I. INTRODUCTION

In the process of conducting live firings of missiles equipped with warheads containing numerous bomblets, a problem arose pertaining to the evaluation of the effectiveness of the bomblets against various targets. The targets included personnel simulators and surface-to-air missiles.

Briefly, it was necessary to determine the probability of kill (P_k) of a group of target items when some or all of them were damaged to unequal levels of kill. In essence, it was required to compute the probability of achieving exactly and/or at least X kills (successes) out of a sample of N trials when the individual P_k values were not necessarily equal.

II. PROCEDURE

Standard textbook methods¹ use the following equation for computing the probability of X successes out of N trials when the probability of success p , is constant from trial to trial and the N trials are independent:

$$\begin{aligned} P(X;N,p) &= \binom{N}{X} p^X (1-p)^{N-X} \\ &= \binom{N}{X} p^X q^{N-X} \end{aligned} \quad (1)$$

where $X = 0, 1, 2 \dots N$,

$$\binom{N}{X} = \frac{N!}{X! (N-X)!}$$

and $q = 1 - p$.

However, in the case under consideration here, the values for p are not necessarily equal and Eq. (1) cannot be used to compute the probability of exactly X successes out of N trials, $P(X;N,p_i)$ which, for the sake of simplicity, we will express as $P\binom{N}{X}$ throughout the

¹ Freund, J.E., "Mathematical Statistics", Englewood Cliffs, NJ: Prentice-Hall, 1962

remainder of this report. Instead, consider the following expression which can be used to determine $P\binom{N}{X}$ for unequal (or equal, for the trivial case) probability values, p_i :

$$P\binom{N}{X} = \sum_{j=1}^{2^N} \beta_j \prod_{i=1}^N p_i^{\delta_{i,j}} q_i^{1-\delta_{i,j}} \quad (2)$$

where the $\delta_{i,j}$'s are chosen to equal 0 or 1 to satisfy Eq. (3) for each j ,

$$j-1 = \sum_{i=1}^N \delta_{i,j} 2^{i-1} \quad (3)$$

and β_j is defined as

$$\beta_j = 1 \quad \text{iff} \quad \sum_{i=1}^N \delta_{i,j} = X \quad (4)$$

= 0, otherwise.

As a simple example, consider the case of determining the probability of at least 1 success out of 3 events and exactly 1, exactly 2, and exactly 3 successes out of 3 events. Using Eq. (3) and Eq. (4) where $j = 1$ to 2^3 and $N = 3$, the $\delta_{i,j}$'s and β_j 's are determined as follows:

For $j = 1$,

$$j-1 = \sum_{i=1}^3 \delta_{i,j} 2^{i-1}$$

$$0 = \delta_{1,1} 2^0 + \delta_{2,1} 2^1 + \delta_{3,1} 2^2$$

In order for the above equation to be valid, $\delta_{1,1}$ must equal 0,

$\delta_{2,1}$ must equal 0, and $\delta_{3,1}$ must equal 0, and therefore the

$$\sum_{i=1}^3 \delta_{i,j} = 0. \text{ Consequently using Eq. (4), for } X = 1, \beta_1 \text{ must}$$

equal 0, for $X = 2$, β_1 must equal 0 and for $X = 3$, β_1 must equal 0.

For $j = 2$,

$$j-1 = \sum_{i=1}^3 \delta_{i,j} 2^{i-1}$$
$$1 = \delta_{1,2} 2^0 + \delta_{2,2} 2^1 + \delta_{3,2} 2^2$$

Similarly, for the above equation to be valid, $\delta_{1,2}$ must equal 1,

$\delta_{2,2}$ must equal 0 and $\delta_{3,2}$ must equal 0, and therefore $\sum_{i=1}^3 \delta_{i,j} = 1$.

Again, using Eq. (4) for $X = 1$, β_2 must equal 1, for $X = 2$, β_2 must equal 0 and for $X = 3$, β_2 must equal 0.

.

.

.

For $j = 8$,

$$j-1 = \sum_{i=1}^3 \delta_{i,j} 2^{i-1}$$
$$7 = \delta_{1,8} 2^0 + \delta_{2,8} 2^1 + \delta_{3,8} 2^2$$

Finally, for the above equation to be valid, $\delta_{1,8}$ must equal 1,

$\delta_{2,8}$ must equal 1 and $\delta_{3,8}$ must equal 1, and therefore the

$$\sum_{i=1}^3 \delta_{i,j} = 3. \text{ Using Eq. (4), for } X = 1, \beta_8 \text{ must equal 0, for } X = 2,$$

β_8 must equal 0 and for $X = 3, \beta_8$ must equal 1. The formation of the $\delta_{i,j}$'s from Eq. (3) and the β_j 's from Eq. (4) for the preceding example in which $N = 3$, can be summarized as follows:

j	$\delta_{1,j}$	$\delta_{2,j}$	$\delta_{3,j}$	$\sum_{i=1}^3 \delta_{i,j}$	β_j X=1	β_j X=2	β_j X=3
1	0	0	0	0	0	0	0
2	1	0	0	1	1	0	0
3	0	1	0	1	1	0	0
4	1	1	0	2	0	1	0
5	0	0	1	1	1	0	0
6	1	0	1	2	0	1	0
7	0	1	1	2	0	1	0
8	1	1	1	3	0	0	1

These tabular values may now be applied to Eq. (2) in which case the probability of exactly 1 success out of 3 events is expressed as:

$$P\binom{3}{1} = \beta_1 * (p_1^0 p_2^0 p_3^0 q_1^1 q_2^1 q_3^1) + \beta_2 * (p_1^1 p_2^0 p_3^0 q_1^0 q_2^1 q_3^1) + \beta_3 * (p_1^0 p_2^1 p_3^0 q_1^1 q_2^0 q_3^1) \\ + \beta_4 * (p_1^1 p_2^1 p_3^0 q_1^0 q_2^0 q_3^1) + \beta_5 * (p_1^0 p_2^0 p_3^1 q_1^1 q_2^1 q_3^0) + \beta_6 * (p_1^1 p_2^0 p_3^1 q_1^0 q_2^1 q_3^0) \\ + \beta_7 * (p_1^0 p_2^1 p_3^1 q_1^1 q_2^0 q_3^0) + \beta_8 * (p_1^1 p_2^1 p_3^1 q_1^0 q_2^0 q_3^0)$$

Since $\beta_1, \beta_4, \beta_6, \beta_7, \beta_8 = 0$ and $\beta_2, \beta_3, \beta_5 = 1$, the above equation

reduces to:

$$P\binom{3}{1} = p_1^1 p_2^0 p_3^0 q_1^0 q_2^1 q_3^1 + p_1^0 p_2^1 p_3^0 q_1^1 q_2^0 q_3^1 + p_1^0 p_2^0 p_3^1 q_1^1 q_2^1 q_3^0 \\ = p_1 q_2 q_3 + p_2 q_1 q_3 + p_3 q_1 q_2$$

Similarly,

$$P\binom{3}{2} = p_1 p_2 q_3 + p_1 p_3 q_2 + p_2 p_3 q_1$$

and

$$P\binom{3}{3} = p_1 p_2 p_3$$

Thus, the probability of at least 1 success out of 3 events is computed by

$$P\binom{3}{1} + P\binom{3}{2} + P\binom{3}{3} \\ = p_1 q_2 q_3 + p_2 q_1 q_3 + p_3 q_1 q_2 + p_1 p_2 q_3 + p_1 p_3 q_2 + p_2 p_3 q_1 + p_1 p_2 p_3$$

In instances in which only the at least case is required, the solution can be determined with the formation of fewer products, thus reducing the number of computations. This procedure can be utilized by taking advantage of complementary logic.

$$\text{Since } \sum_{i=0}^N P\binom{N}{i} = 1, \\ \text{then } \sum_{j=0}^{X-1} P\binom{N}{j} + \sum_{i=X}^N P\binom{N}{i} = 1; \\ \text{Hence } \sum_{i=X}^N P\binom{N}{i} = 1 - \sum_{j=0}^{X-1} P\binom{N}{j}$$

Thus, $P\binom{N}{X}$ can be expressed as

$$P\binom{N}{X} = \sum_{i=X}^N P\binom{N}{i} \quad (5)$$

or

$$P\binom{N}{X} = 1 - \sum_{j=0}^{X-1} P\binom{N}{j} \quad (6)$$

It follows that when $X < \frac{N}{2}$, then Eq. (6) should be used to compute the solution. In the preceding case for $N = 3$ and $X = 1$, if the only requirement had been the at least case, then the solution would be obtained using Eq. (6). Thus,

$$\begin{aligned} \sum_{i=1}^3 P\binom{3}{i} &= 1 - P\binom{3}{0} \\ &= 1 - q_1 q_2 q_3 . \end{aligned}$$

The above procedure requires only 1 product combination rather than the previously computed 7 combinations. The choice of using Eq. (5) or Eq. (6) can best be illustrated by a more realistic example in which case $N = 18$ and $X = 9$. If Eq. (5) were to be used,

then $\sum_{j=9}^{18} \binom{18}{j} = 155,382$ combinations would be required whereas the choice of Eq. (6) would require only $\sum_{j=0}^8 \binom{18}{j} = 106,762$ combinations.

A FORTRAN computer code, NX, has been written for efficiently computing the probability of at least, exactly or both cases as expressed in Eq. (2). This code, which takes advantage of the complementary logic condition where applicable, is given in Appendix A. In addition, a similar code in BASIC is also given in Appendix B for implementation on mini-computers utilizing this language.

The following sample problem was run using the FORTRAN code

given in Appendix A:

Compute the probability of exactly 5, exactly 6, exactly 7 . . . exactly 13 successes out of 13 trials. The individual probabilities p_i are as follows:

$$\begin{aligned} p_1 &= 0.30, & p_2 &= 0.16, & p_3 &= 0.22, & p_4 &= 0.28, & p_5 &= 0.10, & p_6 &= 0.39, \\ p_7 &= 0.33, & p_8 &= 0.51, & p_9 &= 0.44, & p_{10} &= 0.51, & p_{11} &= 0.68, \\ p_{12} &= 0.73, & p_{13} &= 0.94. \end{aligned}$$

The code produced the following solution:

Probability of exactly 5 successes out of 13 trials = 0.237
Probability of exactly 6 successes out of 13 trials = 0.239
Probability of exactly 7 successes out of 13 trials = 0.165
Probability of exactly 8 successes out of 13 trials = 0.079
Probability of exactly 9 successes out of 13 trials = 0.026
Probability of exactly 10 successes out of 13 trials = 0.006
Probability of exactly 11 successes out of 13 trials = 0.001
Probability of exactly 12 successes out of 13 trials = 0.000
Probability of exactly 13 successes out of 13 trials = 0.000
Probability of at least 5 successes out of 13 trials = 0.754

This example required 7,099 product combinations to be formed and computed. Run times were 0.6 second and 2.0 seconds on a CDC Cyber 76 and a CDC Cyber 173, respectively. Using the code listing in Appendix B, the identical results were obtained from a WANG 2200-T mini-computer with a run time of approximately 83 minutes and from a WANG 2200-VP with a run time of 4.5 minutes.

For further information on the subject, the reader is referred to Feller, William, "An Introduction to Probability Theory and It's Applications", New York, NY: John Wiley & Sons, 1968.

III. CONCLUSIONS

A general expression is presented for computing the probability of X kills (successes) out of N trials, with unequal or equal individual probability of kill (success) values. Computer codes in both FORTRAN and BASIC are presented which yield the desired solutions using appropriate main-frame or mini-computers.

IV. ACKNOWLEDGEMENT

The authors would like to express their appreciation to Mr. Larry Losie for his invaluable assistance for formulating the general expressions given in Eqs. (2), (3), and (4).

SUBJECT: Memorandum Report ARBRL-MR-02890, Jan 1979, by M. B. Danish
and J. T. Hundley

SEE DISTRIBUTION

1. The subject report contains two computer programs. The authors have learned of an algorithm which accomplishes the same results, but much faster, as those obtained from the codes given in subject report. The algorithm was published in a formal report at the Naval Surface Weapons Center, Dahlgren, VA in 1975 but distribution was at that facility only, hence the information of importance was not known to these authors at BRL until after ARBRL-MR-02890 was published. It should be noted that the original algorithms used in the BRL version were reported on at BRL in May 1974.
2. In the interest of computing efficiency, we have utilized the algorithm developed by M. A. Thomas and A. E. Taub at the Naval Surface Weapons Center and prepared a FORTRAN and BASIC version to replace those versions originally appearing in ARBRL-MR-02890. The Thomas/Taub algorithm is extremely efficient and can be considered to be orders of magnitude faster than the BRL versions.
3. The reference report is NSWC/DL TN-DK-25/75, Binomial Trials with Variable Probabilities, August 1975, by M. A. Thomas and A. E. Taub.
