ACKNOWLEDGEMENT

The author wishes to acknowledge Mr. Edward Belbot of AMSAA for the computer programming which generated these tables.

A faint table structure is visible in the lower-left quadrant of the page. It consists of approximately 5 columns and 10 rows. The text within the table is extremely light and difficult to discern, but it appears to be a data table with a header row and several data rows.

TABLES FOR COMPARING TWO MEAN-TIME-BETWEEN-FAILURES (MTBFs)
FOR UNEQUAL TEST TIMES

1. INTRODUCTION

In carrying out statistical tests of comparing two mean-time-between-failures (MTBFs), the situation, more often than not, arises where the two test times are unequal. The purpose of this report is to facilitate the carrying out of the exact method of comparing two MTBFs for this situation. To accomplish this purpose, critical values for the number of failures occurring during one of the test times were computed and tabulated for .001, .01, .05, .10, and .20 levels of significance for various combinations of the ratio of the two test times and the total number of failures occurring during both test times. The ratio of the two test times ranges from 0.1 to 5.0 by increments of 0.1 and the total failures range from 1 to 100. All computations were programmed in the FORTRAN programming language and carried out on the Armament Research and Development Command (ARRADCOM) Control Data Corporation (CDC) Cyber 76 Computer located at Aberdeen Proving Ground, Maryland.

2. COMPUTATIONAL EQUATIONS

Consider two independent tests of an item where:

T_1 = total time for test 1

T_2 = total time for test 2

X_1 = number of failures during T_1

X_2 = number of failures during T_2

$MTBF_1$ = theoretical mean-time-between-failures for item during T_1

$MTBF_2$ = theoretical mean-time-between-failures for item during T_2

μ_1 = $T_1/MTBF_1$ = theoretical mean number of failures for item during T_1

μ_2 = $T_2/MTBF_2$ = theoretical mean number of failures for item during T_2

It is assumed that if a failure occurs during testing of the item, the item is repaired (or replaced) and testing continued. If each test is assumed to represent a segment of a homogeneous Poisson process, the times between failure occur independently, according to an exponential distribution and the number of failures according to a Poisson distribution.

If $T_1 = RT_2$, then from the preceding definitions, it follows that

$$MTBF_1 = \frac{RT_2}{\mu_1}$$

and

$$MTBF_2 = \frac{T_2}{\mu_2}.$$

Consequently, testing the hypothesis

$$H_0 : MTBF_1 = MTBF_2$$

against the alternative

$$H_1 : MTBF_1 \neq MTBF_2,$$

is the same as testing

$$H_0 : \mu_1 = R\mu_2$$

against

$$H_1 : \mu_1 \neq R\mu_2$$

where μ_1 and $R\mu_2$ are two Poisson means. Then, by utilizing the joint conditional distribution of two Poisson variables for a fixed total number of failures n , where

$$n = X_1 + X_2,$$

the latter hypothesis test may be shown to be equivalent to testing the hypothesis

$$H_0 : p = \frac{T_2}{T_1 + T_2}$$

against

$$H_1 : p \neq \frac{T_2}{T_1 + T_2}$$

where p is the parameter in the binomial distribution

$$P(X_2; n, p) = \frac{n!}{X_2! (n-X_2)!} p^{X_2} (1-p)^{n-X_2} .$$

Thus, for a given level of significance α , critical values, A and B , of X_2 are found so that

$$P(X_2 \leq A) \leq \alpha/2$$

and

$$P(X_2 \geq B) \leq \alpha/2 .$$

That is, the critical value A , which corresponds to the alternative hypothesis

$$H_1 : p < \frac{T_2}{T_1 + T_2}$$

or

$$H_1 : \text{MTBF}_1 < \text{MTBF}_2 ,$$

is determined so that

$$\sum_{X_2=0}^A \frac{n!}{X_2! (n-X_2)!} p^{X_2} (1-p)^{n-X_2} \leq \frac{\alpha}{2}$$

and

$$\sum_{X_2=0}^{A+1} \frac{n!}{X_2! (n-X_2)!} p^{X_2} (1-p)^{n-X_2} > \frac{\alpha}{2} .$$

Similarly, the critical value B , which corresponds to the alternative hypothesis

$$H_1 : p > \frac{T_2}{T_1 + T_2}$$

or

$$H_1 : \text{MTBF}_1 > \text{MTBF}_2$$

is determined so that

$$\sum_{X_2=B}^n \frac{n!}{X_2! (n-X_2)!} p^{X_2} (1-p)^{n-X_2} \leq \frac{\alpha}{2}$$

and

$$\sum_{X_2=B-1}^n \frac{n!}{X_2! (n-X_2)!} p^{X_2} (1-p)^{n-X_2} > \frac{\alpha}{2}.$$

In the accompanying tables, those cases where the critical values A and/or B cannot be found which satisfy their respective inequalities are indicated by broken lines.

3. APPLICATION

Consider a system under development which is subjected to 2000 and 500 hours of engineering development and operational testing (DT II and OT II), respectively. Suppose, on the basis of 20 failures occurring during DT II and 10 during OT II, it is desired to determine if these results are consistent with the hypothesis that the DT II MTBF does not differ from the OT II MTBF at the 10 percent level of significance. If we designate DT II as test 1 and OT II as test 2, then

$$X_1 = 20,$$

$$X_2 = 10,$$

and

$$R = \frac{T_1}{T_2} = \frac{2000}{500} = 4.0.$$

As we are interested in determining if the DT II MTBF (MTBF_1) is significantly different (greater than or less than) from the OT II MTBF (MTBF_2), this would entail a two-sided test. Then, from the accompanying table for $R = 4.0$ (page 91), X_2 critical values of $A = 2$ and $B = 11$ are obtained for a total number of failures of 30 and a level

of significance of .10. Since the actual number of failures occurring during OT II is not less than or equal to A or greater than or equal to B, we accept (at the 10 percent level of significance) the hypothesis that the DT II MTBF is equal to the OT II MTBF.

Suppose, for the same test results we are only interested in determining if the DT II MTBF ($MTBF_1$) is significantly greater than the OT II MTBF ($MTBF_2$) at the 10 percent level of significance; then, this would entail a one-sided test. From the same table for $R = 4.0$, an X_2 critical value of $B = 10$ is obtained for a total number of failures of 30 and a level of significance of .20 since this is a one-sided test. As the actual number of failures occurring during OT II is equal to B, we reject (at the 10 percent level of significance) the hypothesis that the DT II MTBF is equal to (or less than) the OT II MTBF.

In using the accompanying tables, it should be noted that (--,--) indicates a two-sided test of hypothesis cannot be carried out at its corresponding level of significance whereas (A, --) and (--, B) indicate only one-sided tests can be carried out at one-half their corresponding levels of significance.
