ACKNOWLEDGMENT

This document was prepared under the direction of the Chief for Military Studies and Analyses, CCTC, in response to a requirement of the Studies, Analysis, and Gaming Agency, Organization of the Joint Chiefs of Staff. Technical support was provided by System Sciences, Incorporated under Contract Number DCA100-75-C-0019. Change set one was prepared under Contract Number DCA100-78-C-0035.

SECTION 2. PREPALOC MODULE

2.1 Purpose

The purpose of this module is to perform preliminary calculations on the weapon and target data as stored within the integrated data base. The output data from PREPALOC will be in a form convenient for use by the remaining processors of the plan generator. In addition, the user may select options to modify some of the data at this stage of processing.

Module PREPALOC has three major capabilities: updating of geographic and weapon group data, modification of target values and damage constraints and preparation of data for the fixed weapon assignment capability of program ALOC.

The basic raw geographic data must be data base defined prior to any execution of PREPALOC. Using this data, PREPALOC will calculate and store distances and attrition between all doglegs for use within processors to follow. Based on user inputs, the number of weapons within bomber or missile MIRV weapon groups may be adjusted.

The second major capability of this module is the modification of the target characteristics, VTO, MINKILL, and MAXKILL. VTO is the value of the target relative to all the others. MINKILL is the minimum fraction of target value that must be destroyed, and MAXKILL is the maximum desired fraction of target value destroyed. Any of these parameters may be changed for any target. The change requests can change these parameters for a single target or for a set of targets. The set of targets for which a change is requested is identified by target class, type, an individual identifier (target designator code (DESIG)) or any combination of these. For complex targets, the class, type, designator code, and index of each component will be checked to determine if a target parameter for the complex is to be changed.

In addition, the user can specify the height of burst to be used in any weapon/target combination. The user selects either a ground burst or an air burst at the optimal air burst height. In the absence of any user specification, the most damaging height of burst is used.

The third major capability is the request for allocation of specific weapons to specific targets. This fixing of weapons to targets enables the user to determine part of the weapon allocation while leaving the allocation module free to determine the remaining allocation. In addition, the time of arrival at target or launch salvo number can be fixed for missile weapons. This information will be passed to module PLANOUT which will adjust launch time accordingly. The fixing of weapons remains in effect for the remainder of the plan generation process. Later programs will retain the assignments as best possible. (For example, it is possible to fix a set of weapons from a weapon group with multiple independently targetable reentry vehicles (MIRV) in such a manner that there are no feasible footprints that cover that target set adequately. In that case, some of the fixed assignment requests must be ignored.)

2.2 Input

The entire integrated data base must be completely defined prior to PREPALOC execution. This includes the storage of all targets, related geographic data, weapon type and group characteristics and other supporting data such as warhead and payload information.

2.3 Output

Creation of new records occurs if the user specified fixed assignments. For these cases, records called 'ASSIGN' which stores the fixed assignment under the proper target and weapon group linkage are created. Also, new records (RDDIST, TPDIST and TDDIST) defining the distance between each dependeration corridor recovery base intersection, each penetration corridor target intersection, and each target and the optimal depenetration corridor, are created.

If any of the target modification options are employed, the necessary target records will be modified accordingly. Also, weapon group attributes may be altered if overallocation is specified.

For all executions, distances and attrition rates associated with each penetration corridor will be calculated and stored. Similarly, depenetration distances between doglegs as well as the distance from depenetration corridor to recovery bases are stored.

2.4 Concept of Operation

PREPALOC is designed to operate in two modes: RECALC and non-RECALC. In the RECALC mode all geographic and weapon calculations are performed; in the non-RECALC mode these time consuming functions are **bypassed**. The user will ideally run PREPALOC once in the RECALC mode and then as many times in the non-RECALC mode as is required to make the target parameter changes and fixed weapon assignments needed. The print option functions are also separated such that optional prints may appear in any run once the data to be displayed has been developed.

2.5 Identification of Subroutine Functions

2.5.1 <u>Subroutine GEOPREP</u>. This subroutine performs the calculation and storage of geographic data which links targets to corridors and recovery bases. It is called only in the RECALC mode.

2.5.2 <u>Subroutine WEPPREP</u>. This subroutine calculates weapon group overallocation and sets up the salvoed weapon arrays. It is called only in the RECALC mode.

2.5.3 <u>Subroutine SETRD</u>. This subroutine is called in any execution which contains a SETTING clause. It performs changes to general gaming parameters and weapon group height of bursts. Changes to target parameters are stored on an external data file (25) for subroutine CHGBAS.

2.5.4 <u>Subroutine CHCBAS</u>. This subroutine is called in any execution where subroutine SETRD has stored one or more change requests on file 25. These requests are carried out for the target base according to a preset priority scheme.

2.5.5 <u>Subroutine FIXWEP</u>. This subroutine is called in any execution with one or more FIX clauses. It creates fixed assignment records (ASSIGN) for use by the allocation module.

2.5.6 <u>Subroutine PRNPRP</u>. This subroutine performs all standard and optional prints. It is called at the end of every run and produces those optional prints requested and any standard prints called for by the input.

2.6 PREPALOC Internal Common Blocks

All common blocks used internally by PREPALOC are given in table 1. For definition of common blocks that communicate with the COP, see Program Maintenance Manual, Volume I.

Table 1. Module PREPALOC Common Blocks (Part 1 of 2)

COMMON	VARIABLE OR ARRAY	DESCRIPTION
CRLENGTH	CRLENGTH (30)	Total length of a penetration corridor; indexed by corridor number
DISTEF	DISTEF(50)	Total length of a depenetration corri- dor; indexed by corridor number
	DISTEG(50)	Total length of a depenetration corridor plus distance to nearest recovery base; indexed by corridor number
	DRECOV(50,4)	DESIG of recovery base associated with depenetration corridor; indexed by corridor number, up to four bases
	DISTNA(50,4)	Distance from depenetration corridor to recovery base; indexed by corridor num- ber, up to four bases
	INDXA(50,4)	Ordinal of bases ordered on distance from depenetration corridor; indexed by corridor number, up to four bases
GEOREF	IPNRF	IDS reference code of penetration corri- dor header
	IDPRF	IDS reference code of depenetration corridor header
IFXREQ	IFXREQ(250)	Fixed assignment requests; indexed by group
	IFXHON(250)	Fixed assignment requests honored; in- dexed by group
IFXSW	FIXSW	Fixed assignment switch: true if there are assignments in this run, false otherwise
NTBFLG	NTBFLG(9)	Alphanumeric value to indicate source of values in general gaming parameters. May be DEFAUL for default, UNCHNG for charged during this run

,

Table 1. (Part 2 of 2)

ASSOCIATED COMMON	VARIABLE OR ARRAY	DESCRIPTION
COLLION		
RFPOINTS	RFLAT(20)	Latitutude of a refuel point
4	RFLONG (20)	Longitude of a refuel point
	MREGN	Number of refuel points
SETCOM	NTBCH	General gaming parameter switch: true if changes were made, false otherwise
	DBCH	Target parameter switch: true if changes were made, false otherwise
	NDBCH	Number of target parameter change re- quests written onto file 25 by SETRD
	RECALC	RECALC mode switch: true if RECALC mode active, false otherwise
TSTUFF		Communicates with TOFM
	XTOFMIN	Minimum time of flight
	XCMISS	Missile flight parameter
	XRNGMIN	Minimum range
	XRANGE	Missile maximum range
WEPCOM	IWRCD(250)	Weapon group record IDS reference code; indexed on group
	IWTYP (250)	Weapon group type index
	IWCLS(250)	Weapon group class indicator (1=missile, 2=bomber, 3=salvoed missile)
	NMWTYP (120)	Weapon type name; indexed on type
	IWMIRV(250)	MIRV indicator (O=nonMIRV, 1=MIRV)
	NASM(250)	Number of ASMs in group payload
	NMGRP	Number of groups

9

2.7 Subroutine ENTMOD

PURPOSE:	To control overall flow of processing
ENTRY POINTS:	ENTMOD (first subroutine called when overlay link PREP is executed)
FORMAL PARAMETERS:	None
COMMON BLOCKS:	C15, C30, ERRCOM, IFXREQ, IFXSW, NTBFLG, SETCOM
SUBROUTINES CALLED:	CHGBAS, FIXWEP, GEOPREP, HDFND, INSGET, MODFY, PRNPRP, RETRV, SETRD, WEPPREP
CALLED BY:	COP

Method:

The basic method employed by the driver routine of PREPALOC is to check for particular input clauses in a set order and carry out functions based on their presence. As a preliminary step, the IDS error code "RO4" is set as acceptable so that the retrieval of nonexistent DESIG values will not cause termination and the number table (NUMTBL) is retrieved. The input is then scanned for a RECALC clause, if it exists the general gaming parameters (INITSTRK, CORMSL, etc.) are set to their default values and GEOPREP and WEPPREP are called.

The subroutine now looks for any SETTING clauses. Subroutine SETRD is called for each occurrence. If any SETTING clause called for changes to the target parameters (VALUE, MINKILL, MAXKILL or IDHOB), CHGBAS is also called. Then, the input is scanned for FIX clauses and FIXWEP called at each occurrence. Finally, PRNPRP is called to produce any standard or optional print.

Subroutine ENTMOD is illustrated in figure 3.

Subroutine ENTMOD (PREPALOC) (Part 1 of 4) Figure 3.

2.8 Subroutine CHGBAS

PURPOSE:	To make requested changes to target base parameters
ENTRY POINTS:	CHGBAS
FORMAL PARAMETERS:	None
COMMON BLOCKS:	C10, C15, C30, SETCOM
SUBROUTINES CALLED:	DIRECT, HDFND, HEAD, MODFY, NEXTTT, RETRV
CALLED BY:	ENTMOD (of PREPALOC)

Method:

The target list is examined and each simple target or element of a complex is compared to the list of requested changes to see if any of them apply. When a particular condition is found to apply to a target the attribute involved is altered as per the change request. Change requests have been placed in order by SETRD such that for any given target only the first request to alter a particular attribute is honored.

As the elements of a complex are processed the subroutine keeps track of the overall effects on the complex of any changes and updates the complex the complex record as well when all of its elements have been processed. The effect of any changes to target values is noted throughout the cycle of the target list and, when the first cycle is complete, a second cycle takes place to renormalize all data base values.

Subroutine CHGBAS is illustrated in figure 4.

2.9 Subroutine FIXWEP

PURPOSE:	To create fixed weapon assignments
ENTRY POINTS:	FIXWEP
FORMAL PARAMETERS:	ICPT - index of FIX clause
COMMON BLOCKS:	C10, C15, C30, IFXREQ, OOPS, TSTUFF, WEPCOM, ZEES
SUBROUTINES CALLED:	DIRECT, DISTF, HDFND, HEAD, INSGET, MODFY, NEXTTT, RETRV, STORE, TOFM, WEPIN
CALLED BY:	ENTMOD (of PREPALOC)

Method:

The first step in the FIXWEP process is to retrieve the target list header (TARNUM) and initialize break-point tables. These break-point tables are used to speed retrieval of records on the LISTXX chain. By saving the direct reference code of up to 500 records evenly spaced along the chain, any record may be retrieved by beginning the search at the nearest break-point record that precedes it.

The remainder of the process is driven by the FIX clause which caused the call. The FIX clause is viewed as a series of **subclauses** each of which contains a subject and one or more objects. The subject is a collection of attributes and each object is a collection of values for those attributes. As a subject is read, its component attributes are used to set up a group of switches to indicate the operations to be carried out for each object. The switches are:

> ISRNG - 1 if one DESIG, 2 if two DESIGS IASET - 1 if no set arrival time, 2 if arrival time is set

FIXWEP then reads in each related object and creates ASSIGN records as follows. Each object will set the following values:

IXGRP - the group number ISTSAL - the selected salvo (0 if non selected) AXRV - the selected arrival time (0 if IASET = 1) INMA - the number of assignments (set by NUMALOC) CDSG - the DESIG of the target

If there is a DESIG range (ISRNG = 2) the values of the range are placed in CDSG in order and the process carried out for each.

For each set of the above values, FIXWEP first checks to see if the current group (IGRP) is the same as IXGRP. If not, the current group is modified and the new group retrieved. The target whose DESIG is CDSG is not obtained and the corresponding TARCDE record found through use

of the break-point tables. Now the process loops INMA times. In each loop FIXWEP first checks to see if group resources are exceeded. If not, the process proceeds depending upon whether or not the group is salvoed. For a non-salvoed group FIXWEP simply stores a new ASSIGN record.

For a salvoed group the salvo is determined in one of three ways. If neither a salvo nor an arrival time has been specified, a convenient salvo is selected. If a salvo was specified, it is used. If an arrival time was specified, the time of flight is calculated and the salvo set to fulfill the desired time of arrival. In any case, FIXWEP now checks to see if a weapon is available in the chosen salvo. If so, the ASSIGN record is stored. If not, FIXWEP finds a salvo that is available and uses that salvo instead unless the desired salvo was specified. In the later case, FIXWEP will search all current assignments for the weapon group with the desired salvo and shift to the available salvo that was either assigned with no specification or, failing to find such, one whose arrival time was specified. The new assignment may then be made to the desired salvo.

Subroutine FIXWEP is illustrated in figure 5.

2.10 Subroutine GEOIN

PURPOSE :	To retrieve geographic data
ENTRY POINTS:	GEOIN
FORMAL PARAMETERS:	None
COMMON BLOCKS:	C1Q, C15, C30, CRLENGTH, DISTEF, GEOREF, RFPOINTS, QOPS
SUBROUTINES CALLED:	DISTF, HDFND, NEXTTT, ORDER, RETRV
CALLED BY:	GEOPREP, PR.PRP, WEPPREP

Method:

First the penetration corridor header is retained and its reference code saved. Each corridor is now retrieved. The distances between all legs is summed as the corridor's length (CRLENGTH). Next the depenetration corridor header is retrieved and its reference code saved. Each corridor is now retrieved. The sum of the distances between legs is stored as DISTEF. The recovery bases associated with the corridor are saved in DRECOV and the distance from the base to the corridor is saved in DISTN. The recovery bases are now ordered on this distance - ascending and the ordinal saved as INDXA. The shortest distance (ordinal 1) is added to DISTEF giving DISTEG. When all depenetration corridors have been processed, all refuel **points are collected and saved in the** /RFPOINTS/ block.

Subroutine GEOIN is illustrated in figure 6.

2.11 Subroutine GEOPREP

PURPOSE:To calculate and store geographic dataENTRY POINTS:GEOPREPFORMAL PARAMETERS:NoneCOMMON BLOCKS:C10, C15, C30, CRLENGTH, DISTEF, GEOREF, OOPSSUBROUTINES CALLED:DIRECT, DISTF, DLETE, GEOIN, HDFND, HEAD, MODFY, NEXTTT, RETRV, STORE

CALLED BY: ENTMOD (of PREPALOC)

Method:

Depenetration corridors are processed first. All old TDDIST and RDDIST records are deleted. Then a new RDDIST record is stored connecting the corridors with their recovery bases. Next, penetration corridors are processed. All old TPDIST records are deleted. Then all attributes sectors are calculated and the penetration corridor record (PENCRD) modified.

The subroutine now cycles through the target list. For each target it finds the shortest depenetration distance, taking into account the distance to the corridor, the length of the corridor and the distance from the corridor to the recovery base. A TDDIST record is created for the best depenetration corridor. A TPDIST record is also stored correcting the target list element to every penetration corridor.

Subroutine GEOPREP is illustrated in figure 7.

2.12 Subroutine PRNPRP

PURPOSE:To perform all PREPALOC printsENTRY POINTS:PRNPRPFORMAL PARAMETERS:ICPT - index of ONPRINTS clauseCOMMON BLOCKS:C10, C15, C30, CRLENGTH, DISTEF, GEOREF, IFXREQ,
IFXSW, NTBFLG, OOPS, RFPOINTS, SETCOM, WEPCOM,
ZEESSUBROUTINES CALLED:DIRECT, DISTF, GEOIN, HDFND, HEAD, INSGET, NEXTTT,
RETRV, WEPINCALLED BY:ENTMOD (of PREPALOC)

Method:

The operation of this subroutine depends largely on the ONPRINTS clause and the options the user has exercised. The ONPRINTS clause (if any) is read and the selected options saved as switches. If the RECALC option is active or there have been changes to the general gaming parameters, the "USER INPUT PLANNING PARAMETERS" print is produced. If any FIX clauses were present in the input the "FIXED ASSIGNMENTS" print is produced. If the user has selected print option 1 the geographic data is printed. If the user has selected print option 2 the distances of groups to corridors are printed. If the user has selected print option 3, the "TARGET INFORMATION PRINT" is produced. If the user has selected print option 4, the "PLANNING FACTORS print is produced. Finally, if the RECALC mode is active or there have been changes to the target data base, the class value summary is printed.

Subroutine PRNPRP is illustrated in figure 8.

2.13 Subroutine SETRD

PURPOSE:	To read SETTING clauses
ENTRY POINTS:	SETRD
FORMAL PARAMETERS:	ICPT - index of SETTING clause
COMMON BLOCK:	C10, C30, NTBFLG, OOPS, SETCOM, WEPCOM
SUBROUTINES CALLED:	DIRECT, INSGET, MODFY, RANSIZ, WEPIN
CALLED BY:	ENTMOD (of PREPALOC)

Method:

This subroutine scans an input SETTING clause for data base changes. Any changes which alter either the value of a general gaming parameter or a weapon group's preset height of burst are immediately carried out. The remaining changes each contain four elements: a change criteria attribute (DESIG, TYPE, CLASS, CNTRYLOC, or IREG), a criteria value, a change attribute (VALUE, MAXKILL, MINKILL, or IDHOB) and a change value. These change sets are collected by five separate passes through the SETTING clause and the base essential data stored on file 25. The passes are in a priority base on the criteria attribute (order in DESIG, TYPE, CLASS, CNTRYLOC, IREG). Only one SETTING clause containing this type of change is allowed in any one run of PREPALOC

Subroutine SETRD is illustrated in figure 9.

2.14 Subroutine WEPIN

PURPOSE:	To retrieve weapon data
ENTRY POINTS:	WEPIN
FORMAL PARAMETERS:	None
COMMON BLOCKS:	C10, C15, C30, WEPCOM
SUBROUTINES CALLED:	DIRECT, HDFND, HEAD, NEXTTT, RETRV
CALLED BY:	FIXWEP, PRNPRP, SETRD, WEPPREP

Method:

The weapon group header is retrieved and the groups are processed in order. For each weapon group, the group record is retrieved and its reference code saved in IWRCD. The payload of the group is now scanned to count the number of ASMs and to determine if the group is a MIRV. The group's weapon type record is now retrieved and the type index set. Finally, the group class value is set (1 = missile, 2 = bomber, 3 = salvoed missile).

Subroutine WEPIN is illustrated in figure 10.

1

Figure 10. Subroutine WEPIN (Part 1 of 3)

2.15 Subroutine WEPPREP

PURPOSE:To calculate weapon overallocation and setup salvo
arraysENTRY POINTS:WEPPREPFORMAL PARAMETERS:NoneCOMMON BLOCKS:C10, C30, REPOINTS, WEPCOMSUBROUTINES CALLED:DIRECT, DISTF, DLETE, GEOIN, MODFY, NEXTTT, WEPINCALLED BY:ENTMOD (for PREPALOC)

Method:

All groups are processed in order. Weapon type information is retrieved and the expansion factors GNWPNADJ and GSBL are calculated. The calculations are based on whether the group is a bomber, MIRV or non-MIRV missile. If the group is a bomber group, the fraction of ASMs in the group and the refuel time are also calculated and saved. If the group is a salvoed missile, the values for maximum salvo number (MAXSAL) and the contents of the NSAL array are developed. Finally, all old assignment records (ASSIGN) for the group are deleted.

Subroutine WEPPREP is illustrated in figure 10.1.

SECTION 3. ALOC MODULE

3.1 Purpose

The major purpose of this module is to determine the optimal allocation of weapons to targets, using a Lagrange multiplier technique. The weapons are divided into weapon groups -- each group containing weapons of the same characteristics which are geographically close. Thus, except for time launch interval constraints for some "salvoed" missiles, weapons are considered identical within groups. Each target is considered individually for weapon assignment. The order of investigation is the order of the TARCDE records on the LISTXX chain which was determined by the PLANSET module. When all targets have been processed, another pass over this chain begins. This process continues until the Lagrange method has allocated all the weapons to targets. The assignments are stored as ASSIGN records in the integrated data base during the process.

The user is able to specify weapon assignments through the FIX adverb to the PREPALOC module. In this case the ALOC module will optimally assign those weapons which have not been fixed. In addition, there are capabilities which allow the user to modify weapon range values, to restrict the use of MIRV weapons by target class, and to restrict the use of any weapon group by the value of either of the target attributes FLAG or CNTRYL.

3.2 Input

The precondition of the integrated data base required is that the PREPALOC module has to have been executed. Furthermore, there is an optional input file -- the Weapon/Target Data File. The Weapon/Target Data file contains the information relating each weapon group to each target. The Weapon/Target Data file, if not input, is created by the FRSTGD subroutine on pass one and may be retained for later executions of ALOC. One record is produced for each target whose length depends upon the number of weapon groups and the targets number of hardness components (length = number of groups x $(3 + 2 \times number \text{ of hardness components}) + 1$). This is the file which is created in pass one and may also be used in subsequent runs (see RECALC Mode: Users Manual, UM 9-77, Volume III). The format for the Weapon/Target Data file -- file code 15 -- appears in table 2.

3.3 Output

As a result of its execution the ALOC module creates ASSIGN (record type 70) records in the integrated data base. Further, the attribute NUMALOC is updated in every group to reflect the actual number of weapon allocated from that group.

3.4 Concept of Operation

In order to conserve storage, ALOC is broken up into two main overlays. The first overlay is called ALCINT. This overlay reads any user input, Table 2. Format of Weapon/Target Data File -- File Code 15

STARTING WORD	DESCRIPTION
1	Target Number
2	Time of arrival of group on target
(NWE PGE p^* + 2)	Corridor used by group or reason group is inactive
$(2 \times NWEPGRP + 2)$	Penetration probability of weapon to target
$(3 \times NWEPGRP + 2)$	Kill probability of weapon against first hard- ness component
$(4 \times NWEPGRP + 2)$	Kill probability of weapon against second hardness component**
(5 x NWEPGRP + 2) ***	Alternate kill probability of weapon against first hardness component
(6 x NWEPGRP + 2)	Alternate kill probability of weapon against second hardness component**

* Number of weapon groups

^{**} Does not appear if target has only one hardness component

^{*** (4} x NWEPGRP + 2) -(5 x NWEPGRP + 1) if target has only one hardness
component

including restrictions, modifications, print request and so on. Furthermore, the weapon data is extracted from the integrated data base. The second overlay (ALCMUL) controls the determination of the allocation. The driver routine of this overlay is MULCON. Within the second overlay there are four segments. The first, FGD, obtains target data for pass one. The second, SGD, obtains target data for passes two and beyond. The third segment, STAL, principally routines STALL, WAD and WADOUT, allocates to targets without terminal ballistic missile defenses. The fourth segment, DEFAL, principally routines DEFALOC and RESVAL handles ballistic missile defended targets.

3.4.1 <u>Overlay ALCINT</u>. The routines in this overlay are straightforward and need little explanation beyond that below. However, the routine DATGRP places information on a sequential file (file code 23) which is used by the FGD segment. Table 3 shows the format and content of this file.

3.4.2 Overlay ALCMUL. The design of the weapon-to-target allocator utilizes a hierarchy of subroutines operating at different levels of detail. Figure 11 illustrates this hierarchy. The major functions associated with these subroutines are summarized below and related to the overall concept in subsequent paragraphs.

Subroutine MULCON is the first subroutine in the hierarchy and is responsible for the control and adjustment of the Lagrange multipliers. MULCON monitors the rate at which various classes and types of weapons are being allocated to the target system and makes appropriate adjustments in the values of the Lagrange multipliers. In this role, MULCON does not need any detailed information concerning actual allocation. It is concerned only with the actual rate of allocation of the available inventory as the targets are processed. To obtain the assignment of weapons to each successive target, MULCON simply calls subroutine STALL (Single Target Allocator) for targets without missile defenses, or subroutines STALL and DEFALOC if the target is defended. STALL and DEFALOC utilize the current values of the multipliers to make an allocation to the next target, then return control to MULCON.

The data acquisition for the allocation process is performed by the FRSTGD routine on pass one and SCNDGD on all coner passes. Each of these routines brings in the proper IDS records for the next target and prepares the weapon data for that particular target. The Weapon/ Target Data File is read (or on the first pass in the wECALC mode calculated). On the first pass, FRSTGD then creates a record on file code 21.which, principally, contains the INACTIVE array (see table 4). If the user has requested range modification, FRSTGD may also write a record onto file code 22 in the same format as file code 15 (table 2). This new file serves as a source for replacement record for file code 15. SCNDGD reads each of these files in order to obtain the appropriate information.

63

3.7.2 Subroutine DATGRP

<u>PURPOSE</u>: Assemble weapon data, build payload tables and initialize salvo arrays

ENTRY POINTS: DATGRP

FORMAL PARAMETERS: None

<u>COMMON BLOCKS</u>: C10, C15, C30, CNCLS, FLGSTF, GRPHDR, INITSW, LACB, NOWPS, PAYSAV, PNAV, SALVO, WEPSAV, WPFIX

SUBROUTINES CALLED: DIRECT, GLOG, HDFND, HEAD, NEXTTT, RETRV, SLOG

CALLED BY: INITAL

Method:

After various counters are set to zero, the following process is followed for all weapon groups. First, the TYPE and CLASS are determined and some group attributes are saved. Next the payload for the group is examined and compared with the payloads of previous groups. New payloads are stored and old payloads are indicated via the index in array IPAY. Next the values for file 23 are determined. This file contains any flag, location or MIRV restrictions, range modifications and group parameters that will be required on the first pass. Next, the weapon totals in block NOWPS are updated and the group lambda calculated. Finally, if this is a salvoed group, the salvo arrays are initialized. This final process includes the unpacking of NSAL (9 weapon salvos per word) and repacking into NSALAL (4 weapon salvoes per word).

Subroutine DATGRP is illustrated in figure 18.

it.

allocation; consequently a revised cost (REVCOST) of the allocation based on the new multipliers is of interest, and is probably different than the old cost COST. The reason for the test on PROGRESS before correcting the cumulative differential profit will be discussed in connection with Part IV of the program (part 5 of figure 27).

Subroutine ADDSAL is used to maintain the sums for the salvoed groups.

Part IV: Processing After Allocation

Before calling STALL, CTSPILL is set to 0. (If some elements are spilled, WAD will so note by setting CTSPILL equal to the number of elements spilled.) The calls on TIMEME (5, 6, 7) before and after the allocation cause the time spent during the actual allocation to be recorded in columns 6 and 7 of the TIMEME output print (number 23).

Before calling either allocation routine, however, the program must check the number of fixed weapon assignments. The limitation of weapons allocated to one target is 30 weapons on an undefended target and 30 weapon groups on a defended (i.e., terminal ballistic missile defenses) target. Usually, MULCON calls both STALL* and DEFALOC* on defended targets and chooses the best allocation. If there are more than 30 fixed weapon assignments, STALL* should not be called. If the number of fixed assignments is greater than 30, MULCON checks to see if it is a defended target. If not, an error message is printed and the excess assignments are ignored. Then STALL* is called. If it is a defended target, MULCON sets a dummy low profit (except for verification) and calls only DEFALOC.*

The additional details of the allocation required by later processors are then recorded in /DYNAMI/. PENX and TOARR are required by EVALALOC, while KORRX and RVALX are required by ALOCOUT, FOOTPRNT, and POSTALOC. Subroutine BOMPRM is then called to update the ASM allocation fraction array FASM.

The various running sums are then calculated. If DEFALOC has made the allocation, the KORRX array gives the number of missiles from each group allocated to the target. If KORRX is positive, it represents the corridor. If it is negative, it represents the number allocated. Then the profit and cost data are recorded.

The following quantities are of particular importance:

DPROFIT	=	PROFIT - OPROFIT	
SDPROFIT	=	DPROFIT	
DELTEFF	=	DPROFIT/VALWPNS	
SEDLTEFF	=	SDPROFIT/VALWPNS	

STALL and DEFALOC are called via computer system subroutine LLINK.

These quantities are computed and the last two printed out in the standard ALOC print number 2 to help the user evaluate the progress of the allocation.^{*} The quantity OPROFIT represents the profit of the old allocation to the target evaluated in terms of the present values of the Lagrange multipliers. DPROFIT is thus a measure of the improvement in profit using the new allocation. Until PROGRESS = 1.0 this quantity is summed over all targets (one complete pass only) to give SDPROFIT. Thus, when the multipliers have been near the correct values for one full pass the value of SDPROFIT should be small. To provide a standard relative value for interpreting these quantities, they are divided by the value of all the weapons VALWPNS,

 $VALWPNS = \sum NWPNS(G) * LAMEF(G)$

*

to obtain DELTEFF and SDELTEFF which measure changes in profit as a fraction of the total value of all weapons.

The quantity of SDELTEFF, therefore, provides an estimate of how efficient the allocation would have been if the allocation had been terminated one pass earlier. Presumably, the current efficiency is substantially higher, but SDELTEFF does not, at this point, give any indication of how much. It is nevertheless of value in developing experience on how soon the PROGRESS .75 phase can be terminated. When PROGRESS is equal to 1.00 the multipliers are frozen and this role of SDELTEFF ceases to be relevant. The quantity is then reset to 0. Thereafter it provides a measure of the effect on the profit of closing to the exact stockpile. Usually during the closing phase SDELTEFF goes slightly negative. However, since during this phase we continue to replace allocations originally produced with slightly different values of the multipliers, the value may go positive for a while until the closing forces get large enough to force closure even at some loss of profit. Thus the value of SDELTEFF at the end of the closing phase (PROGRESS = 1) measures the loss in profit associated with closing. In the event that closing requires more than one full pass, a test has been inserted which causes SDELTEFF to continue to accumulate over more than one pass when PROGRESS = 1.0.

Finally when PROGRESS = 2.0 the quantity is again set equal to 0. If a verification pass is carried out, SDELTEFF then measures any increase in profit in the verification pass relative to the final allocation. In this role it defines an upper limit on the inefficiency of the actual allocation.

Ordinarily after all these calculations are performed ASGOUT is called to store the results. However, if PROGRESS = 2 this step is skipped since the integrated data file already contains the final allocation.

The column labelled (P-O)/VWPS in print number 2 contains these variables: DELTEFF on the first line, SDELTEFF on the second.

3.8.2 Subroutine ASGOUT

 PURPOSE:
 To update allocation assignment records in the integrated data base

 ENTRY FOINTS:
 ASGOUT

 FORMAL PARAMETERS:
 None

 COMMON BLOCKS:
 C10, C30, DYNAMI, MULTIP, SPLITS, PAYSAV, TARREF, TGTSAV, WEPSAV

 SUBROUTINES CALLED:
 DIRECT, DLETE, MODFY, MYAPOS, NEXTTT, STORE

 CALLED BY:
 MULCON

Method:

First a logical switch is set for each new weapon assignment to indicate it is unassigned. Next each <u>circoorganment</u> compared to the new assignments to see if all values, save RVAL, of the old assignment are equal to a new assignment. If it does, the RVAL attribute is deleted. Finally, an ASSIGN record is created for all the new assignments for which there is no match.

Subroutine ASGOUT is illustrated in figure 31.

international supervision in the

3.8.3 Subroutine BOMPRM

<u>PURPOSE</u>: The purpose of this routine is to maintain the array containing the fraction of weapons all allocated from each group which are ASMs.

ENTRY POINT: BOMPRM

FORMAL PARAMETERS: IDIFF = -1 if weapons are being deleted +1 if weapons are being added

COMMON BLOCKS: C33, DYNAMI, MULTIP, NALLY, PAYSAV, SALVO, WEPSAV

SUBROUTINES CALLED: None

CALLED BY: MULCON, SCNDGD

Method:

This routine merely updates the ASM fraction array FASM in common block /SALVO/. The important local variables are:

- DONE= a logical array set true if a weapon has already been
processed to update FASMTOTW= total number of weapons allocated from a group on the
target
 - TASM = number of ASMs from a group allocated on the target

FASM(G) is the fraction of currently allocated weapons from group G which are ASMs.

The factor FASM is updated whenever the state of the allocation changes. These changes occur when allocations from a previous pass are removed and when the allocation from the present pass is output. Thus, BOMPRM is called from subroutine MULCON on each target, and by subroutine SCNDGD for each target after the first pass.

Subroutine BOMPRM has one formal parameter IDIFF. If weapons are being removed (previous pass's allocation), then the value of IDIFF is -1. If weapons are being added, then IDIFF is equal to +1. In subroutine SCNDGD, the call to BOMPRM with IDIFF equal to -1 is made after reading the last pass allocation, just prior to the update of the running allocation sums. The call from MULCON with IDIFF equal to +1 is made just prior to the running sum update.

Upon entry to subroutine BOMPRM, the routine checks variable NBLN in /C33/. If this variable is negative, the allocation in /DYNAMI/ was made by subroutine DEFALOC and contains no bomber weapons. In this case, the subroutine returns with no further processing. If the

,

Figure 32. (Part 2 of 2)

3.8.4 Subroutine MYAPOS

<u>PURPOSE</u>: To position records properly before storage of a new ASSIGN record.

ENTRY POINTS: MYAPOS

FORMAL PARAMETERS: IMYAP: 1, Find weapon group and target 2, Find target only

COMMON BLOCKS: C10, C30, GRPHDR, TARREF

SUBROUTINES CALLED: DIRECT, NEXTTT

CALLED BY: ASGOUT

Method:

On first call the array of group IDS reference codes is set to zero. From then on, with each call the saved reference code of the desired group is checked. If it is nonzero it is retrieved. If it is zero, the group chain is cycled up to the desired group, the intervening groups also have their reference codes saved. Finally, when the proper group record has been retrieved, the target record is retrieved.

Subroutine MYAPOS is illustrated by figure 33.

Figure 33. Subroutine MYAPOS

3.8.5 Subroutine PRNTALL

<u>PURPOSE</u>: This routine provides a way of calling the print subroutine PRNTNOW that is conditional on the print control flags set by PRNTCON.

ENTRY POINTS: PRNTALL

FORMAL PARAMETERS: IOPT - Print option number

COMMON BLOCKS: C30, CONTRO, PRNTCN

SUBROUTINES CALLED: PRNTNOW, TIMEME

<u>CALLED BY</u>: MULCON, WAD, WADOUT, FRSTGD, RESVAL, DEFALOC, SETPAY

Method:

To provide convenient control over prints in program ALOC almost all print statements are contained in subroutine PRNTNOW. They are activated by calling PRNTNOW(IOPT) for the appropriate print option IOPT. If it is desired to place the print under data-input control so that the print will not appear unless a specific print request is included in the data deck, this can be accomplished by calling PRNTNOW via a call on PRNTALL. PRNTALL executes the request on PRNTNOW only if the print control subroutine PRNTCON has set the corresponding print control flag IDO(IOPT) active (i.e., = 3).

For each call PRNTALL first checks to see if the print has been set active by PRNTCON. If not, it immediately RETURNS (statement 2) to minimize time wasted on inoperative print calls.

If the particular print is active, PRNTALL immediately calls TIMEME (statement 1) to stop the clock which records active time in the program. This makes it possible to do a test run with an unusual number of prints and still obtain a valid estimate of what the running time would be without such prints. After the call on PRNTNOW, PRNTALL reactivates the clock before returning to the main program.

Before each print option (except 26), PRNTALL prints a heading identifying the optional print.

Subroutine PRNTALL is illustrated in figure 34.

d

3.9 Subroutine FRSTGD

PURPOSE: Assemble allocation data on the first pass.

ENTRY POINTS: FRSTGD

FORMAL PARAMETERS: None

<u>COMMON BLOCKS</u>: C10, C15, C30, C33, DYNAMI, FIL21, FILL, FIRST, GRPHDR, GRPSTF, INITSW, MULTIP, PAYSAV, PNAV, TARREF, TGTSAV, WADWPN, WEPSAV, WPFIX, XFPX

SUBROUTINES CALLED: CRDCAL, DIRECT, FLGCHK, HDFND, HEAD, INICRD, MODFY, NEXTTT, NXSPLT, PKCALC, PRNTAL, RECON, RETRV, TGTCRD, TIMEME

CALLED BY: MULCON

Method:

This routine processes each target in target number order. Each call causes the next target to be retrieved. Since each record on the target list points to either a target or a complex record, the next step in the process is to retrieve the remainder of the target data. Next the weapon data is acquired. This process depends to a great extent upon whether the user has saved file 15 from a previous run of ALOC. If so, this file is read in and unpacked. If not, the file is created by cycling through the weapon groups and calculating the various needed quantities. Much of the group data needed for this process is contained on file 23 where it was stored by DATGRP. If the user has specified range modifications, any information which differs from that on file 15 is written on file 22 in the same format.

During this process, the INACTIVE array is set. This array has an entry for each group and is either set to 0 or 100. 0 implies that the group is available for allocation to the target. 100 indicates that the group is unavailable for one of several reasons: target out of range, time decay requirements, and flag location and MIRV restriction. This array is written onto unit 21.

The final step is to read in any fixed assignments to the target and update the assignment records.

Subroutine FRSTGD is illustrated in figure 38.

First subroutine of segment FGD.

d

SECTION 5. MODULE ALOCOUT

5.1 Purpose

Module ALOCOUT is responsible for selecting optimum DGZs (desired ground zeros), also called weapon aim points for weapon allocated to target complexes. ALOCOUT, also resorts weapon assignments at the group level for use within the Sortie Generation subsystem. If executed as part of mini-allocator process (DATAMAKE), produces a STRIKE format tape rather than resorting weapon assignments. (For format of STRIKE tape see CSM MM 9-77 Volume IV).

Module ALOC specifies weapon groups assigned to targets together with associated targeting data. ALOCOUT extracts data from these records and computes any aiming offsets required by the plan. For simple or multiple targets, no calculations are performed. In the case of complex targets which can have several elements at slightly different coordinates, ALOCOUT employs subroutine DGZ (desired ground zero selector) to select optimum aim points within the target complex.

5.2 Input

ALOCOUT operates after module ALOC assigned weapons to targets. These records (ASSIGN) in addition to the supporting data base structure must be defined for proper execution.

5.3 Output

No new data base records are created during the execution of ALOCOUT. However, the weapon assignment records (called ASSIGN) are modified in two ways. First, for assignments to complex targets or for assignments to cities with nonzero radius, offsets as determined within the module are included within the ASSIGN record. Second, the assignment records at the weapon group level are resorted for use within the Sortie Generation subsystem. For missile groups, the sort is based on decreasing values of attribute RVAL. For bomber groups, the order is based on penetration corridor index and within the corridor sorted based on attribute RVAL. The penetration corridor that contains the largest number of strikes appears first within the sort, followed by the penetration corridor of the next largest number of strikes and so on.

5.4 Concept of Operation

ALOCOUT (that is, subroutine ENTMOD) operates with three overlay links. The first overlay reads the target list (TARNUM) passes controls to subroutine PROCCOMP for offset calculations when applicable and finally supplies optional prints. After all targets have been processed controls passes to the second overlay which consists entirely of subroutine SUMPRN which reorders strikes at the weapon group level and, if requested, produces prints concerning the individual assignments. If part of miniallocator, the second overlay is skipped and the third overlay is executed.

365

5.5 Identificat on of Subroutine Functions

5.5.1 <u>Subroutine PROCCOMP</u>. This subroutine controls the bulk of processing for offset determination. It is executed by subroutine ENTMOD only for those individual targets that require offset calculations. After offsets have been determined the assignment record (ASSIGN) is updated to include the values. Then, PROCCOMP returns to subroutine ENTMOD for acquisition of the next target and the associated strikes.

5.5.2 <u>Subroutine SUMPRN</u>. This subroutine constitutes the entire second overlay of ALOCOUT. Its purpose consists of resorting the weapon strikes at the group level and providing optional prints.

5.5.3 <u>Subroutine MINIOUT</u>. This subroutine controls the third overlay and produces a STRIKE tape.

5.6 Common Block Definition

Common blocks used by EVALALOC are outlined in table 11. Common blocks that communicate with the COP are given in appendix A of Program Main-tenance Manual, Volume I.

366

Table 11. ALOCOUT Common Blocks (Part 1 of 2)

5.7 Subroutine ENTMOD

PURPOSE:	Read user inputs, collect target weapon assignments, and execute subroutine PROCCOMP for DGZ determina- tion.
ENTRY POINTS:	ENTMOD (first subroutine executed when overlay ALOCOUT is called)
FORMAL PARAMETERS:	None
COMMON BLOCKS:	CITY, C10, C15, C30, GRPY, IONPRT, LOCFIN, OOPS, STRIKE, WPGT
SUBROUTINES CALLED:	DGZ, DIRECT, HDFND, HEAD, INSGET, NEXTTT, PROCCOMP, RETRV, SUMPRN, TIMEME, WEPGET
CALLED BY:	COP

Method:

Subroutine ENTMOD reads and stores users input, walks the individual target chain (TARNUM), collects weapon assignments for the current target, and calls subroutine PROCCOMP for DGZ determination if the target represents a complex or is a city (attribute RADIUS greater than zero). After processing all targets, subroutine SUMPRNT (second overlay) reorders weapon assignments on a weapon group basis for use within the Sortie Generation subsystem. Alternately, subroutine MINIOUT is called for miniallocator STRIKE tape.

Module ALOCOUT recognizes user supplied adverbs FINDMIN and ONPRINTS. FINDMIN sets the number of iterations subroutine FINDMIN uses for offset determination. ONPRINTS sets user options; results maintained in array PRINCE.

ALOCOUT now walks the identical target chain (TARNUM) which module ALOC made weapon assignments to. For each target, weapon assignments are stored on chain ASGWPN. If no strike exists processing continues by retrieving the next target on the list. Otherwise, for each weapon assignment, subroutine WEPGET retrieves weapon related attributes and updates necessary counts. Checks determine the nature of the target. Offsets are calculated only if the target represents a complex or is a city and has a nonzero RADIUS.

A complex target (or target complex) is a combination of target elements sufficiently close in geographic location that a weapon on any one of them will have some probability of killing other elements in the complex. Such target complexes are targeted as a unit by the allocator which allocates weapons against their total value, using one set of coordinates. In order to maximize targeting efficiency against such a complex, optimum aim points among the target elements must be selected. These aiming offsets are specified relative to the first target element only and are passed on in that form to subsequent modules.

When ENTMOD encounters a complex target, subroutine PROCCOMP is called. PROCCOMP is responsible for assembling the data on a complex target in a form that can be used efficiently for DGZ selection. Each target component of the complex generates a standardized target element in the arrays used by DGZSEL. (Targets with more than one hardness component generate more than one such target element, and targets with a specified target radius will generate several elements spread over the area of the target to represent a value spread over the area.)

Subroutine ENTMOD is illustrated in figure 68.

and the second

Figure 69. Subroutine COMPRESS

375

5.7.2 Function CUMINV

PURPOSE:	To determine the value X such that Z is the probability that $x \leq X$.
ENTRY POINTS:	CUMINV
FORMAL PARAMETERS:	Z - The probability that $x \le X$
COMMON BLOCKS:	None
SUBROUTINES CALLED:	None
CALLED BY:	PROCCOMP

Method:

Function CUMINV is illustrated in figure 70. By definition,

$$Z = P[x \le X] = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{X} e^{-\frac{t^2}{2}} \cdot dt \text{ for } 0 < Z < 1$$

CUMINV uses the following approximation χ^1 for χ :

$$X^{1} = \pm \left[V - \left(\frac{A_{1} + A_{2} \cdot V + A_{3} \cdot V^{2}}{1 + B_{1} \cdot V + B_{2} \cdot V^{2} + B_{3} \cdot V^{3}} \right) \right]$$

where

$$V = \sqrt{\ln (1/Q^2)}$$
, $Q = Z$ or $1 - Z$ such that $0 \le Q \le .5$

and

A ₁	=	2.515517	$B_1 = 1.43$	2788
A2	=	.802853	$B_2 = .18$	9269
A3	=	.010328	B ₃ = .00	1308

5.7.10 Subroutine PROCCOMP

PURPOSE: To set up arrays in common block /C1/ for the complex target so that the subroutine DGZ can use the arrays during the selection of optimal aim point offsets for the weapons allocated to the target; and to modify target weapon assignments records for inclusion of the computed offsets. ENTRY POINTS: PROCCOMP FORMAL PARAMETERS: None COMMON BLOCKS: CITY, C1, C10, C30, ISKIPD, STRIKE, WPGT SUBROUTINES CALLED: COMPRESS, CUMINV, DGZ, DIRECT, ERGOT1, ERGOT2, HEAD, MODFY, NEXTTT, ORDER, REORDER, TIMEME, VALTAR

CALLED BY: ENTMOD

Method:

When ENTMOD encounters a complex target, PROCCOMP is called in order to assemble data in a form that can be efficiently used for DGZ selection. Each target component of the complex generates a standardized "target element" in the working arrays used by subroutine DGZ (common /Cl/). Targets with more than one hardness component generate more than one such target element, and targets with a specified target radius will generate several elements spread over the area of the target to represent a value over the area. For complexes, individual target elements are obtained by walking the data base chain called 'CMPTGT'.

If the number of target elements so generated exceeds the maximum program dimensions (120), subroutine COMPRESS is called to recombine target elements near each other having nearly the same lethal radius. In any case, for efficiency in DGZ, a call to COMPRESS is made just before calling DGZ. On return from DGZ, PROCCOMP modifies weapon assignment records (ASSIGN) for definition of the computed offsets.

Subroutine PROCCOMP is illustrated in figure 79.

÷.

5.7.14 Subroutine WEPGET

PURPOSE:	Retrieve weapon attributes per assignment, and up- date assignment counts based on corridor.
ENTRY POINTS:	WEPGET
FORMAL PARAMETERS:	None
COMMON BLOCKS:	C1, C10, C30, GRPY, WPGT
SUBROUTINES CALLED:	DIRECT, HEAD, NEXTTT, RANSIZE, TIMEME
CALLED BY:	ENTMOD

Method.

Subroutine ENTMOD executes WEPGET for each target weapon assignment. WEPGET retrieves weapon related attributes (YIELD, CEP, etc.) and defines arrays in common block /Cl/ for use by subroutine DGZ. Also, a count of each weapon assignment categorized by group and penetration corridor is updated.

The weapon attributes necessary for calculating offsets for each strike are indexed at the weapon group level. That is, individual strikes launched from the same weapon group have the same attribute values. Therefore it is necessary to interface with the data base only once per weapon group request. Upon initial extraction, these attributes are written on an indexed random file for future reference.

Subroutine WEPGET is illustrated in figure 83.

5.8 Subroutine SUMPRN

PURPOSE: To sort weapon group assignment chains and print out assignment summaries SUMPRN ENTRY POINTS: FORMAL PARAMETERS: None C10, C30, GRPY, IONPRT, JAZ COMMON BLOCKS: SUBROUTINES CALLED: DIRECT, DLETE, HEAD, NEXTTT, ORDER, REORDER, SORTIT, TIMEME ENTMOD

CALLED BY:

Method:

This subroutine replaces existing ASSIGN records which are in no particular order on the MYASGN chain with the same set of ASSIGN records in the following sorts: For missile groups, assignments are sorted on salvo number ascending, and, within salvo, on the value of the RVAL attribute descending. For bomber groups, assignments are sorted on corridor with the corridor most often assigned occurring first, and, within corridor, on the value of the RVAL attribute descending.

The method used is to cycle the weapon group chain and perform essentially the same process for each group. First a record is read from random access file 25. This record contains counts of the weapon groups assignments. For missile groups the total number is in CORCNT(1) and -1 in CORCNT(2). For bombers the contents of CORCNT(I) corresponds to the number of assignments to corridor I. At this point, if the group is a missile group, the print header is produced. If the group is a bomber group, the assignments are totaled and the proper corridor order is stored in CORORD.

Now the assignments are read from the MYASGN chain and stored. The method of storage depends upon the total number of assignments. If the number is such that the data may be sorted internally, the data is stored in array F. Otherwise, it is written onto a file. The sort keys are created at this time. When the assignments have all been processed, the old assignments are deleted from the MYASGN chain. Then the assignments are sorted either internally by routines ORDER and REORDER, or externally by SORTIT. Now each assignment, in sort is either read from the SORTIT output or retrieved from array F. A new ASSIGN record is stored in the MYASGN chain and the assignment is printed. The bomber header is produced each time a new corridor is encountered.

Subroutine SUMPRN is illustrated in figure 84.
