PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through frequent inspections can unsafe conditions be detected and only through continued care and maintenance can these conditions be prevented or corrected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the spillway design flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. The spillway design flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

PHASE I INSPECTION REPORT

NATIONAL DAM INSPECTION PROGRAM

BRIEF ASSESSMENT OF GENERAL CONDITION

AND

RECOMMENDED ACTION

Name of Dam:

Maple Lake Dam NDI ID No. PA-00766 DER ID No. 52-170

Size:

<u>Hazard</u> Classification:

Owner:

Pine Ridge Community Association Adam Skarzenski, Board Member R.D. 1 Box 224 Bushkill, Pa. 18324

Small (35 feet high; 128 acre-feet)

State Located: Pennsylvania

County Located:PikeStream:Stoffle-Denmark Creek

High

Date of Inspection: 24 October 1979

Based on visual inspection, available records, calculations, past operational performance, and according to criteria established for these studies, Maple Lake Dam is judged to be in good condition. Based on existing conditions, the main and auxiliary spillways will pass an approximate minimum of 48 percent of the Probable Maximum Flood (PMF) before overtopping of the dam occurs. The PMF is the Spillway Design Flood (SDF) for Maple Lake Dam. The SDF is based on the criteria and the downstream conditions. It is judged that the dam could withstand the depth and duration of overtopping that would occur for the 1/2 PMF. Since the dam cannot pass its SDF but would not fail by overtopping during the 1/2 PMF, the spillway capacity is rated as inadequate, but not seriously inadequate.

· Conternation faire

The auxiliary spillway was not constructed to its design dimensions and will not pass its design discharge.

ı

こうちものないでないとう

10

X

No stability problems were evident for the embankment at the time of the visual inspection, but a potential hazard to stability exists due to erosion that might occur when there is flow in the auxiliary spillway.

The following studies and remedial measures are recommended to be undertaken by the Owner, in approximate order of priority, immediately:

(1) Perform a study to determine a means of completing the auxiliary spillway so that it will pass, as a minimum, its design discharge. As part of the study, the Owner should assess the need for protective measures and/or realignments that might be required to prevent erosion of the dam by auxiliary spillway discharges. Take appropriate action as required.

(2) Repair areas of surface erosion on the downstream slope of the embankment.

(3) Remove brush from the embankment.

All investigations, studies, designs, and supervision of construction should be performed by a professional engineer experienced in the design and construction of dams.

In addition, the Owner should institute the following operational and maintenance procedures:

(1) Develop a detailed emergency operation and warning system for Maple Lake Dam.

(2) During periods of unusually heavy rains, provide round-the-clock surveillance of Maple Lake Dam.

(3) When warnings of a storm of major proportions are given by the National Weather Service, the Owner should activate his emergency operation and warning system.

(4) Institute an inspection program such that the dam is inspected frequently. As presently required by the Commonwealth, the inspection program should include a formal annual inspection by a professional engineer experienced in the design and construction of dams. Utilize the inspection results to determine if remedial measures are necessary.

iv

(5) Expand the existing maintenance program so that all features of the dam are properly maintained.

State State State

1

X

a. <u>Authority</u>. The Dam Inspection Act, Public law 92-367, authorized the Secretary of the Army, through the Corps of Engineers, to initiate a program of inspection of dams throughout the United States.

b. <u>Purpose</u>. The purpose of the inspection is to determine if the dam constitutes a hazard to human life or property.

-1-

1.2 Description of Project.

a. Dam and Appurtenances. Maple Lake Dam is a homogeneous, earthfill embankment. It is 35 feet high at its maximum section and 685 feet long. A cutoff trench, 10 feet wide and about 6 feet deep, is located just upstream from the axis of the dam. A rock toe drain is located at the downstream toe of the dam. The embankment is on an earthen foundation.

The main spillway is located at the maximum section of the dam. It consists of a reinforced concrete riser structure near the upstream toe of the dam, a 24-inch diameter conduit, and a concrete outlet structure at the downstream toe of the dam. The riser structure has two weirs, each 4 feet long, located 5.4 feet below the top of the dam. The conduit through the embankment is a corrugated metal pipe encased in reinforced concrete.

The auxiliary spillway is an excavated, trapezoidal channel at the left abutment of the dam. The outlet channel parallels the toe of the dam along the abutment.

The outlet works is located at the main spillway riser. A 12-inch diameter cast-iron pipe, encased in reinforced concrete, extends from the upstream toe of the dam to the riser structure. A sluice gate for controlling flow through the 12-inch pipe is located on the inside face of the riser. A gate operating mechanism is located atop the riser structure.

The various features of the dam are shown on the Photographs in Appendix C and on the Plates in Appendix E. A description of the geology is included in Appendix F.

b. Location. Maple Lake Dam is located on Stoffle-Denmark Creek in Lehman Township, Pike County, Pennsylvania, approximately 3 miles north of Bushkill. Maple Lake Dam is shown on USGS Quadrangle, Lake Maskenozha, Pennsylvania - New Jersey, at latitude N 41° 08' 20" and longitude W 74° 59' 10". A location map is shown on Plate E-1.

-2-

c. <u>Size Classification</u>. Small (35 feet high, 128 acre-feet).

d. <u>Hazard Classification</u>. High hazard. Downstream conditions indicate that a high hazard classification is warranted for Maple Lake Dam (Paragraphs 3.1e and 5.1c (4)).

e. <u>Ownership</u>. Pine Ridge Community Association, Adam Skarzenski, Board Member, R.D. 1 Box 224, Bushkill, Pennsylvania 18324.

f. Purpose of Dam. Recreation.

なるからないで、このではなるないないで、ないないないないであるとなったのであるというというというという

g. <u>Design and Construction History</u>. Pine Ridge, Inc. constructed a dam at the site in 1968. The dam was an earthfill structure about 30 feet high. The dam failed on the night of August 13, 1969 and caused significant property damage. Investigations by the Commonwealth indicated that the cause of failure was piping (internal erosion) in the vicinity of the outlet conduit. The investigations cited generally poor construction as a contributing cause.

Edward C. Hess Associates, Consulting Engineers and Surveyors, of Stroudsburg prepared plans for a new dam at the same site in 1971. Soil and foundation investigations were performed by Northeastern Engineering Company, Inc. of Clarks Summit. Both Northeastern Engineering Company and D'Appolonia-Moody-Hess, Geo-Environmental Services, of Pittsburgh worked on the design of the embankment. Construction work began in 1971 and was completed in 1972 under the supervision of C. L. Dennis of Hess Associates. The original embankment was entirely removed and a new one was constructed.

h. <u>Normal Operational Procedure</u>. The pool is maintained at the main spillway crest level with excess inflow discharging through the conduit. The sluice gate at the outlet works is normally closed. Spillway discharge flows downstream to the confluence with the Delaware River.

SECTION 2

ENGINEERING DATA

2.1 Design.

a. <u>Data Available</u>. Design data available for review included the following: approved design drawings and specifications; a soils investigation report prepared by Northeastern Engineering Company, Inc.; a letter report prepared by D'Appolonia-Moody-Hess, Geo-Environmental Services, concerning the embankment design; and the permit application report prepared by the Commonwealth.

b. <u>Design Features</u>. The project is described in Paragraph 1.2a. The various features of the dam are shown on the Photographs in Appendix C and Plates E-2 and E-3 in Appendix E. The embankment is shown on Photographs A and B. The main spillway is shown on Photographs C and D. The auxiliary spillway is shown on Photographs E and F.

c. <u>Design Considerations</u>. Hydraulic and structural design considerations are covered in Sections 5 and 6, respectively.

2.2 Construction.

a tring a spring of an antipology and the second second second second second second second second second second

a. <u>Data Available</u>. The only construction data available was a dam completion report submitted to the Commonwealth by the engineer who supervised construction. The engineer certified that the dam was constructed in accordance with the approved plans and specifications. Telephone conversations with the engineer indicate that no unusual problems were encountered during construction.

b. <u>Construction Considerations</u>. The available data indicate that the construction of the dam was satisfactory.

2.3 <u>Operation</u>. There are no formal records of operation. Conversations with the Owner indicate that all features have performed satisfactorily since the dam was completed in 1972.

-7-

2.4 Evaluation.

and a product spectral sector and

a. <u>Availability</u>. Engineering data were provided by the Bureau of Dams and Waterway Management, Department of Environmental Resources, Commonwealth of Pennsylvania (PennDER), and by the Design Engineer, E. C. Hess Associates. The Owner made available his Caretaker and a Board Member for information during the visual inspection. He also researched his files for information at the request of the inspection team.

b. <u>Adequacy</u>. The type and amount of available design data and other engineering data are sufficient, and the assessment is based on the combination of available data, visual inspection, performance history, hydrologic assumptions, and hydraulic assumptions.

c. <u>Validity</u>. There is no reason to question the validity of the available data.

as attent to a

SECTION 3

VISUAL INSPECTION

3.1 Findings.

a. <u>General</u>. The overall appearance of the dam is good. Deficiencies were observed as noted below. A sketch of the dam with the locations of deficiencies is presented on Exhibit B-1 in Appendix B. Survey information acquired for this Report is summarized in Appendix B. On the day of the inspection, the pool was 0.1 foot above the main spillway crest.

b. <u>Embankment</u>. Most of the upstream slope was submerged on the day of the inspection. The exposed portion of the slope is protected by riprap and vegetation (Photograph A). No areas of erosion were observed.

The downstream slope is covered with grass except near the toe of the slope, where the rock toe drain was constructed. Some surface erosion of the toe drain material has occurred (Photograph B). No seepage or wet areas were observed. A minor amount of brush is growing at the left end of the embankment at its junction with the auxiliary spillway.

The survey performed for this inspection shows that the entire top of the dam is slightly above its design elevation. The measured topwidth and side slopes of the embankment conform to the design values.

c. <u>Appurtenant Structures</u>. No deficiencies were apparent for the main spillway. Both the riser structure and the outlet structure are in good condition (Photographs C and D). The 24-inch diameter main spillway conduit could not be inspected due to the flow of water through it. The outlet works conduit, a 12-inch diameter cast-iron pipe located upstream from the main spillway riser structure, was submerged and could not be inspected. The Owner stated that the sluice gate for the 12-inch conduit was operated recently and was in good working condition.

-9-

The auxiliary spillway is a trapezoidal channel at the left abutment (Photograph E). The outlet channel parallels the toe of the dam along the abutment at a distance of 6 to 10 feet from it (Photograph F). The side slopes of the auxiliary spillway and its outlet channel are protected by vegetation. It appeared that most portions of the bottom of the auxiliary spillway outlet channel are exposed bedrock. The survey performed for this inspection indicates that the auxiliary spillway was not constructed to its design template. The actual bottom width is 18 feet instead of 25 feet, which is the design width listed in the permit application report. However, the crest is lower than its design elevation. The existing auxiliary spillway section is shown on the survey data in Appendix B.

d. <u>Reservoir Area</u>. The slopes surrounding the reservoir are relatively mild. The watershed has some minor residential development within it, but the watershed is almost entirely wooded.

e. <u>Downstream Channel</u>. The confluence of Stoffle-Denmark Creek with the Delaware River is about 2.5 miles downstream from the dam. Between the dam and the confluence, there are at least two dwellings, one commercial structure, and one cottage that could be flooded if a failure of Maple Lake Dam were to occur. The downstream area is shown on Exhibit D-1 in Appendix D.

1

A COMPANY AND A COMPANY AND A COMPANY

SECTION 4

OPERATIONAL PROCEDURES

4.1 <u>Procedure</u>. The reservoir is maintained at the main spillway crest level with excess inflow discharging through the main spillway conduit and into the downstream channel. The outlet works is used to drawdown the pool level for shoreline maintenance.

4.2 <u>Maintenance of Dam</u>. Grass on the embankment is cut annually. Informal inspections of the dam are made by the Owner about every two weeks.

4.3 <u>Maintenance of Operating Facilities</u>. The sluice gate on the outlet works is occasionally opened by the Owner to check its operational adequacy. The Owner stated that it was last opened during the summer prior to the inspection.

4.4 <u>Warning Systems in Effect</u>. There is no emergency operation and warning system. The Owner stated that the condition of the dam is checked during periods of heavy rain.

4.5 <u>Evaluation of Operational Adequacy</u>. The maintenance program is generally satisfactory, but a few deficiencies exist and require attention. Formal inspections are necessary to detect hazardous conditions at the dam. An emergency operation and warning system is necessary to reduce the risk of dam failure should adverse conditions develop and to prevent loss of life should the dam fail.

-11-

SECTION 5

HYDROLOGY AND HYDRAULICS

5.1 Evaluation of Features.

a. <u>Design Data</u>. The available data indicate that the design crest elevations of the main spillway and the auxiliary spillway were established to provide sufficient storage capacity to contain the runoff from a 100-year rainfall. The auxiliary spillway was designed to discharge 375 cfs, which was the Commonwealth's requirement for a 0.25 square mile drainage area. Data obtained for this Report indicate that there are a number of differences between the design elevations and dimensions and the existing conditions. The differences are shown on the survey data at the end of Appendix B. The spillway capacity used in this Report, 382 cfs, is the combined capacity of the main and auxiliary spillways for the existing conditions.

A drainage area of 0.25 square mile was used in the design of the dam. For this Report, the drainage area was checked using the 7.5-minute USGS Quadrangle. It was found that the available mapping is not sufficiently detailed to provide accurate resolution of the drainage area. The drainage area is not well-defined because a swamp exists at the headwaters. Because of the large contour interval of 20 feet of the USGS mapping, it is uncertain whether runoff into the swampy area would drain into the Maple Lake watershed or into the adjacent watershed. The value used for design, 0.25 square mile, is an acceptable estimate. However, other acceptable estimates determined from the same mapping are as great as 0.34 square mile. The procedures used in the analysis to evaluate the spillway adequacy are described in Appendix D.

b. <u>Experience Data</u>. No records of maximum pool levels are available. The Owner stated that there has been no flow over the auxiliary spillway since the dam was completed in 1972.

-12-

The existing dam is on the same site as a previous dam. The original dam was earthfill and about 30 feet high. It was constructed in 1968 and failed by piping in 1969. The breach that developed during failure was about 20 feet wide. The time required to develop the breach is unknown. A newspaper account indicates that the failure caused substantial property damage and caused evacuation of two dwellings. Neither dwelling was flooded, but water levels were within 0.5 foot of the first floor level of one dwelling.

c. Visual Observations.

(1) <u>General</u>. The visual inspection of Maple Lake Dam, which is described in Section 3, resulted in a number of observations relevant to hydrology and hydraulics. These observations are evaluated herein for the various features.

(2) <u>Embankment</u>. The survey performed during this inspection indicates that the entire top of the embankment is above its design elevation. The existing top of dam elevations were used for the hydraulic analyses.

(3) <u>Appurtemant Structures</u>. The actual dimensions and grades of the auxiliary spillway differ from the design values. The actual values were used for the hydraulic analyses.

(4) <u>Downstream Conditions</u>. No conditions were observed downstream from the dam that would reduce the hydraulic capacity of the spillway. Experience data, described in Paragraph 5.1b., and visual observations indicate that failure of Maple Lake Dam could cause flooding of at least two dwellings located along Stoffle-Denmark Creek. The downstream conditions indicate that a high hazard classification is warranted for Maple Lake Dam.

d. Overtopping Potential.

(1) <u>Spillway Design Flood</u>. According to the criteria established by the Office of the Chief of Engineers (OCE), the Spillway Design Flood (SDF) for the size (Small) and hazard potential (High) of Maple Lake Dam is between one-half of the Probable Maximum Flood (PMF) and the PMF. Because of the downstream conditions and the height of the dam. the PMF is selected as the SDF for Maple Lake Dam. The

-13-

watershed was modeled with the HEC-1DB computer program. A description of the model is included in Appendix D. As discussed in Paragraph 5.1a., the available mapping is not adequate to accurately define the drainage area. The two possible extremes for the size of the drainage area are 0.25 square mile and 0.34 square mile. An analysis was performed for each of the extreme values. The assessment of the dam is based on existing conditions, and the effects of future development are not considered.

(2) <u>Summary of Results</u>. Pertinent results are tabulated at the end of Appendix D. The analyses reveal that for a 0.25 square mile drainage area, which is the design value, Maple Lake Dam can pass about 62 percent of the PMF before overtopping of the dam occurs. For a 0.34 square mile drainage area, Maple Lake Dam can pass about 48 percent of the PMF before overtopping of the dam occurs. In each case, the dam is rated using the existing lines and grades of its features.

(3) <u>Spillway Adequacy</u>. The criteria used to rate the spillway adequacy of a dam are described in Appendix D. The analyses indicate that the spillway can pass an approximate minimum of 48 percent of the PMF without overtopping of the dam. The analyses also indicate that an occurrence of the 1/2 PMF would cause a maximum depth of overtopping of 0.12 foot for a duration of 1.25 hours. It is judged that this depth and duration of overtopping would not cause failure of the dam. Since an occurrence of the 1/2 PMF would not cause failure of the dam, the spillway capacity is rated as inadequate, but not seriously inadequate.

SECTION 6

STRUCTURAL STABILITY

6.1 Evaluation of Structural Stability.

a. Visual Observations.

(1) <u>General</u>. The visual inspection of Maple Lake Dam, which is described in Section 3, resulted in a number of observations relevant to structural stability. These observations are evaluated herein for the various features.

(2) <u>Embankment</u>. The surface erosion near the toe of the dam was not a serious problem at the time of the inspection, but continued erosion is likely. Similarly, the growth of brush at the left end of the embankment is only a minor problem at present, but the root systems can eventually cause damage to the embankment.

During the visual inspection it was observed that the outlet channel of the auxiliary spillway is steep and that neither the end of the embankment adjacent to the auxiliary spillway nor the side slopes of the outlet channel are protected against erosion. A substantial portion of the bottom of the outlet channel is bedrock and would not be susceptible to erosion, but the end of the embankment and the channel side slopes consist of erodible soil materials. High velocities in the auxiliary spillway might cause lateral erosion. Erosion could occur either at the end of the dam or along its downstream toe. Erosion at either location would be a significant hazard to the dam.

b. <u>Design and Construction Data</u>. Stability analyses were performed during the design of the embankment. Soil investigations, soil testing, and preliminary design of alternate embankment sections were performed by Northeastern Engineering Company, Inc. of Clarks Summit, Pennsylvania. Their findings, which included recommended embankment sections and factors of safety for stability, were presented in a report to E. C. Hess Associates. The findings were later reviewed by D'Appolonia-Moody-Hess, Geo-Environmental Services, of Pittsburgh, Pennsylvania. D'Appolonia Moody-Hess prepared a letter report to E. C. Hess Associates and recommended a revised embankment section. The revised

-15-

section was adopted and is shown on Plate E-2 in Appendix E. The stability analyses performed for the adopted section indicate factors of safety of 1.65 for a steady seepage condition and 1.3 for a rapid drawdown condition. During construction, the embankment that had previously been constructed and that had failed was completely removed. The soil materials were stockpiled and re-used for the new construction. Surveys performed for this inspection indicate that the embankment slopes were constructed in accordance with the design drawings. The design and construction data indicate that Maple Lake Dam has adequate factors of safety for stability.

c. <u>Operating Records</u>. There are no formal records of operation. The embankment dam that failed in 1969 was completely removed prior to construction of the existing dam, and, as such, its failure is not relevant to the existing dam. According to available data, no stability problems have occurred over the operational history of the dam.

d. <u>Post-construction Changes</u>. There have been no post-construction changes to the dam.

e. <u>Seismic Stability</u>. Maple Lake Dam is located in Seismic Zone 1. Normally it can be considered that if a dam in this zone has adequate factors of safety under static loading conditions, it can be assumed safe for any expected earthquake loading. Since the available stability analyses for the embankment indicate that the dam has adequate factors of safety for static loading conditions, it is assumed that the seismic stability is also adequate.

SECTION 7

ASSESSMENT, RECOMMENDATIONS, AND PROPOSED REMEDIAL MEASURES

7.1 Dam Assessment.

a. Safety.

(1) Based on available records, visual inspection, calculations, and past operational performance, Maple Lake Dam is judged to be in good condition. Based on existing conditions, the main and auxiliary spillways will pass an approximate minimum of 48 percent of the PMF before overtopping of the dam occurs. The PMF is the SDF for Maple Lake Dam. The SDF is based on the criteria and the downstream conditions. It is judged that the dam could withstand the depth and duration of overtopping that would occur for the 1/2 PMF. Since the dam cannot pass its SDF but would not fail by overtopping during the 1/2 PMF, the spillway capacity is rated as inadequate, but not seriously inadequate.

(2) The auxiliary spillway was not constructed to its design dimensions and will not pass its design discharge.

(3) No stability problems were evident for the embankment at the time of the visual inspection, but a potential hazard to stability exists due to erosion that might occur when there is flow in the auxiliary spillway.

(4) A summary of the features and observed deficiencies is listed below:

Feature and Location	Observed Deficiency
Embankment:	Surface erosion at downstream toe; brush.
Auxiliary Spillway:	Not constructed to design dimensions.

b. <u>Adequacy of Information</u>. The information available is such that a preliminary assessment of the condition of the dam can be inferred from the combination of visual inspection, past performance, and computations performed prior to and as part of this study.

-17-

c. <u>Urgency</u>. The recommendations in Paragraph 7.2 should be implemented immediately.

d. <u>Necessity for Further Investigations</u>. In order to accomplish some of the remedial measures outlined in Paragraph 7.2, further investigations by the Owner will be required.

7.2 Recommendations and Remedial Measures.

a. The following studies and remedial measures are recommended to be undertaken by the Owner, in approximate order of priority, immediately:

(1) Perform a study to determine a means of completing the auxiliary spillway so that it will pass, as a minimum, its design discharge. As part of the study, the Owner should assess the need for protective measures and/or realignments that might be required to prevent erosion of the dam by auxiliary spillway discharges. Take appropriate action as required.

(2) Repair areas of surface erosion on the downstream slope of the embankment.

(3) Remove brush from the embankment.

All investigations, studies, designs, and supervision of construction should be performed by a professional engineer experienced in the design and construction of dams.

b. In addition, the Owner should institute the following operational and maintenance procedures:

(1) Develop a detailed emergency operation and warning system for Maple Lake Dam.

(2) During periods of unusually heavy rains, provide round-the-clock surveillance of Maple Lake Dam.

(3) When warnings of a storm of major proportions are given by the National Weather Service, the Owner should activate his emergency operation and warning system.

-18-

Children an anna an an

Contraction in

(4) Institute an inspection program such that the dam is inspected frequently. As presently required by the Commonwealth, the inspection program should include a formal annual inspection by a professional engineer experienced in the design and construction of dams. Utilize the inspection results to determine if remedial measures are necessary.

ľ

ĩ

(5) Expand the existing maintenance program so that all features of the dam are properly maintained.

HYDROLOGY AND HYDRAULICS

W WE W B

APPENDIX D

HYDROLOGY AND HYDRAULICS

Spillway Capacity Rating:

In the recommended Guidelines for Safety Inspection of Dams, the Department of the Army, Office of the Chief of Engineers (OCE), established criteria for rating the capacity of spillways. The recommended Spillway Design Flood (SDF) for the size (small, intermediate, or large) and hazard potential (low, significant, or high) classification of a dam is selected in accordance with the criteria. The SDF for those dams in the high hazard category varies between one-half of the Probable Maximum Flood (PMF) and the PMF. If the dam and spillway are not capable of passing the SDF without overtopping failure, the spillway capacity is rated as inadequate. If the dam and spillway are capable of passing one-half of the PMF without overtopping failure, or if the dam is not in the high hazard category, the spillway capacity is not rated as seriously inadequate. A spillway capacity is rated as seriously inadequate if all of the following conditions exist:

(a) There is a high hazard to loss of life from large flows downstream of the dam.

(b) Dam failure resulting from overtopping would significantly increase the hazard to loss of life downstream from the dam from that which would exist just before overtopping failure.

(c) The dam and spillway are not capable of passing one-half of the PMF without overtopping failure.

Description of Model:

and the set of the set

If the Owner has not developed a PMF for the dam, the watershed is modeled with the HEC-1DB computer program, which was developed by the U.S. Army Corps of Engineers. The HEC-1DB computer program calculates a PMF runoff hydrograph (and percentages thereof) and routes the flows through both reservoirs and stream sections. In addition, it has the capability to simulate an overtopping dam failure. By modifying the rainfall criteria, it is also possible to model the 100year flood with the program.

GANNETT FLEMING CORDDRY	NUMBER HYDROLOGY AND HYDRAULICS	
AND CARPENTER, INC. Harrisburg, Pa.	MAPLE LAKE DAM	
-	COMPUTED BY DATE CHECKED BY	DATE

DESCRIPTION OF ANALYSIS PROCEDURE

THE HEH ANALYSIS FOR MAPLE LAKE DAM IS COMPLICATED BY TWO FACTORS :

1. GEOMETRY OF FEATURES DIFFERS FROM DESIGN: (a) TOP OF DAM 15 0.4 FOOT HIGHER THAN THE DESIGN TOP OF DAM ELEVATION.

(E) AUXILIARY SPILLWAY CREST IS 0.7 FOOT LOWER THAN ITS DESIGN ELEVATION, BUT THE CREST LENGTH IS 7 FEET LESS THAN THE DESIGN LENGTH.

2. WATERSHED CANNOT BE ACCURATELY DEFINED BY EXISTING MAPPING. THE CONTOUR INTERVAL AND THE TOPOGRAPHY ARE SUCH THAT ACCEPTABLE ESTIMATES OF THE DRAINAGE AREA RANGE FROM 0.25 SQ. MI. TO 0.34 SQ. MI. ALTHOUGH THIS IS ONLY A 60 ACRE DIFFERENCE, IT AMOUNTS TO A 36 PERCENT VARIATION FOR THE SMALL WATERSHED.

THE PROCEDURES ADOPTED FOR ANALYSIS AND THE REASONS THEREFORE ARE AS FOLLOWS: 1. BASE HYDRAULIC ANALYSIS ONLY ON EXISTING CONDITIONS (i.e. ACTUAL GEOMETRIC CONDITIONS). AN ANALYSIS OF DESIGN CONDITIONS IS WARRANTED ONLY WHEN IT APPEARS THAT RESTORING THE FEATURES TO DESIGN CONDITIONS WOULD BE REASONABLE ALTERNATIVE (I.C. FILLING A A LOW AREA). BECAUSE OF THE NATURE OF THE VARIATIONS FROM DESIGN FOR MAPLE LAKE DAM, A "DESIGN CASE" IS NOT WARRANTED. FURTHERMORE, THE UNCERTAINTY FOR THE DEAINAGE AREA WOULD STILL EXIST.

2. PELFORM HYDROLOGIC ANALYSES FOR BOTH EXTREME VALUES FOR THE DRAINAGE AREA. FOR THIS REPORT, RATE THE SPILLWAY ADEQUACY USING THE LARGER VALUE OF 0.34 SQ. MI.

MAPLE LAKE DAM

APPENDIX F

GEOLOGY

Maple Lake Dam is located in Pike County within the Appalachian Plateau Province. The most pronounced topographic feature in the area is Camelback Mountain, which is a part of the Pocono Plateau Escarpment. The escarpment is well-defined southwestward from Camelback Mountain, but is more irregular between Camelback Mountain and Mt. Pocono, which lies to the north. Streams east of the escarpment drain directly to the Delaware River, while those to the west drain to the Lehigh River.

The Pocono Plateau Section lies west of the escarpment. This area is relatively flat, with local relief seldom exceeding 100 feet. The topography has been greatly influenced by continental glaciation. Many features were created by deposition of glacial materials. The entire plateau lacks well-developed drainage.

East of the escarpment is the Glaciated Low Plateaus Section of the province. This area is characterized by pre-glacial erosional topography with locally-thick glacial deposits. Local relief is generally 100 to 300 feet.

Bedrock units of the sections described above are the lithified sediments of offshore marine, marginal marine, deltaic and fluvial environments associated with the Devonian Period. These units include siltstones of the Mahantango Formation, siltstones and shales of the Trimmers Rock, and seven mapped members of the Catskill Formation. These members include sandstones, siltstones, and shales of the Towamensing Member; sandstone, siltstone and shale of the Walcksville Member; sandstones, siltstones and shale of the Beaverdam Run Member; sandstone and shale in the Long Run Member; sandstones and conglomerates in the Packerton Member; and sandstones and conglomerates in the Duncannon Member. Maple Lake Dam is underlain by the Walcksville Member of the Catskill Formation. The Walcksville Member is a cyclic sequence of sandstones and shales with some interbedded siltstones. Sandstones in this member are predominantly medium-to thick-bedded, well-sorted quartz grains in a clay matrix with a silica cement. Within the sandstone there are a few interbedded shale chip conglomerates. Shales occur primarily as non-fissile to sub-fissile thin beds, with some grading into siltstone. All lithologies in this member exhibit low porosity except where fractured by cleavage and jointing.

Sandstones and siltstones associated with the Walcksville Member are reported to maintain steep cut slopes. However, the shales weather rapidly when exposed. Slopes cut parallel to bedding strike may result in block slides on interbedded shales. The sandstones are good foundations for heavy structures.

Bedrock in the area is almost entirely overlain by glacial till of Late Wisconsin Age. This till is an unsorted mixture of clay, silt, sand, and gravel. It is moderately cohesive, and is derived locally from the sandstones of the Catskill Formation.

The records of foundation investigation for Maple Lake Dam indicate that bedrock at the site was overlain with 0 to 6.5 feet of the glacial till. The bedrock exposed at the site was reported to be a medium-hard sandstone with nearly horizontal bedding. The bedrock was reported to be fractured near the surface. The cutoff trench was designed to be constructed to a depth of one foot into sound rock to minimize seepage.
