## INTRODUCTION

Multiple ripping of boards, followed by crosscutting to remove defects, is an operation used by both the hardwood flooring and the softwood cut-up industries. Because of the rising cost of lumber and the increasing demand on the timber supply, utilizing each board more efficiently is becoming more important.

The two steps in making better processing decisions to improve utilization of each board are to: (1) automatically locate defects, and (2) optimize sawline placement based on defect locations.

A system that automatically locates defects in lumber has been developed and is being tested at the Forest Products Laboratory<sup>2</sup>. Boards are scanned with ultrasound under computer control and defect location data are automatically collected. The computer program used was designed to: (1) control the scanning process, (2) store collected data on tape, (3) optimize sawline placement based on defect locations, and (4) draw the board and cutting solution on a line plotter.

The purpose of this paper is to describe RIPYLD (RIP Yield)-that part of the computer program that optimizes sawline placement for maximum yield. RIPYLD obtains the multiple ripping and crosscutting solutions using defect location data, and is an expansion of earlier efforts to maximize cutting yields of boards using computer analyses<sup>3, 4, 5</sup>. In RIPYLD, any kerf width

can be used and cuttings can be any length (either random or specified), and any width.

11 1978

RIPYLD has the option of manufacturing either specified length cuttings or random length cuttings. Up to five cutting lengths and three cutting widths can be used in the specified length option. If the random length option is chosen, three cutting widths and minimum acceptable cutting length must be specified.

Sawing variables are the maximum number of rip saws to be used on any board, and the sawkerf, which will be used in both the rip cuts and crosscuts.

## PROGRAM RPYLD

### Input

Input parameters that must be specified for the RPYLD program are: (a) board and defect information, (b) cutting bill requirements, and (c) sawing variables.

An X-Y coordinate system grid is superimposed on the board, and each unit grid area is designated as either defective (1) or clear (0) (fig. 1). The number of X-grids in the length, the number of Y-grids in the width, and the sizes of X-grid and Y-grid (in inches) must be specified.

### Description

First, all possible combinations of rip widths that will fit within the width of the

board are determined and stored. For example, if the possible rip widths are 2, 2.5, and 3 inches and there are four rip saws available, there are  $3^4 = 81$  possible permutations of rip widths to try. However, if the board is 9 inches wide and the kerf is 0.125 inches, only 27 permutations, including kerfs, will fit within the width of the board (table 1).

Then, for each stored combination of rip widths, the board is "sawn" by the computer. The board is always ripped first, with the first rip width always positioned at the edge of the board with the lowest Y coordinate. Solutions with the first rip positioned at the other edge of the board are not considered. After ripping, the clear areas within each rip are located.

If random lengths are desired, only defects and lengths shorter than the

Table 1. -- Rip combinations of 2.0", 2.5", and 3.0" that fit in 9" wide board

Rip widths (in.)				Total width (in.) (including 0.125" kerf between rips)

3.0	3.0	2.5	--	8.750

Figure 1.--In the X-Y coordinate system grid superimposed on the board, each unit grid area is designated as either defective (1) or clear (0).

specified minimum cutting length are removed by crosscutting. Otherwise, specified lengths are made by crosscutting the clear areas and removing the defects. Longest cuttings are always salvaged first even if a higher yield would result from a combination of shorter cuttings.

For each clear cutting found and cut out, surface area of the cutting is calculated. Surface areas of cuttings are summed to obtain the total yield of the board.

After total yield of clear cuttings from the board for a rip combination is calculated, the yield is compared to the previous maximum yield. If the new yield is greater, it is stored as the new maximum. The new yield is also compared to the previous minimum yield and, if less, becomes the new minimum.

### Output

Output from RIPYLD contains complete information about both the maximum and minimum yield solutions. Included are the percent yield of clear cuttings from the board, the rip width combination, the crosscut locations, and a piece tally if the specified length option is used.

At the Forest Products Laboratory, the same computer (Harris 6024) that is used to collect defect information from the Defectoscope<sup>2</sup> is used to control a line plotter. The minimum or maximum solution is plotted, including the outline of the board, defect locations, rip cuts, and crosscuts. Alternatively, the output could be directed to computer controlled saws, stored on tape, or displayed on a TV screen or printer.

Examples of the plots with RIPYLD solutions are shown in figures 2 through 6. A 90-inch long, 9-inch wide board with the defects found by the Defectoscope, was outlined on a data grid 0.5 inch by 0.5 inch (fig. 2).

The board was "sawn" with a 0.125-inch kerf, into random-length cuttings with a minimum length of 10 inches. RIPYLD chose between rip widths of 2", 2.5", and 3". The optimum yield of 80.84 percent was achieved with a rip combination of 2", 2.5", 2", 2" (fig. 3). The minimum solution with a 65.73 percent yield was from a rip combination of 2", 2", 3" (fig. 4). There was not enough room for another rip at the top of the board, so 1.625" was not utilized.

The same board was again "sawn" with a 0.125-inch kerf and combinations of 2", 2.5", and 3" rip widths (figs. 5, 6). However, here the specified length option was used with a choice of 50", 40", 30", 20", and 10" cuttings. Piece tallies are included on the plots. The optimum solution (fig. 5) was a 2.5", 2", 2", 2" rip combination with 54.80 percent yield. The minimum solution of 44.94 percent yield (fig. 6) was found with a rip width combination of 2", 2", 3". Again, the top 1.625" of the board was not utilized.

### SUMMARY

RIPYLD is a computer program that optimizes the cutting yield from multiple-ripped boards. Decisions are based on automatically collected defect information, cutting bill requirements, and sawing variables. The yield of clear cuttings from a board is calculated for every possible permutation of specified rip widths and both the maximum and minimum percent yield solutions are saved. Solutions include rip cut and crosscut locations as well as the percent yield of clear cuttings.

Figure 2.—Defects were outlined by the Defectoscope on a grid of 0.5 inch by 0.5 inch.

Figure 3.—The board in figure 2 was "sawn" by the computer, into random-length cuttings, 10-inch minimum. This optimum yield of 81% was achieved with a rip combination of 2", 2.5", 2", and 2".

Figure 4.—Minimum solution for the same board yielded 65%, with a rip combination of 2", 2", 3".

WIDTH	LENGTH		
	50"	40"	30"
2	0	0	0
2.5	0	1	0
3	0	0	0
		20"	10"
		2	10
		1	1
		0	0

Figure 5.--The same board "sawn" again, this time with specified-length cuttings ranging from 50" to 10", yielded an optimum of 55% from rips of 2.5", 2", 2", 2".

		20"	10"
		2	4
		0	0
		0	4

Figure 6.--The minimum solution for the same conditions was 45% from rips of 2", 2", 3".

# APPENDIX I

## RIPYLD Variables

### Input

#### Dimensions of data grid

- NP - number of grid units in the board length
- NSCANS - number of grid units in the board width
- XGRID - length of unit grid on X axis (inches)
- YGRID - width of unit grid on Y axis (inches)

#### Defect information

- BOARD(NSCANS, NP) \* 0 if the grid unit is clear
- \* 1 if the grid unit is a defect

#### Cutting bill

- NWIDTH - number of rip widths to choose from (maximum of 3)
- WIDTH(3) - up to 3 widths can be specified (inches)
- RANDOM\*TRUE - random length cuttings
- SAWMIN - minimum length acceptable cutting
- RANDOM\*FALSE - specified length cuttings
- NLEN - number of specified cutting lengths (maximum of 5)
- CUTLEN(5) - up to 5 lengths (inches)
- (Must be in order: CUTLEN(1)-maximum)

#### Sawing variables

- NSAW - number of rip saws available
- KERF - sawkerf for both ripping and crosscutting

### Output

#### Rip combinations

- RIPCOM(81,4) - combinations of rip widths that fit in the board width.  
(Maximum 81 combinations, 4 rip saws)
- NRIP(81) - number of rips that will fit in the board width for each combination stored in RIPCOM

#### Solutions

- MINCOM - index to RIPCOM and NRIP of the lowest yield combination
- MAXCOM - index to RIPCOM and NRIP of the highest yield combination.
- REJECT \* TRUE - no clear cuttings can be found for any rip combination.
- \* FALSE - at least 1 clear cutting is found
- ACT - index to solution of current rip combination
- MAX - index to maximum yield solution
- MIN - index to minimum yield solution
- YIELD(3) - percent of clear area of the board for ACT, MAX, MIN solutions
- PIECE(5,3,3) - piece tally (5 lengths, 3 widths,) for ACT, MAX, MIN solutions
- CROSS(150,3) - X-coordinates of crosscuts for ACT, MAX, MIN solutions
- NXCUT(4,3) - number of crosscuts in each rip for ACT, MAX, MIN solutions

## Crosscut decisions for each rip

### Variables used in flowcharts

I	- present grid position on X axis
BEG	- beginning of defect (grid number)
END	- last defect grid encountered
CLRKNT	- number of clear grids encountered since last defect grid
MINLEN	- number of grid units in the minimum cutting length
XCUT	- subroutine to store crosscut locations and to calculate yield
NP	- number of X-grids in the board
RANDOM = TRUE	- random length option
= FALSE	- specified length option
