  $3.19_{14}^{14}$  (A)<sup>27</sup> and  $3.00_{14}^{14}$  (B).<sup>28</sup>

the state of the second provide

The metal-metal separation in nickel metal is 2.49Å.<sup>29</sup>

The Ni(bqd)<sub>2</sub> unit in Ni(bqd)<sub>2</sub>I<sub>0.02</sub> has crystallographically imposed symmetry 2/m and is therefore planar. Figure 3 shows the structure of the molecule and the atom numbering scheme. The bond lengths and angles in the Ni(bqd)<sub>2</sub> unit are in good agreement with the parameters reported in Ni(bqd)<sub>2</sub><sup>9</sup>, and Ni(bqd)<sub>2</sub>I<sub>0.5</sub>. <sup>8</sup> These values are set out in Table VII. Pd(bqd)<sub>2</sub>I<sub>0.50</sub>  $\cdot$  0.52 <u>0</u>-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> Crystal Structure

The structure of  $Pd(bqd)_{z_{0,50}} \circ 0.52 \circ -C_{g}H_{4}Cl_{2}$  is composed of individual Pd(bqd)<sub>2</sub> units and I atoms exhibiting no unusual non-bonded contacts. A view of the unit cell is presented in Figure 4. The  $Pd(bqd)_{2}$ moieties are stacked along the crystallographic <u>c</u>-axis, such that the coordination planes of the Pd atoms are perpendicular to the stacking direction. Each Pd(bqd)<sub>2</sub> moiety is staggered by approximately 65° with respect to its nearest neighbors along the stacking axis. The iodine atoms also stack one above the other in the <u>c</u> direction, filling the "tunnels" along  $\frac{1}{22}z$  created by the benzo rings of the benzoquinonedioximato ligands. The observed diffuse X-ray scattering pattern, which is identical to that reported for Ni(bqd)<sub>z</sub>J<sub>0.5</sub>, <sup>13</sup> is attributable to the disorder of the iodine atoms along the stacking direction. In addition, the <u>o</u>-dichlorobenzene molecules are believed to reside, in a disordered fashion, in the tunnels of larger diameter (along 00z) created by the oxygen atoms and benzo rings of the benzoquinonedioximato ligands.

The Pd atoms occupy the 4f special positions in the space group P4/mcc; thus, all Pd atoms are equally spaced along the stacking direction by c/2(3. 184(3)Å). This Pd-Pd distance is comparable with the Pd-Pd distances found in the partially oxidized stacked glyoximate compounds Pd(gly)<sub>2</sub>I (3. 244(1)Å), <sup>80</sup> gly = glyoximato, and Pd(dpg)<sub>2</sub>I (3. 26Å) <sup>31a, b</sup> These distances are significantly shorter than the Pd-Pd distances found in the corresponding precursors Pd(gly)<sub>2</sub> (3. 558 Å)<sup>32</sup> and Pd(dpg)<sub>2</sub> (3. 52Å)<sup>31c</sup> and is only slightly longer than the Pd-Pd distances in the unoxidized complexes Pd(bqd)<sub>2</sub>(3. 202(1)Å); <sup>10</sup> Pd(dmg)<sub>2</sub>(3. 253Å), <sup>26</sup> and Pd(CHD)<sub>2</sub> (3. 250Å)<sup>25</sup>. All of the above distances are considerably longer than the metal-metal distance in palladium metal (2. 75Å).<sup>29</sup>

The Pd(bqd)<sub>2</sub> unit has crystallographically imposed symmetry 2/m and is required to be planar. The molecular geometry is essentially that shown for Ni(bqd)<sub>2</sub>- $I_{0,02}$  in Figure 3; the atom numbering scheme is the same. The bond lengths and angles in the Pd(bqt)<sub>2</sub> unit of the Pd(bqd)<sub>2</sub> $I_{0,50}$   $\cdot 0.52$  <u>o</u>-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> crystal structure are in good agreement with the parameters reported in Pd(bqd)<sub>2</sub>, <sup>10</sup> and these values are given in **Table** VII. The most significant differences in the parameters of the Pd(bqd)<sub>2</sub> units in the two structures are in the Pd-N(1)-C(1) and Pd-N(2)-C(2) bond angles, 114.0(6)° and 115.8(6)° in Pd(bqd)<sub>2</sub> $I_{0,50}$   $\cdot 0.52$  <u>o</u>-C<sub>6</sub>H<sub>6</sub>Cl<sub>2</sub> and 122(1)° and 124(1)° in Pd(bqd)<sub>2</sub>. <sup>10</sup> Electronic Spectra

Figure 5 presents electronic spectra of the  $M(bqd)_2$  and  $M(bqd)_2I_x$  compounds as polycrystalline specimens. Data are compiled in Table VIII. Several features are noteworthy. For both nickel and palladium systems, iodination

they are an an and an

does not produce a detectable change in the spectra at wavelengths shorter than ca. 500 nm. Considering the drastic structural change which occurs upon iodination of Ni(bqd)<sub>2</sub> (monoclinic slipped stack structure with Ni-Ni = 3.856(2)Å<sup>9</sup>  $\longrightarrow$  tetragonal stacked structure with Ni-Ni = 3.153(3)Å<sup>8</sup>) it seems unlikely that these bands are metal-metal<sup>3</sup> (intramolecular  $ndz^2 \rightarrow (n + 1)p_z$  transitions with borrowing of intensity from metal  $\rightarrow$ metal charge transfer transitions <sup>33</sup>) in origin. Rather, these are, in all likelihood, M(bqd), molecular transitions. The second noteworthy feature of the electronic spectra is the appearance of a broad transition in the 600 nm region upon iodination. We assign a major part of this absorption to the I<sub>3</sub> chains. As discussed elsewhere, such intense optical transitions are typical of delocalized polyiodides. 3,34 The spectrum of (benzamide)<sub>2</sub> $H^{+}I_{3}^{-}$ , which is also a triiodide chain compound  $\frac{35}{2}$ is presented in Figure 5 for comparison. A recent polarized single crystal reflectance study<sup>14</sup> of Ni(bqd)<sub>2</sub>L<sub>0.50</sub> and Pd(bqd)<sub>2</sub>L<sub>0.50</sub> reached the conclusion that reflectance maxima at 1.6-1.7 eV (775-730 nm)<sup>36</sup> in these materials, which were polarized in the chain direction, were metal-metal  $(d_z^2 \text{ band} \rightarrow)$ p<sub>z</sub> band) in origin. Although such an assignment for the M(bqd), stacks is reasonable, it must be noted that the intense polyiodide transition should also be polarized in the chain direction.<sup>34C</sup> and that the presence of the I. chains cannot be ignored in such analyses.

## Comparison of Metal Bisbenzoquinonedioximate Crystal Structures.

The metrical and oxidation state information contributed by the present investigation now allows a detailed assessment of the crystal structural consequences of partial oxidation. A comparison of unit cell data for the series is compiled in Table IX; bond distances and angles are set out in Table VII. In the nickel system, the unoxidized material, Ni(bqd)2, has a slipped-stack structure.<sup>9</sup> A packing diagram, which has not previously been shown, is presented in Figure 6. As has been noted elsewhere,<sup>8,13</sup> this arrangement of the planar molecules within the unit cell allows more efficient packing (as judged by the density) than a stacked arrangement where the molecular planes are perpendicular to the stacking direction. In contrast to the Ni(bqd)<sub>2</sub> result, the Ni(bqd)<sub>2</sub>I<sub>0.02</sub> structure is an orthorhombic stacked one. Figure 7 compares the packing of all stacked M(bqd)<sub>2</sub>I, structures. The change in crystal structure on proceeding from  $Ni(bqd)_2$  to  $Ni(bqd)_2I_{0.02}$  includes a decrease in the interplanar spacing of 0.22Å, and a decrease in the metal-metal distance of 0.68Å. There is no significant alteration in metrical parameters within the Ni(bqd), unit (Table VII). The crystal structure of  $Ni(bqd)_2I_{0_002}$  evidences large tunnels extending in the stacking direction which contain only a small amount of iodine, but which may have contained larger quantities of material at some time during the crystallization process. That polyiodide species  $(I_2, I_3, etc.)$ were not detected in the resonance Raman examination of this material suggests the predominant presence of iodine as I and that the solid state charge distribution can be formally represented as  $Ni(bqd)_2^{+0.02}(I)_{0.02}$ . The presence of undetected polyiodides (e.g.  $I_3$ ) would mean that the degree of partial

oxidation was lower. Further oxidation of Ni(bqd)<sub>2</sub>

produces'Ni (bqd) $_{2I_{0.50}}$ ' with iodine present predominantly

as  $I_3$ , indicating a formal charge distribution of Ni(bqd)<sub>2</sub><sup>+0. 17</sup>( $I_3$ )<sub>0. 50</sub>/s. The oxidation state change is accompanied by an additional 0.027 a contraction in the Ni-Ni distance. There is no perceptible change in the internal Ni(bqd)<sub>2</sub> dimensions. Interestingly, the angle of eclipsing between Ni(bqd)<sub>2</sub> units changes only slightly upon further oxidation (68°  $\rightarrow$  65°); however, the relative orientation of the stacks changes appreciably. As can be seen in Figure 7, the effect is to provide two sets of tunnels which are nonequivalent in size and in surrounding environment. The smaller tunnel, which contains the iodine, is of approximate cross-sectional dimensions ca. 4.8% x 4.8% and is lined with hydrophobic C-H residues. The larger tunnel is ca. 7.  $4\frac{1}{4} \times 7.4\frac{1}{4}$  in size and is surrounded by C-H groups as well as more polar oxygen atoms (which are engaged in hydrogen bonding). These tunnels contain the solvent molecules. In contrast to this result, the tunnels in  $Ni(bqd)_2I_{0,02}$  are all crystallographically equivalent, have both polar and non-polar regions, and differ in size from those in Ni(bqd)2I0. 50. ca.  $5_{\text{Å}} \times 6_{\text{Å}}$ 

The structure of  $Pd(bqd)_2$  is orthorhombic with molecular planes perpendicular to the stacking direction and a 90° eclipsing angle between neighboring  $Pd(bqd)_2$  units (Figure 7). The degree to which this structure differs from that of monoclinic Ni(bqd)<sub>2</sub> may not be energetically significant since there is evidence<sup>14</sup> (as yet unpublished) that  $Pd(bqd)_2$  can also be crystallized in the same monoclinic form observed for Ni(bqd)<sub>2</sub>. Upon partial oxidation to  $Pd(bqd)_2^{+9.17}(L_3^-)_{0.50/5}$ , the Pd-Pd distance decreases by 0.019Å and the eclipsing angle between the stacked metallomacrocycle moieties decreases by 25°. A spreading out of the lattice in the <u>a-b</u> plane provides tunnels for iodine and solvent inclusion. The arrangement of groups within the unit cell of Pd(bqd)<sub>2</sub>I<sub>0.50</sub>. 0.52 <u>o</u>-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> is identical with that in Ni(bqd)<sub>2</sub>I<sub>0.50</sub>. Indeed, our refinement the published Ni(bqd)<sub>2</sub>I<sub>0.50</sub> crystallographic data, <sup>8</sup> reported for a crystal grown from <u>o</u>-dichlorobenzene, <sup>8</sup> indicates residual electron density in the larger set of lattice tunnels, i. e., those which contain solvent in Pd(bqd)<sub>2</sub>I<sub>0.50</sub>. <u>o</u>-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>. The internal structural parameters of the Pd(bqd)<sub>2</sub> unit insignificantly upon partial oxidation (Table VII).

## Electrical Conductivity

Four-probe, variable temperature <u>c</u>-axis conductivity data for Ni(bqd)<sub>2</sub>-  $I_{0, m} \cdot 0.32$  toluene and Pd(bqd)<sub>2</sub> $I_{0, m} \cdot 0.52$  <u>o</u>-dichlorobenzene single crystals are shown in Figures 8 and 9, respectively. These and related data are summarized in Table X. The range of conductivities observed for the Ni(bqd)<sub>2</sub> $I_{0, m} \cdot 0.32$ toluene crystals is fairly narrow for all samples examined. The wider range for the Pd(bqd)<sub>2</sub> $I_{0, m} \cdot 0.52$  <u>o</u>-C<sub>g</sub>H<sub>4</sub>Cl<sub>2</sub> data includes a single sample of particularly poor conductivity. Nearly all other values were clustered at the high conductivity end of the range. Table X also compared the dc conductivity of selected M(bqd)<sub>2</sub> $I_{0, s} \cdot S$ crystals with measurements at a frequency of 100 Hz. For M = Pd, there is good agreement between the techniques. For M = Ni, there is less good agreement, which is attributed to the integrity of the electrode contacts. The nickel-containing specimens presented the greatest measurement difficulties, and a large number of crystals were rejected owing to fractures and to non-ohmic electrode behavior.

It can be seen in Table X that the conductivities of the uniodinated  $M(pqd)_{a}$  materials are immeasurably low. As has been observed for the metal bisdiphenylglyoximates and similar macrocycles, partial oxidation such as to  $M(pqd)_{a}^{+0.17}$  results in a large increase in electrical conductivity. The enhancement for the bisbenzoquinonedioximates is ca.  $10^{a} - 10^{6}$ . Interestingly, considerably lower conductivities are observed for the Ni(bqd)<sub>2</sub>I<sub>0.02</sub> crystals than for the Ni(bqd)<sub>2</sub>I<sub>0.02</sub>  $\cdot 0.32$  toluene crystals. This may reflect the differences in crystal structure as well as the decreased number of charge carriers generated by the smaller degree of partial oxidation. In the only other case to date where it has been possible to vary the apparent degree of metallomacrocycle oxidation, i. e., Ni(OM TBP)I<sub>x</sub>, CM TBP = 1,4,5,8,9,12,13,16-octamethyltetrabenzoporphyrin, x = 1.05(1) and 2.9(3) (iodine present as I<sub>a</sub><sup>-</sup>), <sup>37</sup> the x = 2.9 materials appear to be slightly less conductive. The difference is not nearly so large as in the present case.

The dc conductivities of the  $M(bqd)_{2}I_{0,50}$  S materials obey eq. (2)

$$\sigma = \sigma_0 e^{-\Delta/kT}$$
(2)

over the range of temperatures shown in Figures 8 and 9. The  $M(dpg)_2I$ compounds exhibit similar behavior.<sup>3</sup> At the highest temperatures some  $M(bqd)_2I_{0,50}$  S samples did display a tendency toward levelling-off in the inp vs. 1/T plot. Efforts to confirm "metal-like" behavior, i. e., decreasing conductivity with increasing temperature, by acquiring additional data at even higher

and the and the set of the second generation

temperatures, resulted in irreversible sample decomposition. Table X contains apparent activation energies,  $\Delta$ , obtained by a least-squares fit to eq. (2). The range indicated represents the largest deviation from the average for the samples plotted. As was noted in the discussion of the M(dpg)<sub>2</sub>I conductivity data, <sup>3</sup> the thermally activated temperature dependence of charge transport in these materials is consistent with either of two theoretical descriptions: phonon-assisted carrier hopping between states localized by static disorder, <sup>38</sup> or an activated carrier concentration in a system with a Mott-Hubbard or some other type of gap. <sup>39</sup> For the former model, the disorder in the I<sub>3</sub> chains would presumably be the source of the disorder, while for the latter model, the classical Mott-Hubbard gap<sup>38d, 39b</sup> is inappropriate for the M(bqd)<sub>2</sub>I<sub>0, 50</sub> S bands, which are ca. 92% filled.

Table X also compares the  $M(bqd)_{2}I_{0.5}$ . S conductivity data with those for  $M(dpg)_{2}I$  materials. Even after adjusting the transport behavior for crystal structure by using the carrier mean free path (eq. (3)), it can be

(3)

$$L = \frac{\pi h A \sigma}{2e^2 N}$$

seen that the bisbenzoquinonedioximate materials are less conductive. Apparent activation energies are, however, more comparable (Table X), and in each bisglyoximate series the  $\Delta$  values for the highest conductor and lowest conductor are similar.

the Albert and water and served groups and

### CONCLUSIONS

The results of the present investigation indicate that the  $M(bqd)_{2}^{L}I_{(.5)}$ materials, M = Ni, Pd, are best formulated as  $M(bqd)_{2}^{L}I_{(.5)}$ . S materials where S represents various amounts of the aromatic solvent employed for crystallization. As deduced from resonance Raman, I-129 Mössbauer, and diffuse x-ray scattering measurements, <sup>45</sup> the iodine is present as  $I_{2}^{I}$ , and thus the  $M(bqd)_{2}^{L}I_{(.5)}$ . S materials are indeed partially oxidized. The formal fractional oxidation state of the  $M(bqd)_{2}$  units is +0.17. Based upon estimated uncertainties in stoichiometry and  $I_{3}^{-}$  content we assign to this oxidation state an uncertainty of 0.02 charge units. It is interesting to note that the degree of charge transferred in the present case is identical within experimental error, to that deduced in the bisdiphenylglyoximate materials,  $M(dpg)_{2}I$ , M = Ni, Pd. Here iodine was present predominantly as  $I_{5}^{-}$  so that the formal oxidation state of each  $M(dpg)_{2}$  moiety was +0.20(4).<sup>3</sup>

In both benzoquinonedioximate and diphenylglyoximate systems, partial oxidation is accompanied by contraction in the interplanar stacking distances. The shortest metal-metal distance observed for a stacked, partially oxidized metal bisdioximate is 3.153(3)Å in Ni(bqd)<sub>2</sub>I<sub>0.50</sub>, <sup>8</sup> with the distance in Pd(bqd)<sub>2</sub>I<sub>0.50</sub>. 0.52 <u>o</u>-dichlorobenzene being only slightly longer, i. e., 3.184(3)Å. Contacts in the M(dpg)<sub>2</sub>I species are somewhat longer with Ni-Ni = 3.271(1)Å and Pd-Pd = 3.25Å. <sup>3</sup> These metal-metal distances are greater than in K<sub>2</sub>Pt(CN)<sub>4</sub>Br<sub>0.30</sub>(2.89j)<sup>4</sup>, <sup>40</sup>as well as in the integral oxidation state face-to-face metallomacrocycle dimers [Ni(C<sub>14</sub>H<sub>18</sub>N<sub>4</sub>)]<sub>b</sub> <sup>48</sup> (<u>A</u>, Ni-Ni = 3.063(1)Å)<sup>27</sup> and [Ni(C<sub>18</sub>H<sub>14</sub>N<sub>8</sub>)]<sub>b</sub> (<u>B</u>, Ni-Ni = 2.788(2) <sup>28</sup> However, since the nickel atoms

and the state and have derived generation

in the latter two compounds are significantly displaced from the ligand planes<sup>41</sup> (and toward each other) it is more meaningful to discuss the interplanar spacing. This value for A is 3.19Å, and for B is 3.00Å, which is in better agreement with the stacked bisdioximate parameters. The attractive forces in the face-to-face dimers are considered to involve both metal-metal  $\sigma$  and  $\delta$  bonding as well as ligand-ligand  $\tau$  bonding. 27, 28 It is likely that similar effects are operative in the stacked bisdioximates. with the result of partial oxidation being to depopulate orbitals (bands) which are metal-metal (e.g.  $nd_{2}^{42}$ ) or ligand-ligand antibonding <sup>43</sup> in character. The lengths of the Ni-Ni and Pd-Pd contacts as well as the relative insensitivity of the stacking distances to metal identity suggests that the metal-metal bonding is rather weak. That the interactions do not persist in solution indicates that the overall attractive forces are not very great. As a point of reference, the interplanar spacing in Ni(Pc)I is 3.244(3) Å, <sup>5f</sup> in graphite is 3.35<sup>4</sup>, <sup>44</sup> and in the TCNQ stacks of typical organic conductors is 3.17-3.301.<sup>45</sup> In the absence of some attractive forces, distances in the 3.0% range are considered to be moderately repulsive. 46

Partial oxidation of the  $M(bqd)_2$  and  $M(dpg)_2$  materials to the 0.17-0.20 formal oxidation state results in an electrical conductivity increase of  $10^3 - 10^8$  in the molecular stacking direction. For  $Ni(bqd)_2I_{0.42}$ , the small degree of oxidation results in a greatly diminished electrical conductivity. For the partially oxidized  $M(bqd)_2$  and  $M(dpg)_2$  materials, there is no clear-cut dependence of the charge transport facility on metal or interplanar spacing. The approximate order of conductivity is

a the second second and the second

Ni(dpg)<sub>2</sub>I > Pd(dpg)<sub>2</sub>I ~ Pd(bqd)<sub>2</sub>I<sub>0, 50</sub> · S > Ni(bqd)<sub>2</sub>I<sub>0, 50</sub> · S. There is no evidence in the present case that the chains of metal atoms provide the major conductive pathway, and judging from results on macrocyclic systems (phthalocyanine, <sup>5b</sup> dibenzotetraazaannulene<sup>5e</sup>) where both metal and metalfree species are conductive when partially oxidized, it is likely that the ligand (i.e., molecular orbitals which are largely ligand in character) plays an important if not predominant role in the conductivity of the bisdioximate materials. The temperature dependence of the conductivity in the present materials is thermally activated with slight, if any, onset of 'metal-like'' behavior at highest temperatures. The functional dependence is reminiscent of ''intermediate conductivity'' TCNQ salts, <sup>45b</sup> and is consistent with phonon-assisted hopping of the carriers between states lozalized by disorder, <sup>38</sup> or with a weakly localized system having a gap and a temperature-dependent carrier concentration. <sup>39</sup>
