                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 93<br>93<br>93<br>93<br>93<br>93<br>93<br>93<br>93<br>93                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 00000000000000000000000000000000000000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 4                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 4                                                                                                                                                                                                                                                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |   Explanation of column headings: Group consists of latitude collected (A=Atlantic) and chemical type designation, e.g. A22.76N3 is sampled at 22.760 and is the third chemical type from this locality. Long.=longitude of the type; N=number of samples which were averaged for the chemical type; R=number of analyses very close to but out-type. S=probable goologic setting: R=present or ancient Mid-Atlantic Ridge Rift Valley, FZ=fracture zone. T= type. S=probable goologic setting: R=present or ancient Mid-Atlantic Ridge Rift Valley, FZ=fracture zone. T= type. S=probable goologic S=submersible, and for DSDP cores, DSDP hole number. Approbable age of extrusive(E) samplatic anomaly age or from age of oldest overlying sediment, the latter indicated by an asterisk. E=mode from magnetic anomaly age or from age of oldest overlying sediment, the latter indicated by an asterisk. E=mode of emplacement as eruptive(E) or inrusive(I). SO=Institution or individual who contributed samples- see acknow-idgements for key to source codes. For drill cores, sequence of listing is sequence of corting, i.e., from top top bottom. երությունը է որ երենում է ուսերությունը, չարչ երությունը կարերությունը է երենությունը համարինը, չէջերնեներին, չ Հերեներությունը է ուսերությունը, չարչ երությունը, չարչ էրությունը էրեներինը համարինը, չերեներինը, չերենեներինը,

to combining the complementary advantages of drilling, diving, and dredging in the same area. The  $37^{\circ}$ N region is the only one sampled by all methods and has yielded the largest data set.

# Regional Setting and Sampling Density

With the exception of drill cores, most samples were collected from the median rift between

Fig. 1. Sample locations

254 MELSON

the equator and 30°N latitude, a distance of about 4100 km (figure 1). Sample density between the equator and 15°N is poor - 17 stations over a distance of nearly 2000 km. 9 of these 17 are within fracture zones, and the most fractionated samples (A0.93N1 and N2, table 1) in the entire collection are from one of these near St. Paul's Rocks. The largest gap in sampling, some 1150 km., occurs between 15°N and 22°N. Sample density is high between 22°N and the Kane fracture zone around 24°N: 17 stations over an along-the-axis distance of about 230 km. Between the Kane and Atlantis fracture zone, 25-29°N, sample density is again low: 8 stations over about 550 kilometers of ridge axis. Moving northward, a gap of about 600 km. exists between the Atlantis and Oceanographer fracture zones. North of the Oceanographer fracture zone, centered around 37°N and including the FAMOUS area, station density reaches a maximum: 67 stations over about 230 km. of ridge axis.

#### Relations To Previous Work on Basaltic Glasses from 0-37<sup>0</sup>N

The bottom samples obtained by ALVIN dives have been previously described in regard to their major element compositions by Bryan and Moore (1977). These samples are reanalyzed here to eliminate between-lab differences. The drill core glass analyses from Leg 37 sites near 37°N. are extensive and permit a look at thick sections of basalt at a single site. Individual analyses of these have been previously reported (Aumento et al., 1977) but here are compiled into averages for individual cooling units. Byerly and Wright (1978) have integrated Leg 37 glass analyses with whole rock analyses and recognized 'chemical types', individual units with compositions different from overlying and underlying units, and 'magma batches', inferred magma compositions serving as a parental liquid for a number of 'chemical types'. Partly using glass analyses as guides to liquid compositions, they correct analyses of slightly altered basalt back to unaltered compositions. Of special significance is their model which sorts out crustal fractionation from high pressure processes and points to an important role for clinopyroxene as an intermediate level fractionating phase or as a residual phase during mantle partial melting.

Bryan and Moore (1977) using analyses of basaltic glass as well as other data put forth a model involving a zoned magma chamber at 37°N to account for the abundance of "primitive" 11quids near the center of the median valley and of more fractionated lavas on the margins. The Leg 37 drill cores show an alternation of "primitive" and "fractionated" lavas (table 1) a view arguing against this model (Byerly and Wright, 1978) for crust formed in Pliocene time.

Basalt from the Leg 37 and FAMOUS sites have been compared (Bryan and Thompson, 1977).

The wider range in composition of the dredged and dive samples compared to Leg 37 basalt is pointed out, a conclusion also evident in the analyses of table 1. Variation trends are shown to be similar for both groups, and a parental liquid for the site 332 bacalt is suggested to have been like a young basalt from the median rift. Variations within all the 37°N group are modeled in a preliminary way using plagioclase, olivine, and clinopyroxene phenocryst compositions and crystal-liquid fractionation. Plagioclase is shown to be a dominant fractionating phase in most calculations, a view in accord with the abundance of plagioclase phenocrysts in many samples. On the other hand, olivine is normally a more common and more abundant phenocryst phase than clinopyroxene in hand specimens, and yet fractionation models relating one liquid to another require that the amount of separated clinopyroxene phenocrysts be greater than that of separated olivine. Bryan and Thompson (1977) suggest a stagnated magma chamber that was isolated from a primitive magma as a source for the site 332 basalt in contrast to the steady state magma chamber postulated to account for wider diversity and more highly fractionated marginal basalt of the present rift valley. Their different models are controversial. For example, 'primitive' and 'fractionated' basalt alternate in the deep site (332B), with fractionated basalt occuring both shallow and deep. This can be seen by inspection of the 332B glass analyses (table 1), which are arranged in "stratigraphic" sequence, top to bottom (A36.88N1, Site 332B=top; A36.88N13= bottom).

Phenocrysts whose compositions indicate that they crystallized in "primitive" liquids have been found in evolved, fractionated liquids in basalt cores from the Miocene 22<sup>0</sup>N drill cores (Dungan et al., 1978). This observation, combined with inclusions of "primitive" liquid compositions in phenocrysts (also Byerly and Sinton, 1979), suggest magma mixing beneath the mid-Atlantic Ridge, or crystal sorting in a zoned magma chamber. This phenomena is also observed at 37<sup>0</sup>N and appears to be widespread beneath the mid-Atlantic rift valley.

The deep holes drilled in Cretaceous Crust during Legs 51, 52 and 53 provided a surprisingly large amount of fresh basaltic glasses. Their analyses and interpretations have been summarized by Byerly and Sinton (1979). They conclude that these baslats are more similar to the FAMOUS basalts than to the recent Miocene basalts from  $22^{\circ}N$ , the approximate region from which they spread in Gretaceous time. They conclude that intermediate to high pressure processes involving clinopyroxene as either a fractionating phase or mantle residual phase accounts for differences in composition observed between their Cretaceous basalt and the recent to Miocene basalt from  $22^{\circ}N$  and  $37^{\circ}N$

## Characteristics of the Data Base

The analyses are limited to major and a few minor elements: Si, Al, Fe, Mg, Ca, Na, K, Ti and P, all reported as oxides, with all Fe reported as FeO.

Analyses are of glass chips from pillow lava rinds performed by an ARL 9-channel electron microprobe. A defocused beam of about 50-microns diameter at 15 kilovolts and 30-microamp beam current was used for all analyses. The large beam size practically eliminates volatilization effects. Correction and normalization procedures and an examination of homogeneity and carbon coating effects are in Melson el al. (1976) and Byer j et al. (1977).

nalyses from a given dredge station, drill site, or submersible station normally fall into one or more groups. Analyses within each group do not differ by more than the analytical precision or by pre-determined tolerances. These group recognition criteria are described in Melson et al. (1975) and are here in modified only to better handle the analyses of glasses in cored pillow lava sequences. For these, each defined chemical type differs from its overlying type in consistently different non-overlapping values for one or more of the oxides.

The data base has a distinct advantage over most in that all analyses were done in the same laboratory using identical analytical procedures. Thus, biases which typically result from different laboratories are eliminated. The number of analysed samples has increased greatly since the inception of IPOD drilling and Project FAMOUS. From 33 chemical groups in 1975, representing 176 analyses, the base has grown to 204 groups, representing 848 analyses (table 1). New relationships have emerged and old ones have been reaccessed. Phenocryst abundances and compositions are not described here. This important area of study is at present incomplete.

The specimen "library" on which the data of table one are based consist of 2.5 cm. diameter lexan discs containing ten peripheral 4 mm diameter holes, each containing polished glass chips of one unknown mounted in epoxy. A central 4 mm hole contains similarly mounted chips of one or more standards run every eleventh analysis. One of these (VG-2, USNM 111240/52) serves as an internal standard used to "normalize" each of the 10 preceding unknowns in a given run. The discs containing the samples analysed in table 1 and in the collections of the U. S. National Museum are available on loan for ion probe, additional electron microprobe and other minimally destructive surface analyses. Researches interested in obtaining chips of the analyzed samples should write those investigators who contributed the samples (see source, table 1 and acknowledgements).

#### The Two Major Cenozoic Groups

Studies of basalt between 0-37<sup>0</sup>N have so far dealt mainly with intra-region variations. The recent publication of such studies and the data of table 1 permit a look at inter-region variations. For table 1 data, the analyses fall into two major Cenozoic groups which correlate with location. Of particular importance in discrimination of these groups are Mg, Ca, Na and Ti. Relationships between Mg, Ti and Na are in figure 2. Starting at the Equator and extending to around 29°N Recent to Eocene basalt is characterized by low Mg and Ca and high Na and Ti. This group, termed here the  $0-29^{\circ}N$  group, includes dredge samples and drill cores to at least Miocene age on both sides of the median valley at  $22^{\circ}N$  (DSDP sites 395 and 396) and to at least Eocene age on the west side of the median valley (A23.42N1 and N2, table 1). The second major group, termed the 36-37°N

The second major group, termed the  $36-37^{\circ}N$  group, is characterized by higher Mg, 'a, K, and lower Ti and Na than the  $0-29^{\circ}N$  group. This group carries this signature to at least Miocene time in this area (DSDP site 335), and includes all dredge, dive and drill samples. Table 2 includes the average compositions of these two groups.

We have no samples of basaltic glass from the MAR between 29 N (Atlantis Fracture Zone) and  $35^{\circ}$ N (Oceanographer Fracture Zone). This region is the contact zone between the two above groups and thus the nature of this contact zone is uncertain based on the data presented here.

Previous work suggested that Ti and Na increased gradually between  $37^{\circ}N$  and the Equator (Shido and Miyashiro, 1973; Melson et al., 1976). Looking closely at the 0-29°N group, we find that samples from 0-15°N have subtle but significant differences compared to samples from 22-29°N. These include the highest Na (greater than 3% in types A5.92N1, A7.15N1 and 7.82N1) and highest Ti (greater than 2% in types A0.33N1, A0.93N2 and A11.02N2) contents in the entire data set. Thus, there is a suggestion of a gradient-like increase in these two elements between the Equator and  $37^{\circ}N$ .

The analyses of Shibata and Fox (1975) show that basalt from the Oceanographer fracture zone is mainly high in Na and T<sup>4</sup> and low in Ca, that is, belongs in the  $0-29^{\circ}$ N group. However, two samples of the 54 analyzed have low Ti and Na and high Ca and are close to some members of the 36-37°N group. From this work, it looks like the change between the  $36-37^{\circ}$ N and  $0-29^{\circ}$ N groups is abrupt and occurs at the Oceanographer Fracture Zone.

At about  $0.93^{\circ}N$  on the north flank of St. Paul's Rocks basalt low in MgO and high in K<sub>2</sub>O, P<sub>2</sub>O<sub>5</sub> and TiO<sub>2</sub> occurs (A0.93NI and A0.93N2, table 1). These highly fractionated basalt samples are unique among the O-37°N samples and will be discussed more fully in relationship to the Sierra Leone'hot spot!

#### Petrogenesis

Th. cocus of this paper is mainly on the definition in space and time of basalt erupted along the Mid-Atlantic Ridge. Nonetheless, a few suggestions are in order concerning genetic re-

MELSON 257

-

 $37^{\circ}N$  group is mainly higher in Ca and Mg and has lower Fe/Fe-Mg than than the  $9-29^{\circ}N$  group; i.e., is more primitive.

Some of the differences in major element composition between the  $0-29^{\circ}N$  and  $36-37^{\circ}N$  groups can be accounted for in terms of a higher diopside component in the later. Presnal (1978) studied the simplified basalt system diopside-anorthiteforsterite from 1 atm. to 7 kilobars. In this interval the first liquids in equilibrium with the 3 phases become less diopsidic as pressure increases: from 30% to 50% diopside. From this line of reasoning, it looks like the higher diopsidic component in the  $36-37^{\circ}N$  group reflects lower pressure melting of a mantle source similar in major element composition to that of the  $0-29^{\circ}N$ group. Or alternatively, more effective re-equilibration of a rising liquid in the  $36-37^{\circ}N$  region. The  $0-29^{\circ}N$  group contains a distinctive high

alumina( $A1_2O_3$  greater than 17%), high Mg, and low Na, K, Ti and si subgroup of 'primitive' aspect (A23.22N1, A24.42N1, and A28.90N1, table 1). These differences lead to a very high normative anorthite+forsterite/diopside ratio compared to all other chemical types in table 1. The high alumina type A28.90N1 was previously reported by G. D. Nicholls (1965) and attributed to partial melting of a hornblende peridotite, a view unlikely in the now documented very low H<sub>2</sub>O content of abyssal basalt from the Mid-Atlantic Ridge. We are left with explanations involving different source mantle composition (higher Al), different partial melting pressures and temperatures and/or different crystal fractionation during ascente.g. rapid ascent leading to retention of much of the plagioclase and olivine which are normally lost by near surface crystal settling and/or flotation.

The high alumina glasses from  $23^{\circ}N$  (A23.22N1, A23.42N1) are paradoxical in that although'primitive' appearing in their high MgC and low TiO (1.11%), suggesting a high degree of partial <sup>2</sup> relting, they are abnormally high in K<sub>0</sub>O, one containing 0.22%, the highest value among the 22--24°N samples. This seeming paradox also applies to the higher content of K<sub>2</sub>O in the 37°N group compared to the 0-29°N group.

# Relationships to 'hot spots'

'Hot spots' as used here are synonymous with major, centralized or elongate active volcanic regions containing unusually thick piles of lavas compared to adjacent regions. Of special importance in the context of plate tectonics are those 'hot spots' which appear to have remained relatively'anchored' or fixed compared to lithospheric plates, leaving traces of abnormal accumulations of lavas outward from the active volcanic zone. In regard to the data at hand, the Azores, Colorado Seamounts, and Sierra Leone Rise - moving successively south along the Mid-Atlantic Ridgeare of interest. These three 'hot spots' may be reflected, for example, in the higher  $K_{2}\mathrm{O}$  contents in nearby abyssal basait described here.

Basalt from 'hot spots' have a number of compositional characteristics which distinguish them from abyssal basalt erupted at considerable distances from 'hot spots' (e.g. White et al., 1978). Of interest here is K\_O, which, along with other large ion lithophile elements, is enriched in most basalt from 'hot spots'. The high K<sub>2</sub>O content of the  $36-37^{\circ}N$  group compared to the  $9-29^{\circ}N$  group may be attributed to a southward flow of Azores basaltic magma, mixing with 'normal','depleted' abyssal basaltic liquids. Such a mixing process has been speculated to be be important in this region by a number of authors, and to be reflected in light rare-earth element enrichment and in higher  $Sr^{87}/Sr^{86}$  ratios. For this case, it looks like a 'damming' of the Azore's liquids occurs at the Oceanographer fracture zone.

The proposed Colorado Seamount 'hot spot' is extrapolated to  $34^{\circ}N$  along the current ridge axis(Burke et al., 1973), the region for which we have no samples. The data of White et al., (1978) do indicate, though, that some of the lavas from the  $34 - 35^{\circ}N$  region do have hot spot' chemical characterisitics. It may be significant too that our most northerly sample in the  $0-29^{\circ}N$  group (A29.86N1, table 1) has the highest K<sub>2</sub>0 content (0.34Z) of this group.

The high K<sub>0</sub>0 content of basalt dredged near St. Paul's Rocks (A0.91N1, 0.93N1 and N2, table 1), and the light rare earth element enrichment (Frey, 1970) and mainly high  $\mathrm{Sr}^{87/86}$  (Melson et al., 1971) of St. Paul's Rocks itself may be in some way connected with the Sierra Leone Rise. Previously, the alkaline nature of the igneous rocks associatwith St. Paul's Rocks were attributed to small degrees of melting beneath a 'leaky' transform fault zone (Thompson and Melson, 1972). Such an interpretation cannot explain the high  $\mathrm{Sr}^{87}/\mathrm{Sr}^{86}$ values. The 'thermal plume' models, which in some versions involves tapping of largely undifferentiated deep mantle with high Rb/Sr, can account for this feature. St. Paul's Rocks is on the same roughly east-west trending fracture zone high which, to the east of St. Paul's Rocks, intersects the Sierra Leone Rise. St. Paul's Rocks may well include among its light-rare earth enriched, high  $\mathrm{Sr}^{87}/\mathrm{Sr}^{86}$  peridotites candidates for 'hot spot' magmas.

## Secular Variations

Two groups were erupted in Jurassic(DSDP site 105, table 2) and Cretaceous time (K-25°N, table 2) from Mid-Atlantic Ridge segments currently between the Equator and 37°N and erupting the just described two major compositional groups. The Cretaceous basalt cored on Legs 51, 52 and 53 is distinct from both the  $36-37^{\circ}N$  group and the  $0-29^{\circ}N$ groups but has affinities with the former. This Cretaceous basalt is readily distinguishable from the  $0-29^{\circ}N$  group by lower Ti and Na, which fall

MELSON 259

in the range of the  $36-37^{\circ}N$  group. This basalt was cored on sea-floor spreading flow lines now extending to about  $19^{\circ}N$  and thus show that a distinct secular change occurred in basalt composition between Eocene and Cretaceous time. There are no drill cores from basement between these ages and thus the character of this change - whether abrupt, transitional, alternating, or some other form - remains unknown. It is now clear that a great deal can be learned about the chemical signature of basalt from a given region by even a single bit or shallow hole into basement. Thus, any future DSDP Atlantic drilling could readily define the nature of this transition.

lasalt cored in Jurassic crust at DSDP site 105 may be either intrusive or extrusive. Its composition falls in the  $36-37^{\circ}N$  group. If it is an artrusive, it was erupted from the MAR segment currently erupting the  $0-29^{\circ}N$  group. This observation and the similarity of the  $25^{\circ}N$  Cretaceous group (K- $25^{\circ}N$ , table 2) to the  $36-37^{\circ}N$  group indicate, albeit weakly at present, that the high Na, Ti, low Ca, Mg  $0-29^{\circ}N$  group has successively migrated northward along the ridge axis since Mesozoic time. Additional basalt drill cores are needed to verify or disprove this suggestion.

## Relationships with Spreading Rate

The current range in sea-floor spreading half rate is about 0.6 cm/yr at  $37^{\circ}N$  to 1.5 cm/yr at the Equator around a seemingly coherent pole of opening around  $62^{\circ}N$ ,  $36^{\circ}W$  (Morgan, 1972). Correlation coefficients were calculated between individual oxide values and latitude, which correlates well with spreading rate. This exercise reveals that there is no correlation. A more interesting result is obtained by plotting the sum of TiO<sub>2</sub> and Na<sub>2</sub>O. two major discriminants for the two major Cenozoic groups, against latitude and spreading rate (figure 3). If we delete the high alumina basalt of the  $9-29^{\circ}N$  group and the high K<sub>2</sub>O basalt dredged near St. Foul's Rocks, we find a suggestion of a correlation between the minimum TiO<sub>2</sub>+Na<sub>2</sub>O and spreading rate. Finally, it is true that the region of the  $9-29^{\circ}N$  group, with the various already described chemical discriminants, is from the region with an average higher spreading rate than for the  $36-37^{\circ}N$  group.

## Summary

(1) Basalt from 0-37°N from Recent to Miocene age show a diversity of compositions reflecting well-documented effects of different parental mantle source compositions, high to low pressure fractional crystallization of plagioclase, clinopyroxene and olivine, and magma mixing. Nonetheless, the basalt major and minor element compositions fall into two distinctive groups which correlate with latitude intervals. Chemicals discriminants among the nine elements reported here are:

260 MELSON

## 0-29°N: High Na<sub>2</sub>0, TiO<sub>2</sub>, low CaO, high P<sub>2</sub>O<sub>5</sub>. low K<sub>2</sub>O 36-37°N: Low Na<sub>2</sub>O, TiO<sub>2</sub>, P<sub>2</sub>O<sub>5</sub>, high CaO, K<sub>2</sub>O, MgO

「「「「「「」」」という

1

1

(2) The contact zone between these two groups appears to be at the Oceanographer fracture zone (35°N) and may be abrupt. This contact may have migrated northward from at least 22°N since the Jurassic based on basalt core compositions from the western Atlantic.

(3) Basalt in the deep drill cores in Cretaceous crust on flow lines from 0-290N form yet another distinctive group. This group is closer to the 36-370N group but has lower MgO. Compared to the 0-290N, it has higher CaO and lower TiO<sub>2</sub> and Na<sub>2</sub>O.

(4) Higher  $K_20$  (and possibly coherent U and Th values) may reflect the effect of the Azores 'plume' in the 370N group. The otherwise more primitive aspect of this group compared to the 0-290N may reflect more extensive pelting due to a higher abundance of radiogenic heat sources in the mantle beneath the Azores platform.

(5) Maximum K<sub>2</sub>O values in abyssal basalt occur near St. Paul's Rocks and may be a reflection of ongoing activity of the postulated Sierre Leone, on St. Paul's Rocks 'thermal plume'.
(6) Each magma type in table 1 is the end

result of a long chain of processes including: (1) parent mantle composition and pressure and temperature intervals and times of partial fusion, (2) subsequent rise of partial melt and consequent "wall rock" interactions and high to intermediate pressure crystal-liquid fractionacion, and (3) low pressure near surface (magma chamber) crystal-liquid fractionation, and (4) mixing with magmas wich different histories and compositions at any stage in the processes. Thus it is expected and observed that most individual glasses f.om single erupted cooling units are commonly unique in regard to one or more elements, to combinations of elements, or to radiogenic isotope ratios. Thus, it not surprising that the search for simple explanations for the diversity of compositions is a frustrating one. It is nonetheless important that the search continue if we are to understand the processes of magma origins and their relationships to the mechanics of spreading centers.

#### Acknowledgements

Volcanic glass samples were contributed by numerous institutions and individuals as follows and indicated in table 1:  $W = \Box_n ods$  Hole Oceanographic Institution through Geoffrey Thompson, Wilfred Bryan and Vaughan Bowen; D = Office of U. S. Naval Research through Peter Vogt and Leonard Johnson, V = from Tjeerd Van Andel now at Stanford University, I = Deep Sea Drilling Project; L = Lamont-Doherty Geological Observatory; S = Anatol Sharaskin; M = University of Miami through Elba and Jose Honnorez, Enrico Bonatti, and Martin Perlmutter; T = University

of Texas through Robert Scott. At the U.S. National Museum, Eugene Jarosewich, Charles Obermeyer and Joe Nelen assisted with the electron microprobe analyses and wet chemical analyses of standards and Richard Johason prepared the polished grain mounts. We gratefully acknowledge all this assistance.

Abstract. The spatial and temporal control provided by recent drilling into the volcanic basement of the Atlantic Ocean, in combination with integrated petrologic and geochemical studies, has afforded new insights into the volcanic processes occurring along mid-ocean ridges. Several lines of evidence indicate that a specific, rather well-defined, "primitive" magma type, characterized by high atomic Mg/(Mg+Fe) values (0.70-0.72), high CaO (12.0-13.5%) and MgO (10%) contents, and low TiO<sub>2</sub> (0.6-0.9%) Na<sub>2</sub>O (<2.0%) and magmaphile trace element (Sm 6-8xch.) abundances, may well be a primary, mantle-derived melt, pare stal to other, more abundant, evolved ocean-floor basalts. Basalts such as these have beer sampled directly at only a few localities, but ...ere is abundant i direct evidence, such as phenocryst compositions, melt inclusion data, and glass and wholerock compositional trends, attesting to their importance in ocean-floor baselt petrogenesis. We believe .at more evolved basalts are derived from thes "primitive" melt compositions by a combination of crystal fractionation and magma mixing. "Primitive" magma is repeatedly injected into a wayma chamber and mixed with a more evolved consaugrineous magma that has fractionat. - fr m previous episcdes of injectics and mixing. This "steady-state" voiel results in the reneration of volumin '13 mode stely evolved . leiitcs, without the necessaty of large magma chambers, and accounts for several enigmatic features of ocean-floor basalts not readily exprained by crystal fractionation trouggles alone. These include: difficulties frequents; encountered in accempts to relate spatially associated basalts to a common r rental magma; the necessity to invoke pyroxene-dominated fractionation, when pyroxene is i minor component or is absent from the phenocryst assemblage; magmaphile element abundances in the evel to basalus that are higher than those predicted solely from crystal fractionation processes;

Mg'-value = mol. prop. Mg/(Mg+Fe) after adjusting Fe<sup>+3</sup>/total Fe as Fe0 = 0.1. 262 RHODES and nickel values that are too high for the amount of fractionation deduced from magm.phile element abundances. This model successfully predicts that both "primitive" and highly differentiated basalts and silicic derivatives will be rare and that moderately evolved basalts should 'ominate layer 2 of the oceanic crust. Gabbroic derivatives of these evolved magmas should be volumetrically important in layer 3, whereas olivine-rich cumulates, troctolites and hely iron-enriched gabbros would be less significant.

## Introduction

Petrologica; and geochemical studies of oceanfloor basalts have benefited substantially from an energetic sampling program within the last decade, and in particular from the spatial and temporal control provided by a combination of drilling into the oceanic basement and detailed sampling by dredge and submersibles along segments of mid-ocean ridges. It is now widely recognized, tellowing O'Hara (1968), that the vast majority of ocean-floor basalts sampled to date are of an evolved nature. That is, their compositions have been modified from those of primary wagnas generated by partial melting within the mant', both en-route to, and during emplacement on t. sea floor. Evidence for this is provided by: (1) petrographic observations, supported by experimental studies, showing that most ocean-floor basaltic liquids are multiply saturated, and that their compositions are controlled by the lowpressure olivine-plagioclase corectic, or olivineplagioclase-cliropyroxene peritectic (e.g., O'Hara, 1968; Kay et al., 1970; Shido et al. 1971; Frey et al., 1974; Bryan et al., 1976; Durgan et al., 1978a; Bender et al., 1978). Mg'values" for basaltic liquids clustering about 0.60 (Figs. 1,2) that are too low for inferred primary mantle derived melts (Green, 1970; O'Hara et al., 1975) and inply substantial olivine fractionation; (3) Ni abundances commonly less than 200 ppm, again indicating olivine fractionation (Sato,

1977); (4) the presence of small negative Eu anomalies in some basalts, especially those with high magmaphile element abundances (Kay and Hubbard, 1978), suggesting extensive (>25%) plagioclase fractionation.

The nature of the evolutionary process is not yet clearly understood, and is a fundamental problem in ocean-floor basalt petrogenesis, with important implications concerning the nature and composition of the oceanic crust and volcanic processes occurring along mid-ocean ridges. For example, consider the following potential but not mutually exclusive possibilities: (1) the evolved basalts that dominate the samples obtained from the oceanic basement may be derived from more "primitive," possibly primary basalts, by crystal fractionation at shallow levels in the crust. If this is the case, then as much as 40 to 50 percent of the magma must solidify to produce the commonly observed varieties of ocean-floor basalts (Bender t al., 1978), with the consequence that huge

olumes of "primitive" magma are required beneath spreading ridges, either in large magma chambers cr within vast interconnecting conduits of dykes, sills and laccoliths, etc. A further requirement of this model is that the cumulates so formed will be dominated by early crystallizing olivine and plagioclase. If layer 3 of the oceanic crust is composed in part of the coarsly crystalline derivatives of basaltic magmas, and their metaphorphosed equivalents (e.g., Dewey and Kidd, 1977),

then dunites and troctolites, with mineral chemistries reflecting the "primitive" nature of the parental magma, should form a substantial component of this layer. (2) If, however, fractionation occurs within the mantle close to the source, possibly at depths of around 25-30 km, there is no compelling reason for the presence of large magma chambers beneath the ridges. The evolved basalts could be derived directly from mantle depths, or could have accumulated in small magma chambers and conduits prior to eruption. If this is the case, then lage 3 should differ substantially from that proposed for the previous model, being dominated by gabbros containing plagioclase, olivine and pyroxene with compositions reflecting the evolved nature of the parental mag.a. (3) A third possibility involves magma mixing, where "primitive" mantle-derived magma is repeatedly injected into a shallow magma chamber and mixed with an evolved, consanguineous magma that has fractionated from previous episodes of injection and mixing (O'Hara, 1977; Rhodes et al., 1978). Again, there is no necessity for large magma chambers beneath the ridges, and gabbroic derivatives are expected to dominate in layer 3 rather than the dunitic and troctolitic derivatives of the first model.

It is the purpose of this paper to explore these evolutionary models and their implications, emphasizing in particular the .ole of magma mixing. Although magma mixing has been largely ignored by petrologists in recent years (c.f. Carmichael et al., 1974) it is becoming increasingly evident, following the work of Wright and colleagues (Wright and Fiske, 1971; Wright, 1973), Anderson (1976) and O'Hara (1977) that it is an intrinsically plausible phenomenon in volcanic processes. In view of the tectonic regime of ocean-ridge volcanism, where magma is being constantly generated and replenished along a narrow zone of activity, it appears likely that new batches of magma will be intruded prior to the solidification of previous magma batches, and therefore that magma mixing is to be expected. Fur- termore, we believe that magma mixing may explain several enigmatic features of ocean-floor basalt petrogenesis not readily understandable in terms of crystal fract onation processes along.

## The Nature of Primary Magmas

Before evaluating the processes of basalt evolution it is desirable to discuss the nature of the primary, mantle-derived melts from which the evolved ocean-floor basalts might be derived. Inspection of Figures 1 and 2 shows that, although the majority of ocean floor basaltic glasses have Mg'-values of about 0.60, a few have higher values, between 0.76 and 0.73. These are the most "primitive" basaltic <u>liquid</u> compositions identified to date. There are no basaltic glasses with Mg'values higher than 0.73, and rocks with higher values invariably show signs of olivine accumulation. Mg'-values between 0.70 and 0.73 are compatible with the most forsteritic olivine

RHODES 263

Figure 2. MgO-FeO\* relationships showing the field for ocean-floor basaltic glasses and selected basalts discussed in the text. Samples F, S, N are primitive basalts respectively from the FAMOUS area (Langmuir et al., 1977), South Atlantic (Frey et al., 1974), North Atlantic (Rhodes and Rodgers, 1972). Samples 1, 2, 3 and 4 are aphyric basalts with olivine on the liquidus, and samples 5, 6 and 7 are also aphyric but with both olivine and plagioclase on the liquidus. Samples 1 and 2 are from the North Atlantic, 45°N (Rhodes and Rodgers, 1972), 3 and 4 from DSDP Site 395 (Rhodes et al., 1978), and 5, 6 and 7 from DSDP Site 396 (Dungan et al., 1978b). The dashed lines indicate Mg'-values from 0.5 to 0... 011vine and clinopyroxene fractionation trends from two "primitive" basalts ( $\Gamma$ ,N) are shown in 2 and 10 percent intervals respectively. Plagioclase fractionation will follow the constant Mg'-value lines. Data for the basaltic glass field are taken from Frey et al., 1974; Melson et al., 1976; Bryan and Moore, 1977; Langmuir et al., 1977

phenocryst cores (Fog<sub>0</sub>) found in ocean-floor basalts, assuming  $K^D$  between 0.27 and 0.33 for olivine-melt partitioning (Roeder and Emslie, 19/0), and correspond closely with values predicted for primary magmas derived by partial melting of mcdel mantle compositions (Green, 1970; 0'Hara et al., 1975; Bender et al., 1978). Sato (1977) and Hanson and Langmuir (1978) predict that primary ocean-floor basaltic magmas in

264 RHODES

equilibrium with olivine-bearing model mantle compositions should contain about 240 to 300 ppm Ni. This is precisely the range found for oceanfloor basalts with Mg'-values between 0.70 and 0.73 (Bougault and Hekinian, 1974; Frey et al., 1974; Langmuir et al., 1977; Rhodes, unpubl. data). On the other hand, the majority of evolved basalts contain less than 200 ppm Ni (Kay et al., 1970), and those with over 300 ppm show signs of olivine accumulation (Blanchard et al., 1976; Rhodes unpubl. data) and do not reflect liquid compositions.

An important aspect of these "primitive" basaltic glass compositions is that, in addition to the high Mg'-values, between 0.70 and 0.73, they have many compositional characteristics in common, and it appears possible to place relatively tight constraints on such "primitive" ocean-floor basalt magma compositions (Rhodes and Dungan, 1977). All are characterized by low TiO2 (0.6-0.9%), Na20 (1.7-2.1%) and magmaphile trace element abundances (e.g., Sm = 6-8xch.), and by high MgO (=10%) and Ca0 (12.0-13.5%) contents and Ca0/A1203 (0.75-0.85) ratios. Figure 3 illustrates the way in which the TiO<sub>2</sub> contents of basaltic glasses con-verge at these high Mg'-values towards a welldefined compositional apex. This is an important observation, bearing on subsequent discussion of basalt evolution, and it must be emphasized that there are no recorved examples of ocean-floor basaltic liquid compositions with Mg'-values greater than 0.70 and TiO2 contents above 1.0 percent.

Basalts with the above compositions are rare, but have been identified at several dispersed localities in the Atlantic Ocean (Rhodes and Rodgers, 1972; Frey et al., 1974; Bougault and Hekinian, 1974; Bryan and Moore, 1977), and typical analyses are given in Table 1. Although

 Watson (1976) interpolated from melt inclusion data.

uncommon, there is indirect corroborative evidence in phenocryst and melt inclusion data attesting to their importance in ocean-floor basalt petrogenesis. As noted earlier, the maximum observed forsterite content of Fogo for olivine phenocrysts in ocean-floor basalts is appropriate for crystallization from a primary magma having Mg'-values between 0.70 ind 0.75. Similarly, Sato (1977) showed that the maximum Ni content of 0.41 percent observed in olivine phenocrysts from ocean-floor basalts is compatible with crystallization from a primary melt immediately following segregation from mantle peridotite. Olivines with such Ni abundances should 'rystallize from basalt magmas containing about 2'0 ppm Ni (Hart and Davis, 1978; Irving, 1978), providing, as suggested above, the MgO content is about 10 percent. Similar relationships also hold for plagicclase phenocrysts. M'crophenocryst data from besaltic glasses, tog..her wit .. experimental melting studies of appropriate compositions, and theoretical calculations based on plagioclase-melt equilibria, all

indicate that plagioclase in equilibrium with common ocean-floor basaltic melts rarely exceeds Ango. Yet many phyric ocean-floor basalts contain plagioclase phenocrysta with complex zoning patterns that are frequently accompanied by compositional breaks and cores that are too anorthitic (Ang4-92) to be in equilibrium with melts appropriate to the whole-rock composition (Donaldson and Brown, 1978; Rhodes et al., 1978). We infer that these refractory cores crystallized from more "primitive" melts, such as the primary magma compositions under discussion, prior to episodes of magma mixing. Evidence supporting this argument comes from experimental melting studies on a single sample of this type (Bender et al., 1978), and from calculations of plagioclase compositions in equilibrium with the proposed primary magma compositions (Table 1), using the expression developed by Drake (1976) for plagioclase-melt equilibria and crystallization temperatures extrapolated from melting studies. The range varies from Ang2 to Ang7 and is in reasonable agreement with the observed phenocryst compositions.

Several authors (Watson, 1976; Donaldson and Brown, 1978; Dungan and Rhodes, 1978) have attempted to deduce the composition of primary ocean-floor pasaltic magmas from compositions of melt inclusions in olivine, plagioclase, pyroxene and spinel phenocrysts. A variety of approaches, ranging from direct measurement to extrapolations attempting to compensate for entrapment at various stages of magmatic evolution, and for reaction with the host mineral, reveal certain welldefined characteristics. All the proposed primary magua compositions have high Mg'-values, about 0.7 or greater. All have low  $TiO_2$  (<1.0%) and  $Na_2O$ (<2.0%) contents and are high in CaO (>12%), with high Ca0/Al203 ratios. In other words, they have strong compositional similarities to the primary magma compositions discussed earlier in this section. Several examples of these malt inclusion compositions are also included in Table 1.

Thus, on the basis of a variety of information, including phenocryst compositions, melt inclusion data, and glass and whole-rock chemistry, it appears that the most "primitive" basaltic compositions identifiable to date from the ocean floor have many striking characteristics in common (Table 1). These include high Mg'-values (0.70-0.73), Ni concentrations between 250 and 300 ppm, high CaU contents (12.0-13.5%), and low TiO<sub>2</sub> (<0.9%), and Na<sub>2</sub>O (<2.18%) and magmaphile element abundances. There is compelling evidence to believe that such compositions, perhaps modified by small amounts of olivine fractionation, are close to those of primary ocean-floor basaltic magmas. This is not to imply that there is only one such composition. Others have been proposed (Bryan, 1978), and it is abundantly clear that, although there is close similarity in major element chemistry, there is no such coherence in trace element and isotopic abundances, (Table 1). Such differences are presumed to reflect heterogeneity in the mantle source, or in the magma generating pro-

RHODES 265

cesses (Langmuir et al., 1977). Despite these caveats, we believe that the wide geographic distribution of these "primitive" magma compositions, coupled with the diverse lines of evidence for their existence, attests to their importance in ocean-floor basalt petrogenesis, and makes them a suitable starting point for the discussion of the evolution of ocean-floor basalts.

# Evolution of Ocean-Floor Basalts

Once a basaltic melt has segregated from its mantle source, the composition may be modified by a variety of processes, including crystal fractionation within the mantle at high to moderate pressure, and crystal fractionation at shallow depths in magma chambers, conduits, or during extrusion on the sea floor. In addition to these, there is the added complication that successive magma batches may be mixed, probably in shallow magma chambers beneath mid-ocean ridges.

Petrographic and compositional data provide strong evidence for low-pressure crystal fractionation, dominated by olivine and plagioclase, in ocean-floor basalts. These minerals constitute the prevailing phenocryst phases (Shido et al., 1971), and basaltic glass compositions follow a narrow trend, apparently controlled by the olivineplagioclase cotectic (Bryan et al., 1976). Experimental melting studies at 1 atm. confirm these observations, demonstrating the importance of olivine and plagioclase as the early crystallizing phases, and the significance of the olivineplagioclase cotectic to ocean-floor basalt petrogenesis (Kushiro, 1973; Fujii and Kushiro, 1977; Dungan et al., 1978a; Bender et al., 1978). Again supporting petrographic evidence, these studies show that pyroxene crystallizes late, anywhere from 40-130°C below the liquidus. depending on the bulk composition. Trace element data are broadly commensurate with the petrographic and experimental conclusions, in particular the depletion in Ni with increasing differentiation and the development of negative Eu-agonalies in otherwise unfractionated rare-earth satterns (Kay et al., 1970; Schilling, 1971; Frey et al., 1974). Figures 2 and 3 illustrate the necessity for coprecipitation of plagioclase and olivine to generate the trends found for ocean-floor basaltic glasses. However, it is important to note that extremely large amounts of crystallization are required for a primary magma of the type discussed earlier to achieve typical ocean-floor basalt compositions solely by crystal fractionation. This varies from about 40-60 percent for the majority of basyles, to 60-80 percent for the high Fe0-TiO2 las its (FeTi basalts of Melson et al., 1976) common in the Pacific.

In early studies of ocean-floo. basalts there was no <u>a priori</u> reason why samples from dredge hauls or shallow drill biles in the volcanic basement, separated by <u>a</u> all or by hundreds of km, should be related to common parental magmas or even similar magma-types. Consequently, it was

266 RHODES

difficult to evaluate the evolution of these basaltic magmas, except in a general sense.

The advent of crustal drilling during the IPOD program, and commensurate detailed studies of a segment of the mid-Atlantic ridge by the FAMOUS project, enabled more in-depth studies to be undertaken. From these studies it is clear that magma is erupted onto the sea-floor in discrete, chemically distinct units. They may be of wide areal extent (Brvan and Moore, 1977), and can attain thicknesses of up to 200 m (Rhodes et al., 1978). These magmatic units may contain many separate individual cooling units, yet they are generally chemically homogeneous, with little evidence of internal differentiation.

Since, at a specific sampling locality, these magmatic units are closely associated in space and time, have probably derived from the same mantle source, and presumably shared the same plumbing system, it might reasonably be expected that they are comagmatic, having episodically erupted onto the sea-floor during continuing differentiation of a common parental magma. Detailed studies show that this is not often obviously the case (e.g., Blanchard et al., 1976; Hekinian et al., 1976; Rhodes et al., 1976; Bryan and Moore, 1977; Langmuir et al., 1977; Rhodes et al., 1978). The dilemma is that it is rarely possible to relate associated magmatic units to one another, to a common parental magma, or to hypothetical primary magmas of the type discussed earlier solely by crystal fractionation processes employing the observed phenocryst phases. Frequently, the magmaphile element content of the more evolved unit is higher than that predicted by crystal fractionation models, or, contrary to petrographic evidence, extensive clinopyroxene fractionation appears to be necessary.

# The Clinopyroxene Problem

We have noted earlier that petrographic evidence, supported by 1 atm. melting studies, indicates that clinopyroxene is subordinate to plagioclase and olivine during low-pressure fractionation of ocean-floor basalts. However, clinopyroxene figures prominently in crystal fractionation models for ocean-floor basalts (Clague and Bunch, 1976), and in order to relate associated magmatic units by crystal fractionation, it is frequently necessary to include clinopyroxene as a major fractionating component, along with plagioclase and/or olivine, even though pyroxene is not present, or is clearly subordinate in the phenocryst assemblage (Thompson et al., 1976; Bryan et al., 1976; Bryan, 1978). This is because there is a tendency for the CaO/Al203 ratio to decrease with increasing differentiation (Figure 4). Two specific examples are shown in Figure 4, one from DSDP Site 396 (Dungan et al., 1978o) and the other from a single dredge haul at 45°N on the mid-Atlantic ridge (Rhodes and Rodgers, 1972). The 396 samples are successive aphyric basalt units with olivine and plagioclase microphenocrysts, whereas the 45°N

Figure 4. The relationship of  $CaO/Al_2O_3$  and TiO<sub>2</sub> content of ocean-floor basalts to crystal fractionation. Symbols and source of data are the same as in Figure 2. Olivine, plagioclase and clinopyroxene fractionation trends from a hypothetical primary magma composition (see text) are shown in 10 percent intervals.

samples are aphyric basalts with only olivine on the liquidus. Since only clinopyroxene can effect a reduction in the CaO/Al203 ratio, it follows that both examples require substantial clinopyroxene fractionation in order to derive the evolved units from the more primitive ones. Thus, it appears that, despite petrographic evidence to the contrary, chemical arguments demand that clinopyroxene has participated in the fractionation process, if the associated basalts are indeed comagmatic, and not derived from separate primary magmas that have retained their integrity through subsequent fractionation, emplacement and eruption. How can these seemingly conflicting arguments be resolved? One possibility is that clinopyroxene fractionation may occur within the mantle at moderate to high pressure where it will be the liquidus phase (Kushiro, 1973; Fujii and Kushiro, 1977; Bender et al., 1978), followed by olivine and plagioclase fractionation at or near the surface. Donaldson and Brown (1978) describe pyroxene megacrysts which may be unstable relicts of former clinopyroxene crystallization, and Bender et al. (1978) suggest that clinopyroxene microphenocrysts or xenocrysts that are minor (<1%) but widespread constituents of ocean-floor basalts (Bryan, 1978), and are characteristically lower in the ferrosilite component than groundmass pyroxene, may be evidence of a prior history of high pressure pyroxene fractionation. Consequently, the ocean floor basalt trends in Figures 2-4 could reflect an initial stage of clinopyroxene fractionation in the mantle shortly after segregation, followed by low-pressure cotectic fractionation of olivine and plagioclase in the crust, which is followed in turn by peritectic fractionation of olivine, plagioclase and clinopyroxene in the more evolved magmas. Although this process is appealing as a mechanism for producing an imprint of clinopyroxene fractionation in magmas that have only olivine or olivine + plagioclase as liquidus phases, Sc abundances in ocean-floor basalts (Frey et al., 1974), commonly in the range of 35-45 ppm, seem to preclude significant amounts of highpressure clinopyroxene fractionation. The specific examples plotted in Figures 2-4 have Sc concentrations of  $38 \pm 2$  ppm, thus placing even tighter constraints on clinopyroxene fractionation. The effective distribution coefficient for Sc in ocean-floor basalts appears therefore to be close to unity, suggesting that the clinopyroxcne fractionation necessary to account for the decrease in CaO/A1203 with differentiation has occurred at low-pressures, accompanied by coprecipitation of plagioclase and olivine.

Rhodes et al. (1978) have suggested that the compositional imprint of clinopyroxene fractionation on basaltic magmas crystallizing only olivine and plagioclase can be produced by magma mixing. This process is illustrated schematically in Figure 5 by means of the ternary system forsteriteanorthite-diopside. Consider a primary magma (P) fractionating within a shallow magma chamber. Olivine will crystallize first, followed by olivine and plagioclase along the cotectic, until plagioclase, oli-ine and clinopyroxene crystallize together from an evolved magma at the peritectic (E). If a new batch of primary magma is injected into the magma chamber, it will mix with the evolved magma to produce a magma such as M, somewhere on the line P-E. The mixed magma (M) will crystallize olivine until it reaches the plagioclase-olivine cotectic, at which point it will follow a crystallization path similar to that above, and the whole cycle may be repeated many times. The important point is that although the mixed magma (M) has only olivine on the liquidus, its bulk chemistry will bear the imprint of the preceding episode, or episodes of clinopyroxene, plagioclase and olivine fractionation. According to this model, the examples shown in Figures 2-4 are mixed magmas resulting from the injection of "primitive" melts, close to the primary magma compositions, into magma chambers containing highly fractionated magmas similar to high FeTi basalts.

#### The Magmaphile Element Problem

A common problem in modeling the crystal fractionation of an assumed parental basaltic magma to produce its evolved derivatives is that the magmaphile element content (TiO<sub>2</sub>, P<sub>2</sub>O<sub>5</sub>, K<sub>2</sub>O and trace elements) of the more evolved basalt is frequently higher than the values predicted by the fractionation model using linear least squares mixing calculations (e.g., Bryan et al., 1976; Bryan and Moore, 1977). In other words, there is a distinct discrepancy between the extent of fractionation calculated from major element data

RHODES 267

hatik in duttion

± e

5)

11

Figure 5. Schematic representation in the system forsterite-diopside-anorthite of fractionation of a primary magma (P) to an evolved magma (E), followed by magma mixing, and the subsequent fractionation path of the mixed magma (M).

and that deduced from the increase in magmaphile elements in the evolved basalt relative to their abundance in the parental basalt (Anderson and Greenland, 1969). Where discrepancies occur, the magmaphile element sbundances nearly always provide the higher estimate.

In part, this is due to the calculation used: the magmaphile element abundances are logarithmically related to fractionation and will tend to be higher than the estimates based on linear mixing calculations. However, this is not the entire explanation, and we believe the excess in magmaphile elements in the more evolved basalt results from magma mixing processes (Rhodes et al., 1978). This is shown in Figure 6, where TiO2 content is plotted against the amount of crystallization necessary for a hypo netical primary magma, similar to those proposed earlier (SiO<sub>2</sub> = 49.9, TiO<sub>2</sub> = 0.7, A1203 = 16.1, Fe0\* = 7.7, Mg0 = 10.1, Ca0 = 13.1,  $Na_20 = 1.9$ ,  $K_{20} = 0.1$ ), to produce a derivative magma composition. Crystal fractionation curves for olivine, plagioclase and clinopyroxene have been calculated using the TiO<sub>2</sub> distribution coefficients of Bougault and Hekinian (1974). It is readily apparent from this diagram that a mixed magma involving, for example, the primary melt and an evolved basalt resulting from 70 percent fractionation, will have a much higher TiO<sub>2</sub> content than an equivalent basalt derived solely by crystal fractionation processes. This diagram also shows the average Mid-Ocean Ridge Basalt composition given by Melson et al. (1976), and the field for ocean-floor basaltic glass compositions taken from the same source (see Rhodes et al., 1978 for computational details).

268 RHODES

The mid-ocean ridge basalt average plots well above the crystal fractionation curves, as do many of the abyssal basaltic glasses, suggesting either that many ocean-floor basaltic compositions result from a combination of crystal fractionation and magma mixing, or that the primary magma composition used in the model is inappropriate for the majority of ocean floor basalts. We do not believe the latter to be the case, for reasons discussed earlier, and also because: (a) the lower boundary of the basaltic glass field closely mimics the fractionation curves, a necessary condition if this model is realistic; (b) the basaltic glass field converges towards the hypothetical primary magma composition, tending to confirm the composition used; and (c) "primitive" basaltic glass compositions with TiO2 contents greater than 1.0 percent are not known.

An analogous but more acute example of the discrepancy in estimates of crystal fractionation is found in attempting to compare estimates of crystal fractionation based on mag\_aphile elements with those based on a highly compatible element such as Ni. The most striking discrepancies are found in those basalts that appear to have undergone only olivine fractionation, with Ni abundances much higher than the magmaphile elementbased estimates of olivine fractionation would suggest. Consider three basalt types, samples from a single dredge haul on the mid-Atlantic ridge at 45°N, with the following chemical characteristics:

|      |     | Mg'-value | <u>TiO<sub>2</sub> (%)</u> | Ni (ppm) |
|------|-----|-----------|----------------------------|----------|
| Туре | 111 | 0.73      | 6.81                       | 249      |
| Type | II  | 0.71      | 1.00                       | 240      |
| Туре | I   | 0.64      | 1.34                       | 197      |

The Type III basalts have the chemical characteristics of primary magma, and since all three basalt types have only olivine as the liquidus phase, it seems reasonable to suggest that they may be comagmatic, related only by olivine fractionation. Inspection of the data shows that this cannot be, the increase in TiO<sub>2</sub> ( $D_{TIO_2}^{TIO_2}$ 0.04) requires about 40 percent crystallization, whereas the decrease in Ni is commensurate with only 2 percent olivine fractionation  $(D_{Ni}^{OL})$ 12). This problem is illustrated in a general sense in Figure 7, where the 45°N data are plotted with respect to four fractionation curves calculated from a hypothetical primary magma. Also plotted are average analyses of aphyric basalts containing only olivine microphenocrysts from DSDP Site 395 (Rhodes et al., 1978) and examples of potential primary magmas. The position of the sample points relative to the lowermost olivine fractionation curve illustrates the problem, indicating that the 45°N samples cannot be interrelated nor can any of the basalt types be derived from the hypothetical primary magma, simply by olivine fractionation. Thus, either each basalt type is derived solely by olivine fractionation

Figure 6. Effects of crystal fractionation and magma mixing on the  $TiO_2$  content of ocean-floor basalts. Olivine, plagioclase and clinopyroxene fractionation curves for a hypothetical primary magma are shown, together with possible mixing trends. The average mid-ocean ridge basalt (MORB) is taken from Melson et al. (1976) and the field for abyssal volcanic glasses from the same sources as Figure 2.

from its own distinct primary magma, or these basalts result from mixing of "primitive" or primary magmas with more evolved magmas in the manner illustrated in Figure 5.

If these basalts are derived from distinct primary magmas directly by olivine fractionation, inspection of Figures 2, 3 and 7 shows that they must possess unique compositions, characterized by high TiO<sub>2</sub> (1.0-1.5%) and FeO (9.5-11.2%) contents. We emphasize that "primitive" basalts (i.e., Mg'-values >0.70) with these characteristics have yet to be identified. It is unlikely that such compositions will exist because, as was shown by Bender et al. (1978), varying amounts of partial melting of a suitable mantle source will produce magmas with relatively constant Mg'-values (0.74-0.76) and with FeO and TiO2 rarely above 9.0 and 1.0 percent, respectively. Furthermore, if the site 395 and 45°N Type I basalts are derived directly by olivine fractionation from high FeO-TiO2 primary melts with Mg'-values close to 0.70 and Ni contents of about 300 ppm, the amount of olivine crystallization required (10% and 7%, respectively) is too much for the observed Ni content (Figures 2, 7).

Consider, then, the mixing of a hypothetical primary magma (Figure 7) with basalts derived from a similar magma by a previous episod. of crystal Eractionation. In addition to the olivine trend, three other fractionation trends are shown in Figure 7. The uppermost one reflects plagioclase and olivine coprecipitation in a ratio of 4:1, with an effective Ni distribution coefficient of 2.4. Below this are two, more realistic models in which olivine crystallizes first. and is joined by

plagioclase, again in the ratio 4:1, after 4 and 8 percent of olivine crystallization. The effects of clinopyroxene fractionation once the peritectic is reached have not been considered, in part because of uncertainty concerning the onset of pyroxene crystallization, and in part because of discrepancies in appropriate values for  $D_{N1}^{Cpx/Iiq}$  (Irving, 1978). Since  $D_{N1}^{Cpx/Iiq}$  is likely to be low, between 1-3, it is unlikely that coprecipitation of clinopyroxene with plagioclase and olivine will result in drastically different interpretations of Figure 7. The point of these fractionation trends is that for reasonably realistic fractionation models Ni should be rapidly depleted, with the consequence that basalts with both high Ni and TiO<sub>2</sub> abundances are unlikely to have been produced solely by crystal fractionation, and can be regarded as mixed magmas. This is shown schematically in Figure 7, where all the basalts under discussion could have been produced by mixing the hypothetical primary magma with evolved basaltic magmas resulting from about 60-70 percent crystallization of a similar primary magma. Although the evolved end-member will most likely be multiply saturated with olivine, plagioclase and pyroxene (E, Figure 5), and be compositionally similar to FeTi basalts, the mixed magma may only have olivine on the liquidus (M, Figure 5). In reality, a single step process such as this seems unlikely. Repeated mixing of small volumes of magma, followed by moderate fractionation prior to the next mixing episode (O'Hara, 1977) will ultimately produce compositions similar to a single-step process involving a highly-evolved end member. Also, repeated episodes of mixing and fractionation will tend to buffer the Ni content at a high level, while continually increasing the magmaphile element content.

100 (P. 101)

#### Discussion

In the preceding section we have attempted to review some of the processes that may modify the composition of an ocean-floor basaltic magma following segregation from its mantle source. The arguments given are to some extent model-dependent, relying heavily on our inferences concerning the compositional characteristics of a primary magma. Several lines of evidence, including theoretical constraints, phenocryst data, the composition of melt inclusions, and bulk compositions of glasses and rocks, suggest that a specific, rather welldefined primary magma-type, although relatively rare, may be of widespread importance in oceanfloor basalt petrogenesis. Consequently, it is upon this composition\_1 type, examples of which are given in Table 1, that we base our evaluation of the processes that modify ocean-floor basaltic magma compositions.

Although the importance of crystal fractionation in ocean-floor basalt petrogenesis has long been recognized, it has become increasingly apparent, through detailed studies made possible by improved sampling, that magnatic processes at mid-

RHODES 269

Figure 7. Effects of crystal fractionation and magma mixing on the TiO<sub>2</sub> and Ni content of oceanfloor basalts. Source of data are the same as in Figure 2. Curve I--olivine fractionation only; Curves II, III--initial olivine fractionation followed by olivine-plagioclase fraction in the ratio 1:4; Curve IV--olivine-plagioclase fractionation in the ratio 1:4  $(D_{Ni}^{P1/liq} = 0.01; D_{TiO_2}^{P1/liq} = 0.04; D_{Ni}^{O1/liq} = 12;$ ol/lic

 $D_{TiO_2}^{o1/liq} = 0.04$ ).

ocean ridges are more complex than earlier studies suggested. Several commonly occurring enigmatic features cannot be explained solely in terms of crystal fractionation. These include: difficulties in relating spatially associated basalts to a common parental or primary magma; magmaphile element abundances in evolved basalts that are higher than those predicted solely from fractionation processes; Ni concentrations that appear to be too high for the amount of fractionation deduced from magmaphile element abundances; and the necessity to invoke clinopyroxene dominated fractionation, when pyroxene is a minor component or is absent from the phenocryst assemblages. The clinopyroxene anomaly may be produced by clinopyroxene fractionation in the mantle at moderate to high pressures, but the evidence is not compelling, and high pressure fractionation may only provide part of the answer. Nost of these features are, however, readily understandable in terms of a combination of crystal fractionation and magma mixing, where "primitive," possibly primary magmas are repeatedly injected into magma chambers containing evolved magmas that have fractionated from previous episodes of injection and mixing (O'Hara, 1977; Rhodes et al., 1978). Such a process explains why it is commonly difficult to relate spatially associated, and apparently comagmatic, basalt-types by crystal fractionation processes. First, differences in residence time and thermal history of the fractionating magma in the magma

chamber prior to the next mixing episode will give rise to evolved magmas with differing compositions. Mixing of these magmas with the incoming "primitive" magma, which also may be more or less fractionated than the previous batch, will produce mixed magmas that cannot be related by simple fractionation models. Second, as is evident from Figure 6, the mixed magmas will always be higher in magmaphile element abundance than magmas of similar major element chemistry produced from the same primary magma strictly by crystal fractionation. Third, the Ni contents will also tend to be higher in mixed magmas. and the Ni and TiO2 abundances will be "decoupled" (Figure 7). Fourth, the necessity to invoke fractionation models dominated by clinopyroxene when pyroxene is rarely a major phenocryst phase is readily explained. Clinopyroxene fractionation has taken place, but in the evolved magma prior to mixing with the "primitive" magma, and the resulting mixed magma bears the chemical, but not the mineralogical, imprint of this earlier process. If magma mixing, accompanying crystal fractionaalon

tion, is, as we believe, a commonly occurring process of fundamental importance to the evolution of ocean-floor basaltic magmas, what are the implications concerning volcanic processes occurring along mid-ocean ridges, and the nature and composition of the oceanic crust?

A major problem of ocean-floor basalt petrogenesis is to reconcile the apparent conflict between the vase volumetric significance of these bacalts and their evolved characteristics. Traditional models involving partial melting followed by crystal fractionation fail to resolve this discrepancy since one would expect relatively "primi-.ive" basalts to be volumetrically more important. On the other hand, a "steady state" combination of magma mixing, of the type discussed previously, together with crystal fractionation provides an effective mechanism for buffering the magma composition (O'Hara, 1977; Rhodes et al., 1978), the dominant product of which will be moderately evolved basalts. Both "primitive" basalts and highly differentiated basalts and their silicic derivatives should be rare, and observations of ocean-floor basalts (Figure 1) confirm this prediction. Because of this buffering process, there is no necessity for the existence of large magma chambers, or large magma volumes, beneath midodean ridge crests: a conclusion that is apparently in accord with recent interpretations of geophysical data (Rosendahl et al., 1976), and with models proposed for the development of the oceanic crust (Sleep, 1975; Dewey and Kidd, 1977). A further consequence of this model is that the crystalline products of this "steady state" mixing and fractionating process will reflect the evolved nature of the parental magma. For most of its history the magma will be multiply saturated, crystallizing olivine, plagioclase and clinopyroxene. It is only immediately following injection of "primitive" magma, and then only for a short part of the fractionating history, that olivine

roxon c alone will crystallize (Figure 5). If layer 3 of the oceanic crust is produced in part by the crystallization of magmas beneath mid-ocean ridges, it follows that this component of layer 3 will be dominated by gabbros, rather than the troctolites and dunites that would result from substantial crystallization of more "primitive" basalts. This suggestion is compatible with the ophiolite-based models of the ocean crust (e.g., Dewey and Kidd, 1977), and reconciles field studies with laboratory based cbservations and experiments.

Abstract. Basement rocks recovered by DSDP and IPOD drilling in the Atlantic are predominantly pillowed or massive basait lava flows which resemble modern Mid-Atlantic Ridge (MAR) basalts in their range of chemical composition and petrographic characteristics. Basalts from the oldest sites drilled (70-150 m.y.) generally resemble modern basalts presently being erupted at the locations on the MAR where these older basalts should have originated; all of these represent "normal" ridge segments unaffected by "mantle plume" activity. The Leg 37 transect drilled opposite the Azores "mantle plume" or "blob" shows evidence of some fluctuation in geochemical parameters, possibly indicating short-term fluctuations in plume activity.

Only two sites (334 and 395) have penetrated layer 3 plutonic rocks, but it is likely that these are tectonically emplaced, and the true thickness of layer 2 has not been defined by drilling. In general, the transition from sediment to basalt basement is sharp. Excellent core recovery at Sites 417 and 418 shows that pillowed and massive flows are incerbedded; dikes and sills are rare at these and other sites, but probably are hard to recognize unless core recovery is very good. Drilling at Site 417 suggests that intense low temperature alteration may be limited to topographic highs which are not immediately buried by sediment. Hydrothermal alteration and metamorphism are not encountered in the sites so far driiled.

Most DSDP and IPOD fites have not been wellplaced to indicate the persistence of "mantle plumes" with time, although north-south geochemical variations in continental triassic basalts resemble those documented for modern basalts associated with the Azores plume and suggest that such plumes may have initiated spreading in the Atlantic. Future drilling should be designed to define the persistence of such plumes in time and space, and also should attempt to penetrate the lower part of layer 2 and the upper part of layer 3 in a crustal section of normal thickness.

#### Introduction

In an earlier paper (Bryan et al., 1976), we summarized results of the Deep Sea Drilling Project (DSDP) drilling in the three major ocean basins, with special emphasis on geochemical variation in basalt glasses. At that time, surprisingly little drilling had been completed in the Atlantic, and with the exception of the Leg 37 holes, the sites had been selected with predominantly nonpetrologic objectives. Recently, deep crustal penetrations have been attempted on Leg 45, Leg 46 and the Leg 51-52-53 "megaleg". While none of the recent drilling succeeded in penetrating the layer 2 -layer 3 boundary, some excellent penetration into layer 2 has been accomplished with above-average core recovery. These new sites have added considerably to our knowledge of the stratigraphy of layer 2 and have produced examples of both the freshest and also the most altered deep ocean crust so far known among the sites drilled in crust over 100 m.y. old.

In this paper we attempt to present a summary picture of the layer 2 basement rocks in the Atlantic in terms of their variation in composition and petrographic character as a function of space and time. We have deliberatery avoided extended speculation on magnatic processes within the crust and upper mantle which may contribute to this variation. Overall, the situation does not seem to warrant serious departure from the position we took in our first paper on Atlantic DSDP basalts (Frey et al., 1974) in which arguments were presented both for significant high-level fractional

BRYAN 273

crystallation and also for melting of contrasted mantle sources in order to explain all of the geochemical variability observed in a rather limited selection of samples. The greater variety of compositions now known from the Atlantic drill holes makes it even more advisable to retain multiple working hypotheses, and enhances the probability that several processes operate at any given site. Indeed, the relative importance of each process is likely to vary from case to case, and probably can be quantitatively evaluated only through detailed study of specific sample sets, a task (or series of tasks) beyond the scope of this paper. However, we will allude to these processes as appropriate within the rather broad and qualitative perspective we prefer to maintain.

Modern dredged basalts show a considerable degree of geochemical variability which is most directly expressed in variations in some of the largeion-lithophile (LIL) elements in basalts which otherwise are very similar in their major element composition. High concentrations of LIL-elements are centered on certain geographic positions along the Mid-Atlantic Ridge, and may be marked by islands (Schilling, 1973; Hart et al., 1973; Schilling et al., 1976). Of these, the best known centers are Iceland, the Azores and Bouvet: other islands in the South Atlantic such as Ascension and Tristan da Cunha are suspected of marking similar centers. At least one other center (at 45°N latitude) is known which has no special physiographic expression. Geochemical parameters vary gradationally away from these centers, and the degree of light rare earth enrichment and strontium isotope ratios are especially characteristic (White et al., 1976; Schilling, 1975). Although the physical significance of these centers remains obscure, they are widely believed to mark the location of upwelling deep mantle which is then partially melted to yield the basalts forming the elevated ridges and islands. Because this mantle probably lies below the level from which magmas are usually extracted, it is believed to contain a much higher proportion of LIL-elements and other components which are preferentially partitioned into the magma during mantle melting, while the uppermost mantle is presumed to have been depleted in these components because of its continued involvement in magma production during earlier spreading events.

Because of these demonstrated along-ridge compositional variations, compositional variation as a function of time can only be evaluated properly if basalts at the various drill sites can be compared directly to basalts presently being erupted at the same point on the Mid-Atlantic Ridge from which these older basalts were derived. Alternatively, basalts from drill holes lying along a common spreading "flow line" may be compared. In such comparisons, allowance must be made for the effects of varying degrees of high-evel crystallization or random variations in degree of mantle melting; such comparisons are most easily made in terms of param-

274 BRYAN

eters not seriously changed by moderate differences in degree of melling or crystallization, such as isotopic ratios, ratio of light to heavy rare earths, or ratios between certain LIL elements. At present, only Leg 3 and Leg 37 have sampled systematically along spreading flow lines, and only Leg 37 data can be related directly back to a thoroughly sampled modern ridge segment. Although Legs 45, 46, 51, 52 and 53 were supposed to drill on a common flow line related to a wellsampled modern ridge segment at 22°-23°N operational considerations forced a shift of the Leg 51, 52 and 53 sites to the south, so that they correspond more closely to a poorly known ridge segment at 18°-20°N. Although we believe variations along the modern ridge are sufficiently well known to permit valid interpolations of modern compositions through this and other poorly sampled ridge segments, the limitations of such extrapolations must be recognized.

Chemical data reported here are necessarily drawn from a variety of sources, and for the most recently drilled sites (395, 396, 417, 418) it has been necessary to rely heavily on shipboard x-ray fluorescence analyses and unpublished data. We have deliberately excluded altered material and, where possible, have used aphyric samples or glasses in order that the data may represent magmatic liquids as closely as possible. To simplify graphical presentations, we have commonly plotted only site averages; but in a few cases, where withinsite variation has seemed especially significant, compositions of specific magmatic types within sites have been plotted. Most of the trace element data also represent aphyric rock or glass and obviously altered material has been excluded. Wherever possible, these data have been taken from our own papers already published or in press, and these references should be consulted for details of analytical procedures and precision and accuracy.

# Compositional Variation in Layer 2

The locations of Atlantic DSDP sites for which significant basalt penetration has been reported are indicated in Figure 1. However, for many of these sites definitive compositional data are lacking, generally because the samples are intensely weathered or because of very limited core recovery Also, data for sites drilled on the Reykjanes Ridg and in the FAMOUS area by Leg 49 were not availably to us at the time this paper was prepared. Althougthe distribution of these sites implies a rather comprehensive sampling of the Atlantic sea floor, the data are, in fact, much more limited. In the South Atlantic, only Sites 14, 15, 18, 19 and 20 have basalt of sufficient freshness for geochemical and mineralogical characterization. In the western Atlantic, data for older sea floor is similar\_y limited to Sites 10, 100, 105, 417 and 418. None of the sites in an old crust in the eastern Atlantic have provided basalt samples of adequate freshness. The only definitive near-ridge sites

Figure 1. Location of DSDP and IPOD drill sites in the Atlantic Ocean which penetrated significant amounts of basement rock. Many of these samples are badly altered or poorly recovered and provide little reliable compositional data; see text for discussion.

lie near 22°N, 31°N, and 37°N. Sampling of the deep crust is equally limited; only Sites 332, 333, 395, 396, 417, and 418 penetrated more than 200 m into layer 2. The limitations posed by this restricted sampling must be kep in mind in the discussion which follows.

Major element data can be summarized concisely in a plot of Fe0<sup>\*</sup>/MgO vs. TiO<sub>2</sub>, where Fe0<sup>\*</sup> represents total Fe as FeO (Figure 2). We prefer FeO<sup>\*</sup>/ MgO to the popular molecular Mg/(Mg + Fe<sup>2+</sup>) ratio for graphical portrayals because the XRF and nicroprobe data do not discriminate Fe<sup>3+</sup> and Fe<sup>2+</sup>, and because of the wider numerical range of the FeO<sup>\*</sup>/MgO ratio. TiO<sub>2</sub> and FeO<sup>\*</sup>/MgO also are the most variable of the major element parameters, and generally correlate well with other important major elements such as CaO, Al<sub>2</sub>O<sub>3</sub>, K<sub>2</sub>O, and Na<sub>2</sub>O. In this plot the data tend to lie within a rough parallelogram-shaped area, with the longest diagonal representing an approximately one to one variation in FeO\*/MgO with TiO<sub>2</sub>. The large dashed field encloses basalt glass data from one small area (the FAMOUS area) on the Mid-Atlantic Ridge, while the smaller dotted field and stars represent basalt glasses from the Mid-Atlantic Ridge at 23° and 22°N, respectively. Several points are made clear by this graphical plot:

1) The limited sam, es recovered by Legs 2 and 3 (Sites 10, 14, 15, 18 19, 20) span most of the range in TiO<sub>2</sub> and FeO<sup>\*</sup>/MgO represented by all the rest of the Atlantic data.

2) The low-TiO<sub>2</sub>, low FeC\*/MgO compositions from Sites 14 and 18 are relatively rare among DSDP basalts, but correspond to the more mafic compositions in the FAMOUS area and at Site 332B.

3) Sites 395 and 396 differ somewhat in their average compositions even though they were drilled in approximately symmetrical positions either side of the Mid-Atlantic Ridge; Site 295 seems to correspond more closely to the modern ridge compositions than does 396.

4) The Leg 37 sites tend toward higher FeO<sup>\*</sup>/ MgO than do FAMOUS area basalts of comparable  $TiO_2$  content.

5) The 150 m.y. old basalts from Sites 100 and 105 generally correspond to the more mafic compositions from Leg 37 and the FAMOUS area.

Figure 2. Variation in Fe0<sup>\*</sup>/Mg0 and TiO<sub>2</sub> for fresh basalt and glass from Atlantic DSDP and IPOD drill sites. Data sources for Sites 10-335 as in Bryan et al., 1976; data for Sites 395, 396, 417 and 418 are provisional, based on shiploard XRF analyses. Dredge data from Melson et al., 1968, and Bryan, 1569, outlined by short dashes; dredge data is from Bryan and Sargert, 1978.

Figure 3. Variation of total normative pyroxene, olivine, and plagioclase for Atlantic DSDP and IPOD sites. Data sources as in Figure 2.

6) Site 417 and 418 basalts tend to lie at the high end of the Fe0<sup>\*</sup>/MgO range compared to other basalts of comparable  $TiO_2$  content.

7) Overall, the compositions of basalts recovered by drilling tend to lie within or close to the range of compositions represented by submersible and dredge samples from two very limited portions of the Mid-Atlantic Ridge at 36-37°N and 22-23°N.

Remembering that these sites represent a very limited sampling of the Atlantic layer 2, the data nevertheless do suggest that these basalts vary in composition within fairly well-defined limits. The restricted range of compositions recovered by drilling at any one site are apparently subsets of a more diverse assemblage which can be generated within a short period of time and limited space at an active spreading center.

This relationship can be portrayed in an even more striking way in the normative pyroxeneplagioclase-olivine ternary (Figure 3) in which, again, most of the data lie within the field of the FAMOUS glasses. The narrow elongated composition field is suggestive of the low-pressure binary cotectic in the system diopside-anorthiteforsterite (Osborn and Tait, 1952) and implies composition control by low-pressure crystal-melt equilibria. It is interesting that very few of these basalts contain either normative nepheline or normative quartz; again, the range of compositions seems to be constrained to those which lie along this cotectic. In an earlier summary (Bryan et al., 1976) we showed that only a few glass compositions lie appreciably off this cotectic. Those few exceptions represented seamounts or other offridge extrusions, and were offset into the plagioclase field. This same effect is shown here by ridge-derived basalts from 22°N and from Sites 417, 418, and 396. Such an offset might result from a shift in the cotectic due to higher volatile cont. ts or to higher confining pressure (Dick and Bryan, 1978; Thompson, Bryan and Melson, in preparation).

We have previously shown (Bryan et al., 1976) that basalts of otherwise similar major element composition may differ considerably in concentration of large-ion-lithophile elements. This contrast can be demonstrated for the Atlantic data, in plots of Ba vs. FeO\*/MgO or in relative enrichments of light vs. heavy rare earth elements (Figure 4a, b, c).

Such large differences in LIL elements such as Ba, REE, or in Sr isotopes (Figure 4d) are generally attributed to differences in the composition of the mantle source rocks. However, as noted at individual sites (Bryan and Moore, 1977; Bryan et al., 1978; Langmuir et al., 1977) whilst incompatible and major elements vary in a systematic manner LIL elements often show a wider range in content than can be attributed to high level fractional crystallization processes. This apparent decoupling of major elements from LTL trace elements is generally attributed to variations in degree of partial melting of the mantle. Such a relation can be expected to arise because LIL elements are very strongly partitioned into liquid relative to mantle mineral phases, and the first few percent of liquid formed will contain most of these components. Further melting serves mainly to increase the proportion of major elements and heavy transition metal trace elements and effectively dilutes the concentration of LIL elements.

#### Petrography and Mineralogy

Water-quenched basalts generally are too finegrained for definitive study of mineral phases other than those occurring as phenocrysts. However, on several occasions drilling has penetrated relatively thick cooling units which display a holocrystalline, doleritic or gabbroic texture. Good coarsely-crystalline plutonic gabbro and peridotite were recovered at Site 334. These are the best examples of "layer 3"-type material so far documented by the drilling project (Hodges and Papike, 1976). These rocks also are unusual in containing amphibole, which was considered to be a secondary phase. Relatively fresh peridotite and gabbro also have been recovered beneath basalt at Site 395.

The majority of the basement rocks recovered consist of pillowed or massive basalt with varying proportions of plagioclase and olivine phenocrysts. Clinopyroxene is a significant phenocryst phase in basalts of relatively high  $TiO_2$  and  $FeO^*/$ MgO content. It is relatively conspicuous, for

Figure 4. A. Variation in chondrite-normalized rare earth data for DSDP and dredged basalts related to mantle plumes; B. Variation in chondrite-normalized rare earth elements and dredged basalts (open hatched field) from normal spreading ridges; C. Variation of Ba vs. FeO\*/MgO for Leg 37 and FAMOUS plume-related basalts (upper field) and normal ocean ridge basalts (lower field); D. Variation in  $\frac{87}{\text{Sr}}$  as a function of latitude in the North Atlantic. Data for A and B after Frey et al., 1974; 5ryan et al., 1976, 1977a, b; for C, Bryan and Thompson, 1977; Bryan and White, 1977; Frey et al., 1974; Bryan et al., 1977a, b; and for D, White et al., 1976.

example, at Sites 11, 15, 332A, 417 and 418, and is sparingly present in some basalts at Site 395. By contrast, the low  $TiO_2$ , low  $FeO^*/MgO$  basalts lack pyroxene, but commonly contain small phenocrysts of spinel.

. . . .

Several studies have shown a tendency for the relative proportions of phenocrysts to fall into fairly distinct groupings, which also can be related to overall phenocryst abundance. Dick and Bryan (1978) showed that the nearly aphyric basalts from Site 396 with less than 5% phenocrysts tended to contian olivine as the dominant phenocryst, while the phyric basalts with 10% or more phenocrysts have plagioclase as the domi.ant phase. This relationship is very similar to that reported by Bryan and Moore (1977) for the FAMOUS area. Staudigel et al. (1979a) showed that phenocryst assemblages at Sites 417 and 418 tend to fall into two distinct groups, one in which plagioclase is almost the only phenocryst, and a sacond in which significant amounts of olivine accompany the plagioclase. The presence of plagioclaseor olivine-enriched phenocryst assemblages tends to cause whole rock compositions to fall to one side or the other of the inferred cotectic line

in the normative ternary (Figure 3). Hence, the cotectic may be computed as a discriminant function between the fields of plagioclase or olivine basalt whole rock data, or may be computed as a regression line from basalt glass data. These relations seem to hold equally well for dredged basalts, as originally noted by Miyashiro et al., (1969).

Plagioclase, pyroxene, and olivine appear as euhedral microphenocrysts in basalt glasses at Site 332 (Bryan et al., 1977a). The three minerals may be closely associated in glomeroporphyritic clusters and show no evidence of a reaction relation either with the liquid or with each other. Bryan (1978) has shown that most olivine and pyroxene compositions from Site 332 and the FAMOUS area correlate with the Fe0\*/MgO ratio of their enclosing liquid as predicted from experimental data, which also indicates that both minerals are in equilibrium with the liquid. This suggests that the three-phase eutectic in the experimental system diopside-anorthite-forsterite is actually the piercing point of a three-phase cotectic in the real basalt system. Orthopyroxene and pigeonite are rare or absent in most DSDP basalts, but hypersthene and pigeonite are present as lamellae in augite in the plutonic rocks at Site 334. Hypersthene also occurs as individual crystals. Detailed description and analyses of these hypersthenes are given by Hodges and Papike (1976). Most of the clinopyroxenes in both the basalts and plutonic rocks are diopsidic augites containing moderate amounts of TiO2 and Al2O3. Aluminous chrome diopside is occasionally observed; an analysis of one of these from a basalt at Site 334 has been given by Bryan et al. (1977a). Analyses of chromian diopside at Site 11 are given by Frey et al. (1974).

Olivines typically show a limited range of composition, between Fog0 and Fog0. In the more mafic basalts, olivine usually contains inclusions of aluminous chrome spinel, and may be intergrown with plrgioclase, forming the "knot" in a "bow-tie" intergrowth. Analyses of olivines and spinels from various Atlantic sites have been given by Frey et al. (1974), Hodges and Papike (1976), and Sinton and Byerly (1979).

Plagioclase phenocrysts generally fall in the range  $An_{80}$ - $An_{60}$  and usually contain significant amounts of iron and magnesium. Bryan (1974) showed that Mg and Fe<sup>2+</sup> must be accommodated in tetrahedral sites. Many of the plagioclases are sector-zoned, suggesting rapid, possibly disequilibrium growth. Good examples have been described at Sites 11, 15 and 105, as well as in modern dredged basalts. Hodges and Papike (1976) found that in the plutonic plagioclase at Site 334 there is almost no magnesium and the iron appears to substitute as Fe<sup>3+</sup> for Al. This again suggests that the Fe<sup>2+</sup> and Mg substitution may be metastable and typical of quickly cooled pillow lavas. Thus the presence of

278 BRYAN

sector-zoning and Mg substitution in plagioclase could be important criteria for distinguishing extrusive basalt from intrusive sills or dikes in drill cores.

Although basaltic compositions predominate in all recovered Atlantic drill cores, Sinton and Byerly (1979) have reported trondjhemitic segregations within massive basalt at Site 418. These consist of sodic plagioclase, quartz, and apatite, and may have associated pigeonite. Their mode of occurrence implies that these patches are extreme differentiates of normal ocean ridge basalt.

### Stratigraphy of Layer 2

Two Atlantic sites (334 and 395) have penetrated gabbro and peridctite, thought to be typical of layer 3, beneath a relatively thin basalt capping. At Site 334, gabbro and peridotite were encountered beneath 50 meters of basalt, and at Site 395, similar lithologies were encountered beneath 57 meters of basalt. These very shallow occurrences of layer 3-type material probably are atypical, and may reflect localized diapiric intrusion of layer 3 material into layer 2 along fault planes. Such an interpretation is supported by the relatively large amount of breccia associated with these piutonic rocks (Hall and Robinson, in preparation).

Excluding these apparently anomalous cases, surprisingly little plutonic rock or intrusive dikes and sills have been encountered at other sites. The three deepest holes at Sites 332, 395 and 418 all penetrated greater than 500 m without encountering layer 3 material, and only a small amount of the basalt recovered is likely to represent intrusive sills or dikes. In general, there is a rather abrupt transition from overlying sediment to basalt; a few layers of volcanic ash or basalt breccia may appear in the sediment above the basalt contact, and small amounts of indurated sediment may be intercalated between basalt pillows. Interlayered sediment was encountered at Site 332 up to 200 m below the top of the basalt sequence. Possibly such sediment is more common than the recovery indicates, due to a tendency for it to be washed out of the core. However, distinct sediment intervals interbedded with basalt were very rare at Sites 417 and 418, where core recovery averaged about 70% in basalt basement.

Recognition of intrusive basalt units is generally based on evaluation of textural criteria, physical relations (contacts) with adjacent rock units, and comparison of chemical composition and magnetic polarity with adjacent rock units. A massive basalt unit, lacking internal quenched glassy intervals and showing an ophitic or gabbroic texture as its center is approached, may be suspected of being a shallow intrusive unit. This interpretation is enforced if the unit is chemically distinct from basalt units above and below, and if it also differs from them in magnetic polarity or inclination. Very few of the massive basalts encountered in the drilling meet all of these criteria. Probably most represent thick TABLE 1. Comparison of Geochemical Variation in Dredged Basalts From the Mid-Atlantic Ridge, 29-40°N, With Average "Normal" Mid-Atlantic Ridge Basalt (After White and Bryan, 1977 - Table 2). Maximum Values are Typical Near 40°N, Minimum Values are Typical Near 29°N.

flows, rapidly extruded and ponded on the sea floor. Dikes are very difficult to identify unless core recovery is very high and the drill fortuitously follows the dike margin for some distance. A few dikes have been recognized on this basis in Holes 417D and 418A. Possibly, massive basalts recovered in these and other holes represent the central portions of relatively thick dikes which have been followed for some distance by the drill. At Sites 417 and 418, where core recovery is sufficiently good to evaluate these possibilities, most contacts between massive basalt and pillow basalt were at a low angle and other features such as crystal settling are more compatible with a tabular, near-horizontal cooling unit. Most of the massive basalts at Sites 417 and 418 have been interpreted ar thick flows because of their generally fine-gradient and chemical and magnetic compatibility 2cent pillow lavas (Bryan, Robinson et al.,

The available evidence then suggests that layer 2 consists mainly of interbedded pillowed and massive basalt flows at least down to a depth of 500 m. At this depth some dikes begin to appear, based on very limited evidence at Sites 417 and 418. The upper several hundred meters of layer 2 (layer 2A?) may include interbedded sediment and may be more fractured and brecciated than the deeper units (layer 2B?). At the sites drilled in older crust (417, 418) induration of sediment and cementation of fractures by calcite effectively eliminates the physical distinction between 2A and 2B (Robinson and Hall, in preparation). Until deeper penetrations are achieved, we can only speculate on the nature of the crust beyond 600 m depth; but because of the persistence of extrusive basalt to the greatest depths drilled (583 m at Site 332) it is not unreasonable to suppose basalt persists to depths of 1.5 ka or more, with an increasing proportion of intrusive dikes and sills below 500 m.

#### Alteration

Previous studies of dredged pillow basalts (Hart, 1969; Hart, 1970; Thompson, 1973) indicate that the reaction of basalts with seawater at ambient bottom water temperatures results in uptake by the basalt from seawater of  $H_2O$ , K, P, Rb, Cs, U, B, and Li, and occasionally Ba and Sr. Elements leached from the rock are Si, Ca, and Mg. Elements such as Ti, Al, Zr, Y, REE are not affected unless extreme alteration occurs.

Studies of the DSDP basalts (Thompson, 1973; Frey et al., 1974) indicate that similar effects occur at depth in the basaltic layer 2. However, as indicated by such workers as Muchlenbachs (1976), Robinson et al. (1977), Aumento et al. (1977), and Bryan et al. (1977b), basalts recovered by the DSDP are not always completely altered, and fresh glass is commonly found. Recently, studies of the alteration products (Hart et al., 1979; Staudigel et al., 1979b: Muehlenbachs, 1970) indicate that alteration into the upper few hundreds of meters of layer 2 takes place predominantly in the first 10-15 million years by penetration of a limited amount of cold sea water. After that period, the system is relatively closed and only minor amounts of seawater penetrate along restricted fractures. The result is limited alteration of the upper 0.5 km of basaltic crust at low temperature. No large scale hydrothermal alteration at elevated temperatures (>100°C) of the basaltic crust has been seen in DSDP cores (although such hydrothermally altered materials are commonly dredged).

Although low temperature alteration of the oceanic crust apparently is not a major process in providing chemical fluxes between seawater and igneous basement, at least based on the observations of the majority of DSDP recovered cores, Site 417A is an exception. Donnelly et al. (1979) have shown

that alteration here proceeded in the same direction as low temperature alteration of dredged basalts and other DSDP basalts, but at slightly elevated temperatures -  $30-40^{\circ}$ C. The net effect is to increase the rate of alteration with extreme exchanges, involving large uptake of K, Rb, B and Li and concomitant loss of Mg and Ca. If Site 417A is representative of only a small percentage of the oceanic crust, then such reactions would have a major effect in chemical budgets and control of seawater composition. More drilling of oceanic crust up to 15 million years old that exists as distinct topographic highs is required to test this hypothesis.

Chemical Variations in Space and Time

Some of the trace element characteristics and ranges of the Mid-Atlantic Ridge and the segment 20-40°N are shown in Table 1. Typically the LILenriched basalts are not greatly different in major element composition or transition metal trace element contents than normal mid-ocean ridge basalts (MORB) (Bryan et al., 1976). Some of the critical diagnostic characteristics of MORB (K, Rb, Cs, Ba, U, and Sr isotopes) can be drastically affected by low-temperature alteration by seawater. The resultant uptake of these ions from seawater gives the basalt the characteristics of a LIL element-enriched basalt. The rare earth elements (REE) are not greatly affected by alteration and can be used as a discriminant, particularly the chondrite-normalized La/Sm ratio (Schilling, 1975).

Geochemical and petrographic data are now available for four sites in crust over 100 m.y. old. Site 417 and 418 are in crust about 107 m.y. old, and Sites 100 and 105 are in crust about 150 m.y. old. These latter sites approach the age of the initial opening of the North Atlantic (about 180 m.y.). In addition, basalts from Leg 3 lie along a spreading "flow line" ranging in age up to about 70 m.y., and basalts from Leg 37 also are arranged along a "flow line" originating in the FAMOUS area and range in age up to about 15 m.y. These data allow some conclusions to be drawn about both shortterm and long-term variations in composition with time, Also, the Leg 37 transect is related to a ridge segment influenced by the Azores "mantle plume", while the Leg 3 transect appears to originate at a ridge segment free of such "plume" influence. The other DSDP sites in the Atlantic typically show basalts that are characteristic of MORB except those associated with volcanic chains alkalic in character (i.e. Site 385, Leg 43) or those that occur as sills or mid-plate eruptives, such as Sites 10 and 138 which are LIL element-enriched in character (Frey et al., 1974; Wright et al., 1972). These basalts are apparently not related to spreading center activity.

Frey et al. (1974) compared the chemical and petrographic characteristics of basplts from the Leg 3 Sites 14, 15, 18, 19 and 20 and showed that, if

280 BRYAN

reasonable allowance is made for high-level fractionation and alteration effects, all of the basalts are LIL element-depleted tholeiites which are typical of the modern spreading center at that latitude '30°S). Our own data for Sites 417 and 418

Staudigel et al., 1979a) show that these sites also are relatively fractionated, LIL element-depleted basalts, characteristics which they share with basalts from Sites 395 and 396 (Rhodes et al., 1978). These characteristics are also shared with basalts at 22-23°N (Melson et al., 1968; Ludden and Thompson, 1978; Thompson et al., in preparation) and suggest that no major changes in geochemical characteristics have occurred over the past 100 m.y. at this latitude.

The geochemistry and mineralogy of basalts from Sites 100 and 105 have been discussed in considerable detail by Ayuso et al. (1976) and Bryan et al. (1977b). These basalts are mineralogically and geochemically comparable to modern ocean ridge basalts erupted beyond the influence of "mantle plumes", a relation that is compatible with a projection of these sites along spreading flow lines to their points of origin on the Mid-Atlantic Ridge. Bryan et al. (1977b) showed that these oldest Atlantic basalts are contrasted geochemically with the continental basalts of nearly the same age on the adjacent eastern margin of North America. These latter basalts appear to be systematically enriched in LIL-elements relative to modern sea floor basalts, probably due to to interaction with continental crust cr sub-continental mantle. Thus, the geochemical characteristics of layer 2 basalt appear to have been established very early in the history of the opening of the Atlantic, and the most important variations appear to be related not to age, but to geographic proximity to "mantle plumes". Unfortunately, no drill sites have been placed in critical locations to test the persistence of these plumes as a function of time. 3ryan et al. (1977b) noted, however, that the overall range and geographic distribution of geochemical variation in the continental basalts in eastern North America resembles that which has been documented along the Mid-Atlantic Ridge (Table 1) south of the Azores (Schilling, 1975; White and Bryan, 1977; White and Schilling, 1978) and suggests that "plume" activity may have initiated opening of the Atlantic.

Data from Leg 37 drill sites suggests that there may be at least short-term fluctuations in LIL-element enrichments on a scale of 10 m.y. or less. This is especially evident in variations in the ra-'io of light to heavy rare earths and in overall enrichment in LILE (Schilling et al., 1977; Bryan and Thompson, 1977). Basalts at Site 335 are light rare earth depleted, while those at Site 332 have relatively flat patterns, and basalts in the FAMOUS area show systematically greater rare earth enrichments than Site 332 (Figure 5). The interpretation of these differences in rare earth enrichments is further complicated by additional data from the FAMOUS area, where basalts closely associated in

Figure 6. Chondrite-normalized La/Sm ratios vs. Fe0\*/Mg0 for three DSDP-IPOD transects. The  $36^{\circ}$ N transect is related to the Azores plume; the 22-23°N and 30°S transects are related to normal ridge segments. Note anomalously low values for Site 335, and general lack of correlation of La/Sm with Fe0\*/Mg0. Data from Bryan et al., 1977a, b; Frey et al., 1974; Rhodes et al., 1978; Bryan and White, 1977; Langmuir et al., 1977; Schilling et al., 1977.

space and time show distinctly different rare earth patterns. These differences have been attributed to variations in degree of melting of a homogeneous mantle source rather than to fluctuations in "plume" activity (Langmuir et al., 1977), a relation supported by the consistently high Ba and  $\mathrm{Sr}^{87}/\mathrm{Sr}^{86}$  ratio in the LREE-depleted FAMOUS basalts (White and Bryan, 1977).

In Figure 6 we show the La/Sm enrichment factor as a function of Fe0\*/Mg0 for the three transects. Although representing a wide range of differentiation, the MORB of 30°S and 23°N show chondrite-normalized La/Sm ratios of 0.5 or less. However, the 37°N basalts of 0, 3, and 9 million years age show high (>0.8) La/Sm. Site 335 at 16 million years is apparently not affected by the Azores 'hot spot' activity suggesting that such events are not continuous in time. Figure 7 shows the La/Sm values plotted as a function of time for all the DSDF sites. At 23°N the DSDP basalts from this transect suggest the Atlantic Ocean has been erupting basalts of very similar composition since it. opening in Juras-

sic times. These three transects also show differences in their REE relative abundances (Figure 4). The typical MORB is depleted in the light rare earth elements, while basalts from  $37^{\circ}$ N, at least for the last 9 million years, are LREE enriched. Available data for fresh basalts from the  $37^{\circ}$ N transect suggests that they are also higher in  $Sr^{87}/Sr^{86}$  (White and Bryan, 1977) and in Ba. They are not greatly different in major element composition, transition metal trace element contents, or in LILE such as Zr, and Y.

These compositional differences with respect to REE, Sr isotopes, Ba, etc. may be related to fundamental differences in mantle sources for the two kinds of basalt. There are also small but significant compositional differences between basalts at any one site. These variations are commonly explained as due to different relative melting effects, mixing of slightly different magmas, and magmatic differentiation (Bryan et al., 1978; Frey et al., 1974; Langmuir et al., 1977; Rhodes, et al., 1978). The nature and relative importance of these latter processes still require some detailed investigation.

### Conclusions and Suggestions for Future Drilling

1) Basalts recovered by drilling show the same range of composition, mineralogy, and textures as modern basalts from the Mid-Atlantic Ridge. The youngest sites (<20 m.y.) include examples of both "normal" and "plume-related" basalts; the oldest sites (>50 m.y.) include only examples of "normal" basalts.

2) Layer 2 is composed predominantly of extrusive basalt with minor intercalated sediment to a depth of at least 600 m. Massive and pillowed lava flows are interbedded, and dikes and sills are rare. The few examples of layer 3 material recovered are at anomalously shallow depths and probably were tectonically emplaced. These plutonic rocks consist of gabbro and peridotite as commonly inferred for layer 3. The "normal" thickness of layer 2 is not constrained by existing drilling data, but is inferred to be at least 1.5 km.

3) The observed chemical and mineralogical characteristics of layer 2 were established very early in the history of opening of the Atlantic and show no major variations as a function of time. Shortterm variations at the scale of 10 m.y. or less are, however, implied by variations in LIL-element enrichments in Leg 37 sites compared with one another to the FAMOUS area.

4) Systematic compositional variation with position along the Mid-Atlantic Ridge has been well documented among modern spreading center basalts, but drill holes in old crust have not been well placed to document the persistence of this modern pattern in crust older than 15 m.y.

5) Low-temperature weathering appears to have

BRYAN 281

Figure 7. Chondrite-normalized La/Sm ratios as a function of age for DSDP-IPOD sites; range of values is indicated by length of bars at each site. FAMOUS area and Sites 332, 333, 334 and 335 are related to Azores mantle plume; Site 335 appears anomalous. Other sites are related to normal ridge segments and show no significant variation with age. Data sources as in Figure 6.

been concentrated in basalts exposed on local highs, while it shows very limited effects in basalts covered by sediment almost immediately after extrusion. There is little evidence of metamorphism or of hightemperature hydrothermal alteration even in the deepest levels penetrated. In particular, absence of metamorphic effects at Sites 395 and 396 is surprising in view of the abundant greenstones recovered in the median valley at 22°N (Melson et al., 1968). These observations suggest that both intense low temperature weathering and metamorphism may be more localized than has often been assumed, with obvious additional implications for chemical budgets arising from rock-water interactions.

Because of its relatively simple spreading history, and because of the presence of several successful deep holes in both young and old crust, we consider the North Atlantic to be an ideal location for additional deep drilling to define the stratigraphy of the deeper part of layer 2 and upper part of layer 3, and to further define both short-term and long-term geochemical variations with time to achieve a better mapping of alongridge variations in old crust. The simplest way to achieve these or jectives would appear to be to continue the Leg 37 transect out to crust of about 110 m.y. age and to place several deep drill holes

282 BRYAN

in 110 m.y. old crust between the end of the northern transect and the existing holes at Sites 417 and 418. Several additional holes should be drilled along a spreading flow line based either on Sites 395 or 417-418 in order to complete a second transect in "normal" crust unrelated to a mantle plume.

# Acknowledgements

We are especially grateful to W. G. Melson, P. T. Robinson, and J. M. Rhodes for discussion of recent IPOD sites and for providing advance copies of data and manuscripts for Sites 395 and 396. Work summarized in this paper has been supported by the National Science Foundation under Grant DES 76-15858. This is WHOI Contribution No. 4189.

## NATURE OF MANTLE HETEROGENEITY IN THE NORTH ATLANTIC :

EVIDENCE FROM LEG 49 BASALTS

J.Tarney<sup>1</sup>, D.A.Wood<sup>1</sup>, J. Varet<sup>2</sup>, A.D.Saunders<sup>1</sup>, and J.R.Cann<sup>3</sup>

Abstract. Previous deductions concerning the nature of mantle heterogeneity in the North Atlantic have been based largely on samples dredged from near the ridge axis. Leg 49 added two further dimensions to this array of data variations with depth and with time - in three critical areas where information was already available from dredging. Three holes at 63° provided information on the compositions of basalts erupted at the Reykjanes segment of the ridge for almost 36 m.y., two holes at 45°N up to 10 m.y. and four holes at 36°N (combined with data from Leg 37) up to 16 m.y. Major and trace element data on more than 150 basalt samples have been used to ascertain compositional variations resulting from fractional crystallization, batch melting and dynamic melting and to define more closely geochemical differences in the mantle source regions in space and time. The resuldemonstrate the following features. (1) An unusually wide range of basalt compositions ma erupted at a single site, although in most case it is possible to relate these basalts to a single source through partial melting and fractional crystallization. (2) Basalts from different sites along the same mantle flow line have remarkably consistent ratios of the more hygromagmatophile trace elements, indicating that the mantle source feeding a particular ridge segment was relatively uniform with respect to these elements for long time periods. (3) There are inter-site differences along a particular mantle flow-line with respect to Rb/Sr, Ce/Yb and <sup>87</sup>Sr/<sup>36</sup>Sr which may reflect smaller scale heterogeneities in the source. (4) There are large differences in hygromagmatophile trace element ratios between different segments of the ridge, but in each case these regional differences are maintained for long

time periods. Basalts from  $45^{\circ}$ N and  $36^{\circ}$ N have similar hygromagmatophile element ratios (but different abundances) and these ratios are different from those at  $63^{\circ}$ N and on Iceland, while both are different from the ratios in 'depleted' MORB from  $22^{\circ}$ N.

The data are difficult to reconcile with mantle plume models invoking mixing of two contrasted 'enriched' and 'depleted' sources or magmas. Rather there are several sources each with a characteristic composition, or range of compositions, feeding the Mid Atlantic Ridge. While compositional and isotopic differences between North Atlantic basalts may partly reflect earlier mantle depletion processes, such as crust extraction, later enrichment events may also have contributed to the observed chemical diversity, particularly in the 45°N region.

#### Introduction

That geochemical differences exist in basalts sampled from different sections of the Mid-Atlantic Ridge is now well established (e.g. Schilling, 1975b). Because these geochemical differences correlate to some extent with variations in Sr isotopes (Hart et al, 1973; O'Nions and <u>Pankhurst</u>, 1974; O'Nions et al, 1976; White et al, 1975, 1976), Pb isotopes (Sun and Jahn, 1975; Sun et al, 1975) and Nd isotopes (O'Nions et al, 1977, 1978; Carter et al, 1978a) there is a concensus of opinion that these differences reflect some sort of geochemical heterogeneity in the mantle source.

The generalised picture emerging from previous studies suggests that the Mid-Atlantic Ridge consists of 'normal segments' together with 'anomalous hot spot areas' (such as Iceland and the Azores) and with transitional zones between (e.g. the Reykjanes Ridge and in the 39°-35°N region south of the Azores). To explain these features, Schilling and co-workers, (Schilling, 1973, 1975a, b, 1976; Schilling and Noe-Nygaard, 1974; Hart et al, 1973: Hermes and Schilling, 1976; while at al, 1973: hermes and Schilling, 1976; while at al, 1973: hermes and Schilling, 1976; while at al, 1973: hermes and Schilling, 1976; while at al, 1973: hermes and Schilling, 1976; while at al, 1973: hermes and Schilling, 1976; while at al, 1973: hermes and Schilling, 1976; while at al, 1973; have proposed models involving mixing of an incompatible element 'depleted' mantle source, feeding the normal ridge segments, with that of an incompatible element 'enriched' mantle source feeding oceanic

islands and rising up in the form of plumes (Morgan, 1971) or blobs in hot spot regions.

Inevitably there have been arguments concerning the extent to which the observed compositional differences can be accounted for by the processes associated with basalt generation (O'Hara, 1977). At one extreme it would be possible to regard each basalt composition as representing the partial melting product of a unique mantle source; while at the other extreme various partial melting and dynamic melting mechanisms (e.g. Langmuir et al, 1977) combined with open and closed fraction: -rystallization (e.g. O'Hara, 1977) and perhaps contauination, are capable in theory of producing a wide variety of magma compositions from a uniform source. The true situation inevitably lies somewhere between these two extremes, and it is important to try to establish which element or element ratio variations can be accounced for by observed fractionation processes within the normal range of basalt generation, and then to consider residual differences in terms of inhomogeneity of the source.

Interple studies of course are invaluable in establishing time-integrated differences in parent/ daughter ratios in the mantle source regions, and while correlations between 143Nd/144Nd and 87Sr/ 86Sr (<u>O'Nions et al</u>, 1977) suggest a degree of covariance between Sm/Nd and Rb/Sr and therefore perhaps other element pairs too, it is neverthe-

26 TARNEY

less vital to establish whether in fact there are significant regional differences in these other elements. This may have a bearing on the processes which have given rise to heterogeneity.

There is however still considerable uncertainty as to the nature, degree and extent of mantie heterogeneity. With the simplistic mantle plume mixing model for example, the spectrum of basalt compositions along the Mid-Atlantic Ridge should reflect the mixing of the two mantle sources once the effects due to partial melting and fractional crystallization have been accounted for. Not all geochemists believe that the data can be explained so simply (O'Nions et al, 1976; Tatsumoto, 1978). Langmuir et al. (1978) have applied mixing equations to the Iceland - Reykjanes Ridge data and have argued that these data are not consistent with either mixing of magmas or of an enriched ocean island source with a depleted ocean ridge source. They concluded that there are either two separate trends in the Iceland - Reykjanes Ridge region, or that the basalts have been derived from a multiplicity of sources which have been isolated for hundreds of millions of years.

Thes Loncepts have generally been discussed using analytical data for a few elements and/or isotopes on a limited number of samples - and, moreover, samples located or dredged near the ridge axis. Leg 49 added two further dimensions to this array of data - (a) variations with time and (b) variations with depth - in critical areas of the North Atlantic where a considerable body of data was already available. Nine holes were drilled at seven sites (Fig. 1) in three different transects across the Mid-Atlantic Ridge at 63°N (Reykjanes Ridge), 45°N (Hudson Geotraverse Area) and 36°N (FAMOUS area). Three sites (407, 408 and 409) were located along the same mantle flow line transverse to the Reykjanes Ridge at 63°N, at approximately the mid-point of the supposed geochemical gradient south of Iceland, and sampled basalts erupted over a 34 m.y. interval between 36 m.y. and 2.3 m.y. ago. Two holes at Site 410 penetrated 10 m.y. old crust west of the ridge axis at 45°N and permitted comparisons with young besalts dredged from the Median Valley at 45°N. Three sites (411, 412, 413) in the FAMOUS area near 36°N were drilled in young (1 m.y. to 3.5 m.y.) basaltic crust and complement earlier drilling on Leg 37 at Sites 332 to 335 (3.5 to 16.5 m.y.).

The recovery at most of these sites was good, and produced a surprisingly wide variety of basalt types. In order to provide a comprehensive body of data as a framework for petrogenetic discussion, over 150 samples h... been analysed for up to 40 major and trace elements by X-ray fluorescence and instrumental neutron activation techniques in four different laboratories. Several elements have been analysed on the same samples in different laboratories, and inter-laboratory agreement has been found to be good. Nevertheless, to avoid possible bias in comparing basalts from different sites, all the diagrams presented make use of data from one laboratory for each element. The complete petrological, mineralogical and geochemical data is listed in the D.S.D.P. Initial Reports (Tarney et al., in press; Wood et al., in press) and only 17 analyses representing the main lithological units are presented here (Table 1).

Much of the discussion will center around 'incompatible' trace elements (i.e. those with a solid/liquid distribution coefficient, D, less than 1). Nevertheless this term covers elements with a wide range of D values (Fig. 7), and for greater clarity we will use the term 'hygromagmatophile' (HYG) for elements with D significantly less than 1, qualified by 'less-HYG' for elements with D near 0.1 and 'more-HYG' for those with D  $\leq 0.01$ .

Mid-Atlantic Ridge 63°N: Sites 407, 408 and 409

These three sites were chosen to lie along a mantle flow line from a single segment of the Reykjanes Ridge, and provide a record of the chemistry of basalts produced during almost 40 m.y. of spreading. Moreover, this transect corresponds with the mid-point of the geochemical gradient south of Iceland suggested by dredged basalts from the Reykjanes Ridge (Schilling, 1973; Hart et al., 1973). Recent work on Iceland has shown that basalts, even in quite restricted areas, may show a wide range of trace element and isotopic compositions (O'Nions et al., 1976; Sigvaldason et al., 1976; Wood, 1978), thus it was important to establish whether the geochemical gradient, based on relatively few samples from each latitude, would remain apparent after more detailed sampling in depth and with time.

Hole 407 (63° 56.52'N; 30° 34.56'W), on magnetic anomaly 13 (35-40 m.y.), penetrated almost 160m. of aphyric or slightly phyric (plagioclase, olivine, minor clinopyroxene) basalts. Geochemical studies have revealed four distinct units, each made up of several flow units. Units 2 and 3 are separated by a major change in magnetic polarity and Units 3 and 4 by a sedimentary horizon. The degree of alteration increases downhole.

Hole 408 (63° 22.66'N; 28° 54.71'W), sited on a topographic high within magnetic anomaly 6 (20 m.y.), penetrated 33m. of vesicular aphyric (or sparsely phyric) basalts. Although there is some geochemical variation within the hole, the basalts belong essentially to one geochemical unit. Alteration is widespread.

Hole 409 (62° 36.98'N; 25° 57.17'W), sited close to the crest of the Reykjanes Ridge, drilled young 2.3 m.y. old crust on anomaly 2' and penetrated 240m. of vesicular basalt, mostly aphyric or sparsely phyric, and relatively fresh. There are four geochemical units, but the major break occurs between Units 2 and 3. A thin interval within Unit 2 consisted of much more evolved basalt.

All the fresh basalts from this transect are hypersthene normative, and follow a distinct trend of iron-enrichment on an AFM diagram. Some of the units, particularly at Site 407. are also Ti-rich (Table 1). A plot of Ce against Y (Fig. 2a) shows that samples from each of the geochemical units fall in discrete and separate fields, each with a constant Cex/Yx ratio (within the limits of Ce precision by XRF). Chondrite-normalised rare-earth patterns of representative samples from cach unit are shown in Figure 3 and confirm that there is a wide variation in Ce<sub>N</sub>/Yb<sub>N</sub> ratio in basalts from this transect, from light-RE depleted to light-RE enriched. Even within one hole (407) there is an appreciable variation in Ce<sub>N</sub>/Yb<sub>N</sub>.

A plot of Y versus Zr (Fig. 2b) serves to distinguish between fractional crystallization and partial melting processes in the petrogenesis of these basalts. The Y/Zr ratio changes only very slightly during fractional crystallization, but the differences in partition coefficient between the two become significant during moderate to low degrees of partial melting, with Y being progressively retained in the source at lower degrees of partial melting (Saunders and Tarney, in press) It can b seen that samples from each unit have constant Y/Zr ratios and plot along lines with zero intercept suggesting that withinunit variation may be attributed to limited closed system fractional crystallization. Units 407-1 and 407-3 have similar Y/Zr and Ce/Y ratios and (although separated by a magnetic polarity reversal) 407-1 can be derived from a liquid similar to 407-3 by fractional crystallization. A least squares solution of the major element oxides for the fractionation of the observed phenocryst mineral compositions using the method of Wright and Doherty (1970) suggests some 407 crystal fractionation of plagioclase + clinopyroxene with minor olivine and titanomagnetite (Wood et al, in press). This is supported by the lower Sr, Cr, and Ni in 407-1, whereas the other incompatible elements increase in proportion to Zr. The more evolved flow unit (Sample 10-2, 22-24cm) at Site 409 can similarly be related by fractional crystallization to the main group of basalts (Unit 409-2).

Attempts to relate the other geochemical units at Site 407 or the two main units at Site 409 by crystal fractionation processes, open or closed, were unsuccessful. In each case the amount of fractional crystallization of olivine, clinopyroxene or placioclase demanded by the increase in incompatible elements is not matched by the predicted reductions in Cr, Ni or Sr expected by applying reasonable partition coefficient data. Nor can differences in Ce/Y, Ce/Yb, 2r/Y ratios between these units be accounted for. In Hole 409 for instance, Unit 409-3 has higher

Major element oxide (wt %) and trace element (p.p.m) analyses of the 17 major lithostratigraphic units recovered by IPOD Leg 49 Table 1.

HYG element abundances than Units 409-1 and 409-2, but also has higher Cr and Ni abundances and more normative olivine, although lower Mg/Fe ratio. A similar relationship obtains between Units 407-2 and 407-4 at Site 407.

In Figure 2b possible partial melting relationships between these units are indicated. For each hole individual units lie close to a single partial melting curve, those with higher Zr also having slightly higher Fe/Mg ratios, but also lower Y/Zr ratios, suggesting retention of Y in the source by a phase such as clinopyroxene. There are however three separate curves, indicating that the source mineralogy or composition at the three sites is different. A small amount of garnet in the source at Site 408 for example would account for the lower Y/Zr ratio (and higher Ce/Y and Ce/Yb ratios) of Site 408 basalts. Unit 407-3 basalts are too low in Cr and Ni and their Mg/Fe ratios are also too low for primary mantle melts. Allowing 35% preeruptive crystallization (ol, plag, cpx) would bring the compositions of these basalts closer to those of Hole 408 and to the more Mg-rich basalts from eastern Iceland (Wood, 1978), all of which have similar Ce/Y ratios. That all the units cannot be related by equilibrium partial melting of a similar mantle source, irrespective of its mineralogy is demonstrated by the strontium isotope data for these sites

Figure 2.(a) Ce versus Y and (b) Y versus Zr for 63<sup>°</sup>N basalts. In (b) fractional crystallization and possible partial melting relationships between the units are indicated (see text).

(Wood et al., in press). There is a si ficant positive correlation between  $^{87}$ Sr/ $^{86}$ Sr ratio and enrichment in S: and with Rb/Sr and Ce<sub>N</sub>/Yb<sub>N</sub> ratios. There is however a much greater difference in  $^{87}$ Sr/ $^{86}$ Sr ratio between Hole 407 and Hole 408 basalts (0.7034) and Hole 409 basalts (0.7029) than there is between the individual units of a single hole, which generally have the same  $^{87}$ Sr/ $^{86}$ Sr ratio (+0.0001). The Sr isotope data do therefore suggest that there are inhomogeneities, at least on an inter-site scale, in the mantle feeding a single segment of the Mid-Atlantic Ridge. Such inhomogeneities are on a similar scale to those previously described in Iceland (<u>0'Nions et al</u>, 1976).

We conclude that, although much of the compositional variability in basalts from the 63°N Reykjanes transect results from fractional crystallization and especially partial melting processes, there are at least two different mantle source compositions which have had a separate time-integrated Rb-Sr history. Note however that none of the basalt types related to these sources has the geochemical characteristics of 'MORB'. All are in fact more radiogenic and are enriched in hygromagmatophile elements relative to MORB. This is readily demonstrated by plotting any pair of incompatible elements such as 2r-Nb, Zr-Ce, Zr-3a, Tb-Ta, Hf-Th etc (see Figs. 8 to 10, and Tarney et al., in press; Wood et al., in press), where basalts from all 63°N sites form a linear array either with zero intercept or with a small intercept on the axis of the 1^ss hygromagmatophile element; basalts of 'MORB type have distinctly different ratios of these elements. In fact it is the consistency of these element ratios in basalts produced over almost 40 m.y. of spreading which is the more remarkable, and implies that the ratios of the more-hygromagmatophile elements in the mantle source are relatively constant. Differences have however developed in the ratios of more-HYG to less-HYG elements and are reflected in Sr-isotope variations.

The act are difficult to reconcile with the mantle plume mixing model for the Iceland-Reykjanes Ridge area (Vogt, 1972; Schilling, 1973; Schilling and Noe-Nygaard, 1974). Evidently there is not a relative enrichment in HYG elements or 87 Sr/86 Sr ratios towards the ridge crest, as predicted by the plume model, but rather a decrease. More-over the most 'enriched' basalts were erupted (at Site 407) some 35 to 40 million years ago when the postulated plume activity was supposed to be at a minimum on the Iceland segment of the ridge. Our data thus corroborate the conclusions of <u>0'Nions et al</u>. (1976) and of Langmuir et al. (1978) who showed that binary mixing of depleted 'MORB' magmas or sources and enriched ocean island material did not satisfy the data.

## Mid-Atlantic Ridge 45°N: Site 410

The area around the Mid-Atlantic Ridge at  $45^{\circ}$ N has been the subject of detailed investigation by the Canadian Hudson Geotraverse project (Aumento et al., 1971) in which samples have been dredged from 40 sites. Although this is a bathymetrically normal segment of the ridge, a variety of tholeiitic, transitional and alkalic basalts with some high-alumina basalts and ferro-basalts have been recovered (Muir and Tilley, 1964; Aumento, 1968) The basalts from this area are well known for their high levels of hygromagmatophile elements, high 87Sr/86Sr ratios (~0.7033) and light RE enriched REE patterns (Frey et al., 1968; Hart, 1971a, b; Aumento, 1971; Erlank and Kable, 1976; White et al., 1975). Leg 49 drilled west of the median valley on magnetic anomaly 5 (ca 10 m.y.).

<u>Hole 410</u> ( $45^{\circ}$  30.51'N,  $29^{\circ}$  28.56'W) penetrated 47m of basement. The upper 26m was a breccia of sparsely phyric (ol, plag, cpx) basalt while the lower unit consisted of a pillow breccia of mugearitic composition (Mg0~4% <u>ne-normative</u>) with up to 10% phenocrysts of titaniferous clinopyroxene, olivine and plagioclase (An<sub>45</sub>).

Hole 410A(120m south of Hole 410) penetrated 49m of sparsely phyric pillcw basalts similar to those in the upper unit in Hole 410.

Site 410 samples range from transitional to mildly alkaline mugearites, and clearly form part of a geochemically coherent group, but trend towards alkali enrichment rather than Fe-enrichment on an AFM diagram. Dredged rocks from 45°N do however include some ferrobasalt differentiates (Aumento et al., 1971) and even plagiogranites (Aumento, 1969). 49°N drilled basalts have very different compositions from those at 63°N (Table 1). They have lower FeO and TiO2 at equivalent MgO values, but much higher levels of K20 and other hygromagmatophile elements. Ratios of more-HYG to less-HYG elements arc also very different from those in 63<sup>0</sup>N basalts and in 'MORB', but there are many similarities in trace element relationships between 45°N and 36°N (FAMOUS area)

290 TARNEY

basalts and to emphasise this, samples from the two areas are included on the same diagrams.

A Ce versus Y plot (Fig. 4a) demonstrates that  $\rm Ce_N/\rm Y_N$  ratios of Unit 410-2 basalts (>6) are different from those of Unit 410-1 and 410A basalts ( $\sim$ 4). This is confirmed by the chondrite-normalised REE patterns of representative samples of the three units (Fig. 5), which all show strongly light-RE enriched concaveupwards patterns, very different from those of Reykjanes basalts. The samples analysed by Frey et al. (1968) from 45°N have similar REE patterns and lie just below those for Unit 410-1. An interesting feature of the REE patterns is that there is little variation in HREE levels. A plot of Y versus Zr (Fig. 4b) also demonstrates that while the Zr concentration almost doubles (from 115 ppm to 206 ppm) Y remains constant at between 24 and 21 ppm. A Ti versus Zr plot (Fig. 6) exhibits the same feature. This relationship contrasts with that in Reykjanes basalts, and in fact in most ocean basalts (Pearce and Cann, 1973), where there is normally a good linear relationship between Y - Zr and between Ti - Zr.

To account for the compositional variation at Site 410 by fractional crystallization presents many difficulties. Separation of a Ti-rich clinopyroxene could probably explain the lack of Ti-enrichment, but although published partition coefficient data for LREE/HREE between ciinopyroxene and liquid (Schnetzler and Philpotts, 1970; Grutzeck et al., 1974) are less than unity, appreciable separation of clinopyroxene would be required to increase Ce/ Yb ratios to the required values. Moreover to prevent Y and HREE levels from rising would require that  $K_{DY+HREE}^{CPX/L}$  be greater than unity, which is three or more times the published values. The Cr, Ni and Sr contents of the mugearites (ca. 200, 100 and 470 ppm respectively) relative to the values in the basalts (190, 90 and 226 ppm respectively) severely restricts the amount of clinopyroxene, olivine and plagioclase fractionation which could have occurred, yet the increase in Zr levels indicates that at least 50% fractional crystallization would be required (and the increase in some of the more HYG elements even more). These conflicting factors argue against fractional crystallization being the main mechanism relating Site 410 lavas. A partial melting relationship is much more likely. The compatible behaviour of Ti, Y and the heavy REE (their concentrations remaining constant in liquids produced by differing degrees of partial melting) indicates that the bulk distribution coefficients for these elements must be close to unity. Moreover since the Ti/Y ratio in Site 410 basalts is invariant and is the same as in other Les '9 basalts it implies that any refractory phase which is holding Y and the heavy REE is reaining Ti in the same proportion. The effic ency of garnet in retaining Y and the

Figure 4.(a) Ce versus Y and (b) Y versus Zr for basalts from 36<sup>°</sup>N (Sites 411, 412 and 413) and 45<sup>°</sup>N (Site 410). In (b) fields for 63<sup>°</sup>N basalt units are shown for comparison.

heavy REE is well known, but there is little data available on Ti partitioning into garnet under mantle conditions. Both titanian and zirconian garnets are known (Dowty, 1971; Huggins et al., 1977) and garnets in ultramafic nodules in kimberlite contain as much or more Ti than coexisting clinopyroxenes (Bishop et al., 1978). That garnet may be a residual phase is also suggested by the lower P/Zr ratios of the more fractionated lavas (Table 1): phosphorus can substitute in mantle garnet (Thompson, 1975; Bishop et al., 1978). Note also that Sc and V are low in 45°N lavas. Other phases which might retain Ti are hornblende (see Basu and Murthy, 1977) and titan-phlogopite (Forbes and Flower, 1974). Note however that the latter would need to melt in significant quantities to account for the high K, Rb and Ba contents and low K/Rb ratios at 45<sup>o</sup>N.

Trace element relationships at  $45^{\circ}N$  are very different from those at  $63^{\circ}N$ . Plots of a more-HYG element against a less-HYG element form a linear array and generally have a small intercept on the axis of the less-HYG element (e.g. Figs. 8 to 10). This produces a small range of ratios, and probably reflects fractionation of HYG element ratios at small degrees of partial melting. However these differences are small compared with the changes in ratios such as Ce/Y, Ti/Zr, Y/Zr which are more strongly dependent on mineral fractionation during partial melting. Thus ratios such as 2r/Nb, Ce/Zr, Ba/Zr, K/Zr, Th/Hf at  $45^{\circ}N$  are very different from those at  $63^{\circ}N$  and in MORB. Trace element ratios determined by <u>Erlank and Kable</u> (1976) on dredged basalts from near the median valley at  $45^{\circ}N$  are very similar to those at Site 410 and confirm that 'enriched' basalts have been erupted at this segment of the ridge for at least 10 m.y.

### Mid-Atlantic Ridge 36<sup>0</sup>N: Sites 411, 412 and 413 (FAMOUS area)

The rift valley at 36°N has been extensively studied by d-adging and by submersibles during the FAMOUS project (<u>Ballard et al.</u>, 1975). In addition, DSDP Leg 37 drilled basement ranging in age from 3.5 to 16.5 m.y. at four sites vest of the ridge. The results have been presented in a series of publications (<u>Hekinian et al.</u>, 1976; <u>Aumento, Melson, et al.</u>, 1977; <u>Bryan and Moore</u>, 1977; <u>White and Bryan</u>, 1977; <u>Lambert and Hcl12..d</u>, 1977; <u>Flower et al.</u>, 1977) and have demonstrated that basalts with a similar range of composition have been erupted at this segment of the ridge for up to 16 m.y. Leg 49 drilling at this latitude not only extended the sampling to very young crust, but also to basalts erupted adjacent to nearby fracture zones.

Schilling (1975a) and White et al. (1975) have suggested, on the basis of dredged samples, that there may be a geochemical gradient south of the Azores, similar to that along the Reykjanes Ridge but extending over a much larger distance (ca. 1000 km). They have interpreted the gradient in terms of overspill from the supposed Azores mantle plume and mixing with a depleted MORB source. The FAMOUS area at 36<sup>o</sup>N lies at an intermediate position on this geochemical gradient. Erupted basalts include many near-primitive high-Mg compositions with low incompatible element levels, but with moderately high <sup>87</sup>Sr/<sup>86</sup>Sr ratios

Figure 6. TiO<sub>2</sub> versus Zr for all Leg 49 basalts, illustrating suppression of Ti-enrichment in the more fractionated basalts from 36°N and 45°N.

(~0.7030; <u>0'Nions et al</u>., 1976) and REE patterns which range from slightly light-RE enriched to light-RE depleted (see <u>Langmuir et al</u>., 1977).

Hole 411 (36° 45.97'N; 33° 23.30'W), sited only 10 km west of the inner rift valley, penetrated 45 m of 1 m.y. old basaltic crust. There are two geochemical units, the upper unit comprising primitive (high-Mg) aphyric or sparsely phyric olivine basalts, and the lower one containing basalts with 10-20% plagioclase megacrysts and associated olivine and clinopyroxene phenocrysts.

Hole 412 (36° 33.74'N; 33° 09.96'W) penetrated "8 m of 1.6 m.y. old crust east of the rift valley and just south of the no-thern valley wall of Fracture Zone B. The basalts belong to one geochemical unit but vary from aphyric to coarsely phyric with plagioclase megacrysts and clinopyroxene and olivine phenocrysts.

Hole 412A (same locality as Hole 412) penetrated 50 m of basalt similar to Hole 412 and a further 80 m of sparsely phyric to aphyric basalts. They all belong to one geochemical unit but there are 3 cycles of Fe-enrichment represented by the flow units within the core. A least squares solution for the major elements (Wright and Doherty, 1970) suggests th t the compositional variation could be accommodated by 25% fractional crystallization of plagioclase, clinopyroxene and minor olivine.

<u>Hole 413</u>  $(36^{\circ} 32.6'N; 33^{\circ} 10.5'W)$  was drilled only 2 km south of Site 412, but into 3.5 m.y. old crust close to and on the south side of Fracture Zone B. The 39 m of basalt penetrated formed two very distinct geochemical units, the upper being a glassy to microcrystalline basalt with ~ 10% olivine phenocrysts and the lower unit a sparsely olivine phyric basalt.

292 TAPNEY

Basalts recovered from the FAMOUS area by Leg 49 have many of the chemical characteristics (high MgO, Cr, Ni, Mg/Fe; low TiO<sub>2</sub> and HYG elements) of other dredged and drilled basalts previously recovered from this area. Many are close to primary magma compositions. Glasses from Units 411-1 and 413-2 (Wood et al., 1978) are in fact among the most primitive liquid compositions sampled on the ocean floor (Frey et al., 1974) with  $SiO_2 = 49\%$ , Mg/Mg + Fe = 0.65 high Al203 (>16%), and low TiO2 (0.8%) and P205 (0.05%). Langmuir et al. (1977) have described similar primitive samples from the FAMOUS area. The sparsely phyric basalts from Unit 413-1 are also very primitive, with Mg/Mg + Fe = 0.70 but have lower  $Al_{203}$  (~14%) and significantly higher TiO<sub>2</sub> (1.5%), P<sub>2</sub>O<sub>5</sub> (0.25\%) and HYG element contents than basalts from Units 411-1 and 413-2. Aphyric basalts from Units 411-2, 412 and 412A are intermediate between these two extremes in terms of HYG element contents and are rather less primitive in having Mg/Mg + Fe = 0.6 and lower Cr and Ni. They also have appreciably less normative olivine and plot close to the Di-Hy join on the Ol-Di-Hy normative diagram, some samples in fact being quartz-normative. Two of these groups of basalts (411-1, 413-2 and 411-2, 412, 412A respectively) correspond fairly closely with two magma types previously recognised from study of Leg 37 samples (Flower et al., 1977); magma types A and B respectively. A magma corresponding to Unit 413-1 was not represented by any of the samples recovered by Leg 37. Basalts from this unit have however many compositional similarities with the more primitive basalts from 45°N (e.g. Unit 410-1).

Ê

A plot of Ce versus Y (Fig. 4a) shows that basalts from the three groups fall into three distinct fields with widely differing  $Ce_N/Y_N$  ratios. Representative chondrite-normalised REE patterns for the different geochemical units (Fig. 5) confirm the large variation in Ce<sub>N</sub>/Yb<sub>N</sub> ratios, from light-RE depleted to light-RE enriched. The variation in REE distributions within the short section cored at Site 413 in fact encompass almost the total Ce<sub>N</sub>/Yb<sub>N</sub> range in samples previously recovered from the FAMOUS area. The REE patterns, like those of 45°N basalts, are concave upwards, show little variation in heavy REE abundance and have unusually high La/ Ce ratios (see also Langmuir et al., 1977). Aplot of Y versus Zr (Fig. 4b) demonstrates that Y remains almost invariant at about 20 ppm in the more primitive lavas despite a three fold increase in Zr, a feature also seen at 45°N. Only in fact in Site 412 basalts is there a colinear relationship between Y and Zr, indicative of approximately 25% fractional crystallization, as noted above. Considering 36°N and 45°N basalts together, the lack of variation in Y and the HREE compared with the six-fold increase in Zr abunance is unusual. Titanium shows a similar, if not identical, relationship with Zr as does yttrium (Fig. 6). In the more primitive basalts with low Zr, TiO 2 varies in sympathy with Zr and appears to

be acting incompatibly. However Unit 412-1 basalts, although having higher TiO<sub>2</sub>, in fact have a much lower TiO<sub>2</sub>/Zr ratio which is identical to that of the more primitive basalts from 45°N. Thus the more primitive basalts from the FAMOUS area cluster tightly about a curve (Fig. 6) which apparently continues through the 45°N samples. The more evolved basalts in Unit 412 rise off this curve with a constant TiO<sub>2</sub>/Zr ratio.

Consideration of major element compositions and trace element abundances indicates that it is impossible to derive these more primitive basalt magma types (with different Ce/Yb ratios) from a single parent magma by open or closed system fractionation. For instance the difference in zirconiumabundance between Units 411-1 and 411-2 would demand ca. 35% removal of crystals. The marked reduction in Ni and Cr could be accomplished by extensive separation of olivine and Cr-spinel, which might account for the observed increase in SiO2 and the trend towards quartz-normative compositions in Unit 411-2. However, in spite of the fact that Unit 411-2 basalts are strongly plagioclase-phyric, little plagioclase must have been removed because Sr is 50% higher than in Unit 411-1. Moreover removal of olivine and spinel should produce a comparable enrichment in all incompatible elements: but in fact they are enriched to widely varying extents. The difference in Ce/Y and Ce/Yb ratios between the two units would necessitate removal of substantial amounts of clinopyroxene, yet this could not account for the major element variation. Even larger problems are apparent in trying to relate Units 413-1 and 413-2 by fractional crystcllization. Both are magnesian, high-Cr and high-Ni basalts, but the differences between the levels of many incompatible elements in these two units could only be reconciled with up to 90% fractional crystallisation, which is clearly inconceivable without changing transition metal levels drastically. Thus either they are related by some process involving partial melting or they are derived from two compositionally different sources.

Arguments favouring heterogeneity in the source regions of FAMOUS area basalts are severely constrained by the fact that Sr-isotope ratios are relatively uniform (O'Nions and Pankhurst, 1976; White and Bryan, 1977) and also that the ratios of the more-HYG elements are very similar (Bougault et al., 1976). Indeed, the two extreme basalt types from Hole 413 have similar ratios of La/Th and Ta/Th. Such considerations indicate that the fundamental differences between the main geochemical units are determined during the processes of basalt generation. Simple batch partial melting of a normal peridotite mineral assemblage cannot however explain the REE data, particularly the lack of variation of the heavy REE. Faced with similar problems in explaining the crossing REE patterns of primitive basaltic glasses from the FAMOUS area, Langmuir et al., (1977) have developed a more complex dynamic

melting model. This integrates varying degrees of batch melting with incremental melting, and makes use of an observation by Dick (1977) on the Josephine peridotite indicating that melt is not always completely extracted. They propose that melting at ocean ridges may take place over a considerable depth range, but with an increasing degree of melting as the mantle Jiapir rises. Melt can be extracted at any point but it is suggested that a small proportion of melt always remains in equilibrium with the mantle residue (sufficient at least to remain fertile enough in HYG elements to yield further basalts). More extensive melting of mantle which has already yielded up an earlier liquid fraction at greater depth may thus produce magmas with much lower concentrations of incompatible elements and in particular lower more-HYG/less-HYG element ratios. Thus a liquid with ratios of more-HYG/less-HYG elements lower than the initial source can be produced, and it is not necessary to invoke an initial source composition which is LREE depleted to produce basalts such as 413-2. Such basalts should normally be accompanied by basalts with more LREE-enriched characteristics. Note that ratios of the more-HYG elements (e.g. Th/Ta) are not significantly changed by this process, although their abundances may vary widelv.

The dynamic melting model is inherently very flexible and capable of reconciling quite diverse basalt compositions to a uniform source. Of the extreme basalt compositions at Site 413, Unit 413-1 would represent approximately a 3% equilibrium batch melt of the initial source, whereas Unit 413-2 would be an incremental remelt of such a source after some basalt had been extracted. The fact that basalt 413-1 occurs near Fracture ZoneB in the FAMOUS area, may be a consequence of more efficient melt segregation '.. this tectonic environment. Basalts with similar geochemical characteristics are common at 45°N, but it seems unlikely that the whole range of basalt compositions at 36°N and 45°N could be accommodated by dynamic melting processes (as opposed to invoking source compositional differences, perhaps involving some more subtle mineralogical control, differences in  $P_{H_2,O}$  etc) because present evidence indicates<sup>2</sup> that 45°N basalts are significantly more radiogenic with respect to Sr and Pb isotopes than those in the FAMOUS area (White et al., 1975; Mattinson, in press) and indeed have isotopic compositions similar to ocean island basalts. Nevertheless it is interesting that on almost all inter-element plots there is a continuum between 36°N and 45°N basalts and that their HYG-element ratios are almost identical and very different from those at 63°N and in 'MORB'.

The two extreme primitive magma types, 411-1 and 413-2, from the FAMOUS area are close to primary magmas and, assuming both have been derived

Figure 7. Chondrite-normalized abundances of 23 elements in Units 411-1 and 413-1 (FAMOUS area), arranged approximately in order of increasing bulk mantle/basalt liquid partition coefficient.

by differing degrees of equilibrium partial melting of a uniform source, can be used to compare trace element behaviour during partial melting. Abundances of 23 elements in these two basalts, normalised to chondrites, are shown in Fig. 7 and have been arranged approximately in order of increasing D by compari \_ enrichment factors. Note that the respective enrichments are specific to the mantle mincralogy in the FAMOUS area and may be complicated by a mineral phase (such as that holding Ti and Y) being consumed at higher degrees of melting. The diagram shows that ratios such as Zr/Y, Ce/Y and La/Sm are greatly modified by the widely differing degrees of partial melting and that ratios such as Zr/Nb, Th/Hf and Ba/Sr are affected to a lesser extent. However ratios of the more HYG elements, K/Rb, Th/Ta, Th/La etc., are essentially unmodified. Ratios between the elements Th, Nb, Ba and La are also chondritic in both basalts and indicate that the mantle has chondritic ratios for these elements, although Ta/Th and Ta/Nb ratios are higher than chondritic. Anomalies are apparent in the abundances of K and Rb (the Rb/Sr ratic of the bulk earth is much lower than chondritic: O'Nions et al., 1977) and in phosphorous (possibly due to entry into the earth's core: Sun and Nesbitt, 1977). Transition metals Cr, Co and Ni are systematically fractionated with respect to chondrites to a greater degree than would be expected from differences in their distribution coefficients (see Langmuir et <u>al</u>., 1977).

#### Discussion

### Variables controlling basalt compositions

It is clear that the processes of partial melting and fractional crystallization can give rise to wide compositional differences in erupted basalts, and many of these processes we

294 TARNEY

have recognised in basalts recovered by Leg 49. Fractional crystallization is certainly responsible for much of the within-unit variation, and some between-unit relationships, but seems incapable of accounting for the wider trace element differences. O'Hara (1977) has suggested that open system fractionation in a continuous but periodically refilled magma chamber can produce a wider range of trace element levels, but as Pankhurst (1977) has pointed out, this is still incapable of accounting for the wide variation in trace element ratios such as we have observed in Leg 49 samples. Fractional crystallization thus seems subordinate to partial melting, and may reflect the fact that continuous sub-axis magma chambers are not an important feature of the slow-spreading Mid-Atlantic ridge; the data are more easily reconciled to a series of short-lived magma chambers. Not all the products of sub-axis crystal differentiation may be erupted into the lava sequence - indeed in ophiolite complexes, plagiogranite differentiates are mostly confined below the sheeted dyke unit (Saunders et al., 1978).

saan ah 🗸 🗸

Polybaric partial melting processes are capable of producing much more chemical diversity (<u>Hanson</u>, 1977), owing to variations in degree of partial melting, nature of residual phases and whether or not they are

Figure 8. Nb versus Zr for all Leg 49 basalts, illustrating regional differences in Zr/Nb ratios. Dashed lines indicate fractional crystallization vectors and solid lines partial melting (see text). 45°N data from Erlank and Kable (1976) and data on 'MORB' type basalts from 22°N and Nazca Plate (Leg 34) shown for comparison. consumed, variation in P<sub>H2O</sub>, fO<sub>2</sub>, etc. controlling the stability of mineral phases. Dynamic melting (Langmuir et al., 1977) provides an added variable in that magma compositions need not directly reflect the composition of the primary mantle source. Modelling back to the initial source is always easier when high-magnesian primary liquids are available (Sun and Nesbitt, 1977), but alas this is the coception rather than the norm. Primary liqu ce with a greater chance of being erupted are those generated at high levels in a rising diapir, or perhaps those adjacent to fracture zones. Magmas generated deep enough to be in equilibrium with garnet may suffer much more crystal fractionation, zone refining, even mixing before eruption (0'Hara, 1965, 1968, 1973). The larger number of samples from a given locality recovered by drilling, as opposed to dredging, provides more information necessary to assess these processes, but there are still many uncertainties. As we have seen however, hygromagmatophile element ratios are much less affected by the range of partial melting processes associated with basalt generation, and can be used, like radiogenic isotope ratios, to decipher differences in the source.

## Regional Comparisons

The three different regions studied are characterised by basalts of distinct compositions. Reykjanes basalts show a trend toward Fe- and Tienrichment similar to that on Iceland, even at Site 407 (36 m.y. ago). Basalts from 45°N instead trend more towards alkali enrichment, whereas FAMOUS basalts include many high-MgO compositions and the trend towards Fe-enrichment is less marked than in the Reykjanes samples. Both at 45°N and 36°N the trend toward Ti-enrichment in the more fractionated basalts is strongly inhibited, and basalts from these two areas include more high-alumina types than at 63°N. Some of these differences could reflect differences in the mantle mineralogy and/or differences in  $P_{\rm H20}$ during basalt generation. This is suggested also by the differences in shape of the REE patterns (Figs. 3 & 5), all those from 45<sup>c</sup>N and 36<sup>0</sup>N having distinctive concave-upwards patterns with high La/Ce ratios.

It is with the more hygromagmatophile elements that regional differences are accentuated. Erlank and Kable (1976) noted significant differences in Zr/Nb ratio between Atlantic basalts. Leg 49 data are plotted on a Zr versus Nb plot in Fig. 8 together with Erlank and Kable's data from  $45^{\circ}$ N, with data on 'MORB' type basalts from  $22^{\circ}$ N drilled by Legs 45 and 46, and with data on 'MORB' basalts from Leg 34, Nazca Plate (Rhodes et al., 1976; Cann and Heath, 1976). Basalts from different regions group into distinct linear arrays with different abundances and ratios of these elements. The data of Erlank

and Kable (1976) from 45°N plot close to Leg 49 data from this area. Note that Zr/Nb ratios are not constant because the correlation lines intercept the Zr axis. In fact there is a linear correlation between Zr/Nb and Ce/Y at 45°N and 36°N (and asimilar but different one at 63°N too) indicating that, at least in part, this results from partial melting. Basalts from 45°N and 36°N have different abundances of Zr and Nb, but lie on the same line with Zr/Nb~5. Reykjanes basalts have distinctly higher ratios (Zr/Nb~10) but it is clear that none of the North Atlantic basalts sampled by Leg 49 has the geochemical characteristics of "'ORB'. Nor, since these ratios are relatively constant in basalts erupted along mantle flow lines for periods in excess of 36 m.y., is it likely that a basalt with the major and trace element characteristics of 'MORB' or MAR 63°N basalts could ever be erupted at 36°N or 45°N segments of the ridge, or vice versa. Preliminary data from 110 m.y. old crust drilled by Legs 51 and 53, which lies approximately along the same mantle flow line from 22°N suggests that basalts with 'MORB' geochemistry have been erupted here since the opening of the Atlantic. Considering that crust along the Mid-Atlantic Ridge is being generated at much the same rate  $(1-2 \text{ cm yr}^{-1})$ , and that basalts from each region studied represent the products of a wide range of partial melting and fractional crystallization processes, it would appear that the observed Zr/Nb ratios (blurred to some extent by these fractionation processes) are characteristics of the mantle source regions. Moreover the volumes of mantle with these Zr/Nb ratio characteristics must be large. It is also apparent that mixing of a high Zr/Nb ratio 'MORB'-type source with a low Zr/Nb ratio 'ocean island'-type source, in the manner envisaged by the plume hypothesis, should produce a scatter of intermediate Zr/Nb ratios rather than the consistent trends observed.

Similar regional differences are observed in equivalent plots of other HYG elements against Zr, such as Ce-Zr, Ba-Zr (Fig. 8) and Sr-Zr differences in the latter two remaining apparent despite the known mobility of Ba and Sr under conditions of mild alteration. Large regional differences are also found in the ratios of the most-HYG elements - yet these ratios, as we have seen, are unaffected by the range of partial melting associated with basalt generation and can only be changed at very small degrees of partial melting. A plot of Th versus La (Fig. 10a) shows that each region, 63°N, 45°N, 36°N and 22<sup>0</sup>N, has a distinct Th/La ratio (or small range of ratios). MORB basalts from 22<sup>0</sup>N have Th/La ratios significantly lower than chondrites, 63°N basalts rather less so, whereas 45°N basalts have Th/La ratios slightly higher than chondritic. Plots of Nb and Ta against Th show similar features. There is less variation in interelement plots of La, Nb and Ta of course (e.g. Fig. 10b) owing to the similarity of their .)

Figure 9. Ba versus Zr for Leg 49 basalts. The greater scatter compared with Fig. 8 is due to the mobility of Ba during alteration, but large regional differences in Ba/Zr ratio are apparent. 45 N data from Erlank and Kable (1976) and data on 'MORB' type basalts from Leg 34 (Nazca Plate) shown for comparison.

values, but significant regional differences do exist. To emphasise the fine detail in the differences between the elements Th, Ta, Nb and La, the abundances in representative basalts from the different regions have been normalised in Fig. 11 to those in a basalt from Unit 409-2, which has the lowest abundances of the samples studied. Two 'MORB'-type basalts from Hole 348 (north east of Iceland) and Hole 395 (at 22°N) are also included. It is clear that 45°N and 36°N basalts have a very similar ratios of these elements irrespective of their abundance, and their sources must in some way be similar. The two 'MORB'-type basalts also have very similar ratios of these elements, but in going from 45°N, 36°N and 63°N to MORB there is a progressive depletion of Th relative to La.

The fact that basalts from 45°N and 36°N have

296 TARNEY

similar element ratios on these and almost all other inter-element plots is particularly interesting in view of the fact that the abundances of incompatible elements at 45°N are all higher than at 36°N. Thus when two different regions with different abundances yield the same ratios this gives added confidence that element ratios differences in other regions provide a valid indication of differing source compositions.

### Nature and Causes of Regional Heterogeneities

We may ask what the processes were that changed the element ratios in the source regions of Atlantic basalts? A solution to this problem would in itself provide some constraints on the nature of heterogeneity. It is evident that the partial melting processes associated with basalt generation do not significantly alter ratios of the more-HYG elements, although where smaller degrees of partial melting are involved, as in the production of alkalic basalts at 45°N, some changes in these ratios are seen. Elements with similar D values have ratios which vary only slightly and may be close to chondritic. Because the volumes of mantle with differing HYG element ratio characteristics appear to be large, it is suspected that a major process (or processes), probably involving crystal-liquid equilibria, has produced the observed chemical heterogeneties.

To change the more-HYG element ratios significantly by partial melting requires very small degrees of melting (because of the very low D's involved). This could be accomplished by a single process, or by a series of processes culminating in the extraction or addition of a small amount of melt. Fig. 11 reveals that the more-HYG elements have behaved independently during such processes to generate the observed variations: i.e. there is not a systematic variation in Th/La or La/Ta ratios between the regions and each region is characterized by REE patterns with distinctive shapes. It would be difficult to account for these features by a single process. Moreover the fact that there seems to be significant inter-site 87Sr/86Sr variation in basalts along a particular mantle flow line while the ratios of the more-HYG elements remain relatively constant also suggests that more than one process may be involved, perhaps operating on different scales, and at different times.

Evidence from Sr and Nd isotopes (DePaulo and Wasserburg, 1976; O'Nions et al, 1977, 1978) indicates that the source regions of oceanic basalts have been variably depleted in Rb/Sr and Nd/Sm relative to the primordial bulk earth on a timeintegrated basis, but this does not ne essarily imply only a single depletion event. Multi-stage depletion-enrichment events are possible and, according to O'Nions et al. (1978) do not necessarily conflict with the Sr and Fb isotopic data on basalts from oceanic regions which yield pseudoisochrons with ages of 1.5-2.0 b.y. for the major fractionation event (<u>Sun and Hanson</u>, 1975; <u>Brooks</u> et al., 1976).

The growth of continental crust may be regarded as a major mantie depletion event, with the effects being integrated over 3.8 b.y. depending on the extent of mantle convection. Processes in subduction zones are capable of significant chemical fractionation, in that material already fractionated as a result of ridge magmatism is subject to further melting with the extraction of lithophile element enriched silicic liquids. In effect the continental material extracted represents a

Figure 10. (a) Th versus La and (b) Ta versus La for Leg 49 basalts, with additional data from  $22^{\circ}N$  and from Leg 38.

Figure 11. Abundances of Th, Ta, Nb and La in selected Leg 49 basalts normalized to the most primitive basalt in Unit 409-2 (Table 1). Two 'MORB' type basalts from Site 348 and Site 395A are included.

very small degree of partial melting of the initial mantle source. Trace element data on Andean calc-alkaline and island arc igneous rocks indicate a marked decoupling in the behaviour of large lithophile ions (K, Rb, Cs, Th, U) and smaller highly charged ions (Ta, Nb, Ti, Zr, P, etc.), with the former group being enriched in intermediate to silicic compositions whereas the latter group is impoverished. This probably arises because minor phases such as ilmenite, rutile, zircon and apatite, in addition to hornblende, pyroxene and garnet, are residual phases during magma genesisin subduction zones and retain the highly charged ions (which are normally incompatible during basalt genesis). Element ratios in continental crust are thus very different from those in 'MORB'. Archaean crust in particular has high Ce/Y and Cc/Yb ratios (Tarney and Windley, 1977) and hence a low Sm/Nd ratio rendering it unradiogenic with respect to Nd isotopes (Carter et al., 1978b). Likewise continental material has high Rb/Sr ratios and high present day <sup>87</sup>Sr/<sup>86</sup>Sr ratios. In both respects these features complement the high  $^{143}\rm Nd/^{144}Nd$  and low  $^{87}\rm Sr/^{86}Sr$  ratios of oceanic basalts (O'Nions et al., 1977).

Depleted material returned to the mantle in subduction zones would mix to varying extents with undepleted pristine mantle, producing both small scale and large scale compositional heterogeneties which may, by the time this material is recycled to younger oceanic spreading centers, give rise to isotopic and trace element differences in erupted basalts. Moreover since the volcanic and plutonic products above subduction zones are themselves very variable (e.g. andesitic island arc or granitic continental margin) the material returned to the mantle may itself be variably depleted.

Such an explanation may account in part for the depleted nature of the mantle source for MORB, in which case the source regions at 63°, 36°N and 45 N could be regarded as progressively less fractionated relative to the primordial mantle. However it is apparent that basalts from these regions have much higher concentrations of elements such as Ta and Nb relative to the values in MORB. in which case it is equally feasible that their source regions have been enriched in these and other HYG elements, irrespective of whether they had been involved in earlier depletion events. Incipient melting processes, producing very small amounts of liquid rich in HYG elements (and perhaps  $H_2O$  and  $CO_2$ ) may have been responsible. These 'liquids need not have been removed from the mantle, but may just have migrated vertically from one region to another. At very small degrees of melting their compositions may have been controlled more by minor mineral phases than by major phases and would thus produce the necessary fractionation of HYG elements. Lloyd and Bailey (1975) suggested that mantle metasomatism may occur in the sub-continental mantle, and similar processes have been invoked to explain the trace element geochemistry of suites of ultramafic nodules in continental basalts (Frey and Green, 1974; Frey and Prinz, 1978). Although the mantle regions underlying the ridge were indeed subcontinental before the opening of the Atlantic ocean, there is no reason why such processes should be restricted to the sub-continental mantle. Hanson (1977) favours a veined mantle in view of the common occurrence of pyroxenite veins in mantle nodules and in ultramafic components of ophiolites.

A mantle region variably veined by HYG-element enriched material does offer some advantages in interpreting the geochemical variations in N. Atlantic basalts. The HYG-element enriched material in the veins would, at mantle temperatures, be in partial isotopic equilibrium with the surrounding depleted mantle to an extent depending on the number and spacing of the veins and the effectiveness of diffusion. At small degrees of melting the veins would contribute significantly to the HYG element content of the melt and HYG element ratios would be governed by those in the veins. However at higher degrees of partial melting the more-HYG element depleted host mantle would be involved and HYG element abundances in the melt would be lower and more-HYG / less HYG element ratios transitional toward those of the host mantle. This could explain why there is an intercept on the axis of the less-HYG element on most regional inter-element plots. However, ratios of the more-HYG elements would be determined by those in the veins except where the proportion of veins was very small.

Such a model may account for the fact that basalts at 45°N and 36°N have similar ratios of the more-HYG elements, but display systematically varying ratios of more-HYG to less-HYG elements. Bearing in mind that the latent heat of fusion exerts a strong buffering effect on the amount of liquid produced during mantle melting, it would be unrealistic to interpret the wide range of HYG element abundances observed in the two areas as simply being due to differing degrees of partial melting. Instead, these features could be reconciled with a higher proportion of veins in the source regions at 45 N. This would allow isotopic differences to develop in proportion to the amount of HYG-element enriched vein material while still maintaining consistent ratios of the more HYG elements.

## Conclusions

Previous deductions concerning mantle heterogeneity in the North Atlantic have been based very largely on samples dredged from the ridge axis. Leg 49 drilling has added two further dimensions (variations with depth and with time) to this array of data and has demonstrated several important features.

1. Basalts recovered from a single drill hole may show a surprisingly wide range of composition, particularly with respect to REE, Ti/Zr ratios, etc., thus making deductions concerning heterogeneity based on these parameters alone of doubtful value. Nevertheless it is possible in most cases to derive all basalt compositions at a single site from the same mantle source through partial melting processes (including dynamic melting) and fractional crystallization. While fractional crystallization is an important cause of compositional variation within a particular geochemical unit, several such units may occur at any one site that can only be related by partial melting processes. This suggests that long-lived sub-axial magma chambers are not an important feature of the slow-spreading Mid-Atlantic Ridge.

2. Basalts from different sites along the same mantle flow line (e.g. 63°N) do show some compositional and isotopic differences which cannot readily be accommodated by fractional crystallization and partial melting. These probably reflect local heterogeneities in the mantle source feeding the ridge. However, in terms of the more-HYG element ratios of basalts at these same sites. it is the constancy (or consistency) of these ratios which is the more striking, implying that the mantle feeding particular ridge segments was uniform with respect to these HYG elements for at least 35 m.y. (at 36°N) and probably since the opening of the Atlantic.

3. By contrast, ratios of the more-HYG elements vary markedly along the Mid-Atlautic Ridge, but i each case these regional differences are maintained at a particular spreading axis for long time periods. HYG-element ratios in the Iceland-Reykjanes Ridge area are different from those at  $45^{\circ}$ N and at  $36^{\circ}$ N, and both are different from the ratios at  $22^{\circ}$ N and in typical MORB. It is appare that the volumes of mantle with these distinctiv element ratios are large, and moreover that the

are not just two contrasted ('depleted' and 'enriched') sources mixing and feeding the Mid-Atlantic Ridge, but rather several sources with their own HYG-element character.

The results suggest that the mantle may be heterogeneous on different scales for different elements, in which case the plume-mixing model would seem to be insufficiently flexible to account for the observed variations. A viable alternative model, bearing in mind isotopic constraints, is to consider the data in terms of depletion/enrichment processes operating throughout earth history. The processes of crustal extraction are capable of causing both depletion and significant fractionation of HYC elements in the residual mantle source. This may not however be the only process. Mantle variably veined with HYG element enriched material offers distinct advantages in interpreting the observed patterns of geochemical and isotopic variation. Further drilling in critical areas of the N. Atlantic would greatly assist in understanding the nature and causes of mantle heterogeneity.

## THE PRIMARY WELT OF THE OCEANIC THOLEIITE AND THE UPPER MANTLE COMPOSITION

L. V. Umitriev, A. V. Sobolev, and N. M. Suschevskaja

Vernadsky Institution of Geochemistry of the USSR Academy of Sciences

### Introduction

The chemical variations of pillow lavas from seismic layer two of the world oceans are relatively limited and markedly distinguished from their continental volcanic counterparts. This has led to the following assumptions: stable and specific conditions of partial melting accompanies the formation of typical oceanic crust, and a specific and uniform upper mantle composition exists at the depth where oceanic tholeiite magma appears. These conditions have characterized the ocean crust formation during the last 150 m.y. All of these considerations support the concept of the oceanic tholaites from seismic layer two occupying a single worldwide basaltic province (Dmitriev, Sharaskin, and Garanin, 1976).

Nevertheless alternative viewpoints based on the diversity of p.'llow lava compositons and also on experimental petrology have been discussed in the literature. These postulate the existence of two or more parental tholeiitic magmas derived from a heterogeneous upper mantle.

For instance, experimental data by Kushiro (1972) show that the minimal changes in the melt composition lead to the appearance of different phases along the liquidus (Figure 1). Composition (T-87) has 9.2 wt 7 MgO and the stable olivine along the liquidus from 1 atm. to 7.5 kilobars pressure. The last corresponds to four-phase equilibrium, whilst the lover (T-89) has 7.4 wt. % MgO yet stable plagioclase along the liquidus within the same interval in pressure. In the last case olivine appeared on the liquidus only with about 2 wt. % H\_O. In this regard recent data on the homogenization of melt-microinclusions in olivine, plagioclase, and spinel occurring in oceanic tholeiites indicate temperatures of formation in the range 1240°-1280°C (Clocchiatti, 19/7; Shugurova and Dolgov, 1976; Karpuchin, Sobolev, Vernadsky Institute of Geochemistry, U.S.S.R. Academy of Science). In light of these data it seems likely that oceanic tholeiites originated under the dry condition. Therefore, the Kushiro and Thompson experiment

requires the simultaneous existence of lherzolitic and pyroxenitic mantle as the source of magma types with compositions (T-87) and (T-89) and are actually primary ; pleiitic melts. This reads to serious consequences relating to global geology, tectonics, petrology, etc.

However, a more or less exact estimate of the real primary (or parental) oceanic tholeiite melt composition is required, and this should be obtained from chemical variations of the quenched basaltic glasses formed on the surface of submarine undersea lava flows. The compositions of these glasses are expected to vary in composition from the primary melt (in cases where phenerrysts did not have time to appear) to the residual melt (when porphyric rocks formed). In both cases the glass composition does not depend upon the mechanical enrichment or depletion in phenocrysts.

The significant deviation of the glass composition from the primary or residual liquid should only be due to the dissolution (or remelting) of phenocrysts. However, this needs a remarkable and gradual change in conditions of the thermodynamic equilibrium during the eruptive process.

More exact information about the primary melt can be obtained through the determination of the composition of microinclusions in phenocrysts homogenized at their trapping temperatures. There are few available published data pertaining to this topic.

Thus the present paper is based largely on the numerous glass composition data available with new information about microinclusions in phenocrysts.

The chemical variation amongst 1600 analyses of volcanic glasses from the world's oceans have been statistically assessed (the original data from W.G. Melson, et al., Catalog, Smithsonian Institution, 1977).

Figure 2 shows the average glass composition for each of 68 Sites from the Atlantic, 47 Sites from the Pacific, and 17 Sites from the Indian Ocean plotted in the olivine-diopsideplagionlase ternary system. Some characteristic compositions and the field of pillow lava compositions are also plotted here.

302 DMITRIEV

Fig. 1. Melting relations for two abyssal tholeiites (T-87) and (T-89) after I. Kushiro (1972). For compositions, see Table 2.

Figure 2 clearly illustrates that (1) chemical variations of tholeiitic glasses are limited in comparison with one for pillow lavas, and (2) all the glasses compositions occupy a compact area bordered by the fivephase olivine-tholeiite point. The point representing alumina-rich tholeiite with the plagioclase as the liquidus phase (T-89) lies outside of the area of the glass compositions. These observations lead to the following

main conclusions.

1. Only one kind of parental (or primary) cceanic tholeiite melt exists. It corresponds to the magnesium-rich tholeiite coexisting with lherzolitic mantle at 5-11 kilobars of pressure. There are no primary melts of alumina-rich tholeiite.

2. The chemical diversity of pillow lavas are explained by various degrees of their mechanical saturation in phenocrysts: olivine, plagioclase, and pyroxene or combinations of all.

3. The restricted range of the natural glass compositions observed does not permit significant remelting or dissolution of the phenocrysts.

Data based on Site 332 B (Dmitriev, 1977; Aumento and Kempe, 1977) confirm these con-

DMITRIEV 303

Fig. 2. Average glass compositions for Sites from world oceans plotted in ternary diagram Olivine (01)-Diopside (Di)-Plagioclase (P1).

1. Atlantic Ocean (68 Sites). 2. Pacific Ocean (47 Sites). 3. Indian Ocean (17 Sites). 4. Average M.O.R.B. (Dmitriev et al., 1976). 5. Points of four-phase equilibrium for 10.5 kilobars (Bence, et al., 1978), 7.5 kilobars (Kushiro, 1972), 5.0 kilobars (extrapolated from Kushiro, 1972), and 1 atmosphere (Tilley, et al., 1965; Tilley, et al., 1966; Brown and Shairer, 1966; Emslie and Lindsley, 1967). 6. Alumina-rich tholeiite (T-89) (Kushiro, 1972). 7. Composition of melt microinclusion in olivine, Site 332 B (see text) "a" and "b" lines estimated for olivine-plagioclase cotectic boundaries for real compositions with normative plagioclase An $_{70}$  and An $_{50}$  respectively (wt. %). The compositions of pillow lavas are inside the dashed area.

clusions totally (see Figure 3). The glass compositions are very restricted occupying a field distinct from the point of alumina-rich basalt.

The individual glass compositions for the Atlantic are plotted on the same ternary system (293 single points for all sites, Figure 4). It is seen here that they form two discrete groups. The first group (crosses) occupies the area between the 7.5-10.5 kilobars five-phase points and the 1 atmosphere point. The second group stretches from the 5 kilobars point to the 1 atmosphere point also. Group " 1 is relatively depleted in TiO2, while group N 2 is markedly enriched in TiC.

The existence of these two single groups was confirmed by a statistical assessment study of the correlation between major elements. Some examples of this statistical operation are demonstrated in Figures 5 and 6. It is seen here that both groups are characterized by similar covariation but differ one from another in the level of element concentrations. It is important to point out that these are

304 DMITRIEV

significant coefficients or correlations for single groups while there are no correlations between the same elements for joined groups (see Table 1).

The more detailed statistical treatment of glass compositions for the Atlantic permits a recalculation of the variation lines for both groups and to determine the compositions of the terminal points on the ends of these lines. These compositions are placed into Table 2 together with primary melt composition estimated by A. Bence, et al. (1978), F. Frey, et al. (1974), and M. Flower, et al. (1977). Composition of the melt inclusion in olivine from Site 332 B (our data, see below), olivine tholeiite (T-82) (Kushiro, 1972), plagioclase tholeiite (T-89) (Kushiro, 1972), and average M.O.R.B. (Dmitriev, Sharaskin, and Garanin, 1976) are also placed in this table. All these compositions and glass variation lines are plotted on Figure 7 as a function of MgO content.

Figure 7 shows the following. All primary melts considered lie inside the oval area.

DMITRIEV 305

in glasses from Atlantic (wt. %).

1. The group N 1 (125 analyses) 2.

The group N 2 (168 analyses) 3. Average M.O.R.R. (Dmitriev, et al., 1976)

Their compositions change depending on pressure as indicated by the arrow. The dashed (1-2) and dotted (3-4) lines most probably reflect the change of residual melt composition due to crystallization of the primary melts. The latter point is confirmed by simple calculations (Figure 8). The same variation lines are plotted in the O1-P1-Di ternary system: the phenocrysts assemblages which must be subtracted from the primary melts (1) and (3) to get the residual compositions (2) and (4), respectively, are indicated. In both cases the extracted phenocrysts make up about 40% wt. of the original primary melts. The orientation of variation lines (1-2) and (3-4) coincide with the directions of the cotectic lines shown on Figure 2. Olivine to plagioclase ratio of the phenocrysts for the first group is markedly higher than for the second group. This could be due to differences in Ca/Ca + Na which can be responsible for the shift of the O1-P1 cotectic boundary.

The observations concerning Figure 7 and 8

306 DMITRIEV

above allow us to conclude that the primary melt formed under decreasing pressure and crystallizatin of this melt led to the similar trends in variation of the glass composition. SiO<sub>2</sub>, TiO<sub>2</sub> (FeO), and Na<sub>2</sub>O contents increase while CaO<sup>2</sup> and MgO decrease during this process. Change of pressure does not signif cantly influence Al<sub>2</sub>O<sub>2</sub> and K<sub>2</sub>O contents in the primary melt<sup>2</sup> whilst the residual melt becomes depleted in Al<sub>2</sub>O<sub>3</sub> and enriched in K<sub>2</sub>O due to crystallization differentiation.

Average MORB, olivine (T-87) and plagioclase (T-89) tholeiites are located mostly outside the field of primary melts and glass variation It is that all of these compositions are saturated in phenocrysts to various degrees.

Figure 9 shows a combination of the diagram used previously for various petrochemical constructions (Dmitriev, 1969; Dmitriev, 1974). Two histograms of "A" and "S" componen for oceanic ultramafic rocks are seen in the lower left part. About 150 analyses of these rocks were used to construct these histograms

Fig. 6. Correlation between  $K_{2}O$  and TiO $_{2}$  contents in glasses from Atlantic (wt. %). For symbols, see Fig. 5.

(Dmitriev, 1969). The biacdal character corresponds to the existence of two main groups of oceanic ultramafic rocks: harzourgite (H) and lherzolite (L). The calculated primary melts of tholeiites for a pressure of 8-10 k bars (point 1) and for 3-5 k bars (point 3) are located in the upper left part of the diagram. Points (1) and (3) corresponding to average lherzolite and harzburgite lie practically along the one straight line. This allows a test of the petrological model of partial melting of the tholeiites from lherzolite to leave harzburgite as residual material (Dmitriev, 1969). The result of these evaluations is shown in Table 3. It is seen that the real average oceanic lherzolite and lherzolites calculated from real harzLurgite and primary melts (1) and (3) have practically the same compositions. We consider this result as confirmation of our estimates for the primary melt composition and also the petrological model for the origin of tholeiite melt from oceanic mantle by 13% of partial melting.

2**2.4**2.7447.

It has been indicated above that very important information about the primary melt can be obtained through the melt microinclusion studies. The technique for the homogenization and measurement of melt microinclusion compositions in olivine and spinels from oceanic tholeiites has been updated. Figure 10 shows the microphotograph of a polyphase inclusion in olivine (Site 332 B) before and after homogenization. The inclusions were heated at  $1270 \pm 10^{\circ}$  C within a CC<sub>2</sub> - CO atmosphere for one hour and then quenched. The compositions

to note the composition of melt cicroinclusions determined also corresponded to the equilibrium with olivine from oceanic harzburgite (Fa=9.5) which is considered to be the residual material after extraction of tholeiitic melt (Dmitriev, 1969). The temperature calculated for this equilibrium under dry conditions and 10 k bar pressure is 1320°C (Vaganov and Kusnetsov, 1976). All of these conditions (temperature, pressure, and composition) are very similar to ones determined recently by A.E. Bence, et al. (1978) (see Figure 11 and Table 2). The maximal temperatures of olivine and plagioclase phenocryst crystallization determined by the homogenization of melt microinclusions in these phenocrysts from basalts of Site 332 B have been plotted on the A. Bence diagram. The results are well in accordance with experimental data and also allow us to assume a

shallow depth of phenocryst appearance in the hel: (about 3-4 km) under dry conditions. The existence of two groups of primary tholeiftic with for the Atlantic is illustrated on the schematical map of the Atlantic Ocean, (Figure 12) from which it is seen that the first group (crosses) occurs north from 36°N south of 25°S along the Mid-Atlantic Ridge. The second group (solid points) is located in the equatorial part of the Ridge.

The geochemical difference between basalts located N and S of 36°N was also noted by W.G. Melson (1978), H. Bougault (1978), and W.B. Bryan (1978) in papers at the Second M. Ewing Symposium and occurring elsewhere in this volume.

If our assumptions about the dependence between primary melt composition and pressure is correct, then the depth of the leiftic magma generation in the mantle of the Atlantic Ocean decreases from North and South toward the equatorial area, and probably from the western margin to the Mid-Atlantic Ridge (see two points at the western Atlantic on Figure 12). From a petrological point of view this phenomenon is explained as the result of the partial -lting of spinel lherzolite to form the first group of primary melt and plagioclase lherzolite to form the second group of melt.

#### Conclusions

1. Most probably the oceanic upper mantle is quite uniform in composition along the depth interval where the oceanic tholeiites originate. This mantle consists of spinel and plagioclase lherzolite and these are the source of tholeiitic melts and also involves the production of harzburgite as the residual matter after tholeiitic melt extraction. There are no indications of the existence of pyroxenitic mantle.

2. The primary tholeiitic melt is enriched in MgO, CaO, and  $Al_2O_3$  and depleted in (FeO),

TiO<sub>2</sub> and alkalies in comparison with tholeiitic pillow lavas. This is due to the significant role of crystallization differentiation during the process of tholeiitic lava formation. It is possible that intermediate magma chambers exist at shallow depth where phenocrysts are formed. The dynamic regime of the eruptive process makes it impossible for significant amounts of the phenocrysts to dissolve in the

312 DMITRIEV

residual liquid. However, it should be emphasized that the primary melt lost some products by differentiation at the depth in mantle.

3. Two main groups of the primary melts exist in the Atlantic. The first was produced by melting of the spinel lherzolitic mantle at a depth of 35-45 km at 1280-1320°C and dry conditions. The second group was formed by the partial melting of plagioclase lherzolitic mantle at a depth of 25-30 km at  $1250-1300^{\circ}C$  and dry conditions. This leads to the geochemical differences between pillow lavas formed by evolution of one or another of these primary melt groups.

The initial crystallization of primary melts probably developed at a shallow depth of about 3-4 km. This is compatible with some geophysical data concerning the existence of the magma chambers at about this same deptn.

4. The now established existence of two groups of primary melts in the Atlantic needs to be discussed from the standpoint of global geology and tectonics. Now it is clear, however, that we need additional data about the distribution of different basalts in seismic layer II in various tectonic environments of the ocean floor.

Abstract. Dati from Leg 37 basement drill sites are compared with the FAMOUS surveys of the Mid-Atlantic R!dge at 36 - 37°N in relation to possible models of crust construction. At the youngest (ca. 3.5 my BP) drill site and in the modern median valley magma compositions range from high CaO to low CaO types of ocean ridge tholeiite. Compositional variation defines several systems of shallow-level fractionation, each characterized by major and lithophile element parameters and tach related to separate parent magma batches. Spat al variation of different systems in the median valley corresponds to the volcanic topography and is reconciled to magnetic and chenical stratigraphy at the drill sites. A hypothesis is advanced to explain the chemical zona.ion and exclusive exposure of low dips in the median valley.

#### Introduction

Until about 4 years ago little was known regarding ocean floor structure, magnetization of ocean crust, and pipcesses of crustal construction along sp eading ridges. In order to investigate these problems basement drilling by the Glomar Challerger was initiated in the Atlantic Ocean and the FAMOUS (French-American Mid-Ocean Undersea Study) project was undertaken, involving a detailed stucy of the median valley of the Mid-Atlantic Ridge at 36 - 37 N by submersible surveys and other means. Since 1974 seven basement drilling legs have been completed in the Atlantic Ocean, largely is part of the International Phase of Ccear Drilling (IPOD). The first of these, Leg 37, (Aumento, Melson et al., 1977) directly complemented the FAMOUS project by drilling 5 deep holes in oceanic basement along a sea floor spreading flow line extending WNW from the present median valley (Figure 1). Sampling at depths up to 583 m within basement led to several new concepts

314 FLOWER

regarding the ocean crust which have been confirmed and refined by later legs.

Our main objective in this paper is to integrate the chemical, lithologic, and magnetic stratigraphy of crustal rocks drilled during Leg 37 with interpretations of volcanic features and processes in the FAMOUS ridge segment in order to understand the dynamic processes of crustal construction at the spreading axis. Although deep crustal drilling and submersible surveying provide distinctly different types of data, each complements the other to a high degree. Submersible surveying allows study of spatial and morphologic relationships of crustal features but provides little data on eruptive chronology and stratigraphy. In contrast, crustal drilling, although areally restricted, provides a detailed record of crustal stratigraphy and permits a chronologic reconstruction of geologic events. Equivalent investigations have been possible previously only at subaerially exposed spreading centers (e.g. Afar and Iceland) where crustal stratigraphic relationships can be viewed in the context of axial eruptive processes (Walker, 1975a; 1975b; Gibson and Piper, 1972).

One of the basic goals of crustal studies in the Atlantic Ocean is to understand 'he processes by which the active zone of the Mid-Atlantic hidge is translated laterally into a rigid suction of oceanic basement. Two extreme, though not mutually exclusive, models for this process are gaining increasing attention. The first, influenced by studies of ophiolite complexes and Icelardic crustal sections, suggests that systematic deformation and burial occur as successive eruptive centers migrate away from the spreading axis to form an imbricate crustal section. An underlying sheeted dike complex is believed to r\_ult from accretion of buried axial feeder conduits (Palmason and Saemundsson, 1974; Kidd, 1977a; 1977b). The other .odel, based on morphologic analysis of the median valley in the

. . .

Figure 1. The 'FAMOUS' region of the Mid-Atlantic Ridge showing principal offsets and Leg 37 sites; the 'AMAR' or south rift lies to the south of Fracture Zone B.

FAMOUS area, argues that volcanic edifices once formed in the valley are not buried by later eruptions but are carried laterally to the flanks of the valley to form a 'welded' crustal layer (Atwater, 1978; Macdonald and Atwater, 1978). Each of the models predicts a specific stratigraphic profile for vertical sections of oceanic crust.

In this paper we resent interpretations of the Leg 37 drill core and FAMOUS surveys from which we attempt to define the nature of the subrift magma supply and conduit systems, the chronology of crustal accretion, and the deformation of eruptive units. These interpretations are then used to critically evaluate the hypothetical models outlined above.

#### The 'FAMOUS' Project

# Morphology of the Median Valley

The FAMOUS region is a 20-km-long segment of the median valley bounded on the north and south by transform faults, Fracture Zone A and Fracture Zone B (Figure 1). This region has been surveyed in detail by submersibles and deep tow package techniques, and extensively sampled by dredging. The results of these investigations have been published in numerous papers, most of which appeared in a special volume of the Geological Society of America Bulletin (Volume 88, Numbers 4 and 5). Further work is in progress in the AMAR (American Mid-Atlantic Ridge) rift, south of Fracture Zone B (Figure 1). Between the two fracture zones the median valley averages 4 km in width and is about 500 m deep. Within an inner rift valley, 1-2 km wide, linear volcanoes form a set of central topographic highs. Recent eruptive activity is concentrated along this central axis but is also evident at the foot of the eastern fa lt scarp where young

flows overlie older sediment-covered units. Between the central topographic highs and the rift walls the flows are everywhere fractured and deformed, but do not appear to be rotated.

Geomorphic analysis of the valley surface (Ballard and Van Andel, 1977) suggests that rifting occurs along the flanks of the central volcanoes so that as crustal dilation proceeds the axis of spreading migrates back and forth across the rift floor instead of following a static central suture. Lava flows often spread up to 500 meters or more from their vents, and surface measurements suggest that spreading is accompanied by subsidence of up to 100 meters, possibly due to collapse of shallow depleted magma chambers (cf. Wright and Fiske, 1971). Troughs flanking the inner rift and uplifted highs at the outer rift margins are associated with dip-slip faulting. Inward-facing scarps with slopes ranging up to 30° are interpreted by Ballard and Van Andel (1977) as slope 'envelopes' or groups of closely spaced faults with individual dips of 60-90°.

Local spreading rates of 13.4 mm/yr (cast) and 7.0 mm/yr (west) result in asymmetric profiles for both inner and outer rifted walls with uplift comparatively compressed to the west (Macdonald, 1977). Macdonald (1977) and Macdonald and Luyendyk (1977) conclude from deep tow magnetic surveys that spreading has been oblique relative to the axial trend for the last 8 m.y. B. P. Ramberg et al. (1977) observe that re-orientation of the oblique spreading pattern has involved complex migration of ridge segments and jumping of shorter ridge segments, resulting in local parallel spreading axes south of 36° 20'N.

The whole FAMOUS-AMAR region is one of interse crustal fracturing. Both Fracture Zones A and B have extensive westward offsets to the south and the median valley merges into these complex zones with increasing width between the confining walls.

#### Lithology and Eruptive Chronology

As summarized by Wekinian et al. (1976) the major basalt types in the FAMOUS region are: 1) Olivine phyric basalt; 2) picritic basalt; 3) plagioclase-olivine-clinopyroxene-phyric basalt; 4) highly plagioclase-phyric basalt; and 5) aphyric basalt. Types 1 and 2 are believed to represent high temperature, primitive lavas whereas types 3, 4, and 5 are interpreted as lower temperature derivatives formed by fracienal crystallization.

Despite the short time span of crustal formation (probably less than 0.5 m.y.) age estimates for the inner rift floor and adjacent walls from manganese and palagonite coatings and fission track measurements suggest three chronologically distinct groups of flows (Bryan and Moore, 1977; Hekinian and Hoffert, 1975; Storzer and Selo, 1974). With decreasing age these are: a) Olivine-rich basalts (lithologic types 1 and 2) forming central hills and more differentiated

plagioclase-olivine-clinopyroxene-phyric basalts (lithologic type 3) associated with flank eruptions; b) phyric and aphyric basalts (lithologic types 3 and 5) concentrated on the eastern part of the inner rift floor; and c) highly plagioclase-phyric basalts (type 4) occurring mostly on the western rift wall.

# Chemical V riation of Basalts

Several hundred chemical analyses have been aade of whole rock and glass samples from the FAMOUS region in order to establish basic compositional trends and to compare these rocks with those from other parts of the Mid-Atlantic Ridge (Bougault and Hekinian, 1974; Bryan et al., 1976; Bryan, in press). Because the composition of whole rock specimens is affected by phenocryst accumulation and by alteration, fresh glass compositions have been used most successfully to establish chemical variations within the FAMOUS region. For any given MgO value, TiO2 is more variable in north rift (FAMOUS) glass samples and CaO and Al2O3 are higher in south rift (AMAR) samples (Figure 2). AMAR and fracture zone basalts are more fractionated than FAMOUS samples but there is no evidence to indicate derivation from chemically different parent magmas. The small segment of the north rift including Mount Pluto and Mont de Venus, studied by the submersible ALVIN, shows a regular spatial patterr of phenocryst assemblages and glass compositions (Bryan and Moore, 1977); Hekinian at al., 1976). These authors found a zonation of several oxides, particularly TiO2, and parameters such as Fe0/Mg0 between axial and valler flank locations. From this zonation they infe a lateral progression from primitive 'axial' to fractionated 'flank' magmas which they believe to be the surface expression of an extensive sub-rift magma chamber spanning the width of the median valley. This model postulates a continuous process of eruption from, replenishment to, and fractionation within a single large magma chamber. The lateral portions of the chamber are postulated to cool more rapidly and hence undergo more fractional crystallization than the axial portions, thus by virtue of, the spreading of eruptive loci leading to the observed zonation. Bryan and Moore (1977) concluded that fractional crystallization of olivine, plagioclase and clinopyroxene can account for most variations in glass compositions despite some difficulties in reconciling litho; ile element contents between proposed paienc and daughter magmas. To overcome this problem White and Bryan (1977) suggest that successive magma batches of variable trace element composition may be injected into the chamber during cooling. Incomplete mixing of the batches coupled with fractional crystallization thus gives rise to the observed surface zonation.

We have re-interpreted the FAMOUS glass data keeping in mind the following lactors: a)

316 FLOWER

Figure 2. Oxide versus MgO plots for FAMOUS -AMAR glass chemical data; (•) symbols denote glass group average: for the Mount Pluto - Mont de Venus region of FAMOUS sampled by ALVIN (Bryan and Moore, 1977) (see toxt); other symbols represent chemical type (•) averages for dredge stations in FAMOUS and AMAR (•) rift segments and Fracture Zone(+) locations, (Bryan, 1978). Chronologic relations of shallow-level co-genetic magmas; b) spatial relations of co-genetic magmas to topographic features, and thus by implication to eruptive conduit systems; c) the role of median valley tectonics in determining the distribution and extent of burial of eruptive sequences; and d) the constraints placed on the stability of sub-rift magma chambers by such parameters as heat flow and spreading rates.

......

If eruptions occur along a more or less constant axial location in the median rift the observed chemical zonation should reflect a simple cecular trend. If, on the other hand, the zonation reflects coeval eruption of flank and axis magmas the completed crust should have a distinctly different chemical imprint either vertically or horizontally depending on the mode of crustal emplacement. One approach to resolving this question is to model the major element compositions in terms of shallow level fractionation processes. For this purpose we have sorted 30 glass analyses (Bryan and Moore, 1977) into cherical groups by using a set of discriminant oxide tolerances (Table 1) and have tested inter- and intra-group relationships by least squares analysis (Wright and Doherty, 1970). Twelve compositional groups were estab-1'shed by this procedure, the average compositions of which are given in Table 2. Each group is characterized by distinct element parameters such as Ca0/Al<sub>2</sub>O<sub>3</sub>,  $K_2$ O/TiO<sub>2</sub> and TiO<sub>2</sub>/Al<sub>2</sub>O<sub>3</sub>. In addition, trace element data from the same glass samples (Langmuir et al., 1977) show that the major element groups have characteristic and distinct ratios of Zr/Y, Ce/Sm and Sm/Yb.

Major element variations indicate that most magma groups cannot be related by simple fractionation models, hence, we infer that they represent discrete magma batches representing independent shallow-level fractionation systems. Exceptions are groups 1, 8 and 12 and groups 7 and 10, each set of which may define a line of liquid descent. Fractionation models relating other groups cannot be accomodated by least squares fits for parent and daughter lavas and fractionating phase compositions because residuals for TiO<sub>2</sub>, Na<sub>2</sub>O, and K<sub>2</sub>O are excessive.

The spatial distribution of these glass groups (Figure 3) shows that most groups have a subparillel linear arrangement, generally coincident with the topographic grain, even though sample

localities may be up to 500 m from source vents. Some magma groups (e.g. 10 and 11) are split into eastern and western segments separated by sequences believed to be younger because of thinner manganese and palagonite coatings (Hekinian et al., 1976). Based on the same kind of age data, group 11 west appears to be an old inlier completely surrounded by vounger basalts. Viewed in this context the observed chemical zonation is the result of a complex combination of fractionated basalts with  $TiO_2 \ge 1$  wt % and Mg/Mg + Fe<sup>+2</sup> ratios between .51 and .66 (e.g. 7 8, 9, 10 east, 10 west, 11 east, 11 west, and 12) and primitive basalts with  $TiO_2 < 1$  wt % and Mg/Mg + Fe<sup>+2</sup> ratios > .66 (e.g. groups 1-6) occurring in linear strips. The probable co-genetic groups (1, 8, 12 and 7, 10) are also colinear with one another and with the topographic grain.

In summary, we believe that the zonation in glass compositions reported by Bryan and Moore (1977) and Hekinian et al. (1976) cannot be due to transverse zonation of a single sub-rift magma chamber. Such a model is precluded by the quantitative incompatibilities of fractionation schemes linking supposedly cogenetic magma groups. This conclusion, coupled with the linear distribution of rocks representing individual magma groups, is compatible with the suggestion of Flower et al. (1977b) that multiple shallow-level fractionation systems co-exist beneath the evolving spreading axis.

#### DSDP Leg 37

Information derived from basement drilling on Leg 37 (Figure 4) provides a radically different perspective to mid-ocean ridge processes. Most shore-based work on Leg 37 material is now finished (Aumento, Melson et al., 1977) and numerous interpretative papers have been published.

#### Lithology and Magnetic Stratigraphy

Recovered basement material is mostly p'llow basalt and breccia with minor interlayered sediment. Basalts drilled at the youngest sites (332 and 333) are similar to those in the FAMOUS rift valley, ranging from coarsely-phyric to aphyric (Aumento, Melson et al., 1977). An

unusual coarsely-phyric three-phase basalt with phenocrysts of olivine, plagioclase, and clinopyroxene was encountered at Site 332. Basalts at 334 and 335 are sparsely phyric to aphyric, and relatively uniform. A plutonic complex composed of rhythmically interlayered twopyroxene gabbro, lherzolite, harzburgite, and dunite was encountered at Site 334 beneath about 50 meters of basalt. This complex was interpreted as a cumulate body extruded onto the median valley floor after solidification (Aumento, Melson et al., 1977).

Downhole magnetic polarity reversals and stable inclination changes at Site 332 correspond closely to major lithologic divisions and appear to define single eruptions or sequences of eruptions. Hall (1976; 1978) has interpreted this to indicate a pattern of tectonic rotation as well as secular magnetic field changes. Eruptive sequences at Sites 334 and 335 are less variable magnetically, with expected polarities and with inclinations close to the paleolatitude dipole values.

# Chemical Variation of Igneous Rocks

Chemical studies of basement samples have been summarized by Flower et al., (1977a; 1977b), Byerly and Wright (1978) and Bryan and Thompson (1977). Here we shall review only the main chemical aspects of Leg 37 basalts and discuss the relationship of chemical groups to the known lithologic and magnetic stratigraphy.

320 FLOWER

Flower et al. (1977b) and Byerly and Wright (1978) identified chemical groupings of glass selvedge and whole-rock analyses and used the concept of 'magma systems' to explain compositional lineages resulting from ascent and fractional crystallization of single parent magma batches. From the stratigraphic succession of magma types and the correspondence of such types with eruptive chronologic divisions, we can gain insights into crustal construction mechanisms and the complex nature of sub-rift magma transport.

1775 Star 1999 Star 1995

Figure 5 shows oxide versus MgO variation for Leg 37 glass groups (from Byerly and Wright, 1978) compared to group averages for FAMOUS samples analyzed by Bryan and Moore (1977). Shallow level magma systems inferred by least squares analysis are outlined. At Holes 332A and 332B magmas appear to derive from at least four separate systems (1-4) none of which correspond to a common line of liquid descent. Magmas from a single system are chemically compatible with simple phenocryst removal and accumulation at shallow levels, but those from different systems exhibit 'decoupling' of lithophile elements (e.g. Zr, Y, Ti and LEE) and major oxides, such that each system follows a unique compositional trend (cf. Langmuir et al., 1977). The chief example of inter-system element decoupling are: a) High-TiO<sub>2</sub> systems at Site 332 (1 and 2) are light rare earth element (LREE)-enriched while a similar system at Site 335 is strongly LREE-

depleted (Schilling et al., 1977); b) low TiO<sub>2</sub> systems (3 and 4) at Site 332 are

Figure 5. Oxide versus MgO plots for Leg 37 stratigraphic glass group averages (taken from Byerly and Wright, 1978); postulated low pressure fractionation systems (from Flower et al., 1976) are outlined for Site 332 compositions; FAMOUS (north rift) glass compositions (Bryan and Moore, 1977) are also outlined for comparison;  $\bullet$  Site 332-1,  $\bigcirc$  Site 332-2, O Site 332-3,  $\blacktriangle$  Site 332-4,  $\Box$  Site 334,  $\triangle$  Site 335. . ....

LREE-depleted while a similar system at Site 334 is LREE-enriched;  $Na_{2}0$  correlates with TiO<sub>2</sub> except for Site 332, group 3 which is  $Na_{2}0$ -rich and TiO<sub>2</sub>-poor; and

c) Ca0-poor magmas at Site 332 are exclusively LREE enriched, but Ca0-rich magmas are both enriched and depleted in LREE and  $TiO_2$ .

Generally, Leg 37 glass compositions do not correspond to FAMOUS glass groups which are typically more enriched in lithophile elements and lower in Al<sub>2</sub>O<sub>3</sub> and CaO for equivalent MgO content (Bryan and Thompson, 1977). Site 335 glass compositions compare most closely with FAMOUS data but are higher in Al<sub>2</sub>O<sub>3</sub> and very different in lithophile element contents. The ranges of CaO, Al<sub>2</sub>O<sub>3</sub>, Na<sub>2</sub>O in Site 332 magmas are interpreted by Flower et al. (1977b) and Byerly and Wright (1978) to reflect buffering of liquid compositions by plagioclase and clinopyroxene in the mantle residue under variable conditions of partial melting. We thus consider low pressure cotectic trends to be superimposed on a range of differing parent magma batches.

Distinct parental magma batches are further defined by lithophile element variation exemplified by REE, Zr, and Y. Zr and Y show partial decoupling from major elements in magma groups at Site 332 and total decoupling between magmas at different sites (Figure 6). Zr/Y ratios are 'polarized', with low Zr/Y ratios characterizing low Ca0 magmas (Site 332, groups 3 and 4) and high Zr/Y ratios characterizing

Figure 6. Zr/Y versus Zr (ppm) for sparselyphyric and aphyric Leg 37 stratigraphic rock group averages defined by Byerly and Wright, (1978); data from Aumento, Melson et al. (1977); ● Site 332-1, 2; O Site 332-3; ▲ Site 332-4; ● Site 333, □ Site 334; ④ Site 335.

FLOWER 321

1

high CaO magmas (Site 332, groups 1 and 2). Zr/Y values at older sites (334 and 335) show no inter-site correlations with any major elemen.: parameter. Polarization and partial decoupling of Ce/Sm ratios from major elements and Zr/Y ratios also occurs at Site 332 (Figure 7) and between sites. Data for FAMOUS glass samples (Langmuir et al., 1977) show a range from chondritic to greater than chordritic Ce/Sm ratios for both low-and high- CaO magmas.

Despite the observed diversity of basal: compositions, Sr and Nd isotope measurement. f FAMOUS and Leg 37 samples indicate an isotop cally homogeneous mantle between 15 m.y. B.P. and present (O'Nions and Pankhurst, 1977; White et al., 1976). We see from Table 3 that there are no linear changes in Ce/Sm or Zr/Y ratios, or in other parameters insensitive to shallowlevel fractionation processes, between FAMOUS and Site 335. Likewise, no linear trends are apparent for major oxides, adjusted to equivalent  $Mg/Mg + Fe^{+2}$  ratios. Because the erupted lavas along the FAMOUS - Leg 37 flow line apparently were derived from homogeneous mantle material we attribute the random variations of parent magma compositions to variable degrees of partial melting. The FAMOUS - Leg 37 data do not support the concept of progressive change in mantle source material due to mantle plume activity (Schilling, 1975; Schilling, et al., 1977).

# Interpretation of Leg 37 Sequences

3. (0.2) (A.C. 7)

In order to relate themical and morphologic features of the median valley to the stratigraphy observed in Leg 37 drill holes we now examine Leg 37 sequences in light of possible dynamic models of crust formation.

Integrated models of eruption, burial, and dike intrusion have been postulated from observations on Icelandic crust (Palmason and Saemundsson, 1974) and on ophiolites (Kidd, 1977a; 1977b). Although differing in detail both models postulate: a) A narrow intrusive zone, 1-2 km wide; b) a wider zone of eruption outflow, perhaps 2-10 km wide; c) subsidence of the erupted rocks along curved trajectories, the configuration of which depends on spreading rate and axis width; d) formation of a sheeted dike complex; and e) development of a basal layer of plutonic rocks formed from an accreting magma storage zone.

A schematic projection of these features is shown in Figure 8. The shape of the magnetic polarity changes is marked by lav./dike isochrons which determine the shape of the anomaly blocks (Kidd, 1977a). Kidd extended this approach by modelling anomalies determined by dike spreading trajectories and the Curie point isotherm of trapped magma. According to these models, a drill hole should first penetrate isochronbounded eruptive sequences, or chemically-defined eruptive phases of 'anomalous' inclination, probably showing one or more polarity reversals. At greater depth the hole should encounter a zone of abundant dikes, finally passing into a plutonic layer.

Alternative 'nonburial' models based on observations in the FAMOUS median rift (Macdonald and Atwater, 1978) predict that a given section of crust is composed of several large volcanic edifices which are transported laterally to the rift wall where they form an accreting eruptive layer. This model postulates that despite at least two episodes of vertical displacement by faulting, tilting of eruptive sequences is minimal, probably not exceeding 4-5° (Atwater, 1978). As a consequence, few if any, down-hole magnetic polarity or inclination changes would be expected and downward chemical variations would be comparatively limited, although compositions might vary laterally from site to site. This model is very difficult to reconcile with data from the crustal sequences drilled by Leg 37 where downhole magnetic, chemical, and lithologic changes are the rule, not the exception. We believe that if downhole changes in magnetic inclination or polarity coincide with compositional and lithologic boundaries of eruptive sequences the magnetic patterns most probably reflect ridge axis tectonic activity rather than faulting of the ocean crust or secular variation of the magnetic field (Hall, 1978; Watkins and Walker, 1977). Such a relationship is strongly supported by Leg 37 observations (Ade-Hall et

al., 1975), and we believe that the magnetic inclination patterns are critical to any interpretation of crustal structure. Figures 9a - 9d show syntheses of eruptive chronology at Leg 37 drill sites based on lithology, whole rock and glass compositions, and stable magnetic inclinations. Eruptive units have been defined in these sequences by assuming that the products of a single eruption have: a) Uniform glass compositions; b) whole-rock compositional variability consistent with effects of posteruptive fractionation; c) uniform magnetic polarity and stable inclination; d) lithology consistent with the compositional variation and e) no major sedimentary or clastic intercalations.

Based on these criteria 25 eruptive units are identified in Hole 332A (330.5 meters of basement penetration), 45 at 332b in Hole 332B (583 meters), 2 at Site 334 (56 meters) and 1 at Site 335 (108 meters). In addition to single eruptive units, larger units representing apparent cycles of eruptive activity can or recognized (Figures 9a - 9d). In most cases these reflect the appearance of magma from a new or dormant system

as interpreted from glass compositional data. In Holes 332A and 332B cycle boundaries defined from glass compositions (shown as solid horizontal lines in Figure 9a and 9b) coincide with sharp changes in stable magnetic inclinations, alteration intensity, and, in some cases, magnetic polarity. Thus, crustal construction at Site 332 was strongly episodic with short-lived eruptive cycles (perhaps a few tens to a few hundreds of years) separated by lengthy periods of volcanic guiescence. Site 332B lavas were probably derived from at least four separate magma systems, and flows from these systems appear to be rhythmically interlayered in the lower parts of the hole (Figure 9b). The chemical and lithologic complexity in the lower part of Hole 332B is matched by greater complexity in the magnetic record, reflected in variations in stable inclinations and in several polarity reversals. The reversals do not indicate intrusions because this entire part of the sequence is pillowed. There is no evidence for mixing of the different magma sources prior to eruption, and it seems most likely that each magma type was derived from near-synchron, is

Figure 8. Schematic burial model for crust accretion, after Palmason and Saemundsson (1974); the dike-fraction encountered in drilled sections will depend on the width of the intrusive zone; 1 - distribution of intrusive dike activity (eruptive feeder conduits);

2 - distribution of lava eruption and outflow extent, resulting dike distribution curve of type a; if diking occurs outside of these limits a dike distribution will approach a curve of type b.

A, B, C, and D represent possible isochron-bounded basalt units that might be encountered in a drill hole.

systems developed independently from separate parent batches.

The lithologic and chemical variations with time shown by magmas from a single system should give at least partial information on the history of crystallization, phenocryst redistribution, and draining by cruption of a single reservoir or series of reservoirs. No gradational lithclogic pattern is evident at Site 332, although complex and rapid interbedding of olivine- and plagioclase-phyric and also coarsely- and sparselyphyric basalts may occur in any one eruptive cycle. This implies that shallow-level phenocryst-liquid fractionation did not produce a single chemical zonation of magma in a single chamber. The compositions of eruptive units probably also reflect phenocryst redistribution due to gravity settling and to flow, and perhaps also periodic magma influx from deeper-seated sources resulting in mixing of primitive and evolved magmas. Neither of these processes, however, can be invoked to explain chemical differences between magmas from different systems (Flower et al., 1977b; Byerly and Wright, 1978).

In summary, the crustal stratigraphy at Leg 37 drill sites, particularly Site 332, indicates a pattern of episodic eruption. Close coincidence of lithologic, chemical, and magnetic boundaries indicates that this stratigraphy was

324 FLOWER

developed during crustal construction in the median rift. Site 332, the early eruptive episodes werr relatively frequent and accompanied by considerable deformation; later episodes reflect longer quiescent intervals between eruptions and more stable tectonic conditions.

#### Synthesis of Ocean Ridge Processes

Any viable ridge construction model must reconcile the evidence deduced from drilling for episodic eruption, interlayering of magmas from different systems, and substantial tectonic rotation during early stages of crustal construction with the apparent lack of tilting and the complex chemical zoning of basalts on the modern median valley floor.

Following Flower et al. (1977b), we believe that the chemical variation of FAMOUS and Leg 37 basalts indicates the co-existence of several independent shallow-level fractionation systems beneath the ridge axis. Dynamic stability of such systems will depend largely on the heat flux and the spreading rate (Sleep, 1975). If approximate isostatic balance is maintained these factors will in turn determine the overall supply of magma, the extent of fractionation, and the degree of magma entrapment at depth.

In reconstructing dynamic processes at the

Figure 9a. Schematic downhole sections showing eruptive units inferred from variations in drill core of lithology,NRM stable inclination and chemical affinity of glass and whole-rock compositions; data sources are Hall and Ryall (1977), Flower et al. (1977a) and Byerly and Wright (1978). The range of stable inclination and TiO<sub>2</sub> data are shown for each eruptive unit and have been extrapolated to probable unit stratigraphic limits. Glass TiO<sub>2</sub> compositions are shown by solid areas; the discrepancy between glass and whole-rock compositions (unshaded areas enclosed by vertical dashed lines) is a measure of whole-rock phyric character, as TiO<sub>2</sub> is not incorporated by phenocryst phases. Major lithologic units and magnetic polarity changes are indicated; 'magma systems' include eruptions inferred to be cogenetic in terms of shallow-level fractionation processes from least squares analysis of glass and whole-rock compositions.

Mid-Atlantic Ridge it is useful to compare and contrast this type of active zone with other volcanic regimes. To make such comparisons, we have estimated magma supply rates for intraplate volcanoes (Kilaues and Mauna Loa), the 'diffuse' spreading axis of Iceland, and the Mid-Atlantic Ridge (Table 4). The estimates show that supply rates from the mantle to the dilating Mid-Atlantic and Icelandic regions (for approximately equivalent conduit network areas) are 1 to 2 orders of magnitude lower than for non-dilating intra-plate systems, whereas the proportions of non-eruptive magma trapped at depth are considerably higher in the dilating regimes. Although magma mixing has been demonstrated for the Kilauea east rift (Wright and Fiske, 1971) where two systems appear to coalesce periodically, it is not a dominant process and it would seem to be of even less significance in a dilating environment. Large, oid-like magma chambers are not in evidence at Kilauea (Fiske and Jackson, 1972) and it seems that magma from adjacent conduit systems of Mauna Loa and Kilauea are chemically independent (Wright, personal

communication). There is seismic evidence for extensive rift-controlled magma transfer both in Kilauea and the Icelandic rift zone (Bjornsson et al., 1978), similar to that we have inferred for the FAMOUS rift zone (Figure 3), suggesting that this feature is common to all three environments.

In the absence of seismic evidence for linear chambers spanning the width of the median valley (Fowler, 1976; Fowler and Matthews, 1974), and considering the chemical evidence for widespread shallow level fractionation and phenocryst accumulation (Flower et al., 1977b; Byerly and Wright, 1978), we conclude that in the FAMOUS region magma ascends along linear cracks corresponding to the axis of dilation, and is temporarily stored in a complex of dikes of extensive linear but restricted lateral extent.

The surface pattern of the median valley suggests that eruptions from multiple systems occur largely in the axial zone rather than at intermediate and flank localities (Figure 3). For the case of a narrow axial zone of eruption the compositional zoning in the basalts may either reflect short-term secular variations in

the magnatic regime or constitute an effect of the physical mechanism of spreading and crustal accretion. The stratigraphic record at DSDP

Site 332 strongly supports the latter interpretation, and implies that the surface compositional zonation is the result of progressive burial as crustal accretion proceeds. The identification of discrete eruptive sequences in the drill core at Site 332 (Figures 9a and 9b) and the correlation of surface glass compositional groups with the topography of the median valley (Figure 3) suggest that each sequence represents a single volcano or chain of volcanoes at the ocean floor. There is some evidence (Flower et al., 1977b) that individual eruptive sequences or volcanoes show an internal progression with time from early fractionated to later more primitive compositions from a given parental magma batch. Thus, there are reasonable grounds to speculate that for continuous crustal dilation (evidenced by rifting of even the youngest volcanoes; Atwater, 1978) each eruptive sequence may form a lenticular edifice whose tilting and partial burial by succeeding eruptions would result in surface exposure of only the more fractionated lava products. The net effort of this would be to hide from view the more primitive and more tectonically deformed basalts as the accreting eruptive pile migrates laterally, giving rise to surface compositional zonation and allowing exposure only of basalts with atypically low tectonic inclinations. For any given section of oceanic crust we predict 20 to 40 such eruptive sequences contributing to layer 2. The role of an oscillating eruptive axis is hard to evaluate, but, if relevant, it would be a further important factor determining patterns of compositional zonation and magnetic inclinations.

In conclusion, we emphasize that drilling results from Leg 37 and surveys of the FAMOUS median valley form an excellent perspective for interpreting Mid-Atlantic Ridge dynamics. In particular we believe that the deep crustal structure revealed at Site 332 resulted from repeated burial of eruptive sequences in the median rift, and that similar processes are occurring in the modern active zone.

#### CONTROLS ON THE MAJOR AND MINOR ELEMENT CHEMISTRY OF MID-OCEAN RIDGE BASALTS AND GLASSES

A. E. Bence, D. M. Baylis, J. F. Bender and T. L. Grove Department of Earth and Space Sciences State University of New York Stony Brook, New York 11794

Abstract. We have modelled the processes of low- and highpressure crvstn' fractionation, magma mixing, and variable degree of part... melting to assess their relative importance in generating the n-ajor element spectrum observed for  $\sim$  1300 crystalline mid-ocean ridge basalts and  $\sim$  1100 basaltic glasses erupted on the ocean floor. Our analysis of these data indicates that the chemistry of crystalline basalts is controlled largely by low-pressure crystal fractionation involving olivine, plagioclase or both. Basaltic glass compositions reflect (a) initial magma compositional differences and (b) crystal-meltcontrols during low-pressure crystallization. Clinopyroxene fractionation can account for the reduced CaO/Al<sub>2</sub>O<sub>3</sub> ratios observed in the basaltic glasses. However, this occurs at low pressure only after significant (in excess of 30%) crystal fractionation of primitive magma compositions and must involve the prior removal of olivine and plagioclase. Highpressure fractionation of clinopyroxene is consistent with experimental and petrographic observations. Clinopyroxene is the liquidus phase for primitive MORB compositions at pressures exceeding 10 kb under anhydrous conditions. Magma mixing in an open chamber can enrich the incompatible components to levels above that expected in a simple low-pressure fractionation model without drastically lowering  $Mg/(Mg + Fe^{2+})$ . Multiple cycles of magma mixing accompanied by extensive fractional crystallization are required to generate the observed variation of  $TiO_2$  in the basaltic glasses. Variable degrees of partial melting of a lherzolite source can generate the range of TiO<sub>2</sub> concentrations in basalt glasses having high and restricted  $Mg/(Mg + Fe^{2+})$ . The entire range of TiO<sub>2</sub> and FeO\* concentrations and Mg/(Mg + Fe<sup>2+</sup>) ratios cannot be generated by variable degrees of partial melting of a chemically homogeneous source.

# Introduction

Subalkaline (tholeiitic) basalts erupted at diverging plate boundaries are the dominant lithology of the upper part of the oceanic crust (layers 2 and 2A). Alkaline varieties appear to be volumetrically insignificant and are apparently restricted to oceanic islands, seamounts, and topographic highs. It has been recognized that the minor and trace element characteristics of these two basalt types require that they must be derivatives of chemically distinct mantle source regions (see, for example, Engel *et al.*, 1965, Gast, 1965, 1968; Kay *et al.*, 1970). These discussions, based largely on studies of samples dredged from ridges, rises, fracture zones, and seamounts, emphasized the pronounced chemical differences between the two groups and the distinct but generally homogeneous character of the subalkaline mid-ocean ridge basalts (MORB's). More recently, because ocean floor coverage has increased dramatically through recoveries by the Deep Sea Drilling Project (DSDP), the International Program for Ocean Drilling (IPOD), submersible operations (e.g., Project FAMOUS) and detailed dredging surveys along ridges (e.g., the Reykjanes Ridge), significant second order chemical variations in MORB's have been noted. These variations are observed in basalts recovered from different ridge systems, from different sites along the same ridge system (e.g., Schilling, 1973) and even from the same submersible (e.g., Project FAMOUS), dredge (Miyashiro *et al.*, 1969) or drill site (e.g., Site 332A of DSDP Leg 37).

Fresh subalkaline MOR basalts and basaltic glasses exhibit a spectrum of major element compositions which are characterized by the presence of normative hypersthene and by the depletion of large-ion-lithophile (LIL) elements (Th, U, K, Rb, Zr, Hf, REE, Y, NB, Ti, etc.). Basalts with normative olivine dominate (olivine tholeiites), but quartz-normative compositions (quartz tholentes) occur as well. The subalkaline basalts are subdivided on the tasts of their abundances of the LIL elements, particularly K and the light rare earth elements (LREE), into high- and low-r, tholentes (Green, 1971). The low-K basalts, which are by far the most abundant, usually contain less than 0.1-0.3% K<sub>2</sub>O and have LREE relative abundances that range from highly depleted [(La/Sm)<sub>N</sub>  $\sim$ 0.4] to slightly enriched [(La/Sm)\_N  $\sim$  2]. Heavy rare-earth patterns are flat at about 12 times chondrites on the average but range from about 8-00 x cc. The high-K tholenites, which appear to be restricted to topographic highs, have moderate light rare-earth enrichment (La/Sm  $\sim$  4-7) and higher K contents (0.3-1 wt.%). These tholeiites are transitional between low-K tholeiites and alkali basalts (Kay et al., 1970). Hawaiian (Schilling and Winchester, 1969) and Icelandic (Schilling, 1973) tholeiites are of this type. Deep Sea Drilling Project sites 2-10 (Frey et al., 1974), 15-151 (Bence et al., 1975), and 26-250A, 251A (Fleet et al., 1976) recovered high-K tholeiitic basalts.

Three factors play major roles in generating the compositional variations observed in fresh basalts erupted at the midocean ridges. These factors are: (1) source region chemical and mineralogical heterogeneities, (2) postmagma generation fractionation effects at low and high pressures, and (3) variable

percentages of partial melting and variations in melting mechanim. All of these factors interact and, because the effects of the three mechanisms can be similar and the observed chemical variations are small, it is difficult, in some cases, to identify the extent to which each has contributed to the si ectrum of compositions observed in spatially related suites such as those recovered by Project FAMOUS. Further, processes such as magma (e.g., O'Hara, 1977; Donaldson *et al.*, 1977) and source (e.g., Schilling, 1973) mixing may be superimposed, further obscuring the cause of the variations.

This paper examines the major and minor element chemistries of crystalline basalts and basaltic glasses recovered by DSDP, IPOD, submersible, and dredging operations from all the oceans to assess the relative importance of the factors that contribute to their chemical diversity. To do this, we have amassed, from the literature and from our own published and unpublished work, a library of major element analyses of crystalline basalts (now in excess of 1300 analyses) and basaltic glasses (\*\* 1100 analyses). The majority of our basaltic glass data (965 analyses) are from the work of Melson et al. (1976). The renainder were obtained at Stony Brook. Both data sets were collected on the glass phase of sparsely phyric rinds from pillows or flow contacts. The glass data can provide information on the initial magma composition and, if petrographic data are available, on the low-pressure phase relationships and on the liquia line of descent of the magma.

Our fractional crystallization and partial melting calculations rely heavily on the experimental work of Roeder and Emslie (1970); Roeder (1974); Bender *et al.* (1978); and Fisk (1978).

# Compositional Variations in Mid-Ocean Ridge Basalts and Basaltic Glasses

To aid in the identification of processes that control the direction and magnitude of changes in MORB chemistry, we separate crystalline basalts from basaltic glasses in the diagrams presented below. Rocks are separated from glasses because crystal fractionation (removal or accumulation of phases) at the emplacement site is an important factor in the chemical variation of the crystalline basalts and its effects are readily distinguished. The glass compositions, on the other hand, reflect the low-pressure liquid-line of descent and reveal differences in initial magma composition. Petrographic examination (see, for example, Shido et al., 1971), confirmed by experimental melting studies (Bence and Hibberson, 1975; Kushiro, 1973; Bender et al., 1978; Fisk, 1978), reveals that olivinc or plagioclase, or both (± spinel), are the important low- pressure liquidus phases in mid-ocean ridge tholeiites Removal or accumulation of these phases through crystal fractionation can generate marked compositional changes. For example, nickel concentrations and the ratio  $Mg/(Mg + Fe^{2^*})$ (Mg#) in basalts are extremely sensitive to olivine fractionation whereas Eu and Al2O3 abundances are plagioclase sensitive. The fractionation effects of both phases can thus be recognized.

The normative mineralogies of the crystalline basalts and basaltic glasses, projected on the Di-Ol-Hyp plane (Fig. 1a) of the Di-Ol-Qz-Ne tetrahedron, illustrate the extreme compositional diversity of the crystalline basalts relative to the glasses. This variation is due to the combined effects of crystal fractionation and chemical weathering on the crystalline basalts. Glass chemistry is more tightly restricted, and chemical variations reflect the liquid lines of descent. For example, a

332 BENCE

plot of normative olivine-plagioclase-pyroxene reveals a linear trend that defines the low-pressure olivine-plagioclase cotectic and olivine-plagioclase-clinopyroxene multiple saturation (Fig. 1b), and indicates that multiphase fractionation at low pressures is an important process that controls basalts glass chemistry.

To aid in the identification of crystal-melt controls on mid-ocean ridge basalt chemistry, a projection scheme that is relevant to this suite of samples is desirable. The phases partiment to the crystallization of oceanic basalts are olivine, plagioclase, high calcium clinopyroxene, spinel and silica, and a projection utilizing these five phases has been calculated. Suc 1 a projection can be useful in several ways: (1) it may reveal the phase responsible for chemical variation between a suite of samples; (2) it may be used to obtain the proportions of phases removed during a fractionation or melting sequence (all subprojections must be considered, of course); and (3) it may reveal the parental magma in a suite of samples and distinguish multiple parent magma types.

The recalculation uses molar units to calculate the proportions of olivine  $(Mg,Fe)_2 SiO_4$ , plagioclase  $Ca_{1-x}Na_x Al_{2-x} Si_{2+x}O_8$ , high-Ca clinopyroxene  $Ca(Mg,Fe)Si_2O_6$ , silica  $SiO_2$  and spinel  $(Mg,Fe)_2 TiO_4$ ,  $(Mg,Fe)Cr_2O_4$ . The scheme is useful for samples with low  $Fe_2O_3$  and  $P_2O_5$  and suppresses Fe/(Fe + Mg) variation, which can be considered by utilizing other projections.

Since  $TiO_2$  and  $Cr_2O_3$  contents are low, the recalculated spinel component is discarded and the *z*-talyses are projected into a pseudoquaternary system; olivine (Ol)-plagioclase (Plag)-clinopyroxene (Cpx)-silica (Qz). Oceanic uasalts contain substantial proportions of all four components, so no simplified projection that resembles a ternary liquidus diagram can be used. Inspection of the ternary subprojections

Figure 1b. MORB chemistry. Normative proportions of pyroxene, plagioclase, and olivine. Top: basaltic glasses. Bottom: crystalline basalts. Glasses plot in the vicinity of the inferred plagioclase-olivine cotectic.

in the pseudoquarternary reveals trends of significant silica enrichment and olivine-plagioclase control in molar proportions 1:2 for the basaltic glasses (Fig. 2a). The Ol-Plag-Cpx subprojection (Fig. 2b) shows a clustering of points that represent the projection, from silica, of the low-pressure olivine-plagioclase cotectic and olivine-plagioclase-clinopyroxene multiple saturation. Preliminary information from experimental studies in basaltic systems indicates that residual liquids in equilibrium with olivine, plagioclase, and clinopyroxene have compositions with a range of silica contents and Fe/(Fe + Mg) ratios but with only minor variations in the relative proportions of olivine, plagioclase, and clinopyroxene. The glass compositions plotted in Fig. 2 may define the projection of a cigar-shaped volume containing liquids that are multiply saturated with the three phases.

The position of the olivine-plagioclase cotectic defined by the glasses and the experiments is in the approximate molar proportions of one part olivine to two parts plagioclase. These proportions are used in the low-pressure modelling calculations. Phenocrysts coexisting with the natural glass compositions confirm the location of the experimentally determined cotectic (Fig. 2a). Glasses that contain olivine crystals lie in the olivine primary phase volume, glasses with

olivine and plagioclase lie closest to the experimentally determined cotectic and glasses containing olivine, plagioclase and clinopyroxene lie at the upper extension of the cotectic.

Oxide-oxide and oxide-Mg/(Mg +  $Fe^{2^{+}}$ ) variation diagrams (Figs. 3-7) which serve to document the chemical diversity of the mid-ocean ridge basalts are useful in identifying the most primitive (i.e., least fractionated) magmas and the effects of low- and high-pressure fractionation and partial melting. Used in conjunction with the ternary subprojections described above, they may place constraints on MORB petrogenesis.

#### **Primitive Magmas**

The recognition of primitive (i.e., direct partial melts of the upper mantle) magmas is of critical importance to MORB petrogenesis because it is these liquids that can provide chemical and mineralogical information on their sources. Two chemical parameters,  $Mg/(Mg + Fe^{2+})$  and Ni, are indicators of primitiveness. Mineral/melt distribution coefficients for FeO and MgO (Roeder and Emslie, 1970; Roeder, 1974; Mysen, 1975; Bender el al., 1978, Fisk, 1978) and Ni (Hakli and Wright, 1967; Henderson and Dale, 1969; Leeman, 1973; Bougault and Hekiman, 1974; Sato, 1977) require that magmas generated by 20-30% partial melting of a peridotitic mantle source dominated by Fugo olivine have Mg/(Mg + Fe<sup>2\*</sup>) ratios of  $\sim 0.74$  (see, for example, Green et al., 1974; Hanson and Langmuir, 1978; Bender et al., 1978) and Ni contents of  $\sim$  250-350 ppm. Only rarely are such high Ni contents observed in a noncumulate basalt (see, for example, Frey et al., 1974), and noncumulate basalts do not have such high Mg/ (Mg + Fe<sup>2+</sup>) ratios. The highest observed ratio is  $\sim$ 0.75 which was obtained for a melt inclusion in spinel (Donaldson et al. 1977). Since the Mg/(Mg + Fe<sup>2+</sup>) ratio is extremely sensitive to olivine fractionation but relatively insensitive to the percentage of partial melting so long as the liquid is multiply saturated with ferromagnesian phases at the source (Hanson and Languir, 1978; Bender et al., 1978), it might be concluded that even the most primitive basalts as defined by the above criteria have experienced minor olivine fractionation. However, the effects of olivine fractionation can be recognized and compensated for. Liquids that are derived from source regions where they are multiply saturated will have Mg/(Mg + Fe<sup>2+</sup>)  $\sim 0.72$ -0.75 (atomic). From Figures 3-8 we see that liquids having these Mg values will also have the following chemistry:  $T_1O_2 \simeq 0.5 \cdot 0.7$  wt.%,  $Al_2O_3 \simeq 16 \cdot 17.5$ wt.%, FeO\*  $\simeq$  8 wt.%, and CaO  $\simeq$  13 wt.%. Parent magmas of the most primitive mid-ocean ridge basalts will have compositions in these ranges.

#### Crystal Fractionation at Low Pressures

Experimental and petrographic studies of mid-ocean ridge basalts confirm that the majority have olivine ( $\pm$  spinel) or plagioclase as liquidus phases at low pressures. Melting studies on Project FAMOUS basalt glass 527-1-1 (Bender *et al.*, 1978) indicate that the crystallization sequence for this relatively primitive composition is olivine  $\rightarrow$  olivine + plagioclase  $\rightarrow$  olivine + plagioclase + clinopyroxene in the pressure interval  $0 \sim 10$  kb. Clinopyroxene crystallizes late in this composition at low P; consequently, it is unlikely to be a significant fractionating phase at low pressures.

Textural arguments indicate that Cr-spinel was the liquidus or co-liquidus (with olivine) phase in the natural sample

334 BENCE

(527-1-1) and, consequently, would be potentially an important fractionating phase. Spinel did not crystallize in the Bender *et al* experiments, because their molybdenum capsules imposed an  $[O_2$  on the basalt that was lower than that under eruptive conditions (quartz-fayalite-magnetite buffer). Thus, the effects of spinel fractionation are not available from the experimental data on 527-1-1. If spinel fractionation is important in mid-ocean ridge basalt petrogenesis it would have a marked effect on the Cr content of the basalts. Chrome abundances in MORB's are rarely reported in the literature and in the infrequent cases that they are, the data are insufficiently precise. In subsequent modelling of basalt evolution through crystal fractionation, we have ignored the effects of spinel.

The effects of olivine and plagioclase fractionation at low pressures on the chemistry of MORB's may be recognized on Figures 2-7. In particular, the variations of  $Al_2O_3$  with MgO and Mg/(Mg + Fe<sup>2+</sup>) (Figs. 3a, b, and 4a, b) are particularly sensitive to olivine and plagioclase fractionation.

The compositional spectrum of the crystallin<sup> $\circ$ </sup> basalts (Figs. 3b and 4b) has a maximum concentration in the range; MgO = 7.9 wt.%, Al<sub>2</sub>O<sub>3</sub> = 14-17 wt.%. Extensions of the fields towards higher concentrations of Al<sub>2</sub>O<sub>3</sub> and MgO reflect the accumulation of plagioclase and olivine, respectively.

The scatter of the crystalline basalt compositions contrasts markedly with the highly restricted glass field (Figs. 3a and 4a). This restriction is a consequence of crystal-liquid controls on the composition of the glass. Petrographic observations on the glass samples analyzed at Stony Brook and the results of low-pressure experimental studies suggest that the region of the glass field where MgO  $\gtrsim$  7 wt.% and Al<sub>2</sub>O<sub>3</sub>  $\gtrsim$  145 wt.% (Fig. 3a) defines the approximate position of the olivineplagioclase cotectic. Many of the glasses with lower  $\stackrel{W}{\to}$  0 and Al<sub>2</sub>O<sub>3</sub> appear to be multiply saturated with olivineplagioclase and clinopyroxene. Few of the crystalline basalts fall in this field.

The calculated low-pressure fractionation liquid line of descent for Project FAMOUS basalt 527-1-1 follows the inferred olivine-plagioclase cotectic (Fig. 2a). This calculation uses the equilibrium mineral/melt partition coefficients measured by Bender et al. (1978) and assumes ideal fractionational crystallizations (i.e., crystals are removed from reactions with liquid). The process is carried out in two weight percent increments. Olivine is the liquidus phase for this composition; however, the calculation assumes that plagioclase commenced to crystallize when normative proportions of olivine:plagioclase reached 1:2 (the molar proportions defined by the position of the olivine-plagioclase cotectic for these compositions) (Fig. 2a). Olivine and plagioclase were subsequently extracted in these proportions. The calculated liquid compositions after 6% and 30% crystallization are reported in Table 1, Columns 2 and 3. The equilibrium liquid line of descent for basalt 527-1-1 (Bender et al., 1978) is also shown on Figure 2a.

The width of the glass field (Fig. 2a) may reflect either a pressure effect on the olivine-plagioclase cotectic or different parental liquids. The extent of silica enrichment cannot be a consequence of the fractionation of a common parent magma but must reflect multiple parent liquids.

After approximately 50 wt.% crystallization, the calculated residual liquid composition reaches the range where clinopyroxene is observed coexisting with olivine and plagioclase in the natural samples (Fig. 2) and in the equilibrium experiments conducted on FAMOUS basalt 527-1-1 (Bender *et al.* 1978). The majority of crystalline basalt compositions (ex-

cepting those resulting from plagioclase or olivine accumulation) fall in the vicinity of the path defined by this trend (Figs. 3b, 4b, 5b, 6b, 7b). Glass compositions show much greater extremes but with more restricted ranges reflecting the degree to which they have crystallized (Figs. 3-7).

Sector -

Several important observations can be made from the variation diagrams:

First, the experimental results confirm that the majority of the basaltic glass compositions reflect crystal-liquid control. Many of those with MgO and Al<sub>2</sub>O<sub>3</sub> in the ranges 7-9 wt.% and 14-17.5 wt.%, respectively, fall in the vicinity of the low-pressure olivine-plagioclase cotectic. The most primitive of these glasses (Mg/Mg + Fe<sup>2\*</sup>)  $\gtrsim 0.65$ ) are characterized by Al<sub>2</sub>O<sub>3</sub>  $\gtrsim 16$  wt.%, MgO  $\gtrsim 8$  wt.%, FeO\*  $\lesssim 10$  wt.%, TiO<sub>2</sub>  $\lesssim 1.0$  w..%. Glasses lying along the olivine-plagioclase cotectic

(Fig. 2) or those more evolved compositions that appear to be multiply saturated with olivine + plagioclase + clinopyroxene have adjusted to low-pressure conditions and cannot be primary liquids.

Second, the evidence for cotectic control on the compositions of the crystalline basalts is largely obscured by the effects of plagioclase and olivine accumulation.

Third, the variation of FeO\* with MgO in the glasses (Fig. 5a) is consistent with a low-pressure olivine + plagioclase fractionation path. The crystalline basalts (Fig. 5b) have three trends consistent with olivine accumulation (high MgO), olivine (+ plagioclase) fractionation (high Fe\*), and plagioclase accumulation (low FeO\* and MgO).

Fourth, the  $TiO_2$ -MgO and  $TiO_2$ -Mg/(Mg + Fe<sup>2\*</sup>) variations in the basaltic glasses (Figs. 6a, 7a) are consistent with

Figure 5. FeO\* vs MgO. (a) Basaltic glasses. (b) Crystalline basalts. Fractionation path as for Fig. 3.

Figure 6. TiO<sub>2</sub> vs MgO. (a) basaltic glasses. (b) crystalline basalts. Fractionation path as for Fig. 3.

cotectic (olivine-plagioclase) and peritectic (olivine-plagioclase-clinopyroxene) controls. Variations of  $T_1O_2$  in the crystalline basalts (Figs. 6b, 7b) also reflect these controls (as well as the effects of olivine and plagioclase accumulation). The nearly six-fold change of  $T_1O_2$  in the noncumulate crystalline basalts cannot be due entirely to evolution of a single parent magma through simple crystal fractionation. Multiple liquids having varying  $T_1O_2$  contents appear necessary. These liquids may be derivatives of variable sources, the same source through variable degrees of partial melting, or they may arise through mixing of magmas in an open magma chamber (O'Hara, 1977; Bryan *et al.*, 1978).

We may conclude from these observations that low-pressure fractionation involving plagioclase and olivine is the most important control on MORB major- and minor-element

336 BENCE

chemistry. However, a single low FeO\*-low  $T_1O_2$  magma cannot give rise to the entire spectrum of noncumulate crystalline basalt compositions through simple low-pressure crystal fractionation.

# Fractionation at High Pressures

Least-squares approaches to modelling compositional variations in spatially related suites of mid-ocean ridge basalts seem to require significant amounts of clinopyroxene fractionation (see, for example, Bryan and Moore, 1977; Bryan and Thompson, 1977; Bryan *et al.*, 1978). However, experimental studies of mid-ocean ridge basalt compositions (e.g., Kushiro, 1973; Bender *et al.*, 1978; Fisk, 1978) indicate that under low-pressure anhydrous conditions, clinopyroxene

Figure 7. TiO<sub>2</sub> vs Mg/(Mg + Fe<sup>2+</sup>). (a) basaltic glasses. (b) crystalline basalts. Fractionation path as for Fig. 3.

Figure 8.  $Al_2O_3$  vs CaO. (a) basaltic glasses. (b) crystalline basalts. Low-pressure (olivine  $\rightarrow$  olivine + plagioclase) fractionation path and high-pressure (clinopyroxene) fractionation path are shown.

follows olivine and plagioclase in the crystallization sequence. Furthermore, clinopyroxene appearance in the equilacium experiments occurs only after considerable crystallization and consequent chemical evolution of the melt. A somewhat earlier appearance of clinopyroxene might be expected under conditions of ideal fractionational crystallization, but again, extensive crystallization (and chemical evolution of the melt) prior to clinopyroxene first appearance is to be expected. It was on these grounds that Bender *et al.* (1978) concluded that low-pressure clinopyroxene fractionation was unlikely to be an important mechanism for MORB petrogenesis.

Under high-pressure ( $\gtrsim 10$  kb) anhydrous conditions, however, calcic clinopyroxene is the liquidus phase for primitive MORB compositions (see, for example, Kushiro, 1973; Bence and Hibberson, 1975; Bender *et al.*, 1978). A small amount of water ( $\leq 0.5$  wt.%) reduces the point of multiple saturation to pressures as low as  $\sim 3$  kb (Bence and Hibberson, 1975). From these results it may be concluded that clinopyroxene fractionation under moderate to high pressures is a viable mechanism for the evolution of MORB's. Petrographic observations of MORB's in the last few years have revealed small percentages of clinopyroxene phenocrysts/xenocrysts whose compositions are readily distinguishable from ground-mass clinopyroxenes (Schweitzer *et al.*, 1978).

We are, therefore, concerned with the extent to which the major and minor elemental spectrum of MORB's may be a consequence of clinopyroxene fractionation under moderate pressure. However, the combined effects of olivine and plagioclase fractionation on the major elements, already recognized as an important process in MORB petrogenesis, obscure the effects of clinopyroxene fractionation. These effects can be separated by examining the variation of CaO and  $Al_2O_3$ .

Figure 8 illustrates the effects of low-pressure (olivine and plagioclase) and high-pressure (clinopyror ne) fractionation on MORB chemistry. Clinopyroxene fractionation was modelled using the high-pressure mineral/melt distribution coefficients determined by Bender *et al.* (1978). These coefficients vary markedly with composition (and temperature) and are constrained by clinopyroxene stoichiometry (Hanson and Langmur, 1978); consequently, they must be continuously changed in a fractionation calculation.

As on the previous variation diagrams, much of the variation in basaltic glass chemistry can be attributed to cotectic control. The crystalline basalt field is dominated by the effects of both plagioclase and olivine accumulation. However, a portion of the spectrum observed on both diagrams is consistent with a small amount of chinopyroxene fractionation.

The two fractionation paths are also readily distinguished on a CaO/Al<sub>2</sub>O<sub>3</sub> (weight) vs Mg/(Mg + Fe<sup>2</sup>\*) (atomic) diagram for the basaltic glasses (Fig. 9). Clinopyroxene fractionation results in lower CaO/Al<sub>2</sub>O<sub>3</sub> and Mg/(Mg + Fe<sup>2</sup>\*) ratios while CaO/Al<sub>2</sub>O<sub>3</sub> increase with olivine + plagioclase fractionation. Plagioclase accumulation accompanied by olivine fractionation could account for a trend having the appearance of clinopyroxene fractionation in the crystalline basalts; however, it cannot explain the ratios of CaO/Al<sub>2</sub>O<sub>3</sub>  $\lesssim 0.75$ in the glasses.

Consequently, it might be concluded that a significant percentage of the more evolved basaltic glasses have undergone clinopyroxene fractionation. Selected trace element data on the glasses (e.g., Sc; V, Cr, La) are needed to substantiate this conclusion.

#### Magma Mixing

Some of the compositional variations observed in midocean ridge basalts may be a consequence of magma mixing, accompanied by crystal fractionation, in shallow magma chambers. Bryan and Moore (1977) and Bryan *et al.* (1978) suggest that fractionation in an open-system magma chamber (O'Hara, 1977) into which successive batches of magma are injected can generate the compositional relationship in basalts from the median valley of the mid-Atlantic Ridge at the Project FAMOUS study area. They suggest that this process can cause enrichment of the incompatible components above the levels that can be explained by simple crystal fractionation. Rhodes *et al.* (1978), utilizing mineralogical, geochemical, and experimental data for DSDP Leg 45 and 46 basalts, conclude that magma mixing occurred in the evolution of these basalts and that it is likely to be a fundamental process in MORB petrogenesis.

We have modelled magma mixing and crystal fractionation for the major elements varying the extent of fractionation, the compositions of the successive magma pulses, and the mixing proportions (assuming complete mixing). These calculations indicate that some of the observed enrichment of TiO<sub>2</sub> and FeO\* in the Project FAMOUS basaltic glasses could be a consequence of magma mixing in an open-system magma chamber. However, such a process is not required to explain the major element data, and the REE data (Langmuir et al., 1977) indicate that other processes must be operative to generate the observed LIL element distributions in Project FAMOUS basalts.

Calculated magnia compositions for a two-stage mixing model involving low-pressure crystal fractionation prior to and following mixing are presented in Table 1. FAMOUS basalt 527-1-1 is used as the starting magma composition for these calculations. Following 30% crystal fractionation (olivine, then olivine + plagioclase) the residual liquid is mixed with a second batch of 527-1-1 composition and subsequently fractionated again (30% crystallization). The fractionation and mixing paths for TiO2-Mg# in this precess are shown on Figures 10a and b. The directions of TiO<sub>2</sub> and FeO\* enrichments on these diagrams are consistent with but not restricted to open-magma chamber mixing and crystal fractionation. By varying the percentages of crystal fractionation, the proportions of the residual and primary magmas mixed, and the number of new magma pulses injected into the chamielements not incorporated in olivine or plagioclase are creasingly concentrated in the melt. At the same time  $Mg/(Mg + Fe^{2*})$  ratio of the melt will not be lower rapidly as in a simple fractionation model. Although process is capable of generating part o the corr

Figure 10. Plots of FeO\* vs Mg/(Mg + Fe<sup>2\*</sup>) (a) and TiO<sub>2</sub> vs Mg/(MG + Fe<sup>2\*</sup>) (b) showing fields for the basaltic glasses and the crystalline basalts. spectrum of MOR basalts and basaltic glasses, confirmation that it is an important process in the petrogenesis of a suite of related basalts would require assessment of the mineralogical and trace element evidence.

#### Partial Melting Controls on Magma Composition

The percentages of partial melting, the mechanism of partial melting, and the residual mineralogy have major controls on the trace and major element abundances in basaltic melts. Hanson and Langmuir (1978) apply trace element modelling to major elements and Bender *et al.* (1978) use this approach to show how the fraction of partial melting and the residual mineralogy can generate part of the compositional spectrum observed in the Project FAMOUS basaltic glasses. They conclude that the spectrum of TiO<sub>2</sub> abundances observed for glasses with restricted ratios of Mg/(Mg + Fe<sup>2+</sup>) could be a consequence of variable degrees of partial melting of a herzolite source containing 0.25 wt.% TiO<sub>2</sub>.

This treatment assumes that the major elements may be modelled in a manner similar to trace elements but with the additional rigid constraint of mineral stoichiometry. The Hanson-Langmuir treatment of FeO and MgO suggests that their approach is valid for these components; however, it is much less likely to be the case for  $Al_2O_3$ , CaO,  $Na_2O$ ,  $TiO_2$ , etc.

We have assumed that the approach is valid for  $T_1O_2$ , which behaves largely as an incompatible element for large percentages of partial melting, and have calculated liquid compositions from the partial melting equation (Schilling, 1966; Shaw, 1970). Melt compositions for different degrees of partial melting of an assumed mantle source (Bender *et al.*, 1978) with the residual mineralogy varying between  $Ol_{55-80}$ :  $Opx_{20-35}$ :  $Cpx_{0-26}$  have been calculated. Only those calculations which meet the stoichiometric restrictions of the residual minerals are assumed to be valid. The effect of variable percentages (10-30%) of partial melting on FeO\*, TiO<sub>2</sub>, and Mg/(Mg + Fe<sup>2\*</sup>) are summarized in Figures 10a and b. These results show that the variation of FeO\* and TiO<sub>2</sub> in MORB's with relatively restricted Mg/(Mg + Fe<sup>2\*</sup>) ratios could be a consequence of variable degrees of partial melting followed by some olivine fractionation from the melt. Magmas with evolved Mg/(Mg + Fe<sup>2\*</sup>) ratios ( $\lesssim 0.65$ ) and high TiO<sub>2</sub> cannot be generated solely through partial melting of a source region which contains o<sup>1</sup>ivine, orthopyroxene, and clinopyroxene as residual phases.

#### Conclusions

The following conclusions arise from this analysis of crystalline null-ocean ridge basalt and basalt glass compositions and our modelling of petrogenetic processes.

- 1. The chemistry of the crystalline basalts is controlled largely by low-pressure crystal fractionation involving olivine and plagioclase.
- 2. Basalt glass compositions reflect (a) initial magma compositional differences and (b) crystal-melt-controls during low-pressure crystallization.
- 3. Clinopyroxene fractionation can account for the reduced CaO/Al<sub>2</sub>O<sub>3</sub> ratios observed in the basaltic glasses. Such a process can occur at low pressures only after significant (in excess of 30%) crystal fractionation of a primitive magma composition and involves the prior removal of olivine and plagioclase. High-pressure fractionation of clinopyroxene is consistent with the experimental and petrographic observations. Clinopyroxene is the liquidus phase for primitive MORB compositions at pressures exceeding 10 kb under anhydrous conditions.
- 4. Magma mixing in an open chamber can enrich the incompatible components to levels above those expected in a simple low-pressure fractionation model without drastically lowering  $Mg/(Mg + Fe^{2*})$ .

# ISOTOPE GEOCHEMICAL STUDIES OF NORTH ATLANTIC OCEAN BASALTS AND THEIR IMPLICATIONS FOR MANTLE EVOLUTION.

R. K. O'Nions, N. M. Evensen, S. R. Carter, and P. J. Uamilton Lamont-Dohert: Geological Observatory of Columbia University, Palisades, New York 10964

Abstract. The avai. able Pb-, Nd-and Sr-isotope determinations on North Atlantic Ocean basalts are reviewed. It is shown that the sub-oceanic mantle which has supplied these basalts has been previously depleted in R) relative to Sr and Nd relative to Sm, and by inference large-ion lithophile elements in general. Basaltic volcanism does not appear to have simpled mantle which is undifferentiated or primordial. The Pb-, Ndand Sr-isotope data are compatible with continuous models of mantle differentiation, although a simplistic incorpretation of the Pb-isotope data alone suggests a single mantle differentiation event about 1.6 Gy ago. The Sr-, Nd- and Pb-isotope data can be used together with trace element abundance data to test simple two-component mixing models. Such models do not satisfy the available data from either Iceland and the Reykjanes Ridge nor the Azores and more complex models involving additional components are required. The degree of heterogeneity is such that the system probably cannot be adequately modelled with a few discrete components.

#### Introduction

In the last few decades, petrologists and geochemists have become increasingly concerned with the geochemistry of oceanic basalts in attempts to determine the nature and chemistry of suboceanic mantle. Classic studies on the origin of oceanic basalts have postulated their derivation from peridotitic sources (e.g., Bowen, 1928) or alternatively from basaltic sources (e.g., Daly, 1944). Models for the generation of oceanic basalts by partial fusion of peridotite were placed beyond dispute by the results of experimental petrology in the 1960's. Similarly, the relationship of alkali and tholeiice basalt types to primary magma compositions was 'argely resolved (e.g., Yoder and Tilley, 196; Green and Ringwood, 1967; O'Hara, 1965, 1968).

The study of radiogenic isotope: in oceanic basalts has proceeded in parallel with these petrological studies and become increasingly im-

342 O'NIONS

portant. In particular, isotopic studies have helped clarify petrogenetic relationships between consanguineous oceanic volcanics and the nature and temporal aspects of sub-oceanic mantle differentiation. At an early stage in these isotopic studies Gast (1960) was able to demonstrate that the Earth has a lower Rb/Sr ratio than chondritic meteorites because of the paucity of 87Sr in the Earth. Subsequently, Tatsumoto et al. (1965) for example, noted that basalts dredged from mid-ocean ridges posess insufficient <sup>87</sup>Rb to support their <sup>87</sup>Sr contents. This observation implied that the mantle source regions of mid-ocean ridge basalts (MORB) had been depleted in Rb relative to Sr by differentiation episodes which occurred prior to the genesis of MORB. This important observati was amplified by Gast's (1968) demonstrations MORB source regions are depleted in other la. ionic-radius lithopile elements in addition to Rb, such as Ba and the rare-earth elements. In the last few years, the measurement of Nd-isotope compositions in oceanic basalts has provided a major stimulus to the understanding and interpretation of mantle differentiation. The combination of Nd-and Sr-isotope data now provide a geochemical framework within which depletion and enrichment of mantle source regions can be both identified and quantified. From the standpoint of the Rb-Sr, Sm-Nd and U-Pb systematics of oceanic volcanics the N. Atlantic is the most thoroughly studied part of the ocean basins. Considerable attention has been devoted to the petrogenetic relationship between magmas erupted in Iceland and on the Reykjanes Ridge as a result of Schilling's (1973) important demonstration that lithopile element abundances vary systematically along the length of the Reykjanes Ridge. The body of isotopic data now accrued on drilled, dredged and subaerial basalts from the N. Atlantic permits an evaluation of the Jifferentiation of their mantle source regions.

Basaltic volcanism has occurred in the N. Atlantic during the last 50-60 My. In principle, some of the chemical characteristics of the mantle sources which have supplied basalts over this time

Fig. 1. Ranges of  ${}^{87}$ Sr/ ${}^{86}$ Sr ratios for submarine ocean ridge and ocean island basalts in the North Atlantic. Only data with  $\pm$  0.0001 (2c) precision, or better have been utilized. Data from Hart <u>et el.</u>, 1973; Hart 1976; White <u>et al.</u>, 1976; O'Nions and Grönvold, 1973; O'Nions and Pankhurst, 1973, 1974; O'Nions <u>et al.</u>, 1973, 1976; Sun and Jahn, 1975).

interval can be determined from isotope studies. The earliest Tertiary volcanics (outcropping in Baffin Island, E. and W. Greenland, Faroes and the British Isles) were erupted in a continental environment during the early stages of continental breakup. However, some of these basalts were contaminated during their passage through the continental crust (Carter <u>et al.,1978a</u>) which has obscured the chemistry of their mantle sources.

In the present article the Sr,- Nd- and Pbisotope compositions of basalts erupted in the N. Atlantic ocean basin are reviewed, and their relevance to the nature and evolution of their source regions is discussed. Particular consideration is given to their relevance to continuous episodic models of mantle differentiation.

#### Review of Sr, Nd and Pb- Isotope Geochemistry

<u>Sr - Isotopes</u>. The earliest Sr - isotope measurements of N. Atlantic basalts were reported by Tatsumoto <u>et al.</u>, (1965) for mid-ocean ridge dredge basalts and Hedge and Walthall (1963) and Gast <u>et al.</u> (1964) for ocean island basalts. These measurements have now been superceded by a large number of high-precision Sr-isotope data.

The ranges of <sup>87</sup>Sr/<sup>86</sup>Sr ratios for dredged basalts from the mid-Atlantic ridge (including the Reykjanes Ridge) are compared with basal<sup>+</sup>s from Jan Mayen, Iceland, Ascension, Canaries and the

Azores in Fig. 1. In general, the MORB have lower  $^{87}$ Sr/ $^{86}$ Sr ratios (0.7023-0.7032) than the oceanic island basalts, although there is a significant overlap with the ranges reported for Iceland and Ascension. Of particular interest has been the demonstration of both local and regional variations in <sup>87</sup>Sr/<sup>86</sup>Sr ratios. For example, Hart et al. (1973) and O'Nions and Pankhurst (1974) demonstrated significant differences in the <sup>8</sup>Sr/<sup>86</sup>Sr ratios of basalts erupted along the Reykjanes Ridge, which more or less, parallels the variation in La/Sm ratios reported by Schilling (1973). Internally, Iceland and the Azores contain basalts with a considerable range of <sup>\$7</sup>Sr/<sup>\$6</sup>Sr ratios. The data of O'Nions et al. (1976) demonstrated that significant  $^{87}$ Sr/ $^{36}$ Sr variations exist in the kecent Icelandic basalts occurring in the active spreading zones and the Snaefellsnes Peninsula of western Iceland and encompass a large proportion of the variations found along the Reykjanes Ridge. Indeed, basalts of the Theistereykir region of N. Iceland, erupted over a few tens of km<sup>2</sup>, have a similar range of <sup>87</sup>Sr/ <sup>85</sup>Sr and Ce/Yb ratios to that of the Reykjanes Ridge basalts (O'Nions et al., 1976). In addition to the resolvable range of E7Sr/86Sr ratios in Recent Icelandic basalts, O'Nions and Pankhurst (1973) suggested that there was a secular decrease in the 97Sr/85Sr ratios from basalts erupted in Iceland from 16 My ago to the present day. It is possible that this apparent secular variation is an artefact resulting from inadequate sampling, although insufficient new data have been obtained to further evaluate this possibility. In addition to the variations in <sup>87</sup>Sr/<sup>85</sup>Sr

In addition to the variations in  $3^{\circ}$ Sr/ $^{cb}$ Sr along the Reykjanes Ridge substantial variations are well documented farther south along the mid-Atlantic Ridge between 50°N and 30°N (White <u>et al.</u>, 1975, 1976; White and Schilling, 1978), with maximum values of  $3^{\circ}$ Sr/ $^{86}$ Sr occurring at about 45°N and between 35° and 40°N with the lowest ratios recorded from 50°N.

Sr- isotope data for Tertiary basalts erurted during the initial opening phase of the N. Atlantic have not been plotted in Fig. 1. It has already been indicated that some of these have suffered significant contamination by continental crust (Carter <u>et al.</u>, 1978a). However, uncontaminated basalts (ca.60 My old) from Baffin Bay, E. and W. Greenland and the Isle of Mull in N.W. Scot and have  $\frac{37}{5r}$ /<sup>85</sup>Sr ratios ranging from 0.7028 co 0.7040 (Carter <u>et al.</u>, 1979).

<u>Nd and Sr Isotopes</u>. <sup>143</sup>Nd/<sup>144</sup>Nd ratios have now been measured in a number of Recent N. Atlantic basalts, including samples from Iceland, the Reysi mes Ridge, and the equatorial mid-Atlantic Ridge. The most useful of these data are those for which  $^{67}$ Sr/ $^{86}$ Sr ratios have been determined on the same samples (O'Nions et al., 1977; Zindler and Hart, 1978). The  $^{143}$ Nd/ $^{154}$ Nd and the  $^{87}$ Sr/ $^{86}$ Sr ratios of such samples are plotted in Fig. 2 and compared with the overall trend defined by oceanic basalts. The inverse correlation be-

**O'NIONS** 343

tween <sup>143</sup>Nd/<sup>144</sup>Nd and <sup>87</sup>Sr/<sup>86</sup>Sr, defined by the oceanic data and the N. Atlantic basalts themselves, was first recognized by DePaolo and Wasserburg (1976b) and O'Nions et al., (1977). This covariance between <sup>143</sup>Nd/<sup>144</sup> id and <sup>87</sup>Sr/<sup>86</sup>Sr in oceanic basalts attests to a coherence in the fractionation of Rb/Sr and Sm/Nd during sub-oceanic mantle differentiation, and leads to an improved estimate (Fig. 2) of the Rb/Sr ratio of the bulk Earth (DePaolo and Wasserburg, 1976h; O'Nions et al., 1977). Those parts of the sub-oceanic mantle with lower <sup>37</sup>Sr/<sup>86</sup>Sr and higher <sup>143</sup>Nd/<sup>144</sup>Nd ratios than the bulk Earth (Fig. 2) have been depleted in Rb relative to Sr and light KEE relative to heavy REE, resulting in a reduced Rb/Sr ratio and increased Sm/Nd ratio (see Table 1 for bulk Earth values.

The inverse correlation between  $^{143}Nc/^{144}Nd$ and  $^{87}Sr/^{86}Sr$ , illustrated in Fig. 2, has been defined only by data obtained on unaltered oceanic basalts. Island arc and altered ocean floor basalts are compared with the trend of una<sup>1</sup>tered oceanic basalts in Fig. 3, illustrating the divergence from this trend caused by the addition of seawater Sr ( $^{87}Sr/^{86}Sr \simeq 0$  709).

The Sr- isotope composition of seawater has been estimated by a number of workers (see Faure and Powell, 1972) and in addition it's Nd - isotope composition has been estimated from the <sup>143</sup>Nd/<sup>144</sup>Nd ratios of Mn- nodules, Fe - rich sediments and fish debris (O'Nions <u>et al.</u>, 1978a; DePaolo and Wasserburg, 1977). Changes in the <sup>143</sup>Nd/<sup>144</sup>Nd ratios of ocean

Changes in the  $^{14^{2}}$ Nd/ $^{14^{4}}$ Nd ratios of ocean floor basalt induced by interactions with seawater have not been detected so far. This is presumably because of the exceeding low concentration of Nd in seawater.

<u>Pb- Isotopes</u>. Pb- isotope compositions of reliable accuracy have been published for N. Atlan-

Fig. 2.  $^{14}3Nd/^{14}4Nd$  versus  $^{87}Sr/^{8b}Sr$  ratios for N. Atlantic basalts from O'Nions <u>et al.</u>, 1977 and Zindler & Hart (1978). The data are compared with the overall oceanic trend and the correspondent bulk Earth composition reported by O'Nions <u>et</u> <u>al.</u>, (1978b).

Column 1: Abundances assuming that Earth has the same relative abundances of Ca, U, Th, Sm, and Nd as carbonaceous chrondites, Rb/Sr = 0.031,  $K/U = 10^4$  and  $^{238}U/^{204}Pb = 10.4$  by weight. Column 11: Abundances assuming that heat lost from the Earth equals heat generated and that the Th/U, Sm/U, K/U, Rb/Sr, and  $^{238}/^{204}Pb$  ratios for the Earth are the same as Column I. Mean global heat flow from Williams and Von Herzen (1975), after O'Nions <u>et al</u>., (1978c).

tic basalts from Iceland (Sun and Jahn, 1975), the Reykjanes Ridge (Sun <u>et al.</u>, 1975), the Canaries and the Azores (Sun, 1973) and the mid-Atlantic ridge (Tatsumoto, 1978). These data are plotted on a  $20^7 \text{Pb}/20^4 \text{Pb}-20^6 \text{Pb}/20^4 \text{Pb}$  diagram in Fig. 4, referenced with a 4.55 Gy isochron and growth curves for  $2^{38}\text{U}/20^4 \text{Pb}(\mu) = 8.0$  and 8.5. The N. Atlantic basalts form a linear array with

Fig. 3. Comparison of  $1^{43}$ Nd/ $1^{44}$ Nd and  $8^{7}$ Sr/86Sr ratios in island arc and altered ocean floor basalts with those in Mn-nodules and metall: 'ous sediments, illustrating the effects of seawate: interaction on the ocean floor and at subduction zones. Data are from (DePaolo and Wasserburg, 1977; Hawkesworth <u>et al.</u>, 1977; O'Nions <u>et al.</u>, 1978b).

Fig. 4. (a)  $20^{7}\text{Pb}/20^{4}\text{Pb}$  versus  $20^{6}\text{Pb}/20^{4}\text{Pb}$  ratios for N. Atlantic basalts from Iceland, the Canaries, the Azores, m.d-Atlantic ridge and the Reykjanes Ridge. Data from Tatsumoto (1978), Sun et al., 1975, Sun and Jahn (1975) and Sun (1973). For reference a 4.55 Gy iso-chron and  $\mu$  ( $^{238}\text{U}/^{204}\text{Pb}$ ) growth lines of 8.0 and 8.5 have been plotted.

(b)  $\mu$  (<sup>238</sup>U/<sup>204</sup>Pb) versus T(Gy) diagram illustrating models capable of producing the Pb- isotope range observed in these N. Atlantic basalts. The  $\mu$  value of the early Earth (before ca.,  $^{\rm L}$  Gy) is uncertain because of the amount of lead (if any) incorporated into the Earth's core. Fractionation models are shown relative to an undifferentiated mantle µ value of 8.0. Two-stage model: single mantle-wide fractionation event at 1.6 Gy. Source regions of the most radiogenic volcanics would have acquired  $\mu$  values as high as 20. Multi-stage model: continuous fractionation of µ from 3.8 Gy (approximate time of commencement of continental crust stabilization). Curve indicates the maximum increase of  $\boldsymbol{\mu}$  with time to produce the most radiogenic volcanics. From 3.8 Gy to 2.5 Gy  $\mu$  could only have increased by c:., 20%.

the oceanic island basalts generally containing more radiogenic lead than the submarine ridge basalts. The true significance of such linear arrays has been debated for many years. The central problem has been to distinguish between (1) a simplistic two-stage episodic mantle evolution or (2) a more complex multi-stage continuous mantle evolution. This question will be discussed in more detail in a subsequent section of this paper.

## <u>Differentiation and Evolution of Mantle Magma</u> <u>Sources</u>

The most important recent advances in the use of isotope geochemical data from oceanic basalts are based upon the improved estimates of the Sm/Nd and Rb/Sr ratios in the bulk Earth (E undifferentiated mantle). Estimates of the elemental abundances are also much improved (O'Nions et al., 1978c). The current best estimates and sources of these critical bulk Earth parameters are reported in Table 1. It should be noted at this juncture that it is assumed that the isotopic compositions of the erupted basalts are equal to those of their source, which was in isotopic equilibrium at the time of melting, and have not been modified during their ascent to the surface. The possibility of local disequilibrium during melting has been extensively discussed recently (e.g., O'Nions and Pankhurst, 1974; Hoffman and Hart 1978). For the situation where the mantle is partially molten for a long period prior to the extraction of melt, Hoffman and Hart (1978) have shown from kinetic considerations that the degree of isotopic disequilibrium should be negligible. Furthermore, disequilibrium melting models were found to be incompatible with the isotopic and trace element variability of oceanic basalts by O'Nions et al. (1976) and White et al. (1976).

Previously O'Nions et al. (1978b) and Carter et al. (1978b) have compared the single-stage time-integrated Rb/Sr and Sm/Nd ratios of basaltsource regions, as computed from their measured  $^{87}\mathrm{Sr}/^{86}\mathrm{Sr}$  and  $^{143}\mathrm{Nd}/^{144}\mathrm{Nd}$  ratios, with the bulk Earth Rb/Sr and Sm/Nd ratios. The fractional differences have been expressed in terms of ASR and AND parameters. In Fig. 5 AND and ASR values are compared for both the Recent N. Atlantic basalts (see Fig. 2) and uncontaminated, Tertiary basalts (ca60 My) from Baftin Bay, E. and W. Greenland and N.W. Scotland. Without exception these basalts have negative  $\Delta SR$  and positive  $\Delta ND$  values. Thus, compared with undifferentiated mantle of the bulk Earth composition, the sources of all these N. Atlantic basalts have been depleted in Rb relative to Sr and Nd relative to Sm (equivalent to light REE depletion). This includes basalts erupted at so-called hot-spot sites as well as in submarine ridge environments. It seems inescapable that during the 60 My evolution of the North Atlantic (from the time of continental break-up co the present day) only depleted mantle sources have been sampled. Mantle sources which could be considered in anyway undifferentiated, primary, pristine or even enriched were not sampled by basaltic volcanism and probably do not exist in the N. Atlantic upper mantle in any significant quantity. It must be noted that the mantle sources of basalts erupted in Iceland and other so called 'hot-spots' are less unique amongst

O'NIONS 345

a v na star a star a star a star a star a star a star a star a star a star a star a star a star a star a star a A v na star a star a star a star a star a star a star a star a star a star a star a star a star a star a star a

oceanic basalts than has sometimes been implied and furthermore have not been isolated from the mantle differentiation processes involved in the generation of continental crust. The overall depletion of the upper mantle caused by the removal of lithopile elements to the continental crust throughout the last 3.8 Gy of Earth history is clearly evident in the source regions of all N. Atlantic basalts discussed here.

Having compared the N. Atlantic upper mantle within the bulk Earth framework, it is germane to discuss the timing of the mantle differentiation events responsible or the observed depletion. It is now abundantly clear that this problem is closely tied to the generation of the continental crust. (e.g., O'Nions and Pankhurst 1978; O'Nions et al., 1978, a, b). Although comparatively little is known in detail about the rate of crustal growth through time, it is well-established that the earliest preserved granite crust dates from about 3.8 Gy ago. A substantial proportion of the continental crust (approximately half) had been produced by 2.5 Gv ago and the remainder has been added in a quasi-continuous manner (cf. Moorbath, 1975; O'Nions and Pankhurst, 1978;

Fig. 5.  $\Delta ND$  versus  $\Delta SR$  for Recent and Tertiary N. Atlantic basalts.  $\Delta$  parameters are defined as the percentage deviation of the single-stage (SS) parent-daughter ratios from the bulk Earth (BE) composition. For example:

$$\Delta ND = \frac{147}{147} \frac{\text{Sm}}{144} \frac{144}{\text{Nd}} \frac{\text{SS}}{\text{Sm}} = \frac{147}{144} \frac{\text{Sm}}{144} \frac{144}{\text{Nd}} \frac{\text{BE}}{\text{BE}} \times 10^2$$

where

$$\frac{147}{\text{Sm}/144} \text{Nd SS} = \frac{143}{\text{Nd}/144} \frac{\text{Nd} \text{ measured} - 0.50682}{((\text{Exp } \lambda^{147} \text{ . T}) - 1)}$$
  
and T = 4.55 Gy

All samples plot in the  $-\Delta SR/+\Delta ND$  quadrant indicating that their mantle source regions were depleted in Rb and light REE relative to the bulk Earth composition.

346 O'NIONS

Fig. 6. Sm-Nd evolution diagram for basalts from Iceland and the Reykjanus Ridge. For amounts of melting in excess of 2%, the 147Sm/144Nd values will be within 20% of their source values. The best-fit line corresponds to an age of ca. 200 My., and the initial ratio  $\sim 0.5128$ , see text for a discussion of the significance of the observed correlation. Data from O'Nions <u>et al.</u>, (1977) and Zindler and Hart (1978).

McCulloch and Wasserburg, 1978). The implication of these observations is that Rb/Sr, Sm/Nd and U/Pb must have been fractionated in the mantle prior to 3 Gy ago and chemical heterogeneiities must have existed (see O'Nions and Pankhurst, 1978; Sun and Nesbitt, 1977). Recognition of mantle heterogeneiities dating from the earliest Archaean may be hindered by two factors: 1) Those parts of the mantle containing evidence of early mantle differentiation may not be sampled by contempol, volcanism. 2) The long-lived heterogeneiities may have been eradicated by convective motions resulting in mantle mixing.

motions resulting in mantle mixing. The <sup>147</sup>Sm/<sup>144</sup>Nd and <sup>143</sup>Nd/<sup>144</sup>Nd ratios of N. Atlantic basalts are plotted on a Sm-Nd evolution diagram in Fig. 6. The slope of the best-fit line to the data plotted in Fig. 6 corresponds to an age of 190+70 My. This age is only geologically meaningful however, if the Sm/Nd ratios of the basalts are equal to those of their source regions, and all source regions had identical <sup>143</sup>Nd/ <sup>144</sup>Nd ratios 190 My ago. A similar analysis of the available Rb-Sr data for these and other samples yields apparent times of a mantle fractionation

38
event ranging from 200 My to 500 My if assumptions analogous to those outlined above are adopted (0'Nions <u>et al.</u>, 1976; Langmuir <u>et al.</u>, 1978; White and Schilling, 1978).

The linear array of Pb- isotope compositions shown in Fig. 4 can also be used to estimate the timing of mantle differentiation. This array can be modelled by (i) a two-stage episodic model to imply a major fractionation event 1.6 Gy ago or alternatively (ii) a multi-stage model. In the latter case the linear array could merely result from mixing of two distinct end-member compositions as suggested by Sun et al. (1975) and Tetsumoto (1978). The  $\mu$  - time relationships for a twostage episodic model interpretation is compared with that of a continuous fractionation model in Fig. 4. Both models are capable of producing the range of Pb- isotope composition observed in the N. Atlantic basalts, but have very different implications for the evolution of the mantle.

The Sm-Nd, Rb-Sr  $\cdot$  , Pb isotope data considered above pose the  $f(\cdot)$  wing questions:

1) If the Sm-Nd acca reflect a unique fractionation event in the mantle approximately 200 My ago, was the mantle undifferentiated until that time?

2) Can the two stage model interpretation of the Pb- isotope data (1.6 Gy fractionation event) be reconciled with the Sm-Nd and Rb-Sr systematics?

The answer to the first question is straight-forward. The initial  $^{14}$  Nd/ $^{144}$ Nd ratio of the mantle-isochron interpretation in Fig. 6 is 0.5128 whereas undifferentiated mantle is predicted to have a lower  $^{143}$ Nd/ $^{144}$ Nd ratio (0.5124) 200 My ago. Therefore, the time integrated Sm/Nd ratio of these source regions between 4.55 Gy and 200 My ago was greater than the bulk Earth " ine, indicating the light REE depletion had already occurred during this time interval. With respect to the second question, regardless of whether the Pb-data are interpreted using a two-stage or a multi-stage model, it is evident that some fractionation event(s) affected the U-Pb system 10<sup>9</sup> y or more ago. Hence, both the Sm-Nd and U-Pb systems suggest the occurrence of early (>10<sup>9</sup>y) mantle fractionation events, but the Sm-Nd system indicates more recent fractionations also. The data presented for the N. Atlantic basalts in this paper are compatible with the following statements:

1) U/Pb, Sm/Nd and Rb/Sr have been fractionated in the mantle since at least the beginnings of continental growth 3.8 Gy ago.

2) The present heterogeneiities in U/Pb, Rb/Sr and Sm/Nd ratios are mainly the result of more recent fractionations which occurred on a time scale closer to  $10^8$ y than  $10^9$ y.

3) The fractionations of Sm/Nd and Rb/Sr in the mantle during the last 5 x  $10^8$ y or so are responsible for a considerable amount of the present variability of  $^{143}$ Nd/ $^{144}$ Nd and  $^{87}$ Sr/ $^{86}$ Sr in the upper mantle.

4) The variability of Pb- isotope (particularly  $^{207}\text{Pb}/^{204}\text{Pb}$ ) compositions reflect still earlier

differentiation events occurring on a time scale of  $\ge 10^9$ y ago. At this time  $^{2.35}$ U was relatively more abundant than at present. More recent ( $\sim 10^8$ y) fractionations of U/Pb have produced comparatively little variability in  $^{2.97}$ Pb/ $^{2.04}$ Pb because of the low abundance of  $^{2.35}$ U.

All three of these parent-daughter systems appear to be compatible with continuous or multistage fractionation models. The tendency towards continuous eradication or 'smoothing-out' of chemical heterogeneiities produced in the earlier epochs of mantle evolution attest to the efficiency of mantle convection processes in removing them - at least within the upper mantle.

## Dynamical Processes in the Mantle

Isotopic variations in oceanic basalts can be used to impose some constraints on dynamical processes in the mantle. In favorable circumstances they can be used in conjunction with concentration data to test models of scurce and magma mixing, and partial melting. Several attempts have been made to test source and magma mixing models for Iceland and Reykjanes Ridge basalts (Sun <u>et</u> <u>al.</u>, 1975; O'Nions <u>et al.</u>, 1976; Langmuir <u>et al</u>., 1978). Mixing equations have been derived by Lancelot and Allegre (1974) and Vollmer (1976) and provide the rationale for each of these attempts.

Sun et al., (1975) used Pb- isotope and concentration data for Reykjanes Ri 3e basalts, and demonstrated that linear plots of  $^{207}\text{Pb}/^{204}\text{Pb}$  and  $^{206}\text{Pb}/^{204}\text{Pb}$  versus  $^1/\text{Pb}$  were consistent with binary mixing models. This result implied that melting and crystallization differentiation processes had not modified the Pb- concentrations sufficiently to mask the correlations. From this observation one might expect that similar correlations should exist between  $8^7 \text{Sr}/8^6 \text{Sr}$  versus 1/Sr and 143Nd/144Nd versus 1/Nd. O'Nions et al., (1976) showed that a plot of  $\frac{87}{\text{Sr}}$  versus  $\frac{1}{7}$  Sr was not linear and did not lend support to this model. These Sr-data together with the Nd- isotope and concentration data of O'Nions et al., (1977) are compared in Fig. 7. From this diagram it is apparent that a linear correlation does not exist between 143Nd/144Nd and 1/Nd either, but <sup>87</sup>Sr/<sup>86</sup>Sr does correlate linearly with Sr. Thus, these data taken together provide little support for a simple binary mixing model. If the isotopic variations in Icelandic and Reykjanes Ridge basalts are indeed the result of mixing of two end members then the combined effect of melting and crystallization have fractionated at least Rb/Sr and Sm/Nd in such a way as to destroy consistent correlations.

Despite these inconsistencies there are reported correlations between  ${}^{87}\mathrm{Sr}/{}^{86}\mathrm{Sr}$ ,  ${}^{14}\,{}^{3}\mathrm{Nd}/{}^{14}\mathrm{^4Nd}$ ,  ${}^{147}\mathrm{Sm}/{}^{144}\mathrm{Nd}$ ,  ${}^{87}\mathrm{Sr}/{}^{86}\mathrm{Sr}$  and  $\mathrm{Ce}_{\mathrm{N}}/\mathrm{Yb}_{\mathrm{N}}$  in the N. Atlantic basalts. The significance of these first two correlations has been discussed above. O'Nions <u>et al.</u> (1976) attributed the third correlation to the generation of heterogeneous mantle several hundred

million years ago and Langmuir <u>et al.</u> (1978) in a more detailed discussion have shown that mixing models involving three or more sources can also accomodate the data. Further efforts to quantify the actual number of discrete sources beneath Iceland and the Reykjanes Ridge would now appear to be a very difficult exercise. Similarly an extension of this approach to identify a particular mantle component to be included in a dynamical model of mass transport (such as a mantle plume) would be unproductive, since it is now clear that whatever form the mantle source supplying basalts to Iceland has, it must be heterogeneous.

Marked correlations between trace element abundance ratios such as Ba/Sr, Rb/Sr, and  $^{87}Sr/^{86}Sr$ have been documented for the Mid-Atlantic Ridge basalts between 30°N and 50°N (White <u>et al.</u>, 1975; White and Schilling, 1978) and models involving more than two components must be appealed to. At the present time a unique solution to the data available does not exist and it is almost a matter of personal taste whether one attributes the variations to a number of mutually intermixing mantle plumes, or simply to mantle heterogeneities without any implications concerning the physical nature of the mass transport processes.

#### Depletion and Enrichment Processes

Earth differentiation has proceeded with the progressive removal of large ion lithopile elements from the upper mantle to the continental crust. The production of partial melts in the mantle and their physical removal from the residium is the prime mechanism of element transport and fractionation. The transport of large ion lithopile elements from the mantle to the continental crust must have been dominated by such processes.

It is now well established that the singlestage time integrated Sm/Nd and Rb/Sr ratios of the N. Atlantic mantle sources are respectively higher and lower than those of the bulk Earth. The actual measured Sm/Nd and Rb/Sr ratios of some ridge basalts also bear this relationship to the bulk Earth composition. However other basalts, particularly ocean island basalts, have relatively high Rb/Sr ratios and are enriched in the light REE (e.g., Schilling, 1973; O'Nions et al., 1976). The relationship of the measured parent-daughter ratios of N. Atlantic basalts to the bulk Earth composition is illustrated by  $\delta'ND$  and  $\delta'SR$  parameters in Fig. 8. The  $\delta'$  parameter is the fractional deviation of the measured parent-daughter ratio in a particular basalt from that of the bulk Earth. Also plotted on this diagram are the  $\Delta ND$  and  $\Delta SR$  values for the N. Atlantic from Fig. 5. Small degrees of melting (2-5%) are not expected to produce rore than a 20% change in  $\delta$ 'ND, thus if the source egions shown are applicable, then "he generation of some basalts appear to require even greater fractionations of Sm/Nd. The mechanism whereby this occurs is presently obscure, but it is not the result of simple par-

348 O'NIONS

Fig. 7. Plots of  ${}^{87}\text{Sr}/{}^{86}\text{Sr}$  versus Sr and  ${}^{1}/\text{Sr}$ and  ${}^{14}\text{3}\text{Nd}/{}^{14}\text{M}$  versus Nd and  ${}^{1}/\text{Nd}$  for basalts from Iceland and the Reykjanes Ridge. For a simple two component mixing model  ${}^{87}\text{Sr}/{}^{86}\text{Sr}$  and  ${}^{14}\text{3}\text{Nd}/{}^{144}\text{Nd}$  are predicted to correlate with  ${}^{1}/\text{Sr}$  and  ${}^{1}/\text{Nd}$ respectively. These data are inconsistent with such a simple model. Data from O'Nions <u>et al.</u>, 1976, 1977.

tial melting and must include more complex processes of enrichment. In view of the correlation evident in Fig. 6 and the correlation of  $Ce_N/vb_N$ with  $^{87}Sr/^{86}Sr$  (O'Nions <u>et al.</u>, 1976) it seems that the enrichment may pre-date the contemporary melting event by several hundred millions of years. If such fractionations of REE commonly occur in the upper mantle then the isotope systematics of Recent basalts require that they are short-lived heterogeneiities

Later P.

#### Concluding Remarks

Studies of oceanic basalts have proved to be one of the most successful ways of studying the composition and differentiation history of the Earth's mantle. Sufficient Nd and Sr isotope measurements exist on a world wide basis to define the basic parameters (Sm/Nd and Rb/Sr) of the bulk Earth compostion and thus provide a frame work within which mantle evolution can be examined

Fig. 8. Plot of  $\delta$ 'ND and  $\delta$ 'SR values for N. Atlantic basalts compared with the range of their  $\Delta$ ND and  $\Delta$ SR values.

$$\delta' ND = \frac{({}^{147} Sm/{}^{144} Nd)_{meas} - ({}^{147} Sm/{}^{144} Nd)_{BE}}{({}^{147} Sm/{}^{144} Nd)_{BE}} .10^{2}$$

and  $\delta$ 'SR is defined in an analogous manner. The source regions of the basalts have time-integrated Sm/Nd and Rb/Sr ratios indicated by the plotted  $\Delta$ ND and  $\Delta$ SR values. Partial melting of such sources produces changes in  $\delta$ 'ND of ca., 20% for 2% melting. Some basalts with  $\delta$ 'ND around -40% could not have been generated by such simple melting processes and some re-enrichment of the source or more complex melting and fractionation process is indicated.

The N. Atlantic is a well studied ocean basin, particularly in the vicinity of Iceland and the Azores. The conclusions drawn from these isotopic studies of N. Atlantic basalts may be summarised as follows:

1) Uncontaminated basalts erupted in the N. Atlantic over the last 60 My have been generated from depleted mantle. This includes early Tertiary basalts erupted in continental environments at the time of continental break-up (now preserved in Baffin Island, E. and W. Greenland and N.W. Scotland), recent ocean floor basalts and oceanic island basalts including Iceland and the Azores.

2) Single-stage time-integrated Rb/Sr and Sm/Nd as computed from the initial <sup>87</sup>Sr/<sup>86</sup>Sr and <sup>143</sup>Nd/<sup>144</sup>Nd ratios, are respectively less than and greater than the bulk Earth values. This requires a depletion of Rb relative to Sr, and light rare-earths relative to heavy rare-earths in their source regions.

3) The most depleted mantle in a time-integrated sense has been sampled by submarine mid-Atlantic Ridge basalts and by some Iceland and Ascension basalts, yet insignificant volumes of undepleted mantle have been sampled.

4) The timing of mantle fractionation events can be estimated from the Rb-Sr, Sm-Nd and Pbisotope systematics of the erupted basalts. If the Rb-Sr and Sm-Nd data are interpreted as mantle isochrons they suggest fractionation events some 200 - 500 My ago. However, the Sr.-Nd data indicate that the source region must already have been depleted at that time. The simplest interpretation of the Pb - isotope data yields a conflicting result and requires a mantle wide fractionation event 1.6 Gy ago. However, the isotope data are also compatible with multi-stage fractionation models.

7) Correlations between <sup>87</sup>Sr/<sup>86</sup>Sr and Sr, <sup>143</sup>Nd/<sup>144</sup>Nd and Nd, indicate that simple two component mixing models cannot explain the isotopic variations in Iceland and along the Reykjanes Ridge, however, the few available Pb- isotope data are compatible with such a model. More complex (3 or more) source mixing models may accomodate the data, but attempts to quantify the actual number become exceedingly difficult.

The North Atlantic has become a testing ground for petrogenetic hypotheses and models of mantle evolution and Earth differentiation. Opinions have differed considerably amongst the reseachers involved over the years, but a measure of agreement and consensus is beginning to emerge. The debates have been vigorous and furthermore added a stimulus to geochemical and petrological studies in general.

Abstract. Alkali metals prove to be very sensitive to alteration process even if this process is moderate. It is very difficult to use these elements to trace magmatic processes since their concentration may vary within an homogeneous "unaltered" unit.

From all the basaltic units investigated, a classification of "low partition coefficient" elements is presented (Sc, Ti, V, Y, Zr, Nb, La-Tb, Hf, Ta, Th).

The incompatible elements ratios (Y/Tb, Zr/Hf, Nb/Ta) are constant in the samples studied and are nearly equal to the same ratios in chondrites. This is consistent with the existence of an homogeneous primordial mantle at the scale of the North Atlantic, compatible with a chondritic composition of the earth.

More than two distinct mantle sourced derived from the primordial mantle (invoking the possibility of mixing of sources), are needed to explain the data. Moderate "incompatible" or hygromagmaphile" element/highly "hygromagmaphile" element ratios are function of a partial melting.

Partial melting (variable), magma chamber dynamics (possibility of mixing) and only one or two eruptions is a cycle frequently repeated : variability of partial melting and limited sampling of liquids derived from the same initial liquid explain the variable rare-earth patterns encountered in one single hole and makes it difficult to determine the proportion of minerals crystallizing.

352 BOUGAULT

#### Introduction

Several sites have been drilled into the oceanic crust in the North Atlantic up to and including Leg 53 of the Glomar Challenger (DSDP-IPOD program) : Leg 37, sites 332 to 335 at 36° N along a track perpendicular to the ridge ; Leg 45 sites 395 and 396 at 22° N almost symmetric with respect to the ridge in crust about 7 and 10 m.y. old ; Leg 46, site 396 again ; Leg 49, three sites 407, 408, 409 at 63° N, along a track perpendicular to Regiptanes Ridge, one site 410 at 45° N and three sites 411, 412 and 413 at about 36° N near the FAMOUS area ; the megalec (Legs 51, 52, 53) at 25° N, at 110 m.y. old sites 417 and 418. In addition the FAMOUS operation at 36° N provided an intensive sampling both by dredging and by submersible in the Rift valley and adjacent fracture zones.

During the drilling program, we have operated the CNEXO X-ray fluorescence van on board the Glomar Challenger to obtain on board major elements analysis (and some trace elements during Legs 45 and 46).These shipboard chemical data have been useful in defining the different basalt units and for selection of samples for shore-based studies (Bougault, 1977). Our contribution to the shore based studies has been the systematic study of trace elements both through X ray fluorescence spectrometry and neutron activation analysis in samples which have been selected on board for shipboard analysis (XRF : V, Cr, Ni, Co, Rb, Sr, Y, Zr, Nb ; NAA : Sc, Ni, Co, Zr, La, Eu, Tb, Hf, Ta, Th). ALLE PRESS WAY DESCRIPTION AND A REAL MENTAL PRESS AND A DESCRIPTION AND A DESCRIPTION AND A DESCRIPTION AND A

Leg 53 marks the end of first phase of the IPO: program as far as drilling the crust in the Atlantic Ocean is concerned and we feel it is important to draw out major conclusions which now

<sup>†</sup> Contribution n° du Département Scientifique, Centre Océanologique de Bretagne.

Fig. 1 : Cs versus Rb in Hole 417 A. The black dots represent the data below core 30 and the squares represent the data above core 30. The triangles represent altered samples in Hole 417 D.

can be made. Discussions related to alteration, magnatic units, fractional crystallization, magmatic cycles, partial melting, heterogeneity or homogeneity of the mantle or upper mantle can be now made as a consequence of the data which have been made available through the DSDP program and FAMOUS operation. We have analysed more than 400 samples; results (sample by sample) are given (or will be) in DSDP Initial Reports, in Arcyana (1977) and in Bougault *et al.* (in press) and are not duplicated in this paper; only tables for specific samples or group of samples necessary for the discussion are reported.

#### Alteration process. Alkali metals and strontium

Basalt alteration is discussed with respect to the behavior of alkali metals ( $K_2O$ , Rb, Cs) and Sr. Two examples are considered, sites 417 and 418 (Leg 51) on one hand, and site 395 (Leg 45) on the other. Basalts of sites 417 and 418 have experienced a high degree of alteration which resulted in extensive change of major element composition. Site 395 basalts experienced only slight alteration and can be considered to be fresh samples on the basis of their low water contents.

At site 417, the variation of alteration effects are observed at two scales, which may be related to water circulation.

- Within a single core (e.g. core 35 of hole 417 A), Rb varies from 12 to 29 ppm, Cs from 0.22 to

Best Available Copy

0.56 ppm and  $K_20$  from 0.98 to 2.04 §. This is probably due to local cracks or fissures through which water circulates resulting in the formation of alteration minerals (Joron *et al.*, in preparation).

- Major interstice differences are observed between hole 417 A and hole 417 D (and 418 A) which are about 400 meters apart (Joron et al., in preparation). Hole 417 A is highly altered ; the volcanic pile has been divided into several zones according to the occurrence of different minerals : montmorillonite and celadonite occur in all zones ; chlorite, scolecite and analcite occur in different zones (Legs 51, 52; scientific party; in preparation). Potassium varies from  $\sim 6$  \$ K<sub>2</sub>O in very highly altered zones (top) to classical values in oceanic tholeiites (< 0.2 1) at the bottom. Thus a general decrease of alteration is observed from the top to the bottom. At the opposite, in hole 417 D, some 400 meters from hole 417 A, strikingly fresh basalts were recovered including fresh glass.

This difference in alteration between 417 A and 417 D (110 m.y. old) only 400 meters apart is explained by a difference in topography between both holes. The 417 A altered site is a topographic high which remained unburied approximately 20 m.y. after eruption (lack of cretaceous sediments) (Leg 51, 52; scientific party, in preparation). According to Donnelly (1978) "we might regard the hill as a sort of upside down drain, which, lacking an impermeable sedimentary cap, becomes the principal conduit for convective effluent water".

If this interpretation is correct, it means that much of the alteration process (at least the type of alteration observed) takes place shortly after eruption. When the basalts are covered by a sufficient sedimentary thickness they are protected from further sea water circulation.

A good correlation is found between Cs and Rb (fig. 1) (K versus Rb is also similar). But the dispersion of points is far greater than the analytical precision ( $K_2O + NO.O2$  1, Rb + 2 ppm, Cs + 0.02 ppm). The abundances of these elements

TABLE 1. Comparison of uptake of alkali metals from sea-water and residence times of alkali metals in the ocean. Sca-water concentrations and residence times are from Goldberg (1965).

|                                                           | K                   | Rb                  | Cs    |
|-----------------------------------------------------------|---------------------|---------------------|-------|
| Uptake<br>Altered sample/<br>sea water<br>proportional to | 44.7                | 242                 | 1 120 |

correlates positively with the abundances of alteration minerals (unaltered to highly altered samples) but the elemental ratios, at least in first approximation, may be a function of the proportion of the different kinds of minerals present in the different zones. This could account for the dispersion of points observed in Figure 1. If sea water circulation is responsible for alteration, the uptake by rocks of alkali metals from sea water can be defined by the ratio of the concentration of these metals in altered rocks (in hole 417 A, initial concentration in fresh rocks can be neglected compared to concentration due to alteration) to sea water concentration. Thus, the figures mentioned Table 1, which represent the ratio of concentrations of one representative sample to sea water concentrations (for K, Rb and Cs), are proportional to the uptake of these metals. Cs uptake is higher than Rb uptake which in turn is higher than K uptake. We observe that the uptake of investigated elements varies in the opposite way compared to residence times (table 1). These observations are in agreement with a sea water origin of alkali metals

in altered basalts and if so, alteration of the oceanic crust could play a role in the budget of these clements in sea water.

The variation of Rb, Cs and Sr with depth in hole 417 A is given in figure 2. As previously mentioned a general decrease in concentration of Rb and Cs is observed. This agrees with the general decrease of alteration with depth (core numbers). The variation of Sr in alteration is very slight compared to the variation of alkali metals. In core 35 for instance the Rb concentration is 25 times higher than in unaltered samples while for Sr the enrichment ratio is 1.5. If we take into account that Sr occurs largely in carbonate phases, leaching moderately altered samples with acid solutions may enable us to measure reasonable values for  $^{87}Sr/^{86}Sr$  (if no isotopical equilibration).

Fig. 4 : Way used to classify the elements according to their partition coefficients (see text). A versus C would show a similar figure.

In hole 395 A (leg 45, 22° N, 7 m.y. old) most samples selected for shipboard analysis can be considered to be fresh (il<sub>2</sub>0<sup>-</sup>, loss on ignition). In this hole, within a single homogeneous unit 200 meters thick we observe the variation of alkali metals due to moderate alteration of samples which otherwise are considered fresh. Table 2 shows the values obtained for a high partition coefficient element (bulk partition coefficient) Ni, and four low partition coefficient elements Ti, Tb, La, Ta together with K20, Rb and Cs. The Ni, Ti, Tb, La and Ta concentrations do not vary throughout this unit. The major elements and some other trace elements investigated confirm this homogeneity. Only the alkali metals (and Sb) show variation in the unit (Bougault et al., in press) with the greatest variation exhibited by Cs. In addition, with the exception of  $K_20$  in 55  $\neq$  1 49-54,  $K_20$ , Rb and Cs covary. Figure 3 shows the variation of Cs versus K<sub>2</sub>O for three different units of hole 395 A of Leg 45.

These observations indicate that the use of alkali metal concentrations in oceanic basalts as petrogenetic indicators should be made with extreme caution. Alteration processes can produce extensive variation in the concentration of these elements, even when the samples appear from other criteria to be fresh.

# Partition coefficients and physico-chemical properties of trace elements

Through the behavior of trace elements, it has been attempted for several years to model the different parameters or processed involved in magma genesis. This modelling requires the knowledge of the mineral/melt partition coefficients for the trace elements and phases involved in the process to be modelled. Rare earths, K, Rb, Sr, Ba and the first transition series elements have been the object of numerous investigations of this type. This section is concerned with elements which behave incompatible or low bulk partition coefficient (< 1) or are "hygromagmaphile" (Treuil, 1973). These elements are presented in Table 3.

ALC: NO DECK

**BOUGAULT** 355

From the data obtained in the Nor h Atlantic we will classify these elements acco.ding to their bulk partition coefficients and then discuss this classification with respect to their physicochemical properties.

This classification utilizes the relative behaviors of the trace elements in fractionation processes. Considering three elements, A, B, C: A is plotted versus B and B versus : for different series of samples from series x to (Fig. 4). If we know from previous investigation that the bulk partition coefficient for C (D<sup>C</sup>) is 'ower than the bulk partition coefficient for A (D<sup>f</sup>), the partition coefficient of B (D<sup>B</sup>) can be classified with respect to A and C by comparing the position of the different series of samples (from x to y) and the observed range of slopes. In the given example, D<sup>B</sup>

Figures 5 and 6 show such a comparison for elements belonging to the third transition series : Tb, Hf, and Ta. Hf and Ta are fractionated to a large degree, whereas the fractionat on of Tb and Hf is less. We know from other investigations (comparing Ta to La) that D<sup>Ta</sup> is lower than D<sup>Tb</sup>. From the position of each series of samples in each diagram, it is deduced that  $D^{Hf}$  lies between  $D^{Ib}$  and  $D^{Ta}$ . Following the same method of comparison, it can also be deduced that  $D^{Th}$  is lower than  $D^{Ta}$  (Fig. 7). In this way, a classification based on rock/melt partition coefficients is obtained. This classification is as follows :

# $pSc > p^V > p^Y \approx p^{Tb} > p^Ti > p^{T}r \approx p^Hf > p^{Nb} \approx p^Ta$

Is this classification compatible with the properties of elements ? To account for the "incompatible" or "hygromagmaphile" (haracter of these elements, two processes at least have to be considered :

i) Cation substitutions in the structure of a mineral. No stabilization through crystal field (Burns, 1970; Curtis, 1964) needs to be considered since all cations investigated have a rare gas configuration. The ease with which such cations enter a crystal structure depends mainly upon their

Fig. 6 : North Atlantic : Hf versus Ta.

ionic radii and their charges ; this corresponds to the "incompatible" character of the elements with respect to the host structure.

red

leir

ii) Complex formation in the liquid (Treuil, 1973). This also depends upon charges and sizes of cations, but in a different way, for instance through the ratio n/r (charge/ionic radius) ; the higher is this ratio. the greater is the stability of a complex. The possibility of complex formation accounts for the "hygromagmaphile" character of these elements.

Table 3 shows for the elements of concern, the charge most common in nature, the ionic radius and charge/ionic radius ratio.

If we consider only the size of the ions, we note that the ionic radius decreases from Y to Zrto Nb (0.92, 0.79, 0.69 Å) and thus it is not possible to explain why the partition coefficients decrease from Y to Zr to Nb. But if we consider charges (3, 4 and 5 respectively, incompatibility increasing with respect to crystal structure) and even more n/r (3.26, 5.06, 7.25; possibility to form complexes in the liquid increasing) it is possible to explain why the partition coefficients decrease from Y to Zr to Nb.

Considering elements belonging to groupe IIIA, IV A, V A, of the second and third transition series, we observe that for each of the element pairs, Y-Tb, Zr-Hf and Nb-Ta, the two lons have the same charge and the same ionic radius (as a consequence the same n/r ratio). Consequently it can be concluded that each element in the pair processes the same incompatibility with respect to a crystal structure and the same possibility of forming complexes in the melt. The elements in each pair do not fractionate with respect to the other since they have equal or nearly equal partition loefficients.

A State of the second second

# BOUGAULT 357

pla is close to  $D^{Ta}$  or  $D^{Nb}$  in spite of their differing charges, ionic radii and n/r ratios. La is more incompatible based on ionic radius, less incompatible based on charge and less hygromagmaphile based on n/r than Ta (see Table 3). These different effects compensate to produce similar partition coefficients for both elements. Despite the similarity in  $D^{La}$  and  $D^{Ta}$  (or  $D^{Nb}$ ) it is important to keep in mind the differences (radius, charge, n/r) which exist between La and Ta when compared to Nb-Ta similarity. This point will be discussed later.

In the group IV A elements ( $Ti^{4+}$ ,  $2r^{4+}$ ,  $Hf^{4+}$ ,  $Th^{4+}$ ) (table 3) the low value of DTh is a consequence of its large ionic radius (1.02 Å) as compared to  $2r^{4+}$  or  $Hf^{4+}$  radii (0.79 and 0.78 Å). A similar observation can be made comparing  $2r^{4+}$  -  $Hf^{4+}$  (0.79 and 0.78 Å) to  $Ti^{4+}$  (0.68 Å). Within a column the classification of the elements according to their partition coellicients is dominated by the incompatible character rather than by the hygromagmaphile character of each element. Sin. ar deductions can be made considering  $Sc^{3+}$ ,  $Y^{3+}$  and the heavy rare earths ( $Tb^{3+}$  for instance).

From the results for the group III A (Sc, Y, heavy rare earths) and group IV A (Ti, Zr, Hf and Th) elements the following rule can be formulated :

(a) within a group (column) the higher is the ionic radius, the lower is the partition coefficient. Considering the second and third transition series (Y, Tb,Nb) and (heavy rare earths, Hf, Ta), it can be deduced :

(b) the higher is the possibility to form complexes in the liquid (n/r), the lower is the partition coefficient.

 $D^V$  is an exception to the rules : it satisfies rule (a) but does not satisfy rule (b), since its partition coefficient is classified between Sc and Ti. A possible explanation of this anomaly is that V may have a lower state of oxidation. If so, p'r would be lower and V would not be anymore in a rare gas configuration. Consequently it would be subject to some crystal field stabilization in octaedral structures.

Additional information is also available. These include the non-fractionation of 2r/Hf and Nb/fa. Knowing D<sup>La</sup> and D<sup>Tb</sup> it is possible to place limits

5 N. 213

on D's for other elements and classify them accordingly.

Mantle homogeneity or heterogeneity : Y/Iu, Zr/Hf, Nb/Ta, La and Th. A comparison with chondrites and lunar samples

In the previous section, it has been shown that within each etement pairs Y-Tb, Zr-Hf, Nb-Ta, fractionation of one element with respect to the other is not observed. In fact, two conditions are required to maintain Y/Tb, Zr/Hf, Nb/Ta ratios constant or nearly constant (fig. 8, 9 and 10) for all studied samples, although the absolute concentrations vary over a wide range (for instance, Nb varies between 2 to 90 ppm). These conditions are : (1) little or no fractionation of the elements in the pair has occurred, and (2) the ratios in the source regions prior to magma generations were constant and equal to that in the derivative basalts.

Because the samples studied were recovered in different parts of the North Atlantic(latitudes from 22° N to 63° N; crustal ages from 7 m.y. at 22° N to 110 m.y. at 25° M), the point (2) can be interpreted in terms of homogeneity of the mantle at the scale of the North Atlantic. These couples of elements give us the opportunity to compare the primordial mantle with chondrites. Table 4 shows the values obtained for the ratios of these elements both in the North Atlantic samples and in chondrites. The Y/Tb ratio in chondrites is from Frey *et al.* (1968) and the range of ratios for 2r/Hf is obtained from Ehman and Rebagay (1970) and Ehman and Chi (1974) Ganapathy *et al.* (1976) give lower range of values for 2r/Hf in chondrites. Ehman *et al.* (1975) mention the difficulty in obtaining precise ratios of 2r/Hf in chondrites

BOUCAULT 359

because of the small size of samples available and because of low abundance levels and error limits (+ 10 ).

Very little data are available for Nb and Ta. The values of 14 and 17 are from Graham and Mason (1972) and Vinogradov (1962).

The limits of the ratios reported in Table 4 for the North Atlantic samples include both analytical errors and possible fractionations within element pairs. The limits for Nb/Ta correspond very closely to analytical error limits whereas the limits for Y/Tb and Zr/Hf are approximately twice that of the analytical error limits. This suggests that despite the range of variation of concentrations (shown in Table 4 by the factor of variation), Y/Tb and Zr/ Hf may fractionate a little more easily than Nb/ Ta. This can be attributed to some slight differences between partition coefficients and to the orders of magnitude of the partition coefficients (Nb and Ta being the lowest).

Taking into account the chondritic data, analytical precisions, and comparisons of data from different laboratories, the ratios of Nb/Ta, Zr/Hf and Y/Tb attributed to a primordial mantle favor a chondritic composition for the earth.

Ehman et al. (1975) found Zr/Hf ratio to be  $39 \pm 1$  in the Palisades Sill (New Jersey), 39 in two chilled margins and  $47.3 \pm 0.8$  in the Littletown metamorphic series. These figures are in good agreement with our own data for oceanic rocks but contrast with the range of values that these authors have found for lunar rocks. Wanke et al. (1975) similarly found variations in Zr/Hf for lunar rocks as well as for Nb/Ta using the data of Willis *et al.* (1972). These authors attempt to explain the possible fractionation of Zr-Hf (and Nb-Ta) invoking possible different oxydation states of these elements. They state that achondrites which have Zr/Hf ratio higher than chondrites may reflect an even greater fractionation. This model is supported by oxygen fugacities calculated from  $Eu^{2+}/Eu^{3+}$  which decreases from achondrites to lunar ferro-basalts to tc:restrial rocks. If such an interpretation is correct, *i.e.* the possibility

360 BOUGAULT

of Di-Hf or Nb-Ta fractionating by changing oxygen fugacity, we would conclude that relatively stable conditions exist in the terrestrial mantle.

A plot of La versus Ta for the North Atlantic samples defines two different lines. One of them includes samples recovered at 36° N, 45° N and 63° N which have large variations in absolute concentration. The second line includes samples recovered at 22° N (young crust) and 25° N (old crust). The similarity of DLa and DTa was deduced from the first line on the basis of a constant ratio for  $\perp$ large variation of absolute concentrations. We also mentioned previously that this similarity can be explained by a compensation of the incompatible and hygromagnaphile characters of La and Ta. However, because of differences between ionic radii and charges it is more likely that a fractionation may occur between La and Ta rather than between Nb and Ta. Large variations in the percentage of partial melting (see below) do not affect the La/ Ta ratio. For this reason we interpret the two different La/Ta ratios as characteristic features of the mantle sources related to the two groups of samples. The highest La/Ta ratio corresponds to a characteristic "depleted" oceanic mantle ( $22^{\circ}$  N and  $25^{\circ}$  N) and the lowest ratio corresponds to a less depleted mantle ( $36^{\circ}$  N,  $45^{\circ}$  N,  $63^{\circ}$  N). If a "primordial mantle" is confirmed through

If a "primordial mantle" is confirmed through the constant values of Y/Tb, Zr/Hf and Nb/Ta ratios, then it may be deduced that one mantle type may derive from the other type through a mantle differentiation process. The variation of Ta/Th ratio (fig. 7), two elements which have very low but slightly different partition coefficients would reflect different degrees of this differentiation. The jump of La/Fa ratio would correspond to a major change of the solid (mineralegical for instance) through mantle differentiation.

BOUGAULT 361

# Multiple source model, mixing of sources, mixing of magma, partial melting

Langmuir et al. (1978) propose a method for testing different kinds of mixing in which an hyperbolic function represents the behavior of two elements or of ratios of two couples of elements.. We postulate that the ratio of two hygromagmaphile elements is not (or little) modified through fractional crystallization process. Then, the ratios of two elements have to be interpreted in terms of partial melting, mantle sources, mixing of magmas and (or) mixing of sources. Figure 13 represents the plot of Hf/Ta(deduced from fig. 6) versus Ta/Th (deduced from Fig. 7). If the studied samples were derived from two end members, the points defined by the various basaltic units should lie on an hyperbolic line. This is obviously not the case.

Partial melting and magma mixing. The variation of the ratios of two elements with percentage of partial melting is a question of the magnitude of the difference between their bulk D's which in turn are dependent upon the residual mineralogy. If both partition coefficients are low ( $\sim 0.01$  or lower; ex.: Ta, Th) the ratio varies little, when the partial melting degree is sufficiently high. If the D's have different orders of magnitude (0.1 and 0.01; Tb/La, Ti/Th, Hf/Ta ...) the elements fractionate. We can test such possibilities of variations in the data of Leg 49 site 409 and from the FAMDUS area.

Site 409 (Leg 49): Unit b cannot be derived from unit a through fractional crystallization process. The similar Ta/Th and La/Ta ratios (fig. 7 and 11, and Table 5) and the increase of hygromagmaphile element concentrations from unit a to b (table 5) are consistent with fractional crystallization. However, at the same time Ni (and Cr) should decrease while the opposite is observed (Table 5). Partial melting can generate the observed elemental relationships. For similar Ta/Th or La/Ta ratios we observe different Fi/Th, Tb/La ratios (Table 5) and a different Hf/Ta ratio (fig. 6). In addition, one unit in hole 407 also has the same Ta/Th ratio and a different Hf/Ta ratio (Fig. 13). Rare earth patte s for these three basaltic units (Wood *et al.*, in press) are presented figure 14. These patterns, for a single Ta/Th ratio, vary in the same way as the Hf/Ta ratio.

FAMOUS area : The three samples reported in Table 5 may be considered as unfractionated on the basis of their MgO  $(Mg^{2+}/Mg^{2+} + Fe^{2+})$  and Ni values. Each of them belongs to one of the three basaltic units of the FAMOUS area (Fig. 13). For similar Ta/Th ratios different concentrations in Ta, Th and other hygromagmaphile elements are

observed. These features are believed to be due to different degrees of partial melting. Different Hf/Ta ratios (fig. 13), different Ti/Th and Tb/La ratios (Table 5) are observed together with different rare earth patterns (fig. 15).

The hole 409 example, no more than the FAMOUS example, is not compatible with magma mixing. Rhodes *et al.* (in press) interprete the different Ti concentrations observed for a single Mg/Fe ratio as the result of mixing a new unfractionated magma with a magma which has already undergone some fractional crystallization. The different Ti (and other low partition coefficient element) concentrations related to unfractionated magmas (FAMDUS example) cannot be interpreted in the same way. This observation does not mean that magma mixing does not exist but we would not consider this process as a rule as suggested by Rhodes  $e_{\pi}$  al. Mixing of mantle sources or evolution of separate sources. The variation of Hf/Ta ratio (fig. 13) or of rare earth patterns (fig. 14, 15) with partial melting makes it difficult to recognize mixing of sources on Hf/Ta (or Sm/La) versus Ta/Th (or isotopic ratios) plots. Data for a large number of samples are required to be and recognize through the effects of partial melting variations in Hf/Ta representative of the source or as a consequence of the mixing of sources (Schilling, 1973). Langmuir et al. (1978) suggest that if mixing can be diagnosed from ratios of elements it should be confirmed by other elements or ratios of elements. On figure 15, an hyperbolic line could fit the points representing the different groups. If it is assumed that the scatter within groups is due to variable degrees of partial melting it could be concluded that

**EOUGAULT** 363

mixing of two different mantle sources is possible. But, considering another ratio, La/Ta (Fig.11, 12), only two values have been found (Fig. 13) making impossible an hyperbolic fit of La/Ta versus Ta/Th. Consequently, it is necessary to consider more than two sources. Langmuir  $e^+ al$ . (1978) using other elements and other samples conclude that several models are possible. Mixing of sources is one of them, but even then more than two mantle sources are required. If several mantle sources are required, it is necessary to account for a multiple source model (O'Nions *et al.*, 1976). Each source would be derived from a primordial mantle which is evidenced by Y/Tb, Zr/Hf, Nb/Ta.

### Co, Ni, Cr : fractional crystallization process

Because of their ionic configuration (presence of d electrons), Co<sup>++</sup>, Ni<sup>++</sup> and Cr<sup>+++</sup> ions are subject to crystal field stabilization in octaedral structures (Burns, 1970; Curtis, 1964). The partition coefficients found agree with this observation (Bougault and Hékinian, 1974; Dale and 'Henderson, 1972). Crystal field stabilization has the effect of giving these elements a quite different behavior than low partition coefficient elements.

From theoretical considerations Co, Ni and Cr (to a lesser extent) should vary within a narrow range in the liquid phase as partial melting proceeds. This is independant of the chosen model and the type of initial solid material, except chromium which may depend upon spinel content (Bougault  $et \ al.$  (a), in press). Olivine being the major constituant of the solid and melting in low proportion relative to clinopyroxene for instance acts as a buffer for Co and Ni during the melting process. In addition, the results found for Ni, Co, Cr in the undifferentiated samples mentioned above fit with the theoretical calculation obtained from concentrations observed in peridotites and currently accepted bulk partition coefficients (Bougault et al., in press (a) ). Thus, variations in the concentrations of these

three elements in basalts are largely due to fractional crystallization.

Because these three elements are enriched in minerals like olivine, clinopyroxene and spinel, it is important to note that basalt samples used for interpretation of the Ni, Co and Cr abundances should be free of these minerals. Glasses, aphyric basalts and plagioclase phyric basalts are appropriate. Plagioclase is a diluant of Co, Ni and Cr.

In the samples that we have analysed Co varies within a narrow range 40-50 ppm, Ni between 30 to 250 ppm and Cr between 30 to 600 ppm. This is observed for most of the oceanic tholeiites with the condition of selecting samples as mentioned above. Two ways of interpretation of these data can be given according that oxide and sulphide phases are involved or not in the process of fractionation.

i) The large variation of Ni reflects crystallization of olivine (Kd = 12) and or clinopyroxene (Kd = 4.4). However the narrow range of variation of Co (40-50 ppm) precludes that more than a few percents of olivine or (olivine + spinel) have crystallized because the Co partition coefficients in these minerals are 3 and 5 respectively. More likely the bulk partition coefficient of Co is probably close to one in order to explain its narrow range of concentration. This implies that a low Kd mineral with respect to Co has also crystallized, *i.e.* plagioclase.

Accepting the Rayleigh distribution during crystallization, the relationship between Cr and Ni in the liquid is :

$$\log [Cr] = \frac{D^{Cr} - 1}{D^{Ni} - 1} \log [Ni] + K$$

D<sup>CT</sup> and D<sup>Ni</sup> being respectively the bulk partition coefficients of Cr and Ni ; K is a constant depending upon partition coefficients and initial concentrations of Cr and Ni. Data for glasses, aphyric samples or plagioclase phyric samples are

364 BOUGAULT

plotted in figure 16. The scatter may be partly due to the presence of olivine, spinel or clinopyroxene phenocrysts in some of these samples. The upper part of the field (Ni : 250 ppm, Cr : 600 ppm) correspond to the most primitive liquids. The field cannot be a consequence of the fractionation of olivine alone ; Ni would be depleted extensively whereas Cr would be unchanged in the liquid (Kd<sup>CT-</sup> is around 1). Olivine + spinel is possible in the early stages but we have seen above that this possibility is also limited by the Co range of variation. The scattering in the upper part of the field (early stages of crystallization) is probably due to different proportions of olivine (+ small amount of spinel) and plagioclase removal. The lower part of the field tends to be narrower and the slope  $\frac{D^{Cr} - 1}{D^{Ni} - 1}$ 

is compatible with plagioclase-clinopyroxene fractionation with very little or no olivine. The FAMOUS data, which fall along the average line which could be defined for the overall field is not a straight line (as suggested by the relationship from the Rayleigh law); the variation of slope needs a variation in bulk partition coefficients attributed to variation of partition coefficients themselves and the proportions of minerals as crystallization proceeds. Precise calculations of the amount of minerals crystallizing at different steps is difficult for several reasons. The basalts investigated to not derive from the same initial liquid produced by the same partial melting, even in a single hole. Ti, and other hydromagmaphile BOUGAULT 365

Fig.13 : North Atlantic : Hf/Ta versus Ta/Th.

elements do not increase regularly as Cr and Ni decrease (Bougault, 1977). Major element relationships show the same results : Ti does not fit (Bryan and Thompson, in press). Magma mixing (Rhodes *et al.*, in press) is an additional possibility.

ii) Oxides and sulphides even if in low proportions are an additional difficulty in estimating, through trace elements, the nature and the proportions of crystallizing minerals. If opaque minerals occur as crystallizing phases, they would probably deplete the liquid in Co and Ni and in addition in Cu and Zn as well. Such a fractionation does not fit the observed behavior of Co, Cu and Zn since these elements are not depleted. However, if sulfides are considered as an immiscible liquid, sulphides could be a buffer in respect of these

Fig.14: Variation of rare earth patterns in Hole 409 (from Wood *et al.*, in press). 407 a pattern is also shown: both units of 409 and 107 a have similar Ta/Th and La/ Ta ratios.

Fig.15: Variation of rare can'th pattern in the Famous area (from Wood et al., in press). Both samples have similar 'a/th all. Ta ratios.

elements except for elements whose bulk D relative to crystallizing phases is higher than D relative to the immiscible liquid (Cr and Ni possibly). This late interpretation is only tentative as liquid (sulphides) - liquid (silicate) partition coefficients are not known for the investigated elements in these types of rocks.

Before drilling into the oceanic crust started, the hypothesis to find in a single hole different units deriving one from each other from the same initial liquid through fractional cryst distance process seemed reasonable. This hypothesis now appears to be wrong. No more than one

Fig. 16 : North Atlantic : leg Cr vers - F

TABLE 6. Occase baselt veneries is an apped of the

eruptions occur involving the same initial liquid. Partial melting, formation of a magma chamber (possibility of mixing), crystallization and one or two eruptions seem to be a cycle that is frequently repeated. This corresponds to the notion of magma cycles proposed by Flower *et al.* (1977). This is why, accepting the hypothesis of dynamic melting (Langmuir *et al.*, 1977) or melting **a** solid which is already a residue (Bougault *et al.*, in press), different percentages and mechanisms of melting can explain the different rare earth patterns found within a single hole.

#### Conclusion

The major features resulting from this study are summarized in table 6. These include :

Y/Tb,  $2r/Hf \perp d Nb/Ta$  ratios are constant in basalts from the North Atlantic (22° N to 63° N) and do not vary with age. The values of these ratios, which are close to chondrite values, are in agreement with an homogeneous primordial mantle and with a coondritic composition of the earth.

100

deren ver daven desemberentigen förstredet – ander der i Verk K. Reihen 2000 kom (A. G. - A. G. B. D. -

Highly "incompatille" or "hygromagmaphile" element ratios (La/Ta, Ta/Th) require several mantle sources derived from the initial primordialmantle.

The variability of partial melting is responsible for the variation of moderately "incompatible" to highly "incompatible" element ratios.

High partition coefficient elements bring some constraints about the proportions of minerals which crystallize; it is not possible to deduce quantitatively these proportions of minerals since very few baseltic units, even in a single hole, derive from the same initial liquid (variability of partial melting).

The variation of alkali metals cannot be used to trace magnatic processes because of their extreme sensitivity to alteration.

Abstract. A 200 m section of drilled basalt in the Cretaceous basement of the western North Atlantic (hole 417A, Deep Sea Drilling Project) recovered the most altered basalt found to date in the world ocean. The very high uptake of potassium (690 g/cm<sup>2</sup> for the 200 m thickness) requires the passage of very large volumes of sea water through the rock. The mineralogy of the rocks (k-feldspar, celadonite, smectite, zeolites) suggests very low temperatures, and we conclude that the water of alteration was the effluent warm water discharging from a cell of convecting water in the cooling oceanic crust. The character of the rocks and the absence of much of the earlier sediment support this idea.

The principal implication of this discovery is that only a small fraction of cceanic floor altering in this way could account for the excess of potassium inferred to be entering the oceans over that accounted for in oceanic sedimentation. A further implication is that the direction of both potassium and magnesium fluxes is opposite to that inferred for higher temperatures of alteration.

#### Introduction

Extensive alteration of the oceanic crust has been recognized for several years (e.g., R. Hart, 1970; Matthews, 1971), but nearly all of the examples have been of dredged basalts, metabasalts, and gabbros. Attempts to relate mineralogical and chemical character of these samples to the problem of elemental fluxes (Wolery and Sleep, 1976; Humphris and Thompson, 1978a) suffer in two ways from this limitation: 1) rocks available for dredging are those which occur on fault scarps, and a special structure such as this might imply a special process, such as hydrothernal alteration concentrated along the faults; and 2) rocks which are dredged regardless of their location are those which have been exposed directly to sea water, and their alteration might be typical of only a few meters of uppermost oceanic crust.

Numerous observations in recent years have led to the conclusion that water circulates through oceanic crust and provides an important means of heat transfer. The observations include the discrepancy between observed and calculated heat flows in younger crust (Wolery and Sleep, 1976), the direct observation of hot springs on the ocean floor in very young crust (Edmond, et al., 1977), and several instances of anomalously high and low heat flow values in younger oceanic crust (Anderson, et al., 1978). Experimental studies of basalt-sea water interaction (e.g., Mottl, 1976) and observations of Icelandic hydrothermal wells (Tomasson and Kristmannsdot+1, 1972) illustrate the importance of higher temperatura

alteration both in speed of reaction and amount of elemental exchanges, lut tell us relatively little about lowe temperature processes. Finally, cons derations of elemental fluxes into and out of the oceanic reservoir (e.g., Maynard, 1976; Drever, 1974), emphasize the problem of imbalances of certain elements, such as potassium and magnesium, and imply that the occanic crust might be extensively involved as a sink or source for several chemical species. Thus, an example of severely altered oceanic crust for which e: tensive warm water circulation can be inferred is of special interest, a'd the calculated elemental fluxes are of potentially great significance.

A site drilled during Leg 51, Deep Sea Drilling Project, yielded the first appreciable recovery of significantly altered oceanic crust, and as such deserves careful consideration for its implications for oceanic crustal alteration. Hole 417A was located on crust about 110 million years of age, and is approximately equidistant from Puerto Rico and Bermuda. It penetrated 200 meters of crust, with about two thirds recovery, and showed extensiv: alteration even in the deepest core recovered. Hole 417D, which was about 450 meters away, penetrated an equivalent basalt section, but w' h two significant differences: the basalt was generally very fresh and the top of the basement was reached about 140 meters deeper with the entire sedimentary section present, whereas about 15-20 million years of sediment was missing from site 417A. We concluded (Donnell, et al., in press) that the altered basalts from hole 417A represented extensive alteration which resulted from long-term circulation of warm (about 30°C) water through the crust, that this circulation was thermally driven and resulted ultimately from crustal cooling, and that the contrast in alteration between the two holes resulted ultimate..y from the difference in topography. Hole 417A was located on a topographic mound that remained free of sediment and became an upside-down drain for effluent convecting warm water, while hole 417D was located in a topographic depression and was quickly covered by sediment which retarded extensive water circulation.

Character of Site 417 Basalts

The basalts at hole 417A are brownish to brown-gray in color, especially in the more altered portions, while the

370 DONNELLY

basalts at hole 417D are gray in color. The mineral content and chemical composition at hole 417D vary little with depth. Fresh glass is common in this hole, and although there are scattered chemical and mineralogical signs of mild alteration (higher  $K_20$ , oxidation of iron, occurrence of veins with calcite, smectite, celadonite), the phenocrysts are commonly unaltered and the basalts as a whole would be characterized as very fresh. The basalts at hole 417A are sufficiently altered that inferences about its original composition would be very difficult to draw if this hole had been the only one drilled. However, the phenocryst content (the phenocrysts are extensively pseudomorphed but can, in most cases, be identified) is fairly uniform and similar to that at hole 417D, leading to the view that the original compositions were probably very similar. Also, one lithologic unit, a massive, ophitic basalt in the lower part of the hole, and portions of thick pillowed flows above this unit are fairly fresh, based on K<sub>2</sub>O content and on oxidation state of the iron. These are similar to the fresher basalts at hole 417D, leading again to the conclusion that the original basalt at hole 417A was probably essentially the same as that at 417D. Minor element distributions (especially Zr and Y) also support the conclusion that these basalts were originally essentially the same composition.

In detail the two sections are not correlative. At hole 417A there is a high content of hyaloclastite and a distinctive coarse-grained, ophitic, massive basalt occurs near the base of the drilled section. At hole 417D there is far less hyaloclastite, and a finergrained massive basalt appears at a different horizon. We conclude that the two sections cannot be demonstrated to be precisely correlative sections which were separated by post-extrusive faulting, and we suggest that the shallower hole 417A represents an original accumulation of flows and hyaloclastites which formed a topographic high on the sea floor. Readers familiar with the results of drilling at these two holes will recall that a fault has been proposed (largely on paleomagnetic grounds) separating the two holes. The existence or non-existence of this fault does not affect the present discussion. We are concerned here with two drilled basement sites which were originally essentially identical in chemical composition and mineralogical character but

which are not correlative on a layer-bylayer basis. For a reason which is not ertirely clear but which may be the result of original constructional norphology, one of the occurrences (417A) existed as a topographic high shortly after eruption and the other (417D) occupied a much lower position.

The mineralogy of the basalts at hole 417A is consistent with a very low temperature alteration, and indeed consists dominantly of minerals characteristic of authigenesis in oceanic sediments.<sup>1</sup>  $\Lambda$ more extended and detailed account of the mineralogy of both the altered and fresh basalts of these two holes (as well as of a third hole, 418A, located about 6.5 km from 417A) will be found in the Initial Reports of the Deep Sea Drilling Project (Humphris, et al., in press; Juteau, et al., in press; Scheidegger and Stakes, in press; Rusinov, et al., in press; Pertsey and Rusinov, in press; Mevel, in press; Pritchard, in press). Basically all of the basalts at these sites are plagioclase-phyric with a widespread development of olivine and clinopyroxene phenocrysts. Although the mineralogical evidences of alteration are far more prominent at hole 417A, the differences between 417A and 417D are largely of degree and not of kind. Thus the basalts at 417A are highly oxidized with extensive replacement of plagioclase and groundmass by K-feldspar. Calcite and clay minerals (smectites and a green, micaceous mineral) are ubiquitous at 417A but more restricted at 417D. At both sites we find a dioctahedral smectite which is more or less interlayered with mica layers. At 417D a trioctahedral saponitic smectite occurs at lower levels. The micaceous phase is K- and Fe-rich with variable Mg. It is transitional in composition and x-ray character between a interlayer suectite and a mica (celadonite). Generally the micaceous phase is more abundant at 417A.

At hole 417A zeolites are conspicuous and include analcime, matrolite, phillipsite, and chabazite. The zeolites tend to occur somewhat deeper than the K-feldspar-rich upper samples, but the overlap is broad and no genetic implication is suggested by this poor zonation. At holes 417D (and 418A) zeolites are found in more limited quantities.

J.R. Cann (this volume) names the mineral assemblage found at site 417A the "brownstone facies" and identifies it as a very-low-temperature facies transitional to weathering. Pyrite is scarce but widespread at hole 417D. In hole 417A hydrated iron oxides appear to take its place, suggesting, in parallel with the bulk chemistry (below), a far more advanced degree of alteration at 417A. Such mineralogical differences as exist between the two holes would appear to suggest that at 417A there was a long exposure to oxidizing solutions, while 417D was exposed more briefly to reducing solutions.

The dominant mineralogy (K-feluspar, celadonite, analcime, smectite, calcite) is characteristic of very low temperatures of alteration. Oxygen isotopic evidence (Muchlenbachs, in press) indicates alteration at temperatures of about 30°C. The extent of alteration is not simply related to original textural and structural variations in the basalt. Thus, the abundance of hyaloclastite and the thinness of the pillow basalt units in the higher portions of the hole may explain the more intense alteration here. Conversely, wo lithic units near the bottom of the help have minimal fracturing and minimal alteration. However, beneath these the lowest unit at Hole 417A is a highly altered basait breccia.

### Chemistry of the Altered Basalts of 417A

Samples were selected so as to be as representative as possible of the basalt types. Chemical analyses were by wet (rapid) techniques; and the methods and results are given and the method discussed in more detail in Donnelly, et al., (in press).

The potassium values of the shallower, more altered samples, are the highest ever recorded for oceanic basalts, and in one case exceed 9 weight percent  $\kappa_20$  on a water-free basis. The highest K20 values occur in the most severely altered basalt ("red-brown") and i. basalt breccia fragments in dominantly hyaloclastic units. The lowest K20 values are from the centers of the larger pillows in the lower units and from the massive, ophitic basalt near the pottom of the cored section. For budgetary calculations (tables 1 and 2), we have assumed an original K20 value of 0.11, based on the eleven "freshest" 417D basalts analyzed. The excess potassium at 417A is found to be 690 g/cm<sup>2</sup> K for the 200 meter column drilled.

The relationship of potassium with depth for Holes 417A and 417D is shown in Figure 1. The clustering of low values for 417D, with a scattering of higher values, is broadly related to ...e degree

Table 1 Budgetary Calculations

Table 1 gives average water-free compositions for hyaloclastite, basalt, and the total for 417A; and the sum of the weights of each oxide for 417A, assuming a 200 meter column 1 cm<sup>2</sup> in cross section. These are calculated on a core-by-core basis, using average densities and compositions for each core. The average composition of the eleven freshest 417D samples is also given. Assuming that the 417A rocks were originally the same in composition as 417D, the calculated weight of each oxide prior to alteration for 417A is calculated for two cases; assumed constant aluminum during the alteration, and assumed constant citanium. The original calculated density and porosity (the latter assuming an original rock density of 2.9 g / cm<sup>3</sup>) are also given.

of fracturing and is typical of other drilled sites. The relative potassium values for the less altered hole 417D are more erratic than for 417A; consequently, the estimate of average potassium contents core-by-core is less meaningful. We find an average composition of about 0.28 percent K<sub>2</sub>O for Site 417D, but with a very high standard deviation, the

372 DONNELLY

excess potassium calculated from this value on the order of 33 g/cm<sup>2</sup> K for a 200 meter column. This value may be typical of older "fresh" basalts, but quantitative data to support this speculation are still largely lacking. Figure 2 shows the relationship between K<sub>2</sub>O and H<sub>2</sub>O. The samples from 417D show the typical rise of K<sub>2</sub>O with absorbed

Table 2 assumes that Si, Fe total, Al, and Ti are all conserved during alteration within the errors inherent in this calculation. It converts the gains and losses in the 200 meter column of rock into total moles. The electrical balance is maintained by consuming H in the form of HCO<sub>3</sub><sup>-</sup> and converting this to  $CO_3^{2-}$ . The evolved oxygen is assumed to be H<sub>0</sub>. The oxygen consumed to produce ferric iron is calculated for two cases: original Fe<sub>0</sub><sub>3</sub>= 1.50 and Fe<sub>2</sub>0<sub>3</sub> = 3.0. The excess Ca and CO<sub>3</sub> are calculated as CaCO<sub>3</sub>, which is converted to an equivalent column, 1 cm<sup>2</sup> in cross section. Finally, the amount of water that must be moved through the rock is calculated as a multiple of the void volumes for the column, using the calculated original porosities. This assumes that K is the limiting species and that it is completely removed from seawater.

water seen in most oceanic basalt occurrences. The 417A samples, however, show a tendency towards migh higher values of K20 at given water values, especially in the brecciated basalts and "red-brown" basalt margins. This figure suggests that these rocks have absorbed considerable quantities of water but might have been altered under different conditions. leading to a relatively higher "efficiency" of potassium absorption relative to water absorption.

a) b)

As Figure 3 shows, calcium is depleted as strikingly as potassium is enriched, with an inverse relationship between these elements. The shallower "fresh"looking basalts have lost approximately two-thirds of their original calcium, and the most severely altered rocks about

nine-tenths. The removal of magnesium parallels that of calcium (Figure 4), but the amounts removed are far less. In other environments considered to represent higher temperature alteration, magn(sium is enriched rather than depleted (Humphris and Thompson, 1978a). In the present case, there is little doubt that depletion is the general rule. The flux of this element depends critically on the conditions of the alteration process (Thompson and Humphris, 1977). Hyaloclastites are not so depleted in magnesium as the altered basalts, but in no case are they enriched in magnesium. Although fewer analyses of sodium were available for this study, this element appears to be slightly depleted (Figure 5). Fresher samples have abundant plagioclase, but more altered rocks have

Figure 1. Diagram relating  $K_20$ , calculated on a water-free basis, to depth, for Holes 417A and 417D. The tops of the basalt have been matched in position. Various symbols indicate lithologic types. Lithologic units are circled where more than one sample is given, and identified by italicized number. "Doleritic basalt" refers to massive basalt of unit 18.

K-feldspar and zeolites (variably Na-, Ca-, or K-rich) replacing the plagioclase.

Several minor elements were analyzed during this study. However, the relatively large changes in major elements are paralleled in only a few of the minor element species. Thus, boron, barium, and lithium (Donnelly, et al., in press), and rubidium and cesium (Joron, et al., in press) are all increased in the altered rocks with distribution patterns similar to that of potassium. Transition metals (nickel, vanadium, copper, etc., Donnelly, et al., in press) are relatively unchanged. Elements which are regarded as the most stable during low-temperature alteration processes (zirconium, yttrium, titanium, Donnelly, et al., in press) are somewhat depleted in hyaloclastites, with yttrium virtually absent. Possibly some of the smectite component of the hyaloclastite represents aqueous transport and precipitation of most of the constituents of basalts as dissolved species, with these three elements having been conspicuously untransported.

374 DONNELLY

#### Budget of Alteration

The relatively high recovery of rock at Hole 417A permits an estimate of the total flux of major elements for the 200 meter column of rock drilled here. The calculation (Tables 1 and 2) was made by averaging the composition of the basalt core-bycore, and calculating the weight of each oxide in each core using measured rock densities. Hyaloclastite was found (six samples analyzed) to have a consistent chemical composition throughout, and its density was taken as  $1.5 \text{ g/cm}^3$ . The fraction of basalt and hyaloclastite was measured from shipboard photographs, and unrecovered intervals were assigned the values of adjacent recovered intervals. The composition of the presumed original fresh basalt was taken by averaging the freshest samples from Site 417D. Of

Figure 2. Diagram relating K.Q., calculated on a water-free basis, and  $H_2O^+$  for Holes 417A and 417D. Symbols for various lithologies indicated. "Lowest breccia" refers to unit 19, "Dolerite" refers to unit 18, Hole 417A. course, mild alteration has occurred at that site, and a minor degree of potassium absorption for the hole has been allowed for, as noted above. The formation density and porosity of the original basalt at hole 417A is not known, but can be estimated if we assume that some chemical element has been unchanged during alteration, and we know the weight percentage of this element at Hole 417D. As Table 1 shows, if we assume constant aluminum, then the basalt at Hole 417A must have had a porosity of 6 percent, if the rock density was originally  $2.9 \text{ g/cm}^3$ . There is some reason to believe that aluminum might not be the best normalizing element; the abundance of phyric plagioclase casts some doubt on the constancy of this element, and the amount of Al relative to Ti, Fe, and Si is slightly higher at Hole 417D, even though the latter three elements are fairly constant with respect to each other. A second calculation assuming that titanium, instead of aluminum, is constant gives an original porosity of 13 percent, which seems to be more in accord with measured and inferred values for shallow portions of the crust. The relative constancy of TiO2 in the Hole 417D basalts supports normalization against this element.

A further problem in calculating the chemical exchange is that the original oxidation state of the iron is not known. Calculations have been made using differing values of original ferric iron,

Figure 3. Diagram relating CaO, calculated on a water-free basis, to depth, Hole 417A. Sumbols as in Figure 1.

1990 - C

and their effect on the total chemical change is fairly minor.

As Figure 6 shows, the loss of calcium, magnesium, and sodium is not balanced by the gain of potassium. The only ion available to maintain electrostatic constancy is hydrogen, which we assume must come from the breakdown of bicarbonate ion, producing hydrogen ion for alteration and creating carbonate ion. The balance of chemical species gained and lost under differing assumptions is shown in Table 2. We are assuming that the relative gains and losses of total iron, silicon, aluminum, and titanium are sufficiently small that they are not included in the balance. Potassium is the principal metallic ion gained from seawater, but hydrogen is apparently the major consumed species. Calcium is the principal effluent metallic ion, and carbonate the principal ionic species. There is a slight uptake of phosphorus and a loss of manganese shown by these equations, but neither element changes very much. The alteracion process, then, takes up potassium, phosphorus, and bicarbonate, and releases calcium, manganese, sodium, carbonate, and oxygen (probably as water). The minor phosphorus (as well as barium, rubidium, and cesium) could be obtained from small amounts of trapped calcareous ooze, but the very large amounts of potassium have

Figure 5. Diagram relating Na<sub>2</sub>O, calculated on a water-free basis, to depth, Hole 417A. Symbols as in Figure 1.

to come ultimately from seawater. The hydrogen ion taken up during alteration combines with oxygen in the silicate minerals to form water, as shown in Table 2. Further oxygen consumed during oxidation of the iron must come from dissolved oxygen in seawater. If we assume that the oxygen content of the seawater is about 4 ml/l, then the molecular ratio  $K^+$  /  $O_2$  is about 56, and as Table 2 shows, oxygen might be a limiting species, requiring on the order of twenty times as much water for alteration as does potassium. Bicarbonate poses a parallel problem; it is normally about one-fifth the molecular abundance of potassium in seawater, and a similarly large amount of water might be required to furnish the necessary bicarbonate. However, in the case of oxygen we know neither the oxygen content of the water, nor, more important, whether the oxidation was completed during the process of chemical exchange. In fact, the higher contents of ferric iron in the otherwise fresh (low K) units of hole 417A as well as the whole of 417D, especially when compared to such well studied younger

376 DONNELLY

basalts as holes 332A and 332B (Robinson, et al., 1977), suggest that oxidation may continue long after the other alteration has been completed. In the case of bicarbonate, we do not know the  $HCO_3$ content of the circulating water; if it passed initially downward through sediment before entering the basement, it might have acquired considerable initial alkalinity. Thus, in assuming that potassium rather than oxygen or bicarbonate is the limiting species, we are proposing a conservative limiting case. Doubtless more water moved through the system than these estimates suggest.

For the two cases (titanium constant or aluminum constant), we calculate slightly differing volumes of the amount of seawater required to alter the basalt, assuming that the limiting element (potassium) is completely rem, ved. Because the two cases lead to d.ffering original porosities, we find two quite different values for the ratio between volume of water required and volume of voids, i.e. number of times the voids must be filled. In the aluminum-constant case, to supply the necessary potassium we find an original porosity of 6 percent, a required volume of 1.76 m<sup>3</sup> per cm<sup>2</sup> column 200 meters long, and 1570 volumes of the voids. For constant titanium, these figures are 13 percent, 1.66 m<sup>3</sup>, and 542 void fillings.

The discharge of calcium and carbonate ion supersaturates sea water for calcium carbonate. The total excess calcite corresponds to the equivalent of about 24 meters of CaCO<sub>3</sub> in the constant-aluminum case, and 20 meters in the constant-titanium case. Much of this excess calcite is now seen as the ubiquitous void and fracture fillings, but some discharged into seawater. Seawater is generally close to

Figure 6. Diagram relating  $K_20$  to MgO + CaO + Na<sub>2</sub>O for Holes 417A and 2417D. Units are moles per 100 grams. Symbols as for Figure 2.

saturation at the depths of most mid-ycean ridges; the effect of discharge of Ca2+ and CO3 ions into seawater might be to supersaturate it, or raise it to satura-tion level if it is slightly undersatured. A common observation, exemplified clearly at hole 417D, is that the basal meter or so of sediment has nearly perfect preservation of the calcareous fossils, and is overlain directly by sediment with no preserved carbonate. We might speculate that the interval of preservation corresponds to an important discharge of the products of basement alteration, even though the vent from which the effluents issue may be several hundred meters away. The recovery of this calcareous sediment could mistakenly be interpreted as accumulation above the lysocline.

The recognition of extensive alteration by warm water to depths of at least 200 m sub-basement requires a mechanism to drive the large volumes of water and thus rules out simple weathering. We propose that the water is the effluent portion of a convection cell driven by

Figure 7. Diagram relating K<sub>2</sub>O to iron oxidation, plotted as ratio of ferric to total iron, for basalts of holes 332B (data from Aumento, Melson, et al., 1977), 417D, and 417A. Symbols for latter two holes as in figure 1, except that symbols for dolerite and "red brown" basalt have been merged with flow symbol, for 417A and glassy selvage has been merged with hyaloclastite for 417D. Inverted triangle shows median sample.

Figure 8. Summary diagram relating  $K_20$  to iron oxidation for sites 332B, 417D, and 417A. Circled fields enclose central twothirds of samples. Arrows show trends towards more oxidized samples. Data from figure 7.

the cooling of basalt. The inferred contrast in original topography between 417A and 417D completes the model: the elevated basalt area remains free of sediment cover for several (up to about 20) millions of years and persists as a porous, upside-down drain. The "recharge" area (using a hydrologic analogy) is the lower, sediment-covered area. The relative areas of "recharge" areas affected by downward moving of cold water to "drains" with upward moving warm water is probably high, and is equivalent to the probability of drilling blindly into a "drain" as well as to the ratio of the amounts of water affecting the basement rocks in the two areas. Thus, the geometry of the convective cells results from early-formed topographic singularities.

The minimum heat necessary to drive the convective water can be calculated by assuming a temperature rise of 30 degrees celsius (coresponding to oxygen isotopic measurements). The heat required for the cases of constant aluminum and constant titanium are nearly the same, because the volumes of water moved are nearly the same. They correspond to about 5 x  $10^7$  calories for a 1 cm<sup>2</sup> cross section column 200 meters long. The original heat in a column of basalt, assuming 100 cal/g for latent heat of cooling and 0.3 cal/g<sup>o</sup>C for specific heat of basalt cooling from 1100°C shows that the 200 meter column could not in itself supply more than half the necessary heat. We could heat no more than  $0.8 \text{ m}^3$  of water with this basalt, but we need to move through at least 1.7-1.8 m<sup>3</sup>. Thus, the heat necessary must come in part from depths greater than the observed alteration, i.e. the cooling crust in general.

#### Ageing vs Mesothermal Alteration of the Oceanic Crust

The recovery of 500+ meter drilled sections of oceanic crust of approximately similar composition during Legs 37 and 51 through 53 of the Deep Sea Drill ing Project affords us an invaluable opportunity to add the dimension of time to the alteration process. As figure 7 shows, the relatively fresh basalts of the upper 200 m of hole 417D are similar to the basalts of Site 332B (age approximately 3 million years) except that the older basalts are more oxidized and tend towards higher K<sub>2</sub>O values at a given level of oxidation. Figure 8 summarizes the groupings of basalts (circles enclose about two-thirds of the available analyses and arrows indicate trends towards more oxidized samples). If we assume that the basalts of 417D represent what those of 332B might look like after the passage of about 107 million years, then we note the relatively greater importance of oxidation than of potassium uptake with ageing.

Petrographic study of the 332B basalts show two stages of alteration. The first stage alters olivine and glass but produces a little chemical change, other than hydration of the glass. A later but more restricted alteration occurs along fractures and produces yellow to red oxidized basalt containing some high-K smectites. The limit of this alteration would presumably be met when production of hydrated phases causes the tiny fractures to close, terminating water circulation. The more advanced alteration at hole 417D indicates that the basalts at hole 332B have not reached this stage, or, more probably, that some minor tectonic activity re-opened fractures.

As shown also in figure 2, the uptake of potassium in 417A contrasts with that at 417D in more than degree: at equivalent water contents and levels of iron oxidation, the 417A basalts have taken up more potassium than those at 417D. Samples from the two holes shown in figure 8 have different trends, and we suggest that the difference represents the nature of the early alteration process. The warm temperatures may be responsible for the difference in potassium uptake. Interestingly, there are several samples from 417D with more than 2 percent K<sub>2</sub>0, which is a very unusual value in even the more altered pillow basalts. Thus, the very slight temperature differences between dredged pillow basalts at O°C and ageing crust with a probable temperature slightly higher than zero may

378 DONNELLY

account for this mild potassium uptake in older crust. The assessment of potassium uptake or release by the crust will depend critically on an extensive knowledge of temperature distribution and water access during the ageing process.

Evaluation of Elemental Fluxes - the Problem of Dredged vs Drilled Basalts

Previous studies of dredged pillow basalts (e.g., S. Hart, 1969; R. Hart, 1970; Thompson, 1973) clearly indicated that basaltic rock exposed to seawater indergoes reaction even at ambient bottom water temperatures. Chemical changes included uptake from seawater by the rock of H<sub>2</sub>O, K, P, Pb, Cs, B, Li and occasionally Ba and Sr. Elements leached from the rock included Si, Ca and Mg. Ferrous iron was oxidized but elements such as total Fe, Mn and Na show less obvious effects; Ti and Al, and trace elements such as 2r and Y, were apparently unaffected.

The rates of reaction during submarine weathering of the rocks were apparently slow. R. Hart (1970) calculated rates from plotting the composition of oceanic basalts reported in the literature against their calculated age. In 1973 Hart again calculated rates of exchange using the relationship of change in density with change in composition of weathered basalts, and the rate of change in seismic velocity seen in layer 2 across ocean basins. T.:ompson (1973) calculated rates of exchange from detailed studies and mass balance in individual dredged pillows or cooling units from DSDP cores. In a more systematic and detailed study of dredged pillow basalts recovered on a transect from the median valley of the Mid-Atlantic Ridge at 23°N out on to the western flank and representing an age range of 0 to 57 million years, Thompson and coworkers (Thompson and Rivers, 1976; Rivers, 1976; Thompson, et al., in preparation) calculated rates of alteration at low temperature. Thompson and Humphris (1977) summarized these and previous calculations by Hart, and they are shown here in Table 3. Trace element uptakes (Rb, Li, B, Cu and Zn) are of the order 1 to 2 x 10-12g/cm<sup>3</sup>yr. These exchanges were considered to represent a maximum rate for low temperature weathering, the exposed basalts representing a large water/rock ratio. It was indicated that these fluxes operating over an 85 million year period, equivalent to 200 x 10<sup>6</sup> km<sup>2</sup> of sea floor, would have to be representative of the upper 0.6km of oceanic basement, or even greater depth,

| Table | 3 | Rates of exchange between dredged |

+ taken up by rock from seawater

- lost from rock to seawater

Rates calculated assuming constant volume; rates do not significantly change if calculated assuming constant Ti or Al. Data from R. Hart (1970, 1973) Thompson (1973) and Thompson, et al (in preparation)

to account for the uptake of the annual river input of K<sub>2</sub>O (Maynard, 1976). Such effects were apparently not seen at depth in the oceanic crust when deeper DSDP drilling cores were recovered, e.g. sites 319, 320, 321, of Leg 34 in the Nazca plate (Thompson, et al., 1976), site 332, Leg 37 in the Atlantic (Aumento, Helson, et al., 1977) and even site 417D or 418A, Leg 51-53 (Staudigel et al., in press, a,b). In dredged pillow basalts, original K20 contents of about 0.08 weight percent were increased to 0.2 to 0.4 weight percent (except palagonitized margins which reached as high as 1.0 weight percent K20). The DSDP cores typically showed  $\bar{K_{20}}$  increasing to 0.15-0.18 weight percent altrough K20 ranged higher in small alteration veins or palagonitized regions. The DSDP basement lithic units also showed less Si, Mg and Ca loss, with the Ca commonly being reprecipitated as carbonate in the basaltic pile.

At hole 417A the direction of chemical fluxes, e.g., uptake of K, H<sub>2</sub>O, P, Ba, Li, B, Nb, Cs (Donnelly, et al., in press, Joron, et al., in press) and removal of Ca, Mg, and some Na, as well as oxidation of iron, is in the same direction as for dredged basalts, but reaches far higher values. Assuming an available time period cf 20 million years before sedimentation sealed the system to vater flow, and taking the estimated 820 g/cm<sup>2</sup> per

200 meter column as the added  $K_{20}$  we find that the flux is about 2 x  $10^{-9}$  g/cm<sup>3</sup> year, which is beyond the range shown in table 3.

Before consideration of the potential role of such fluxes in affecting seawater composition and elemental budgets in the marine environment, it is pertinent to realize that other and different reactions of seawater and basalt occur. From experimental studies (e.g. Motul, 1976; Bischoff and Dickson, 1975), observations in natural seawater hydrothermal systems, such as at Reykjanes in Iceland (Tomasson and Kristmannsdottir, 1972) and from studies of hydrothermally altered basalts from the ocean floor (Humphris and Thompson, 1978a, b), it is clear that high temperature (>200°C) reactions of seawater and basalt result in rapid chemical exchanges. In general at higher temperatures lig is taken up by the rock from seawater and also probably Na, whereas Si, Ca and K and probably Fe and Mn are leached from the rock. Of the trace elements B, Li, Cu, Ni, Zn, Ba, and Sr are mobilized and sometimes removed: elements such as Zr, Y and the rare earths are apparently largely unaffected.

In Table 4 we show the major chemical fluxes that may result from high temperature (>200°C) basalt seawater interaction as calculated by a number of workers from different observations. The magnitude and effect of such fluxes depends of course on the amount of oceanic crust undergoing such reaction with seawater. If one-fifth of the annually produced new oceanic crust (8.8 x 10<sup>15</sup>g/yr, density 2.9g/cm<sup>3</sup>) undergoes reaction and is hydrothermally altered, this could result in fluxes of Mg uptake from se water up to 348 x  $10^{12}$ g/yr nagnesium, shown in parentheses in Table 4. These values compare with an estimated input of Mg into the oceans by the rivers of 130 x  $10^{12}$ g/yr (Garrels and Mackenzie, 1971). Drever (1974) has indicated that a sink of 69 x  $10^{12}$ g of Mg per year is all that is required clearly quite compatible with the hydrothermal estimated sink. At these high temperatures potassium is lost, but K20 input from hydrothermal alteration seems relatively small compared to other fluxes. Humphris and Thompson (1978a) noted that hydrothermally altered basalts recently exposed on the seafloor did not greatly differ in their K20 contents from their fresh precursors, possibly due to uptake of K20 from seawater at low temperatures when reexposed. The net effect of basalt-seawater

interactions on oceanic budgets must consider cold weathering, warm alteration

involving very large volumes of water, and high-temperature (>200°C) hydrothermal alteration. R. Hart (1973) considered that weathering was the major sink for K20, and hydrothermal alteration the najer sink for Mg and Na, and he calculated a net effect without consideration of the opposite effects of these two processes. Wolery and Sleep (1976) considered that the fluxes calculated for low temperature weathering of dredged material were indicative of only the upper few tens of meters of oceanic crust and thus not important: hydrothermal alteration, because of the large volumes of scawater that must be pumped through the oceanic crust near the spreading centers to cool the lithosphere, was for them the major process governing chemical exchange between the oceanic basement and seawater.

However, if site 417A is at all representative of a few percent of the upper part of layer 2 of the ocean crust, warm water alteration may be also be an important process. In this case the net Mg sink would be lessened or reversed, and the  $K_{20}$  sink increased. Reactions similar to those that occur at site 417A must be restricted to oceanic crust younger than 15 million years, where sufficient heat is still available in the cooling lithosphere to drive the water. At temperatures greater than about 100°C the

380 DONNELLY

chemical nature of the alteration process would change.

#### Conclusions

The basalts of hole 417A exhibit a degree of alteration hitherto unseen in oceanic rocks. If such sites comprise even a percent or two of the oceanic crust, then the elemental fluxes seen here would be of first order importance. Although none of the other dozen or so deeply drilled holes (that is, holes drilled many tens of meters into the oceanic crust) revealed such altered basalts, several earlier holes with penetration of a meter or so recovered suspiciously highly pctassic samples. These sites include sites 137 and 138 (eastern Atlantic), 192 (northern Pacific), and 235 (western Indian Ocean), all of which recovered basalts with K20 values of 2 percent or higher.

There is little doubt that the forced passage of warm to hot water through a cooli:  $\gamma$  oceanic crust could result in immense elemental fluxes. At high temperatures Mg is taken up and K released, and at lower temperatures the reverse is observed; thus, it is conceivable that these effects might cancel each other. Much depends on the length of time that water is exposed to rock at various temperatures; under some conditions highly

undersaturated hot water could be discharged directly into seawater with little other than a local thermal effect. Or water with high K and with low Ng might lose its K and recover Mg if allowed to interact with wall rock at lower temperatures prior to discharge. Further recovery of dredged rocks will do little to settle the controversy, because of the problems listed above. Only extensive crustal drilling to relatively shallow depths (one hundred meters should be fully adequate to assess the type and extent of alteration) will provide the answers needed. Drilling of older, sediment covered crust provides an opportunity absent in younger crust: the opportunity to drill topographic highs which cannot be penetrated in the absence of a sediment cover. It is not possible a priori to assign relative importances to the two temperature ranges, but the recovery of one well documented, clear example and four additional possible examples with very limited penetration and recovery emphasize the importance of the warm water process.

Acknowledgements. Discussions with several 'Megaleg' co-workers have been most valuable, especially Matthew Salisbury, James Lawrence, and Karlis Muehlenbachs. Mike Mottl and Bill Bryan critically reviewed a related paper. Chemical analyses were performed by Max Budd, Department of Geological Sciences, State University of New York, Binghamton, and D. C. Bankston and M. Sulanowska at the Woods Hole Oceanographic Institution. NSF Grant GA-22971 is gratefully acknowledged. We are especially grateful to John Tarney for a thoughtful review.

# Introduction

Weathering on the continents takes place in a flow system. Dilute rain and ground waters, of quite constant composition at a given location are renewed continuously at the exposed mineral surfaces. This reaction medium is relatively acidic and poor in cations the average ratio of cation equivalents to protons being of order 10<sup>3</sup>. The net result, for silicate weathering, is a replacement of the cations in the alumino silicate lattices by protons. Resulting structural accomodations lead to release of silica along with the cations and the production of stripped or degraded phases, clays. If primary weathering is regarded as the titration of quenched, high temperature, disequilibrium igneous rock by acidic volcanic volatiles then the continents are inevitably over-titrated, acting as a sink for protons.

Cceanic weathering is a distinctly different process. The environment is static: the cation to proton ratio is of order  $10^{7}$ : lowtemperature reactions between basalts and seawater therefore involve changes in the cation ratios of the two phases with comparatively minor net exchange of protons. The trend is towards equilibrium rather than reduction of the weathering substrate to a refractory residue.

The primary source of protons for continental weathering reactions is the acid volatiles released by volcanoes. Of these the strong acids hydrochloric, sulphuric, nitric and hydrofloric are neutralized rapidly by the rocks. Of the weak acids only carbonic is important, boric being present in minor quantities. The centrality of carbonic acid lies in its being not only weak but also volatile as CO<sub>2</sub>: it is the only acidic species which can be regenerated - i.e. neutralized, and then recycled through the system. Mass balance calculations indicate that the rate of weathering on the continents depends critically on this recycled acid (e.g. Garrels and MacKenzie, 1971). If there is nowhere a backtitration of the products of continental weathering then the process will run down rapidly as the available protons are fixed in clays.

An appreciation of this problem by Sillen (1961) led him to hypothesize that the degraded products of continental weathering are in fact reconstituted in the ocean by rereaction with seawater. That is to say the reaction in a proton-rich, cation poor environment is reversed by interaction with a cation rich, proton poor solution - seawater. The observed load of degraded and partially degraded alumino-silicates carried by rivers to the ocean is ample to allow this process (MacKenzie and Garrels, 1966). In addition, by its very nature the overall cycle acts to stabilize the major ion chemistry of the ocean since it is closed.

The profundity and generality of this reverse weathering hypothesis and its implications for the stability of seawater composition over geologic time have led to its gradual acceptance and elaboration since the original proposal in 1959. This despite the almost complete lack of supporting field or laboratory evidence for the occurrence of the proposed reactions under oceanic conditions (e.g. Drever, 1974 for summary).

Over the past decade our understanding of the marine geochemical cycle has been radically transformed by the realization that crustal formation in the intrusion zone at the ridge axes is accompanied by pervasive hydrothermal activity (Elder, 1965, Deffeyes, 1970, Talwani et al., 1971). The generally observed negative anomaly in conductive heat

TABLE 1. Contributions of the various proton carriers to the reverse weathering process

loss from young crust (Anderson et al., 1977), the seismic properties of the upper crust (Fox et al., 1973) and the isotope equilibrium temperatures in dredged samples (Muchlenbachs, 1976) are together compelling evidence for the global significance of this process. The drastic chemical transformations observed in laboratory studies of seawater-basalt interactions at high temperatures and sea floor pressures indicate major associated effects on the chemistry of the circulating waters (Bischoff and Dickson, 1975, Hajash, 1975, Seyfried and Bishop, 1977, Mottl and Holland, 1978). The discovery and sampling of extensive fields of hot springs on the Galapagos Spreading Center (Sclater and Klitgord, 1973, Lupton et al., 1977, Corliss et al., 1978) provided the first direct evidence for the existence of the process. The chemical data confirm the experimental work at least in general: coupled with the global flux estimates derived from the He-3, heat relationship (Jenkins, et al., 1978) these data provide strong evidence that ridge crest hydrothermal metamorphism exerts a pronounced infinance on the major and minor element chemistry of the ocean. The possibility therefore exists of an alternative to the Sillen hypothesis at least as reneral and perhaps more amenable to direct investigation. In this paper therefore the existing chemical data from the hot springs will be discussed in relation to the reverse weathering problem.

#### Requirements

For ridge-crest hydrothermal metamorphism to be the mechanism of reverse weathering the seawater-basalt interactions must result in a net production of protons i.e. the charge balance must be conserved through hydrogen ion rather than any other cation. If not then a budget problem is created at the expense of one resolved. This consideration constrains quite sharply the kind of processes which can act as effective back-titration reactions.

384 EDMOND

They must produce protons or 'proton carriers' e.g.  $CO_2$  itself, calcium through the subsequent reaction:

$$Ca^{2+} + HCO_3^- = CaCO_3 + H^+$$

reduced iron or manganese via the oxidation reactions:

$$Mn^{2+} + 1/2 O_2 + H_2O=MnO_2 + 2H^{+}$$

or H<sub>2</sub>S:

$$H_2S + 20_2 = S0_h^2 + 2H^7$$

The required proton flux can be estimated from the published mass balance schemes developed to 'confirm' the Sillen hypothesis (MacKenzie and Garrels, 1966). The 'primary' bicarbonate, that not derived from weathering of carbonate rocks amounts to about 35% of the total annual river lux of approximately  $3 \times 10^{13}$  eq/yr i.e. the hydrothermal solutions must provide a net proton flux of  $10^{13}$  eq/yr.

# The Galapagos Data

1. Temperature. The <sup>3</sup>He data (Jenkins et al., 1978) give a ratio to heat of  $22 \times 10^{-18}$  moles/calorie. Assuming this ratio is general for all hot springs and accepting the average annual flux of <sup>3</sup>He to the ocean as 4 + 1 atoms/cm<sup>2</sup>/sec (Craig et al., 1975) then '... associated heat flux is 4.9+1.2 x 10 cal/yr in remarkable agreement with the geophysical estimates (Williams and Von Herzen, 1974, Woolery and Sleep, 1976). If the average exit temperature of the hot springs is 15°C (the highest sampled at the Galapagos site) then a volume of seawater equivalent to the whole ocean must pass through the ridge crest every 360,000 years. This exit temperature cannot however be representative of that in the reaction zone given the extensive chemical modifications observed. It is almost certainly an artifact of dilution by 'ground waters' of approximately ambient composition of the primary end member solution as it ascends through the pillow pile at the ridge crest (Corliss et al., 1978). If it is assumed that equilibrium is reached at some high temperature in the reaction zone, that no subsequent reactions take place during ascent to the surface and that dilution is indeed with waters of ambient temperature and composition then various solution geothermometers can be used to estimate the conditions in the equilibrium regime.

The silica data from all the hot springs sampled define a single linear relationship with temperature (Fig. 1). Due to various 

Fig. 1. Silica versus temperature. The four vent fields are identified by symbol: Clambake  $\bullet$ ; Dandelions +; Oyster Beds 0; Garden of Eden X. The scatter in the data reflects the uncertainty in the temperature which, due to entrainment of ambient water at variable rates during sampling, can be as much as  $\pm 0.5^{\circ}$ C for some samples.

sampling and instrumental difficulties the uncertainty in the temperature measurements ranges up to about  $\pm 0.5^{\circ}$ C. This appears to be the major cause of scatter in the Si-T relationship in that plots of all other parameters against silica are much tighter than against temperature (Corliss et al., 1978).

In many continental hot spring systems the subsurface reservoir temperature can be estimated with high accuracy from the silica data by assuming equilibrium saturation with respect to quartz at the end-member, no requilibration during transport from the reaction zone to the surface and no mixing with extraneous waters (Fournier and Rowe, 1966). Corrections are made for adiabatic cooling and for compositional effects associated with flash boiling. The relationship given by Truesdell (1975) is:

 $T = 1533.5/(6.989 - \log Si) - 273.15$ 

where T is the reservoir temperature in degrees Centigrade and the silica concentration is in micromoles yer liter. The general success of this approach, confirmed by down hole temperature measurements validates these assumptions.

In the Gala<sub>P</sub>agos system dilution with local 'ground water' apparently does occur. Hence the mixing assumption must be relaxed to include entrainment of water putatively of the temperature and composition of the ambient seawater. One therefore wishes to determine the point of intersection of the extrapolation of the measured Si-T relation with the quartz solubility curve. The Si-T equation is

# Si = a + b∆T

where a is the ambient value ( $\label{eq:mol}$ ), b is the Si gradient in  $\mu mol/\ell/^{\circ}C$  and  $\Delta T$  is the temperature increment. Substituting in the Truesdell equation:

# $6.989T - (T + 273.15)\log(a + b\Delta T) + 375.6 = 0$

Solving for T ( $\Delta$ T = T - 2.05) gives the extrapolated quartz saturation temperature at 285°C. A more elaborate treatment of the problem, following Walther and Helgeson (1977), does not seem warranted by the data. Secondary quartz is a common high temperature reaction product in sea floor basalts (see e.g. Humphris and Thompson, 1978; Coleman, 1977; Cann, 1969). The amounts of silica involved in solution reactions probably s small proportion (<1%) of the .otal available in the rock. Equilibrium control by a volumetrically minor phase is therefore quite reasonable.

It can be objected that during mixing cristobalite or entire soluble silica phase may precipitate as is observed in some continental systems: alternatively the waters in fact may be dissolving volcanic glass of high but indeterminate solubility. In either case, the 'quartz saturation temperature' is merely an artifact of the final observed Si-T dilution line. It is important therefore to establish other measures of the end-member temperature. Based on the experimental work the most obvious is the 'zero magnesium temperature'. This parameter is derived from the observation of rapid uptake of the seawater magnesium by basalt at elevated temperatures to form a sepiclite or chlorite (Bischoff and Dickson, 1975). In systems with are not rock limited the magnesium concentration is reduced effectively to zero in a few hours. Given the observed gradients in 'soluble' elements, e.g. Li and Ba, such is certainly the

EDMOND 385

case at the Galapagos. The data for Mg fall on a uniform decreasing trend with temperature (Fig. 2) which extrapolates to give zero concentration at  $295^{\circ}$ C.

Recent data for sulphate; to be published elsewhere, also extrapolates to zero at around 300°C. Application of the empirical Na-K-Ca geothermometer of Fournier and Truesdell (1973) is beset with complications. The sodium variation in the hot springs is imperfectly known being a few tenths of a percent at most at the highest temperatures sampled. More fundamentally the success of the scheme apparently is based on cation exchange equilibria with feldspars and hence of dubious application to tholeiitic systems. Olafsson and Riley (1978) found for the Reykjanes brines that the computed temperature based on the compositional data gave values about 60°C below those measured. Application of the geothermometer to the experimental data of Bischoff and Dickson (1976) and Mottl (1976) failed to give any systematic relation - a calibration - with the reported laboratory temperatures. With the present data (Fig. 3,4) the geothermometer gave a maximum temperature for the case of invariant sodium, the value being 180°C.

From this discussion it would appear that the water leaves a reaction zone depleted in magnesium (and sulphate) and at equilibrium with quarks with a temperature of between 275 and 300°C. During ascent to the surface vents major entrainment of 'ground water' of approximately

386 EDMOND

Fig. 4. Calcium versus silica. Regression lines for the various fields are drawn. Garden of Eden and Dandelions display the same relationship within analytical accuracy.

ambient composition occurs the exit temperature being determined by the extent of this latter process. Further, during actual sampling of the hot springs further admixture of ambient waters may occur. Hence the measured data fall on dilution lines whose slopes are characteristic for each element and, in general, for each field.

# The Carbonate System: $A_t$ , $\Sigma CO_2$ , Ca

For the ridge crests to be a significant factor in the global weathering balance the flux of protons and proton carriers into the water column must be on the order  $10^{13}$  eq/yr. Accepting the global hydrothermal heat flux as  $5 \times 10^{19}$  cal/yr gives a net concentration gradient with hot spring temperature of 200 µeq/ $\ell$ /°C. Of course this assumes constant relative composition gradients in all hot springs, a condition not fulfilled even between the four vent-fields sampled to date! However the calculation is important in placing the ridge crest processes in the overall context of the aqueous geochemical cycle.

The alkalinity decreases with increasing temperature (Fig. 5). The average slope is approximately  $-30 \ \mu eq/l/^{\circ}C$ . Two groups of points fall markedly off the trend: those for several but not all of the Dandelion vents are high and apparently real: those for the Oyster Bed samples collected on Dive 726 are systematically low by as much as 100  $\ \mu eq/l$ . This may be caused by oxidation of reduced

# Fig 5. Alkalinity versus silica.

sulphur compounds before analysis since these samples, unlike the others, had to be stored for a day before processing. The data from the Garden of Eden fall slightly above the main trend. In the absence of samples in the intermediate range this is assumed to be a real effect. The scatter in the data overall is appreciably greater than the analytical uncertainty (~0.25%, most samples were run in duplicate): the same is true for H2S suggesting that there is a range of products formed during oxidative reaction of the sulphide in the sub-surface mixing zone producing variable additions of protons. This has been shown to be the case in fresh water systems where thiosulphate, polysulphide, and native sulphur can amount to over half the non-sulphate sulphur (Boulegue, 1977).

The ECO<sub>2</sub> content of the hot spring waters (Fig. 6) increases with temperature. However, there is considerable scatter in the data much of it probably analytical since the measurements were made at sea using a simple gas chromatograph. The Garden of Eden samples fall low at approximately 5  $\mu$ mol/ $\ell$ /°C and the Dandelions high at about 30. Clambake and Oyster Beds scatter about a slope of 15. Extrapolation of this trend to the reaction zone temperature gives a CO<sub>2</sub> excess of 4200  $\mu$ mol/ $\ell$ : a similar calculation for He-3 gives 6.2 x 10<sup>-12</sup> moles/ $\ell$ . As pointed out by Corliss et al. (this volume) this indicates a very high extraction efficiency for helium but a much lower one for CO2. Clearly much more precise data will be required to resolve this question.

Calcium increases with temperature in all the vent fields (Fig. 4). However there are variations in the slope between the different fields. Clambake is highest at  $80 \ \mu mol/\ell/^{\circ}C$ , Dandelion and Garden of Eden are intermediate at  $64 \ \mu mol/\ell/^{\circ}C$  and Oyster Beds is markedly lower at 38  $\mu$ mol/t/°C. Other measured species e.g. Li, Ba, Mn, Fe also show significant variations between fields. However the systematics are not the same for each element. Because of this a simple aging effect can not be the only factor in determining the spread in the trends.

The effective flux of protons carried by the alkalinity - CO<sub>2</sub> - calcium system is obtained from the sum of the slopes for Ca and CO<sub>2</sub> minus that for alkalinity. On the basis of the data for the latter two species it is possible co assign only crude averages to the trends: these are taken as 15 µmol/l/°C and  $-30 \ \mu ec/l/^{\circ}C$  respectively. The total flux hence varies between 125 and 83 µeq/l/°C of proton equivalents. The extreme ranges of the data give 156 and 64  $\mu$ eq/ $\ell$ /°C. It is clear that around 50% of the primary flux of bicarbonate from continental weathering of non-carbonate rocks is back-titrated by rlug. crest hydrothermal solutions. Calcium is the responsible proton carrier for about half of this.

The annual consumption of alkalinity is  $1.5 \times 10^{12}$  eq/yr, about 5% of the river flux or 14% of that not balanced by formation of oceanic carbonates (MacKenzie and Garrels, 1966). The CO<sub>2</sub> flux is very approximately  $0.75 \times 10^{12}$  moles/yr equivalent to about 7% of the annual sedimentation rate as carbonate and about 4.5% of the annual consumption of CO<sub>2</sub> by continental weathering. For comparison the flux in the photosynthesis respiration cycle is estimated at  $4.7 \times 10^{15}$  moles/yr and that from anthropogenic fossil CO<sub>2</sub> release at  $4 \times 10^{14}$  moles/yr.

The addition of calcium is between 1.9 and 4 x  $10^{12}$  moles/yr, 15 and 30% of the river

Fig. 6. Total  $CO_2$  versus silica. Lines of gradient 30, 15 and 5 µmoles  $CO_2/l/^{\circ}C$  are indicated.

EDMOND 387

Fig. 7. H<sub>2</sub>S versus silica.

flux. Holland (1978) estimates that about 75% of the latter is derived from the solution of sedimentary carbonate rocks. Hence the ridge crests are a source of 'primary' igneous calcium comparable to that from the continents. Approximately one third of the carbon required to precipitate this calcium as carbonate is derived from the ridge crest. The remainder, an average of  $2 \times 10^{12}$  moles/yr, must be obtained from metamorphic processes and primary outgasing in non-ridge crest environments. In a recent compilation Holland (1978) estimated this combined flux at 7.5±2.5 x  $10^{12}$  moles/yr. While the necessary amount of CO2 is within the quoted uncertainties une general arguments supporting the value itself are very extended and will require a great deal of information before they can be considered substantiated.

# Reduced Species: H<sub>2</sub>S, Mn<sup>2+</sup>, Fe<sup>2+</sup>

The  $H_2S$  levels vary widely between rent areas but more or less linearly within a given field (Fig. 7). A crude average is about 7.5  $\mu$ mol/ $\ell$ /°C equivalent to 15  $\mu$ mol H<sup>+</sup>/ $\ell$ /°C. Manganese shows the same separation between fields as calcium (Fig. 8). The Mn/Ca ratio is about 0.04 resulting in an average flux of less than 3  $\mu$ mol Mn/ $\ell$ /°C equivalent to 6  $\mu$ mol H<sup>+</sup>/ $\ell$ /°C. The iron trends vary greatly between vent fields (Fig. 9). In Clambake the values are very high and after a sharp increase at low temperature rise linearly with temperature (and H<sub>2</sub>S!) with a gradient of

388 EDMOND

2.5  $\mu$ mol/ $\ell$ /°C. In the other fields the highest values are less than  $1 \mu$ mol/ $\ell$ . These trends all show a maximum generally at the higher end of the temperature range sampled. There is no obvious explanation for this behavior. Examination of particles filtered in situ by SEM and EDAX indicates that Fe-S bearing phases are rare (Corliss, personal communication). Taking, for purposes of illustration the average gradient as 0.5  $\mu$ mol/ $\ell$ /°C as ferrous iron the equivalent 'proton flux on oxidation is  $1 \mu$ mol/ $\ell$ /°C.

1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 - 1997 -

Since these reduced species show widely varying behavior between vent fields the calculated evenage fluxes are of course subject to very wide uncertainty. The contributions to the proton balance of the figures presented here is roughly 10% of the total. The oxygen 'demand' is about  $16.6 \ \mu mol/k/^{\circ}C$  of which 90% is from H<sub>2</sub>S oxidation. This corresponds to an ocean wide consumption rate of 8.3 x  $10^{11}$  moles/yr or less than 0.1% of the marine photosynthesisrespiration cycle and about 10% of the total weathering cycle.

The Mn-Fe ratio varies from 1.2 in Clambake to between 10 and 100 in the other fields. The spread in the manganese temperature slopes may be related to ageing effects in the hot spring systems since it is similar to that

Fig. 9. Iror. versus silica. Notice the logarythmic concentration scale for iron.

observed for barium (Corliss et al.,  $J_{278}$ ). However the ratio of the slopes is about 30, much lower than the average tholeiite values of about 330, suggesting either that manganese is not as labile as barium in the primary water - rock interaction or that it undergoes secondary removal processes.

### Conclusions

The contributions of the various proton carriers to the reverse weathering process are summarized in Table 1. The calculated extreme range is between about 40 and 90% with the main contribution ( $\sqrt{50\%}$ ) coming from calcium. Alkalinity consumption is next in importance although the oxidation of H<sub>2</sub>S is comparable in two of the vent fields. The CO<sub>2</sub> flux is highly uncertain but appears to be larger than for manganese or iron.

The charge balance in the hydrothermal solutions is maintained by a decrease in sulphate, an increase in potassium, and positive and negative variations in chloride and sodium (calculated). The elegance of the Sillen hypothesis where cation removal is balanced by immediately concomitant proton production is therefore lost. The ridge crest contribution to reverse weathering - the back titration of the bicarbonate fixed during continental weathering - is decoupled from the cycles of the major ions and to a large extent independent of them.

800

ion

Clearly the discussion presented above involves extrapolations of very large magnitude. However there are internal regularities in the system which make these justifiable. Of the major ions i.e. species strongly subject to charge belaves constraints, impresium and sulphate are quantitatively removed; potassium release is strictly rock limited and therefore relatively constant; calcium is modulated by uptake or release of sodium and chloride. The severity of these constraints can only be established through the discovery and exploration of additional hot spring areas over the range of ridge crest environments.

SOME IMPLICATIONS OF HEAT/MASS RATIOS IN GALAPAGOS RIFT HYDROTHER'AL FLUIDS FOR MODELS OF SEAWATER-ROCK INTERACTION AND THE FORMATION OF OCEANIC CRUST

John B. Corliss and Louis I. Gordon

School of Oceanography, Oregon State University

John M. Edmond

Department of Earth and Planetary Sciences, Massachusetts Institute of Technology

High heat flow was recognized very early as one of the unique features of mid-ocean ridges (Hess, 1962). As the plate tectonic model for mid-ocean ridges became accepted, quantitative models of their thermal structure were developed (Turcotte and Oxburgh, 1967; McKenzie, 1967) which gave rough agreement with this observed trend of increasing heat flow approaching the ridge axis. Although these models predict high heat flux at the spreading axis, detailed surveys of conductive heat flow on mid-ocean ridges show considerable scatter in measured values and mean values lower than those predicted by the models (Talwani et al., 1971; Lister, 1972). These authors suggested that convective circulation in sea water through the newly formed crust was responsible, and Lister (1972, 1974, 1977) has pursued this model in some detail.

Another early discovery regarding mid-ocean ridges was the discovery, by Bostrom and Peterson .0660 that they appear to be the locus of Fe and Mn enrichments in metalliferrous deep sea sediments. They attributed this to volcanic emanations from the mantle accompanying submarine eruptions at the ridge axis. Corliss (1971) proposed that the metal enrichments in these sediments resulted from the hydrothermal convection of sea water through newly formed basaltic crust.

In early 1977, the first in situ observations of these mid-ocean rift thermal springs were made from the deep submersible ALVIN on the Galapagos Rift. In the initial report of the results of this study (Corliss et al., 1978), it is success that uhe ratio of the concentration of various elements in the fluids to the temperature, and thus the "heat content", or enthalpy, of the fluids show consistent patterns in several vent areas. These data, combined with estimates of the initial composition of the magma can be used to examine heat and mass fluxes of the hydrothermal systems.

# The Chemistry of the Vent Waters

Samples of submarine hydrothermal fluids were collected by ALVIN from four vent areas on the axis of the Galapagos Rift (Figure 1). Eightyeight 8.8 liter samples of vent waters and ambient waters were collected, and have been extensively analyzed both at sea and in shore based labs.

The properties of the water samples can be considered the result of two mixing processes. The first is subsurface mixing, in which an initial end member fluid, which interacts at high temperatures with the rocks at depth, mixes, as it rises through the crust to the sea floor, with a descending flow of cold sea water. The second is surface mixing, in which this water, as it flows from fissures in the rocks, mixes with ambient bottom water during sampling (Corliss et al., Since the ultimate end members are the 1978). same, this can be considered to be one continuous mixing process. In this model, the temperatures of the waters sampled, or more precisely, their enthalpy, will fall on a linear mixing line between the enthalpy of the high temperature end-member interacting with rocks and ambient seawater. The same is true of all conservative components of the fluid, i.e. elements which are not dissolved by or precipitated from the fluids during mixing and cooling. Table 1 lists several elements which have been measured in the vent waters and which appear to behave conservatively in these systems. Figures 2 a, b and c are plots of Si, He<sup>3</sup> and Ba in the samples.

Since silica is supersaturated during ascent and mixing, this assumption may be questioned for this component. In fact, this is the basic assumption used for application of the silica thermometer to hydrothermal systems, and research on land geothermal systems indicates that the ascending supersat-

CORLISS 391

Fig. 1. A map of the thermal spring area on the Galapagos Rift. The active vents were located along the axial ridge, a topographical high in the center of symmetry of the rift. The active thermal springs are named, from west to east, the Clambake, the Dandelions, the Oyster Bed, and the Garden of Eden.

urated solutions do not dissolve or precipitate silica if the flow rate is rapid (Fournier and Truesdale, 1974). We measured vertical flow rates of 2 to 10 cm/sec immediately above vent opening where the water was rising and mixing with ambient water. At this rate, the fluids would rise 1 km in 3 to 14 hours. This flow rate is for the diluted fluid reaching the surface. Assuming that the vertical heat flux is constant, the vertical mass flux of high temperature fluid is considerably lower, approximately inversely proportional to temperature, but the vertical velocity could be as high or higher if the cross sectional area of the fissure system through which the plume rises at depth was smaller. Given the same permeability the higher density contrasts at high temperatures should lead to greater bouyant forces and resultant vertical velocities. The remaining elements in Table 1 are undersaturated in the reducing H2S-bearing seawater solutions and thus the assumption of conservative behavior seems justified. Transition metals which form stable sulfides (Fe, Cu, Ni, Zn, Cd, etc.) precipitate from these fluids at low tempera-

392 CORLISS

tures and thus are not conservative (Edmond et al., in prep.).

The slope of the mixing lines in Figure 2 provides the most important input to this discussion of thermal models of the hydrothermal heat flux: the ratio of element flux to heat flux in the hydrothermal fluids. These values, from Corliss et al., (1978) or unpublished data, are listed in Column 2 of Table 1. This ratio for Si is consistent for all vent areas. The same is essentially true for  ${}^{3}$ He, although the ratio is slightly offset to higher temperatures in the Garden of Eden (Jenkins, et. al., 1978). For Ba and Mn, three vent areas, the Dandelions, Oyster Bed and Garden of Eden fall on one mixing line while the Clambake falls on a separate line with higher Ba contents. For Li, the Clambake, Dandelions and Garden of Eden fall on one line, while the Oyster Bed has lower Li. The Sm and Eu gradients are from Clambake samples analyzed by Conard and Corliss (unpublished data). The K gradient is small compared to the ambient value, but does reveal a significant flux from the rocks.

# Composition of the Erupted Magmas

The other important inputs to this discussion are estimates of the composition of the Galapagos rift erupted magmas with regard to the elements listed in Table 1. The estimates used in this paper for the Galapagos lavas are listed in Column 4. For some components, the abundances measured in the rocks are not likely to have changed during eruption and cooling, but for He,  $CO_2$ , K, Li, we must use care in selecting data, since the gases can be lost during cooling, and the alkalis removed by hydrothermal leaching from non-glassy slowly cooled rocks, or added from sea water at low temperature.

It has been shown that the rapidly quenched glassy portions of erupted mid-ocean basalts (MORB) retain gases dissolved in the melt (e.g., Funkhouser, et al., 1968). This has lead to the use of glassy pillow margins for a number of studies of the gases and other volatile phases dissolved in oceanic tholeiite lavas (e.g., Dymond and Hogan, 1978; Craig and Lupton, 1976; Moore et al., 1977; Delaney et al., 1978). The major uncertainty in using the abundance of gases (e.g. He, Co<sub>2</sub>) in glassy margins as representative of the initial magma concentrations results from the strong gradients in gas concentration across the margin resulting from degassing from the interiors of the rocks during slow cooling.

Dymond and Hogan (1978) present evidence to support the conclusions that (1) the relatively uniform values for  $He^3/He^4$  found in oceanic rocks imply a constant proportion of primordial and radiogenic He in the upper mantle and, (2) loss of He during quenching leads to large variations in He concentration in glassy rocks. Since these isotopes are derived from completely different sources, these observations imply that the total initial He in MORB magmas is uniform, and that

the maximum observed values in glassy rocks are the best approximations of this initial value, regardless of their geographic location. One value used here for He<sup>4</sup> is the average of analyses of glass from four very fresh young basalts corlected by ALVIN on the Galapagos rift in the area of hydrotnerral venus (J. Dymond, unpublished data). The He is determined by the consistent <sup>3</sup>He/<sup>4</sup>He ratio reported from the Galapagos vent waters by Jenkins et al. (1978). The four values are tightly clustered ranging from 4.20-4.84 x  $10^{-6}$  cc/gm (STP) with a mean of 4.51±.30 cc/gm (STP). This uniformity is somewhat surprising given the above discussion of degassing and large concentration gradients within pillows.

The other value used, 20  $\mu$ c/gm, which is the highest reported for He in MORB, also provided by Dymond (unpublished data), is from Cayman Trough basa.ts collected by R. Ballard. These rocks were erupted at a depth of 4000 meters, compared to 2500 meters, for the Galapagos Rift. The ambient pressure difference is presumably responsible for retent.on of more gas in the Cayman rocks.

For CO<sub>2</sub>, no measurements are available for the Galapagos Rift rocks, but two recent studies have provided considerable insight into the distribution of CO<sub>2</sub> in mid-ocean ridge basalt magmas. Moore et al. (1977) found that vesicles in the glass fraction of mid-ocean ridge basalts are -95% CO<sub>2</sub>, and estimated the CO<sub>2</sub> content of these rocks by measuring the volume percent vesicles. Using values for the solubility of CO<sub>2</sub> and assuming that saturation of the melt was indicated by the presence of the vesicles, they arrived at an estimate of 800-1600 ppm CO<sub>2</sub> in the melt. Delaney et al. (1978) measured CO<sub>2</sub> directly, obtaining values from 800 to 2300 in glassy pillow basalt margins. In the absence of data on the Galapagos Rift rocks, we shall use these two extremes in our calculations.

The use of analyses of fresh glassy samples also minimizes the problem of low temperature alteration and high temperature hydrothermal leaching. The Li data in Engel et al., (1965) show the effect of rock alteration. In eight rocks with  $Fe_2O_3/FeO$  ratios less than .40, and  $H_2O^+$  less than .70%, the Li content averages 4.7 ± 1.3 ppm. In two altered samples with Fe<sub>2</sub>O<sub>3</sub>/FeO of .72 and .57, and  $H_20^+$  of 1.50 and 1.06%, the Li content is 27 and 21 ppm respectively, presumably reflecting addition of Li during low temperature oxidative interaction with sea water. There remains the possibility that the low Li samples are holocrystalline rocks from which Li segregated into a residual component of the melt and extracted by high temperature interaction with sea water with minimal alteration of the rock (Corliss, 1971). Until these analyses can be completed on the Galapagos Rift glasses, we must use the mear of Engel et. al.'s values on unaltered rocks (5 ppm).

The Ba concentration used (12 ppm) is the average of analyses by isotope dilution given by Hart (1976). It is important to note that White and Bryan (1977) have reported on fresh, glassy

basalts from the Famous area on the mid-Atlantic ridge and find a range of values from 30 to 91 ppm. Ba covaries somewhat with the rare earths, alkalies and other alkaline earths, suggesting that this is a primary fractionation not related to alteration. Since it appears from the Galapagos thermal water data that Ba is readily leached from the rocks, some of the low values for Ba previously reported may be data on nonglassy rocks which have been leached at high temperatures by sea water. In the absence of Ba data for the Galapagos rock, we use Hart's average in our calculations.

For the remaining elements (Si, Mn, K, Sm, Eu), the data are from our analysis of the Gal-pagos Rift glass (Corliss, 1978). The rocks are predominately high in Fe, Ti, and the rare earths. The data used here are from averages of the nonfractionated samples.

# A Conceptual Model for the Galapagos Rift Thermal Springs

Lister (1977, 1978) has proposed that seawater convection through oceanic crust occurs in two stages. The first, the active stage, occurs as water penetrates into newly erupted rock by a process of cooling, contraction, fracturing, and penetration of water resulting in increased cooling, etc., a feedback process which Lister (1974) has exhaustively examined. In the active stage, the water penetration into the rock by fracturing is rapid (~10 m/year), the water temperatures reach 200-350°C and the heated water ascends to the rock surface in a few hours. The system has a lifetime on the order of hundreds of years, and since the penetration rates are much greater than the spreading rate, the phenomena must be episodic. According to Lister, this initial stage cools the crust to some depth where active penetration is halted by the inability of the rock to maintain open fractures at high temperatures and high overburden pressure, or alternatively, by encountering ultramatic rock which undergoes a volume increase during alteration (serpentinization) which offsets the volume decrease due to thermal contraction.

The second, or passive stage of hydrothermal circulation, occurs when this permeable, watersaturated crust is heated from below by conduction. This passive system continues for as long as thermal gradients and permeability are sufficient, and in fact may continue at some level throughout the life of the oceanic crust. The pattern of heat flow observed and the large area of hydrothermal mounds south of the Galapagos Rift (Williams et al., 1974; Corliss et al., 1978 are presumably produced early in this passive stage.

This model seems to fit very closely the conditions we find at the Rift axis springs. The active thermal springs which we located and sampled at the spreading axis are all within 100 meters of the center of topographical symmetry, along the axial ridge (Figure 1). The SiO<sub>2</sub> thermometer suggests temperatures at "300°C, the may make mixing line extrapolates to zero at about this the temperature and the observed flow rates suggest ascent the bourd bound. Preliminary work by Turekian (pers in the  $Pb^{210}$  content of clams living in the this to verify areas suggests that the age of the clammand, in turn, the vents is tens of years or les. The occurrince of dead vent areas with Mn stained rocks ar slowly dissolving clam shells reveals in solving clam shells reveals

Ophiolite complexes provide a very useful source of information to allow us to see beneath the sea floor, since they record the tectonic, magnetic and hydrothermal processes which form the upper oceanic crust. Figure 3 is a steadystate cross section of the upper oceanic crust, including convecting seawater, at the spreading

isotropic Gobbre

nuiate Compiex

Vooted from Devey and nidd 1977

Fig. 3. A steady-state model of the formation of oceanic crust (modified from Dewey and Kidd, 1977). This figure reveals several aspects of the formation of the crust which are relevant to this discussion:

(1) The width of the dike intrusion zone is -50 meters whereas the extrusive rocks can flow to a distance 2 to 4 km from the rift axis leading to an accumulation of up to 1 km of extrusive rocks. The cooling of these surface flows can provide -25% of the missing conductive heat flux on the Galapagos Rift.

(2) The dike complex is formed by rapid quenching between intrusions resulting from seawater circulation.

(3) The isotropic gabbro is cut by the dikes, which are quenched against it, suggesting that this gabbro is plated onto the upper surface of the magma chamber as a result of the removal of heat by seawater.

(4) The "magma chamber", the stippled zone underlying the isotropic gabbro, is inferred from Sleep's (1975) thermal model which does not take into account hydrothermal heat loss at the axis. It may consist of a "nush", a self supporting framework of 70% crystals and 30% residual liquid. (Sleep, 1975) If all the remaining 75% of the missing conductive heat at the Galapagos Rift is extracted at the axial vents we sampled, the cooling of the crust should extend to depths greater than the depth of the magma chamber.

axis, modified from Dewey and Kicd (1977), with input from Kidd (1977), Parmenties and Spooner (1978), Coleman (1977) and our observations on the Galapagos Rift.

One important implication of these observations relates to the effects of hydrothermal cooling on the dike complex and underlying cumulate complex. The dike injection zone is restricted to a width of about 50 meters (Kidd, 1977), has a vertical thickness of up to 1.5 km., and is composed of individual dikes from 10 cm. to 5 m. thick. (Coleman, 1977, P. 55-56). The active springs we located on the Galapagos Rift are restricted to a narrow band along the axial ridge. Thus it appears that the initial "active" cooling stage occurs at the point of dike formation.

The dikes are intruded into the previously cooled, water saturated, permeable dike complex. Cooling of each newly intruded dike results from the penetration of water into vertical fractures which form as the dike is cooled and subsequent convection of the heat to the surface. Dredged holocrystalline rocks with parallel margins which show effects of sea water leaching (Corliss, 1971) are presumably formed here.

The cooling effect of the hydrothermal circulation must also extend down into the naoma chamber. This assertation is supported by the statement of Coleman (1977, P. 54) that "Nearly all exposures studied (by Coleman) and cited in the literature provide clear evidence that the diabase dikes are chilled against the gabbro and that they also pinch out downward into it". As stated by Dewey and Kidd (1977), "the fact that the dikes...are "rootless" requires that they were fec from a magma chamber and that the gabbro they cut was plated onto the roof of that chamber.' Thus, the thickness of the dike complex and the solidification of the roof of the magma chamber are related to the rate and extent of heat extraction by the rift axis thermal springs.

Lister (1974) suggested that the existence of a layer of "sheeted dikes" up to 1 km thick requires cooling by convective circulation of sea water, for if they were cooled only by conduction to the surface, the individual dikes would not cool enough to solidify between eruptions. Lister (1977) subsequently concluded on the basis of a model by Sleep (1975) that water percolation probably does not play a major role in the formation of the sheeted dikes. Sleep modeled the formation of oceanic crust assuming only conductive cooling and derived the temperature distribution within the crust at various spreading rates. The J185°C isotherm, which is approximately the liquidus of the magma and which Sleep suggests is the top of the "magma chamber", appears at increasing depths at decreasing spreading rates: approximately 700 m at 5 cm/year, 1100 m at 3 cm/year and -3.5 km for 1 cm/year. The solidus of these liquids, if we assume they are equivalent to the Hawaiian tholeiites of the Alae lava lake, is 980°C (Peck, et al., 1966). The depth to this solidus in Sleep's

model is approximately 400 m, 850 m and 1800 m for the same spreading rates. Presumably, the temperature required to quench dike margins is nearer the solidus temperature and from observations of dikes cutting gabbro, they can extend below the sheeted dikes. Studies of the grain size changes along dike margins in ophiolites at various depths into the dike complex may allow more insight into the temperature contrasts between the magma and previously formed dikes.

The presence of hydrothermal vents at the Rift axis clearly shows that convective cooling of the dikes occurs. Nothing in the thermal models eliminates the possibility that the dike complex is cooled to low temperatures (e.g. 300°) at the spreading axis, and that the isotropic gabbro plates onto the base of the dike complex as a result of continuing convective heat transfer. Cooling of the gabbro could continue some distance from the actual site of dike injection. The vertical chimney of rising water cooling the youngest dikes could draw water horizontally across the upper portions of the isotropic gabbro whic' conducts heat from the crystallizing magma below. It should be possible to incorporate this convective cooling into a thermal model such as Sleep's to examine its effects quantitatively; this is beyond the scope of the present discussion.

# Extracted Heat and Aveilable Heat

We shall proceed now to consider the heat/mass relationships in the hydrothermal fluids in the light of this knowledge of the geologic setting of the convective systems. At this point it is useful to state explicitly the assumptions of the model encountered to this point:

- 1. That the sampled fluids represent mixtures of ambient sea water and fluids produced by the interaction of sea water with rocks at high temperature.
- That during the mixing of these end-members several components of the fluid behave conservatively, i.e. are not precipitated or dissolved.
- That enthalpy is conserved during mixing, i.e. heat is not gained by, or lost from, the fluid by conduction during mixing and ascent.
- That the heat/mass ratios of the sampled fluids are representative of the fluids produced by these systems.
- That the concentration of various components in the initial melt can be estimated by analysis of the quenched erupted liquid.
- 6. That some of these components of the initial basaltic magma are quantitatively extracted from the rock into the hydrothermal fluid.

The assumption that the sampled fluids are representative is supported by the fact that four vent areas were sampled which are presumably in different stages of their life cycle. The possibility exists that radical changes in fluid composition during the evolution of the systems

may occur requiring modification of the generalizations made here.

The assumption that some components are quantitatively extracted from the rocks by sea water interactions seems well founded. The rapid and complete 1 of gases during cooling of pillow interiors is shown by the common observation that they are completely depleted in rare gases, relative to the glassy margins. This indicates that the cooling and crystallization of the magma results in rejection of the gases into residual phases where they can be dissolved and transported by sea water. For some other elements, it is clear that only a very small fraction of the element present is extracted.

If we make the assumption, for the present, that the extraction i3 complete for all elements (F = fraction extracted = 1), we can multiply the heat extracted in calories per µmole of fluid component (R) by the µmoles of each component present in a kilogram of the magma ( $C_r$ ) and arrive at a figure for the heat extracted per kilogram of rock indicated for each element.

$$Q_{o} = RFC_{r}$$
(1)

Interesting features of these figures, given in column 6 of Table 1, are:

- 1. The model gives values for extracted heat which are constant within a factor of 20 for components whose concentration in the rock varies over a factor of  $10^5$  (He, CO<sub>2</sub>, Li and Ba).
- The Mn value is somewhat higher than these elements, and K, Si and the rare earths have very high apparent basalt heat contents.

This last observation is clearly due to the fact that these elements are not removed quantitatively from the basalt, so that a mass of basalt greater than a kilogram provided the component and thus could provide significantly more heat per unit mass of element.

Keeping in mind the uncertainties in the data, it is interesting to consider how much heat would reside initially in a kilogram of magma which solidifies and cools to form part of the crust, and to compare the value with these calculated values of extracted heat.

If we assume that the convective system cools crustal rocks initially emplaced as liquids, the heat extracted from a given mass of rock is the heat required to cool that mass of liquid from some initial temperature to the liquidus, crystallize it, and then cool it from the solidus to its final temperature, or

$$O_{T} = (\rho C \Delta T + L) \frac{1}{2}$$
(2)

ρC = volume heat capacity of the basalt solid and liquid, (cal/cm<sup>3</sup>C)

- L = the latent heat of crystallization of basalt, (cal/cm<sup>3</sup>)
- ΔT = the temperature change, from the initial temperature of the erupted magma to the final temperature after cooling. (°C)

Sleep (1974, 1975) has considered vertical temperature distribution at the spreading axis within the rising solid mantle diapir (from 100-33 km), the zone of partial melting (33-5 km) and the crust (5-0 km). Assuming cooling along the solid adiabat is -1°C/km, the initial temperature difference in the crust from this effect is negligible for our purposes. Sleep assumes an initial erupted magma temperature at the surface of 1180°C.

The final cooled temperature is less readily estimated. If the initial estimates of the deep end-member temperatures in the Galapagos vent areas of 300° are correct, and the mixing model is real, the surface temperatures are 20°C and the average temperature in the column is 160°C. Presumably when the "active" stage ends, the temperature will be somewhat lower. Table 2 lists values of Qr for a range of reasonable temperatures. If both the heat and the fluid components leached from the rocks were quantitatively extracted from the same mass of rock, the apparent quantity of heat extracted, along with the components of the magma which are quantitatively removed by the sea water, (Column 6, Table 1) would be identical to the amount of available heat (Table 2). Given the uncertainties of the model, the fact that estimates of the available heat  $(Q_r)$  fall in the middle of the range of apparent extracted heat contents  $(Q_p)$ for the readily extracted elements is encouraging.

It is useful to categorize the possible causes for discrepencies between these values; this is done in Table 3. The only component of the fluid for which  $Q_e$  is clearly less than  $Q_r$  is He if we use the data from the Galapagos Rift rocks. Loss of heat from the rising plume by conduction to the rock and subsequent horizontal conduction within the rock mass is not likely to be significant. The primary reason is that the area away from the vertically rising warm plume is presumably saturated with flowing cold water which forms the descending portion of the convection cell and recycles the heat into the system. The possibility that R is too low because of gain of He from previously cooled rocks is also very unlikely; rapid degassing during initial cooling is clearly demonstrated by the absence of He in pillow interiors compared to quenched pillow margins. It is more likely, in spite of the consistent values from four different rocks, that He is lost from these rocks, and

TABLE 3. Possible Causes of Discrepancies Between Extracted Heat  $(Q_e)$  and Available Heat  $(Q_r)$ .  $\zeta_2 = RFC_r$  and  $Q_r = (\rho c \Delta T + L) \frac{1}{\rho}$  (See Text)

that the true value of  $C_r$  for He is closer to the Cayman Trough data. One remaining explanation, considered in a later section, is the migration of He from within the magma chamber up to the site of water rock interaction.

#### Extraction Efficiency

For the remaining elements, the estimated  $Q_e$  is either comparable to  $Q_r$  or somewhat larger (CO<sub>2</sub>, Li, Ba, Mn) or dramatically higher (K, Sm, Eu,

398 CORLISS

SiO<sub>2</sub>). It is clear that for the latter elements the assumption of complete extraction does not apply. These elements are not quantitatively removed from the basalt, so that the water must interact with a mass of basalt greater than one kilogram to extract the mass of the component present in one kilogram of rock. Since heat is extracted more efficiently, apparent extractable heat per kilogram of rock (Qe) is greater than that actually available from a kilogram of rock (Qr). If we assume a value of  $Q_r = 4 \times 10^5$ , and that  $Q_e = Q_r$  for F = 1, we can calculate a value for apparent extraction efficiency, F', from the relation  $F' = Q_r/Q_e$ . These values are tabulated in column 7 of Table 1. These numbers suggest that a very small fraction of the rare earths and silica are extracted from the rocks, somewhat more potassium, and from 2.5 to 6.0% of the mangamese. The holocrystalline rocks studied by Corliss (1971) had lost ~10% of their manganese compared to the glassy pillows they were associated with, which is in reasonable agreement, but were depleted by ~20% in Sm, which does not agree with the smaller extracted fraction suggested by the thermal spring data. It is possible that the rare earth elements and for that matter, K and SiO2, may precipitate through low temperature interaction with rocks during ascent of the fluids, which would have the same effect on  $Q_{e}$ , but this is clearly an <u>ad hoc</u> argument.

The calculated values of Qe for CO2, Li, Ba and Mn are not well enough known, given the data we have on rock abundance, to allow us to attribute the variations to specific processes cited in Table 3, but it is useful to discuss these processes. The sequence Mn, Ba, Li would appear to be a sequence of increasing extraction efficiency with the present data suggesting that the removal of Ba and Li is as efficient as the extractior of CO2. Since CO2 should be quantitatively extracted, it would appear that the values of Cr for Li and Ba must be too low, that the rocks in which this data was measured may have been holocrystalline rocks from which Li and Ba had been previously extracted. For elements for which  $Q_e > Q_r$  and F = 1, e.g. CO<sub>2</sub> with the present data, one interesting possibility is the conduction of heat to the site of water rock interaction.

# The Heat Budget and Depth of Cooling of Hydrothermal Systems

In the model of Figure 3, from Dewey and Kidd (1977), we can see that the cooling and crystallization of the "isotropic" gabbro which is plating onto the upper surface of the magma chamber could contribute significantly to the heat which drives the seawater convection. This heat is conducted through the rock layer which separates the upper margin of the magma chamber from the circulating water. It is important, in this context, to distinguish between depth of water penetration, depth of cooling and depth of extraction. Mobility of some components of the melt, e.g., He, might allow extraction from depths greater than the actual depth of water penetration. Similarly, conduction of heat allows hydrochermal cooling to penetrate further than the water actually penetrates. We can pursue this possibility by examining the amount of heat required to cool the rock at the rate new magma is supplied.

One way to calculate the depth of hydrothermal cooling at the spreading axis is to estimate the heat loss due to seawater convection by comparing the measured conductive heat flux with the models of total heat input, and then calculate the depth of rock which must be cooled to provide this heat flux. Given the half spreading rate, u (3.5 cm/ yr for the Galapagos Rift), the heat required to cool a given mass of rock,  $Q_r$  (in cal/kg, Table 2), the rock density,  $\rho(2.9 \text{ gm/cm}^3)$ , and the depth of cooling  $D_r$ (km) the rate of heat removal by hydrothermal convection is, in dimensionless form,

$$q_r = 2\rho u Q_r D_r$$
(3)

(For q<sub>r</sub> in cal/cm sec, and other terms in the units given, the right side is multiplied by  $3.17 \times 10^{-6}$  to convert years to seconds and km to cm.) For  $\Delta T = 1000^{\circ}$ C,  $Q_r = 3.99 \times 10^5$  cal/kg (Table 2), the relationship between convective heat loss and depth of heat extraction is  $q_r = 25.7 D_r$ .

Von Herzen, Green and Williams (in Corliss et al., 1978) have estimated the hydrothermal convective heat loss at the Galapagos Rift from extensive heat flow data on crust from 100,000 to 1,000,000 years old. The relationship  $h=12t^{-1/2}$ gives the theoretical variation of conductive heat flux with crustal age where h is in heat flow units  $(10^{-6} \text{ cal/cm}^2 \text{ sec})$ , and t is the age of crust in m.y. (Lister, 1977). This equation, integrated over the last 1 m.y., gives a mean heat loss of 24 H.F.U. The mean measured conductive heat loss for this interval measured by Von Herzen et al., is 8 H.F.U. This indicates a missing heat flux of 16 H.F.U., or, including both sides of the spreading axis, a value of 112 cal/cm sec for the hydrothermal heat flux per unit length of ridge crest. If this heat is vented entirely during the initial cooling of the crust, it would require extraction of the heat from the upper 4.36 km of the crust ( $\Delta T = 1000^\circ$  and including the latent heat).

Consideration of figure 3 reveals an important modification which must be made to these calculations. As Kidd (1977) and Dewey and Kidd (1977) have pointed out, the width of dike injection may be narrow (Kidd estimates ~50 meters) whereas the width of extrusion is a few kilometers. This results in the accretion of ~1 km of surface flows by the time the crust has spread to the edge of the zone of extrusive accretion (Kidd, 1977). These extrusive flows are cooled by seawater convection, but the time lapse between eruptions is presumably long enough to allow each flow to be cooled separately. This circulation produces the typical chemical effects seen in young extrusive rocks, e.g. deposition of yellow and orange staining which is observed photographically on exposed rocks and also on dredged rocks. This cooling of extrusive rocks also contributes all of their content of gases (CO,, He, etc.) and heat to the global hydro+hermal flux, and may be important in providing a flux of elements such as Fe and Mn to the deep sea environment. The cooling of these flows will also contribute to the missing 112 cal/ cm sec of heat flux at the mid-ocean ridge, and may be the source of small off-axis thermal anomalies observed during the Deep Tow surveys of the Galapagos Rift. The heat flux (q ) contributed by the cooling of these extrusives can be calculated from equations (2) and (3), assuming T =1150°C, since the final temperature of these surface rocks is lower than the mean for the dike complex and upper isotropic gabbro. This re-sults in a flux of 29 cal/cm sec from this source leaving 83 cal/cm sec to be accounted for by axial vents. This modifies the depths of extraction of heat for the axial vcnts to  $D_r = 3.23$  km.

We can substite  $Q_e$ , the apparent heat extracted for each component, into equation (3)

# $qe \approx 2 u Q_e D_e$

 $D_e$  is the depth from which the given component must be extracted to give the observed heat/mass ratios in the fluids, providing the actual heat supplied from the rocks is  $Q_r$  (3.99 cal/kg for  $\Delta T \approx 1000^\circ$ ), the heat is extracted from 3.23 km of rock, and the heat flux,  $q_r = 83$  cal/cm sec.

To clarify the meaning of this relationship, we substitute from (1):

$$q_e = 2\rho u RFC_r D_e$$
 (5)

and see that  $2puFC_{T}D_{e}$  is the rate of supply, by the processes that generate new crust, cf a given rock component to that portion of the crust (depth =  $D_{e}$ ) from which that component is extracted by seawater. Thus,  $q_{e}$  is the hydrothermal heat flux deduced from this mass flux plus the heat/ mass ratio for the components. If we assume a heat flux of 83 cal/cm sec ( $q_{e} = q_{r}$ ) and  $D_{r} = 3.23$ km, we can calculate the apparent depth of extraction for each component, which is simply, from (3) and (4),

$$D_e = D_r Q_r / Q_e = D_r F'$$
 (6)

These values, for elements which are strongly extracted from the rocks, are listed in Table 1, column &

# Depths of Penetration and Extraction

The values for  $D_e$  indicate that He is extracted from 3 to 12 km of the crust, CO<sub>2</sub> from ~1 to 2 km of crust, while the heat is extracted from ~3.2 km of crust, the depth of cooling. A somewhat ad hoc explanation can be proposed for this:

(1) The CO<sub>2</sub> is initially dissolved in the magma, remains uniformly distributed due to low diffusion

rates, is fractionated into residual phases during crystallization of the magma and quantitatively removed from the rock during penetration of the water into the rock. Thus the depth from which  $CO_2$  is extracted is the depth of actual initial water penetration at the spreading axis.

(2) The conduction of heat upward from the roof of the magma chamber where the isotropic gabbro is plating out, to the circulating seawater, combined with convection within the magma, which delivers heat to the roof of the magma chamber, allows extraction of heat from the upper 3.2 km of crust. It is worth noting that this depth assumes cooling through an average  $\Delta T$  of 1000°C. This conductive cooling beyond the depth of penetration is likely to become less effective at somewhat higher final temperatures. Thus the "final" temp erature in the isotropic gabbro (below 1 km) at the cessation of the "active" rift axis convection may be somewhat lower, and more rock must be cooled to provide the same convective flux. If the "final" mean temperature below 1 km was 500°C, the total depth of cooling would be 4.26 km.

(3) The He contained in the magma may be extracted from a greater depth than the water penetrates, which requires transfer of He from the convecting melt to the site of water rock interaction, or enrichment of the rocks interacting with the water by prior fractional crystallization. There is a limit to the depth of extraction of He imposed by the nature of the formation of the crust. Since the crust is produced by partial melting and is underlain by residual harzburgite depleted by the melting process, the maximum depth of extraction is equal to the thickness of the crust. This means that the maximum value for De for He must be ~5 km. Given these constraints, the minimum mean concentration of He in crustal rocks is  $~7.9 \times 10^{-6}$  cc/gm STP.

As Craig and Lupton (1976) have pointed out, diffusive transfer of He should lead to fractionation and thus changes in the He<sup>3</sup>/He<sup>4</sup> ratio. Their model dealt with molecular diffusion through glasses at low temperature and may not be quantitatively relevant to this discussion. The  $He^{3}/He^{4}$ ratio in the vent water  $(10.8 \times 10^{-6})$  (Jenkins et al. 1978) is slightly lower than the value for "high He<sup>3</sup>" from glassy rocks reported by Craig and Lupton (11.9 - 13.2 x  $10^{-6}$ ). If the Gala-pagos magmas have He<sup>3</sup>/He<sup>4</sup> ratios in this range, then the role of extensive diffusion which fractionates isotopes in delivering He to the convecting seawater is limited. Crystallization of the magmas during plating of the isotropic gabbro to the roof of the magma chamber would fractionate He into intergranular boundaries, where it could migrate without significant isotopic fractionation down the temperature gradient, i.e., up to the penetrating water. The same effect would result if the basalts interacting with the water were enriched in He, and other gases for that matter, by fractional crystallization or vertical migration of gas bubbles (vesicles) in the melt. Thus the depth of excraction of He and other gases,

400 CORLISS

like the depth of cooling, might be somewhat greater than the depth of penetration of the convecting seawater.

# Summary and Conclusions

We have arrived at a model which encompasses all of the observed variations in  $Q_e/Q_r$ , i.e. the ratio of "extracted" heat to available heat in the rocks of the Galapagos spreading center. Limited extraction from the rocks (F << 1) accounts for those components whose concentration in the vent water is relatively low ( $Q_e >> Q_r$ , e.g. SiO<sub>2</sub>, Sm, Eu). For some elements with Qe approaching  $Q_r$  (Mn, Ba, Li) we assume F is approaching 1 and that the depth of extraction is equal to the depth of penetration. For those components which we presume are quantitatively extracted (F=1), the variations in  $Q_{p}/Q_{r}$  are accounted for by assuming that heat is conducted to the site of water-rock interaction ( $Q_e > Q_r$ , e.g.  $CO_2$ ) or that the component can migrate from the magma to the site of water-rock interaction ( $Q_e < Q_r$  e.g. He).

In spite of some ad hoc reasoning, the model gains support from some independent observations on the expected behavior of the chemical components considered and from studies of exposed ophiolite complexes. The values of F' derived are not unreasonable from our knowledge both of the chemistry of the elements and observations of fresh and altered crustal rocks.

For the values of  $D_e$  to be applicable to the vents we sampled, we must assume that all of the missing heat is extracted by these rift axis systems, which in turn requires cooling of the large fraction (~3.2 to 4.2 km) of the oceanic crust at the axis. The evidence from ophiolites suggests that cooling penetrates into the magma chamber at the site of dike injection. This seems to conflict with recent seismic studies of the rift axis on the East Pacific Rise at 9°N which suggest that a low velocity zone interpreted to be a magma chamber persists for some time. (Orcut, et al., 1975, Rosendahl, 1976, Rosendahl, et al., 1976) The resolution of this conflict is not clear. The spreading rate is 6 cm/yr in the region studied compared to 3.5 cm/year for the Galapagos Rift. Sleep (1975) would suggest a narrower magma chamber on a slower spreading rift. The crustal model proposed by Rosendahl et al. does include a layer overlying the magma chamber analogous to the plated isotropic gabbro. If off-axis hydrothermal activity removes heat by convection, the heat supplied by axial water circulation (qr) is less, and the required depth of heat extraction  $(D_r)$  is reduced. Some undetected convective heat loss may occur at the sediment mounds, 10 km south of the axis. (Williams, et al., 1974, Corliss, et al., 1978)

The results inferred from the model calculations are strongly dependent on the assumptions of the model, which have been explicitly stated. These assumptions are subject to testing by further work currently under way, including further analyses of rocks and additional sampling of hydrothermal vents. The measured heat/mass ratios in the fluids, the inferred heat/mass ratios in the basaltic magmas with which they interact, theoretical models regarding water-hot rock interactions and observations from ophiolite complexes can be combined to examine several aspects of the thermal and chemical behavior of hydrothermal systems at mid-ocean ridges. The following general statements can be made:

(1) If Kidd (1978) is correct, convective cooling of the dike complex and at least the upper part of the gabbro takes place in the immediate vicinity of the rift axis (within ~100 meters). In fact, the existence of the dike complex may be dependent on hydrothermal cooling.

(2) The heat/mass ratios calculated for elements which are expected to be quantitatively or nearly quantitatively extracted from the rocks show close agreement with the heat/mass ratios inferred for the magma.

(3) The calculated extraction efficiency of the system for elements not quantitatively extracted also agrees with their expected behavior during water-rock interaction.

(4) The ophiolite model implies that ~25% of the missing conductive heat flux predicted from heat flow data on the Galapagos Rift is released by convective cooling of the extrusive pillow lavas and sheet flows over the width of the axial valley.

(5) If we assume that all of the remaining missing conductive heat flux is removed from the crust by the rift axis hydrothermal systems, the crust will be cooled to a depth of 3.2 to 4.2 km at the rift axis.

(6) If the inferred magma compositions are correct, they imply that the depth of water penetration, the depth of heat extraction and the depth from which various components of the magma are removed can be different, and additional data on magma composition, and heat/mass ratios in the hydrothermal fluids, should allow us to characterize these variables with increasing accuracy.

# CHEMISTRY OF RIDGE-CREST SEDIMENTS FROM THE NORTH ATLANTIC OCEAN Martha R. Scott, Patricia F. Salter, and Leo A. Barnard Department of Oceanography, Texas A&M University, College Station, Texas 77843

Abstract. The influence of ridge crest hydrothermal activity on sediment chemistry has been compared at several sites on the Mid-Atlantic Ridge. For this study gravity cores and surface sediment grab samples from the FAMOUS Area at 37 N were analyzed for metal content and found to be enriched in metals with respect to average North Atlantic pelagic sediment: Fe(x3), Mn(x2), Cu(x4), Ni(x2), Co(x3), Cr(x3) and Zn(x2). Enrichment factors of sediment from the TAG hydrothermal field are similar: Fe(x1.5), Mn(x1.5), Cu(x3), Ni(x4), Co(x5) and Cr(x4). Neither area shows the extreme enrichments reported for East Pacific Rise sediments (Bostrom and Peterson, 1969). All seven of the cores from the FAMOUS Area showed an upper red brown layer up to 50 cm thick with pronounced metal enrichment, and a lower section that was grey, had less metal enrichment, and had intermittent thin, dark Mn-rich layers with higher metal content. Only two of the cores showed slight Mn depletion in the lower section with respect to average North Atlantic Pelagic clav.

Sediment accumulation rates were determined by the <sup>230</sup>Th excess method for four cores from the FAMOUS Area. The analyses led to the discovery of anomalously high U concentrations and  $^{234}\text{U}/^{238}\text{U}$  activity ratios in these sediments. The distribution of the anomalous values suggests post-depositional injection of hydrothermal fluids from below. A maximum value of 45 ppm U (carbonate-free basis) was observed. The high U concentrations are associated with anomalously low  $^{230}$ Th/ $^{234}$ U ratios, thus making the use of the  $^{230}$ Th excess method extremely difficult. Best estimates of accumulation rates from radiometric, paleontological and spreading rate data yield rates of .96,  $.9\overline{4}$ , .50 and  $.35 \text{ cm}/10^3 \text{ y}$  for the cores. These rates are minimum estimates, and are considerably slower than the 14C rate of 2.9 cm/103 y measured chemical studies of the East Pacific Rise sediments by Nozaki et al. (1978) for the FAMOUS Area, and 1.8 cm/10<sup>3</sup> y for the TAG area sediment (Scott <u>et al.</u>, 1978). Metal accumulation rates for Fe and Mm in the TAG area, the FAMOUS Area and  $45^{\circ}N$  (Cronan, 1972) are much slower than for East Pacific Rise sediments. The same relationship holds for trace metals with the exception of TAG area sediments which appear to be accumulating Ni, Co, Cu and Cr at rates aprroaching East Pacific Rise values.

A scanning electron microscope and EDAX survey of ferromangenese micronodules in one of the FAMOUS Area cores showed significant variation in the nature of these concretions with depth. The core top micronodules were well formed and contained significant amounts of Fe, Mn and Cu. Below the color change the micronodules appear to have had much of their ferromanganese cement dissolved in reducing conditions. Pyrite concretions are also found below the color change, commonly inside foram tests.

The distribution of metals in FAMOUS Area sediments appears to result from three processes: metal enrichment by hydrothermal fluids delivering dissolved material which precipitates from the overlying sea water; diagenetic remobilization of metals from a reduced layer probably formed by anaerobic metabolism of organic matter; and post-depositional injection of hydrothermal fluids at the base of the sediment column.

## Introduction

Metal enrichment of ridge crest sediments has been one of the many clues to resolving the processes that occur during formation of new oceanic crust. The work of Bostrom (Bostrom and Peterson, 1966, 1969; Bostrom et al., 1969; Bostrom and Valdes, 1969) and others (Bender et al., 1971; Arrhenius and Bonatti, 1965; Heath and Dymond, 1977; Cronan, 1972) have shown that general enrichments of sediment in Fe, Mn, Co, Ni, Cu, Hg, As and other trace metals can be widely observed at spreading centers, and in basal sediments to either side of spreadin, centers \_\_\_\_\_\_\_. (von der Borch and Rex, 1970; von der Borch 1971; Cronan et al., 1972; Cronan and Garrett, 1973; Horowitz and Cronan, 1976; Dymond <u>et al.</u>, 1976; Bos-trom <u>et al.</u>, 1973; Dymond <u>et al.</u>, 1977). Detailed (Dasch et al., 1971; Bender et al., 1971; Dymond et al., 1973; Corliss et al., 1978) and of the Mid-Atlantic Ridge (Cronan, 1972; Horowitz and Cronan, 1976; Bostrom et al., 1969; M. Scott et al., 1974, 1978) have led to the conclusion that large amounts of sea water circulate down fissures in the newly formed crust, become heated and laden with materials dissolved from the basalt, and exit through hydrothermal vents at the sea floor, adding the newly

Figure 1. Location of gravity cores taken in the FAMOUS Area. Asterisks represent gravity cores; circles locate earthquake epicenters (from Reid and MacDonald, 1973; Spindel <u>et al.</u>, 1974; Francis <u>et al.</u>, 1977). The triangle marks hydrothermal deposits. The inner valley floor is stippled, and the outer walls of the rift valley are marked with vertical stripes.

acquired metals to the marine system. This general concept of the hydrothermal processes associated with active spreading centers is supported by geophysical studies and models for heat flow in these systems. Wolery and Sleep (1976), Lister (1972, 1974), Williams and von Herzen (1974), Spooner and Fyfe (1973) and others have concluded that the circulation of sea water through newly generated basaltic crust is the process that controls the heat flow distribution at active ocean ridges.

The effect of this hydrothermal system on the chemistry of the ocean may be enormous. Wolery and Sleep (1976) estimate that the entire ocean may be cycled through the active ridge crest system in only 5-11 million years. One effect is the addition of Fe and Mn, much of which precipitates shortly after entering the ocean. The patchy and localized distribution of the large Fe and Mn oxide deposits discovered so far (M. Scott <u>et al.</u>, 1974; ARCYANA, 1975; Moore and Vogt, 1976; Corliss <u>et al.</u>, 1978) indicate that such concentrated deposits form only near the vents themselves. The more general case is Fe and Mn enrichments of the sediments accumulating in the ridge crest area.

This paper examines in detail a series of sediment cores and surface sediment samples from the FAMOUS Area at  $37^{\circ}N$ , and compares these samples with sediments from the TAG hydrothermal field (R. Scott et al., 1974) and from other parts of the ridge crest in the North Atlantic Ocean.

The ridge crest sediments are enriched in a number of trace constituents such as Co, Ni, Cu, Cd, Zn and others which cannot clearly be shown to come from the hydrothermal process itself, but may be derived from sea water by the precipitating Fe and Mn oxides (Dasch <u>et al.</u>, 1971; Dymond <u>et al.</u>, 1973). This seems all the more probable because of the low trace metal content of the oxide deposits near vents (M. Scott <u>et al.</u>, 1974: Moore and Vogt, 1976; Hoffert <u>et</u> <u>al.</u>, 1978) compared to the metal enriched sediments. The Fe and Mn added to the sediment probably traveled some distance through sea water in particulate form.

# Geologic Setting

The area of the Mid-Atlantic Ridge selected for study by the FAMOUS project is located southwest of

Figure 2. Location of surface sediment samples taken in the FAMOUS Area. Asterisks represent the sample locations. The area within the box includes surface samples taken near Mount Pluto. The inner valley floor is stippled and the outer walls of the rift valley are marked with vertical stripes.

the Azores between 36°N and 37°N. Detailed investigations have been made of geological and geophysical processes involved in the formation of new oceanic crust at this active spreading center. The intensive studies resulted in the collection of magnetic, gravity, seismic refraction, earthquake, heat flow and bottom current data for the area. This research provides the best available background information for studies of the geochemical processes taking place at the ridge crest. This study of sediment chemistry has been conducted on seven gravity cores taken by the R/V KNORR and fifteen surface grab sam ples taken by the ALVIN as part of the FAMOUS project.

The detailed bathymetry and location of the FAMOUS sediment samples are shown in Figures 1 and 2. The rift valley in the study area is approximately 45 km long and 30 km wide. The valley is offset at each end by east-west trending transform faults. The northern fault area is designated as Fracture Zone A (FZA) and the southern fault area as Fracture Zone B (FZB). The three sections of the rift valley separated by these fractures zones are designated from north to south as Rift Valley 1, 2 and 3 (RV1, RV2, RV3), as shown in Figure 1.

Most of the surface samples used in this study are located between Mount Venus and Mount Pluto, which appear to be the sites of the most recent volcanic activity (Ballard and Van Andel, 1977). No temperature anomalies or hydrothermal deposits were found the ridge valley (Fehn et al., 1977; Ballard et al., 1975; ARCYANA, 1975). But periodic Hg anomalies observed by Carr et al. (1975) may be related to volcanic activity. The talus deposits along the scarps bordering the valley floor may mask the actual hydrothermal deposits (ARCYANA, 1975). The faults forming the valley wall exhibit a .igh level of earthquake activity averaging 10 to 30 events per day (Spindel et al., 1974; Reid and MacDonald, 1973; Francis et al., 1977).

Sediment thickness in the FAMOUS area rift valley is highly erratic but generally increases with distance from the valley axis (MacDonald and Luyendyk, 1977). The inner valley floor is covered with a thin veneer of sediment (ARCYANA, 1975; Luyendyk and MacDonald, 1977), although sediment cover up to 1-2 m thick has been observed in some areas of the

SCOTT 405

Figure 3. Detailed map showing TAG Hydrothermal Field (R. Scott <u>et al.</u>, 1974) and location of sediment cores and dredge samples. Total length of core recovered is noted by sample locations.

inner valley floor (Needham and Francheteau, 1977). The sediment outside the inner valley floor accumulates in ponds, usually in faulted depressions. The sediment distribution is dominated by downslope movement which is probably the result of fairly fast bottom water currents (up to 20 cm/sec) (Keller, <u>et</u> <u>al.</u>, 1975) and high degree of tectonic activity present in the area.

Fracture Zone A transects the Rift Valley. The intersections between the fracture zone and the separated rift valley segments are marked by circular depressions separated by a low sill. Gravity core 139 was taken in the western depression and Core 118 was taken on a terrace area just south of the eastern depression (Fig. 1). Most of the terrain in the fracture zone is covered by sediment with rock

outcrops usually present at the summit of fracture blocks (ARCYANA, 1975). The fracture zone is the site of considerable tectonic activity indicated by abundant earthquake activity (Fig. 1) (Reid and Mac-Donald, 1973; Spindel <u>et al.</u>, 1974; Francis <u>et al.</u>, 1977). Heat flow measurements along FZA show a bimodal distribution, with values of about 0.6 H.F.U. to the west and values averaging 2.2 to the east (Williams <u>et al.</u>, 1977). Two hydrothermal vents were observed by the ARCYANA (1975) in the central portion of the fracture zone (Fig. 1). The vents are located near the summits of two hills capped by black Mn encrustations from 10 to 50 cm thick. The deposits show the extreme fractionation of Fe and Mn typical of hydrothermal deposits (Fe/Mn ranges from 0.2 to 237) (ARCYANA, 1975), but no

Data taken from TUREKIAN and IMBRIE, 1966; CRONAN, 1972; BOSTROM and VALDES, 1969; HOROWITZ and CRONAN, 1976; VAN DER WEIJDEN et al., 1970; EL WAKEEL and RILEY, 1961; BRUTY et al., 1972.

Table 1. Chemical Composition of Sediment Cores from the FAMOUS Area.

temperature anomalies were noted in this area (Fehn <u>et al</u>., 1977).

Fracture Zone B is located at the south end of RV2 and can be divided into two sections, the western depression (> 2700 m depth) and the eastern depression (> 2900 m depth) (Fig. 1). The depressions are formed by the intersections of the fracture zones with the two sections of the rift valley it offsets. The depressions are separated by a sill about 800 m high and 9 km wide on which three of the surface grab sample sites were located (Fig. 2). The fracture zone has heavy sediment cover with local exposures of weathered basalt talus and greenstones (Ballard et al., 1975). The average heat flow in the western depression is 5 H.F.U. (Williams et al., 1977) compared to a world average of 1.5 H.F.U. Three of the gravity cores analyzed in this study were taken from the high heat flow area (Fig. 1). The remaining two gravity core locations are in the eastern depression of FZB (Fig. 2).

A number of other studies have dealt with the chemistry of Mid-Atlantic Ridge sediments (Bostrom <u>et</u> al., 1969; Cronan, 1972; Horowitz, 1974; Horowitz and to salt solutions of the elements of interest. Cronan, 1976) but only the TAG hydrothermal field has had reported hydrothermal oxide deposits as well as metal enriched sediments (R. Scott et al., 1974; M. Scott <u>et al.</u>, 1974; R. Scott <u>et al.</u>, 1976; Rona <u>et</u> <u>al.</u>, 1976; M. Scott <u>et al.</u>, 1978). Figure 3 is a sediment sample location map of the TAG area (M. Scott et al., 1978). The hydrothermal field itself, shown in Figure 3, is a 100 km square area on the eastern valley wall of the median valley covered with thick, rapidly deposited MnO2 coatings (R. Scott et al., 1974; M. Scott et al., 1974). The deposit has apparently formed at a vent site at the base of the valley wall covered by talus. Sediment thickness in the area is quite variable. Samples 4A, 4B and 4H represent cores of ponded carbonate

sediment collected from the median valley. A study of bottom photographs of this section of the median valley shows ripple-marked sand and other evidence of the strong bottom currents responsible for sweeping sediment off some portions of the valley floor into sediment ponds of uneven distribution (Temple et al., 1978). Betzer et al. (1974) have reported that iron and manganese rich particles are far more common over the hydrothermal site than to either side of the ridge crest. The TAG area has more numerous fault blocks than the FAMOUS area, and lacks the terraces between the inner and outer valley wall (Temple et al., 1978). Otherwise the two areas are similar.

# Chemical Analyses

Sediment samples from the FAMOUS Area were analyzed for Fe, Mn, Al, Cu, Ni, Co, Cr and Zn by atomic absorption spectrophotometry (Salter, 1977). The reference standards used include CRPG-BR, CSJ-JB-1, USGS-BCR-1, and matrix standards made by adding Ca Relative precisions for the elements were Fe ± 4%, Mn ± 4, Al ± 3%, Cu ± 5%, Ni ± 8%, Co ± 5%, Cr ± 10% and Zn ± 5%. The data are listed in Table 1. Uranium and thorium isotopes were analyzed by alpha spectrometry using a procedure similar to that of Ku (1965). Table 2 includes the isotopic data on the samples; the errors listed represent lo from the counting statistics. The CaCO3 content of the sediments was determined by an EDTA titration of the acid soluble Ca, modified from the procedure of Turekian (1956).

# Results

The most conspicuous chemical trends in the FAMOUS Area Sediments were evident on visual inspection of

Table 2. Chemical Composition of Surface Sediments from the FAMOUS Area

Data taken from TUREKIAN and IMBRIE, 1966; CRONAN, 1972; BOSTROM and VALDES, 1969; HOROWITZ and CRONAN, 1976; VAN DER WEIJDEN et al., 1970; EL WAKEEL and RILEY, 1961; BRUTZ et al., 1972.

Table 2. Chemical Composition of Surface Samples from the FAMOUS Area.

the cores. All of the surface grab samples and the upper parts of the gravity cores were markedly enriched in Fe and Mn, and had a reddish-orange color which faded into a light tan or grey with depth in the core. Intermittent dark, Mr-rich bands appeared in several of the cores. The high concentration of biogenic CaCO3 (Table 1), common in ridge crest cores, obscures variations in metal concentrations. This effect has been typically corrected for by ratioing the metal concentrations to aluminum in a variety of ways. In this paper a direct metal to aluminum ratio is used. Aluminum is relatively immobile during weathering, so that it is considered a reliable indicator of detrital material. It does not appear to be a significant component of hydrothermal solutions formed by sea water leaching of basalts (Hajash, 1975; Bischoff and Dickson, 1975; Seyfried and Bischoff, 1977). Figures 4a-4g show variations with depth in the seven gravity. cores from the FAMOUS Area discussed herc. Figure 5 is a similar diagram for Core 4A from the TAG area (M. Scott et al., 1978). Included on the diagrams are the metal to aluminum ratios for North Atlantic average pelagic clay (Turekian and Imbrie, 1966; Cronan, 1972; Bostrom and Valdes, 1969; Horowitz and Cronan, 1976; Van der Weijden et al., 1970; El Wakeel and Riley, 1961; Bruty et 11., 1972). The Fe

(Table 1, Figs. 4a-4g) decrease below the color change to values near the average for North Atlantic Pelagic clays. The trace metals Cu, Ni, Co, Cr and Zn are also enriched in these sediments in the upper Fe and Mn enriched layers. In general the trace metal enrichment is lower below the color change than above it. There appears to be an increase in some of the trace metals toward the bottom of Cores 139, 118, 52 and 124 (Figs. 4a, 4b, 4d and 4f). This feature is shown by the uranium profiles for the four cores on which uranium analyses were made (Figs. 4a, 4b, 4d and 4e). In addition to enrichment at depth the uranium concentrations showed enrichment toward the tops of these same cores relative to average pelagic clay.

and Mn enrichments in the upper parts of the cores

Metal enrichment of the FAMOUS Area sediments varieu in both space and time. In addition to the major color change boundary in these sediments, there are abundant dark layers in some of the cores. Analyses of several of these layers showed them to be highly enriched in manganese and other metals. Cores 120, 124 and 147 (Figs. 4b, 4d and 4g) from Fracture Zone B show several dark layers in each core, but the layers were not noted in Cores 52 and 125 from the same area (Figs. 4a and 4e). These Mn rich bands may represent periodic, localized pulses of intense

Figure 4a.Core 52 Vertical distribution of metals in FAMOUS Area cores plotted as metal to Al ratios. The average North Atlantic pelagic clay ratios are shown by vertical lines labeled N. Atl APC (Table 1). The heavy horizontal line with vertical stripes reprezents the location of the color change in the cores. The thinner horizontal lines show the positions of dark Mn-rich bands.

hydrothermal activity in the area. The samples analyzed (Figs. 4b, 4d and 4g) show increased Co, Ni and Cu. These features will be discussed below.

Uranium and Th isotope measurements were made on four of the cores (Table 3) so that sediment and metal accumulation rates could be determined for the area. Cores 52, 124 and 125 were found to have anoma lously high concentrations of U near the bottom of the cores. All of the cores also show anomalously Efforts to arrive at a sedimentation rate for Conhigh  $^{234}$ U/ $^{236}$ U activity ratios in some samples (Table 124 from the isotopic data lead to a value of 0.35 3). These unusual U concentrations and isotope activity ratios are related to the hydrothermal activity in the FAMOUS Area, and make it necessary to use caution in interpreting <sup>230</sup>Th excess data for sediment accumulation rates.

The plots of exponential decrease of the 230Th excess with depth in the sediment are shown in Fig. 6 for Cores 52, 118, 124 and 125. The sedimentation rates given with the plots were derived from the slopes of the lines through the data points. The semi-log plot of <sup>230</sup>Th versus depth for Core 52 is linear and the slope gives a sedimentation rate of 0.98 cm/10<sup>3</sup> y. Two data points with anomalously high U were omitted from the plot (75-77 cm and 86-88 cm, Table 3). Points at 30-32 and 50-52 cm fall off the line because of anomalous U activity ratios (Table 3).

The <sup>230</sup>Th excess versus depth plot is linear for Core 118 despite some anomalous <sup>234</sup>U/<sup>238</sup> ratios in the data. The slope of the line gives a sedimentation rate of 0.35  $cm/10^3$  y. This rate is much lower than determined for the other cores, but 118 is located on the slope of a scarp rather than in a depression as the other cores are, and might be expected to have a lower accumulation rate. The high  $^{234}$ U/ $^{238}$ U ratios for the two bottom points result in an overcorrection for supported <sup>230</sup>Th contributing to the lower apparent rate (Table 3).

Efforts to arrive at a sedimentation rate for Core cm/10<sup>3</sup> y (solid line, Fig. 6), but anomalous Th and U contents make this value suspect. Moreover, for a total core length of 120 cm, this sedimentation rate results in an age for the bottom of the core of 343,000 years. Paleontological data (S. Gartner, personal communication) for this core indicates that the sediments are late Pleistocene - early Holocene (less than 100,000 years old). The age of the crust in the inner valley floor determined by paleomagnetic data and spreading rates is about 100,000 ± 30,000 years (Needham and Franchetau, 1974; Hekinian and Hoffert, 1973; MacDonald, 1977). It is not known whether the core reached basement, so a minimum sedimentation rate of 0.94 cm/10<sup>3</sup> y is calculated for Core 124 from paleontological data and core length (dashed line, Fig. 6).

Core 125 is located close to 124 and is expected to have a similar sedimentation rate. The isotopic rate of 0.19  $cm/10^3$  y is unrealistically low for the same reasons discussed for Core 124, and a more re-

Table 3. Uranium and Thorium Isotopic Analysis of the FAMOUS Area Sediments

Table 3. Uranium and Thorium Isotopic Analysis of FAMOUS Area Sediments.

liable minimum rate of 0.50 cm/10<sup>3</sup> y is calculated (dashed line) based on core length and palernto-logical and paleomagnetic evidence.

All of the sedimentation rates determined for the FAMOUS cores above are slower than the <sup>14</sup>C rate of 2.9 cm/10<sup>3</sup> y determined for a core taken by the ALVIN in the inner valley near the center of Rift Valley 2 (Nozaki <u>et al.</u>, 1977). The discrepancy is not surprising considering the uneveness of the sediment cover discussed above and the nature of the U data from the hydrothermally altered sediments.

Ku <u>et</u> <u>al</u>. (1972) have measured sedimentation rates for the Mid-Atlantic Ridge at 42°N and  $: ^{\circ}$ N by <sup>230</sup>Th excess, <sup>231</sup>Pa excess and paleontological methods, and M. Scott <u>et</u> <u>al</u>. (1978) have measured the sedimentation rate for Core 4A from the TAG area at 26°N. A comparison of the sedimentation rates along the ridge is given in Table 4. Cores located in the median valley are marked with an asterisk in this table. Median valley cores analyzed in this work show lower sediment accumulation rates than those r: orted by Nozaki <u>et al</u>. (1977) and M. Scott <u>et al</u>. '<sup>1</sup> 78). As discussed above, these should be cons.Jered minimum rates. The carbonate free sedimencation rates determined for FAMOUS median valley

cores in this study range from .19 to .04 cm/10<sup>3</sup> years, values close to those reported by Goldberg et al. (1964) for 24°N on the ridge. However, Ku et al. (1968) have suggested the latter rates are too low because of the assumption of constant  $^{230}\text{Th}/^{232}\text{Th}$  with depth in the cores. The sedimentation rates listed in Table 4 are variable from place to place, reflecting the uneven sediment cover, high bott: currents and tendency toward ponding in d pressions. The rates of detrital material accumulating in the median valley appear to be lower than in the abyssal plains at the same latitude. The  $^{230}\text{Th}$  ercess method must be used with caution in these sediments because of anomalous U concentrations and isotope ratios.

# Discussion

Metal to aluminum ratios for FAMOUS Area sediments are higher than the same ratios for average North Atlantic pelagic clay by factors that vary from element to element. The average enrichment factors are Fe(x3), Mn(x2), Cu(x4), Ni(x2), Co(x3), Cr(x3)and Zn(x2). These factors are similar to the ones reported for sediment from the TAG Hydrothermal

## 4b. Core 118

Field (M. Scott <u>et al.</u>, 1978): Fe(x1.5), Mn(x1.5), Cu(x3), Ni(x4), Co(x5) and Cr(x4). Neitne: area has the extremes of metal enrichment reported for the East Pacific Rise by Bostrom and Peterson (1969) and others.

The surface samples taken near Mount Pluto in the inner rift valley were analyzed to locate possible hydrothermal vents by using metal distribution patterns. However, there were neither enough samples nor the correct spacing to serve that purpose. A transect from the west wall across the top of Mount Pluto to the east wall of the inner rift valley (Fig. 7) does show a slight increase in metal concentrations from WSW to ESE. There is also a decrease in the Fe/Mn ratio in the sed.ments from west to east across the rift valley. The ratio varies from 42 near the west wall to 17 near the east wall. This distribution suggeses the possible location of a hydrothermal vent somewhere along the scarp that marks the west wall, because the Mn would be expected to remain in solution longer than the Fe (Krauskopf, 1957). A description of a factor analysis study of the FAMOUS Area surface and gravity core samples will be presented elsewhere (Salter, 1978, in prep.)

Table 5 gives the chemical composition and metal to Al ratios for sediments from a variety of areas influenced by ridge crest hydrothermal activity. The ratios for FAMOUS Area sediments are similar to those in sediments from other areas along the Mid-Atlantic Ridge at 45°N (Horowitz and Cronan, 1977), at 26°N (M. Scott <u>et al.</u>, 1978) and in basal sediments of DSDP cores in the Atlantic (Dymond <u>et al.</u>,

のもんだいたいでないたりなどのでいて

1973; Horowitz and Cronan, 1976). A comparison of the profiles of metal to Al ratios for the FAMOUS cores (Fig. 4) and TAG Core 4A (Fig. 5) further illustrates this general similarity. lowever, the TAG sediment did not show a color change with depth. The decrease in metals at 30 cm coincides with a layer of tasaltic glass fragments. All of these Mid-Atlantic Ridge sediments are much less metal rich than sediments from the East Pacific Rise, particularly in the case of Mn. The Fe/Mn ratios of FAMOUS sediments average about 15, compared to a ratio of about 3 for the East Pacific Rise sediments. The differences observed in the sediments from these two active spreading centers may be related to water circulation differences in the hydrothermal systems of fast and slow spreading ridges (R. Scott et al., 1978). However, the general metal enrichment trends appear to be similar for all these active ridge sediments.

Metal accumulation rates for the FAMOUS Area sediments have been calculated from the metal analyses (Table 1), the sediment accumulation rates (Fig. 6) and the dry sediment density calculated by the method of Lyle and Dymond (1976). These data are listed in Table 6. The commutation rates of hydrothermally derived metals in the FAMOUS Area are minimum rates only because of the uncertainties in the sedimentation rates discussed above. The metal accumulation rates for other areas on the Mid-Atlantic Ridge and for East Pacific Rise sediments (Table 6) show the same trends observed in the metal to Al ratios. The data for Mid-Atlantic Ridge sediments in Table 6 have been corrected for the accumulation of metal

SCOTT 413

4c. Core 120

CORE 124

in detrital components by using the metal to Al ratios of average North Atlantic pelagic clay. The non-detrital accumulation rates are given in parentheses. The TAG area and 45°N sediments are accumulating hydrothermal Fe and Mn at rates much faster than indicated for the FAMOUS Area, and slower than rates for the East Pacific Rise. The low FAMOUS

Area rates may be an artifact of low sediment accumulation rates based on anomalous radiometric data, as mentioned. Non-detrital accumulation rates for Ni, Co, Cu and Cr in FAMOUS Area sediments are similarly low. TAG area sediments are accumulating these metals at a conspicuously higher rate, equivalent to or higher than the East Pacific Rise rates.

**CORE 147** 

A STATE OF STATES

Core 147 4g.

Only one core from the TAG area was analyzed, so it is not clear whether this is a widespread phenomenon in that locale. The 45°N sediments show trace metal accumulation rates intermediate to those for TAG and FAMOUS sediments

among the three areas along the Mid-Atlantic Ridge. The TAG area appears to have a more highly frictured basaltic crust than does the FAMOUS Area. The less extensive fracture system in the FAMOUS Area could restrict the surface expression of sea water-basalt interaction or cause the expression to be more localized. A more thorough survey of other ridge crest areas is needed before we can assess chemical trends in hydrothermal systems along ridge crests.

Examination of the chemical and isotopic analyses of FAMOUS Area sediments suggests that several processes have operated on these sediments to produce the observed chemistry. The overall pattern of metal enrichment suggests that Fe and Mn were added to the water column by hydrothermal fluids venting at the sea floor. The other metals may have been added by the same process or extracted from sea water by the precipitating Fe and Mn oxides, which would then carry them to the sediment.

The presence of a marked color change strongly suggests that the sediments have become reducing at depth. This change would cause remobilization and upward diffusion of Fe, Mn and other metals, and their subsequent reprecipitation in the oxidizing upper layers of the sediment. Ku and Bischoff (1970) indicate little change in the Fe and Cu concentration

(reported in Ku et al., 1972) have described brown oxidizing sediments overlying greyish sediments in sediments collected from the Mid-Atlantic Ridge at 40°N. The pore water Mn concentration was as high as 3 ppm in the greyish sediments. Turekian and There are few geophysical or geological differences Bertine (1972) have suggested that organic-rich sediments in sediment ponds along ridge crests may cause enrichment of sediments in Mo and U. This process could also remobilize sedimentary Mn and Fe. However, note that nearly all of the samples of FAMOUS sediments analyzed had Fe/Al and Mn/Al ratios equal to or higher than the value for average North Atlantic pelagic clay (Fig. 4). The overall metal enrichment at the surface is not generated soley by oxidation-reduction reactions, and such processes operating in the lower layers have not depleted Fe and Mn values below average pelagic values.

Comparison of the metal profiles for the FAMOUS sediments with metal profiles for sediments known to have undergone reduction and remobilization or metals (Bonatti et al., 1971), indicates that simple diagenetic remobilization of metals alone cannot account for the distribution of metals in the FAMOUS sediments (Figs. 4a-4g). Co and Ni do not generally exhibit a depletion with depth in these sediments, although they would be expected to follow Mn to some extent during remobilization. Cores 52, 124 and 139 even show an increase in Co and Ni at depth. The Fe and Cu profiles shown by Bonatti et al. (1971)

Figure 5. Vertical distribution of metals in Core 4A from the TAG area (M. Scott <u>et al.</u>, 1978) shown as metal to Al ratios. The vertical lines marked APC represent metal to Al ratios for average North Atlantic pelagic clay.

across the redox boundary, but the FAMOUS Area sediments show an increase in these elements above the color change. Furthermore, in the core analyzed by Bonatti <u>et al.</u> (1971) Cr increased sharply below the redox boundary, but the FAMOUS sediments show higher Cr in the upper layers and little variation in the concentration below the color change. It is possible to build at least a circumstantial case for a temporal increase in hydrothermal input of Fe, Mn and other metals during the deposition of the upper layers of the sediment. A diagenetic remobilization of the metals superimposed on this effect could produce the observed distribution.

Post-depositional injection of hydrothermal fluids at the base of the sediment column has also been operating in the FAMOUS Area. A well-documented case of this phenomenon in the Galapagos Rift has been described by Corliss <u>et al</u>. (1978). Evidence for this process in the FAMOUS Area is most easily seen in the U data for the cores (Table 3; Figs. 4a, 4b, 4d and 4e). The U concentrations at the bottoms of Cores 52 and 125 (Figs. 4a and 4e) are an order of magnitude greater than in the rest of the cores (6.7 and 9.3 ppm). Core 124 also exhibits high U concentrations. The  $^{230}$ Th/ $^{234}$ U activity ratios associated with the anomalously high U concentrations in these cores should still be considerably out of

equilibrium (much greater than 1) because these sediments are less than 100,000 years old. However, the measured  $^{230}\text{Th}/^{234}\text{U}$  activity ratios range from 0.12 to 3.53 (Table 3). These anomalously low  $^{230}\text{Th}/^{234}\text{U}$  activity ratios without an associated anomalously high  $^{234}\text{U}/^{238}\text{U}$  ratio suggest that the U at this depth in the core is not contemporaneous with the time of sediment deposition. That is, there has been post-depositional injection of U-rich hydrothermal solutions at depth in these sediments.

The possibility exists that the U enrichment is the result of the diagenetic process described by Turekian and Bertine (1971). This seems unlikely, because the source of the U would have to be sea water, and the U enrichment should begin closest to the source in the vicinity of the redox boundary (color change) and work its way downward. Instead the major enrichment in the FAMOUS cores shows up at the base of the cores and decreases upward. There is also a slight enrichment at the tops of the cores, which probably represents scavenging of U out of sea water by the precipitating Fe hydroxides.

Uranium enrichment of ridge crest sediments has been previously reported by a number of authors (Veeh and Bostrom, 1971; Scott <u>et al.</u>, 1972; Piper <u>et al.</u>, 1975; Fisher and Bostrom, 1969; Rydell and Bonatti, 1973). Injection of U-rich hydrothermal

fluids at the base of the sediment column has been suggested by Rydell <u>et al.</u> (1974). Clogging of hydrothermal vents by sediments and continued emission of fluids from the vents appears to be the most probable mechanism, and fits the description of the well-documented Galapagos Rifts sediment

mounds (Corliss <u>et al.</u>, 1978). Cores 52 and 124 (Figs. 4a and 4e) show increases in Fe, Cu, Ni, Co, Cr and Zn at the base; these enrichments may also be related to injection of slightly reducing, possibly acidic metal-rich hydrothermal fluids from below. Core 52 is located in the high heat flow

Depth into Core (cm)

Figure 6. Sedimentation rates for gravity cores in the FAMOUS Area. <sup>30</sup>Th excess on a carbonate free basis is plotted as a function of depth into the core. The indicated sedimentation rates are based on solid lines best fitting the<sup>230</sup>Th excess data. The dashed lines for Cores 124 and 125 are sedimentation rates based on paleontological and geophysical data.

area of Fracture Zone B; all of the gravity cores are located in or near the fracture zones.

Uranium activity ratios in the FAMOUS Area cores are anomalous in several of the samples, with  $^{234}\text{U}/^{238}\text{U}$  ratios well above the sea water value of 1.15 ± .02 (Table 3). The relationship between uranium enrichment and anomalous ratios is not a simple one. Figure 8 shows that the samples with the highest activity ratios do not occur in the layers most enriched in uranium. Unusual uranium concentrations and isotope ratios were noted by Ku et al. (1972) in Mid-Atlantic Ridge sediments, by Rydell and others (1974) in an East Pacific Rise core, and by Rydell and Bonatti (1973) in marine metalliferous deposits. Rydell and Bonatti (1973; have developed a mixing model for sea water uranium and hydrothermal uranium to explain the distribution of isotope ratios and concentrations of U in metalliferous deposits. Their model is based in part on a plot of  $^{234}\text{U}/^{238}\text{U}$  ratios versus U/Al ratios similar to the one shown for FAMOUS sediments (Fig. 9). Samples with very high ratios have low U concen-

trations; samples with high concentrations have ratios close to the sea water value of 1.15. The explanation suggested by Rydell and Bonatti (1973) is that sea water uranium is adsorbed by Fe and Mn particles forming in the water column, thus diluting the high isotope ratios typical of the hydrothermally derived U. But in FAMOUS Area sediments most of the uranium enrichment appears to come from below rather than from particle scavenging of the overlying seawater. If such injections of uranium are occurring at the base of the sediments, they are not associated with uniformly high isotope ratios as suggested by Rydell and Bonatti (1973).

The anomalous U activity ratios in Core 124 at 41 cm (Fig. 4d) and in Core 118 at 31 cm (Fig. 4b) are associated with Mn rich bands. These bands may represent pulses of hydrothermal contributions to the sediment that are localized enough to retain a hydrothermal fingerprint in their  $^{234}\text{U}/^{238}\text{U}$  activity ratios. Other samples with anomalous ratios are not associated with Mn rich layers. Both Mn and  $^{234}\text{U}$  may be redistributed by hydrothermal fluids injected into

Figure 8. Vertical distribution of uranium and 2340/2380 activity ratios in FAMOUS sediments. The average North Atlantic pelagic clay U/Al ratio is shown on the graphs as a vertical line. The stippled area covers the expected sea water range of activity ratios.

the core, and circulation patterns of such fluids through the sediments may be quite complex (Corliss et al. 1978).

As pointed out by Rydell and Bonatti (1973) U is much less mobile under reducing conditions than oxidizing conditions. Thus a hydrothermal solution carrying dissolved U would have to be only mildly

Uranium anomalies in these sediments may result from remobilization of uranium in the sediments by circulating fluids rather than by interactions between the hydrothermal fluids and basalts. It should channel analyzer. be noted that the Th concentrations in some of the samples are unusually low or high (Table 3). Similar cm level. It is well formed and smooth, with little discrepancies have been noted by Ku et al. (1972) and evidence of the nucleus around which it is growing. Rydell et al. (1974), but the anomalies are not consistent and do not suggest large scale Th remobilization.

An additional line of evidence concerning the chemical evolution of the FAMOUS sediments is a study of the ferromanganese micronodules found in the sedi-

422 SCOTT

ment. Similar concretions have been reported in other metalliferous sediments (Bischoff and Rosenbauer, 1977; Heath and Dymond, 1977; Cronan, 1972). Micronodules were found at all levels in Core 52, but the morphology and chemistry of these microconcretions varied with depth in the sediment. The sediment samples were sieved through several nylon reducing at most, or contain high concentrations of a screens (100 to 400 mesh) and the dark micronodules ligand such as  $CO_3^-$  to keep U in solution. were hand picked under a binocular microscope. The were hand picked under a binocular microscope. The particles were studied with a JOEL JSM-U3 Scanning Electron Microscope and subjected to X-ray analysis with an EDAX energy dispersive spectrometer and multi-

Figure 10a is a typical micronocule from the 0-2 Fe, Mn and Cu are strongly represented on the EDAX record. Micronodules from deeper in the core below the color change are much different in appearance. Although still black to brown in color, these concretions appear to have had much of their ferromanganese cement dissolved in reducing conditions.

Figure 9. Plot of uranium isotope ratios versus uranium to aluminum ratios for FAMOUS Area sediments.

Figure 10b, a photo of a micronodule from the 84-86 cm level of Core 52, illustrates this phenomenon. Note that the biogenic debris around which the micronodules nucleate and grow is conspicuous in this sample. The EDAX scan shows Mn, a trace of Fe, and Cu. Strong fractionation of Fe and Mn is typical for micronodules in the lower part of the core. The change from well preserved, rounded grains to highly eroded grains is progressively more exaggerated with depth below the color change.

Figure 11 is a picture of pyrite concretion from the 96-98 cm layer of Core 52. Similar pyrite concretions occur throughout the sediment below the color change, commonly as fillings in foraminifera tests.

The changes in micronodule morphology and chemistry with depth in Core 52 mirror the changes in sediment chemistry. Oxidized upper layers contain well formed microconcretions. Sediments below the color change, considered to be a redox boundary, contain micronodules that are severely eroded by chemical solution of their ferromanganese cement. The pore fluids and local environments in the sediment become reducing enough so that pyrite concretions form during  $SO_4^{-}$  reduction. Exaggeration of the amount of deterioration of the micronodules toward the base

of the core suggests that reducing hydrothermal fluids may be in part responsible for dissolving the Fe and Mn.

### Conclusions

Mid-Atlantic Ridge crest sediments in the FAMOUS Area show patterns of metal enrichment similar to those for sediments elsewhere on this same active ridge and to sediments on the East Pacific Rise. The major differences observed in ridge crest sediments include the much greater metal to Al ratios and metal accumulation rates for East Tacific Rise sediments, and the lower Fe/Mn for the East Pacific Rise sediments. These differences may be related to the differences in hydrothermal circulation in fast and slow spreading active ridge areas.

FAMOUS Area sediments have undergone several processes affecting the metal concentrations and distributions with depth. In addition to the general enrichment in Fe, Mn and trace metals above average North Atlantic pelagic clay values, the cores exhibit a marked increase in these metals above a conspicuous color change present in all of the cores. The color change is strongly suggestive of a redox boundary formed by anaerobic metabolism of organic matter at depth in the cores. The Fe and Mn distributions are consistent with such a model, but these metals are only rarely depleted below average pelagic values

in the lower parts of the sediment. Moreover, the distribution of trace metals with respect to the color change boundary and the presence of numerous Mn-rich bands in several of the cores suggest that fluctuations in the '.ydrothermal input of metals may be partly responsible for the observed depth profiles of the metals.

Anomalously high concentrations and  $^{234}\text{U}/^{238}\text{U}$  activity ratios exist in all of the cores analyzed for U and Th isotopes. The U enrichment is most pronounced at the base of the cores, and is paralleled by slight enrichments in Cr, Zn, Co and Ni. These trends suggest the influx of hydrothermal fluids at the base of the core. Such fluids would probably be reducing and would contribute to redistribution of metals in the sediment column.

Ferromanganese micronodules have been recovered from all levels of FAMOUS Core 52. The micronodules are well preserved in the core top and are increasingly eroded at depth, probably by solution of Fe and Mn under reducing conditions. Pore fluids and local microenvironments have attained low enough Eh for the formation of pyrite aggregates and framboids below the color change.

The distribution of metals on FAMOUS Area sediments Bostrom, K., and D. Fisher, Volcanegenic uranium, is considered to result from three superimposed processes: metal enrichment by hydrothermal solutions delivering dissolved material which subsequently pre- Bostrom, K., T. Kraemer, and S. Gartner, Provenance cipitates from the overlyin. sea water; diagenetic remobilization of setals from a reduced layer formed by anaerobic metabolism of organic matter; and postdepositional injection of hydrothermal fluids at the base of the sediment column.

# OPHIOLITIC ROCKS AND EVIDENCE FOR HYDROTHERMAL CONVECTION OF SFA WATER WITHIN OCEANIC CRUST (Abstract)

## E.T.C. Spooner

Department of Geology, University of Toronto, Toronto, Ontario M5S 1A1, Canada.

A significant amount of evidence in support of the general hypothesis of sea water circulation within oceanic crust has now been obtained from examination of ophiolitic complexes. Although it is uncertain how representative of ocean crust ophiolitic sequences actually are, information from the Troodos Massif, Cyprus, in particular, indicates that formation of cupriferous pyrite ore deposits, which are economically exploitable on land, was an integral part of the convective process. It is possible, therefore, that comparable deposits might be present in oceanic crust. Observations on Cyprus permit the geometry of circulation to be deduced. In this particular case, it appears that flow approximated to a series of axially symmetric cells which contained central plumes of hot ascending fluid the positions of which were fixed through the time with respect to enclosing rock (Spooner, 1977). Studies of hydrothermal convection in a permeable medium with an open top and a cylindrical shape using finite difference approximations suggest that this mode of circulation is possible at low to moderate values of the Rayleigh number (Parmentier and Spooner, 1978).

The clearest evidence for water/rock interaction in ophiolitic rocks is provided by the occurrence of non-isochemical, hydrothermal metamorphism of ocean-floor origin. This has been documented from ophiolitic rocks in Cyprus (Gass and Smewing, 1973; Spooner et al., 1977), Newfoundland (Williams and Malpas, 1972; Coish, 1977), E. Liguria, Italy (Spooner and Tyfe, 1973; Spooner et al, 1977) and S. Chile (Stern et al, 1976). Zeolite to amphibolite facies metamorphic assemblages, which usually pseudomorph original igneous textures, have been observed in metabasic pillcw lavas, sheeted dykes the upper parts of layered plutonic sequences, and associated lithologies. Usage of isotopes (H/D; <sup>13</sup>C/<sup>12</sup>C; <sup>18</sup>O/<sup>16</sup>O; <sup>87</sup>Sr/<sup>86</sup>Sr) as geochemical tracers has confirmed that the interacting fluid was of sea water origin (Spooner et al., 1974; Heaton and Sheppard, 1977; Spooner, 1977):-

e.g. 1 Zeolite to amphibolite facies metabasic rocks from the Troodos Massif, Cyprus are variably enriched in  ${}^{87}$ Sr relative to fresh rocks (Spooner et al., 1977). Initial  ${}^{87}$ Sr/  ${}^{86}$ Sr ratios as high as 0.70760 ± 0.00003, for an interstitial zeolite sample, and 0.7069, for a metabasic rock, have been recorded. These compare with low values obtained for fresh gabbroic rocks of 0.70338 ± 0.00010 to 0.70365 ± 0.00005. Upper Cretaceous sea water, with a ratio of  $\sim$  0.7076, was the only possible contaminant (Spooner et al., 1977).

e.g. 2 Heaton and Sheppard (1977) have shown that the isotopic composition of hydrogen in water in equilibrium with chlorite and amphibole samples from metadolerite dykes and metagabbros from Cyprus was indistinguishable from that of sea water.

Whereas hydrothermal metamorphism occurred during in-flow and through-flow of sea water it appears that, in Cyprus, sulphide ore deposits formed at the positions of discharge. In general terms these deposits consist of a lens of massive ore underlain by an approximately pipe-shaped stockwork. The massive ore consists of a porous, crudely colloform textured mass of fine-grained pyrite and chalcopyrite with accessory quantities of marcasite, sphalerite and galena. The voids in the massive ore are frequently partially filled with sooty fine-grained framboidal pyrite. The lenses occur intercalated within the pillow lava sequence and their attitudes are confc able with the local stratigraphy. (Description summarized from Hutchinson and Searle, 1971; Constantinou and Govett, 1973). A large lens, for example that at Skouriotissa, had a maximum thickness of  $\sim$  50m, and was approximately elliptical in plan (long axis =  $\sim$  500 m; short axis =  $\sim$  350 m) (Constantinou and Govett, 1973). It contained pre-production ore reserves of∿6 million tonnes at 2.3% Cu (Bear, 1963). An important point is that the evidence suggests that this massive ore actually formed on the ocean floor -- it does not replace pre-existing rock, can show alteration near the top to a goethitic material (ochre), which has been interpreted as a submarine weathering product of ore (Constantinou and Govett, 1972), and is either

SPOONER 429

- A.

overlain by unmineralized deep-water marine sediments itself, or by unmineralized pillow lavas which are overlain by pelagic sediments (Robertson, 1975).

Stockworks, which occur below massive ore and which were clearly feeder zones, consist of highly altered and mineralized material of basaltic origin. Mineralization occurs as veins, veinlets and disseminated impregnations of sulphides. The alteration silicate mineralogy of the reconstituted pillow lava consists of quartz-chlorite-illitesphene. Uneconomic alteration pipes characterized by pyritisation penetrate 1-2 km down into the ophiolitic sequence. Stockworks are normally elliptical in cross-sectional shape. A good idea of dimensions is provided by the Limni deposit in western Cyprus with a long axis of  $\sim$  800 m and a short axis of ∿ 400 m (Trennery and Pocock, 1972; Adamides, 1975). It contained pre-production reserves of  $\sim$  4 million tonnes at 1.37% Cu (Bear, 1963) and has proved to be economically exploitable for  $\sim 200$  m below the original ocean floor.

About 20 deposits have been worked in Cyprus. They are normally a few million tonnes in size (e.g. ave. of eleven listed deposits = 3.6 million tonnes) but can be as large as 15 million tonnes (e.g. Mavrovouni). Copper grades are extremely variable but are typically between 0.8 and 2 wt%. Along the 80 km long northern pillow lava outcrop in Cyprus 15 deposits occur with an imperfectly regular distribution characterized by a mean halfspacing of 2.6 km  $\pm$  1.4 km (1 $\sigma$ )(Spooner, 1977).

Examination of fluid inclusions and the hydrogen, oxygen and strontium isotopic composition of ore deposit material from Cyprus has shown that the sulphides were precipitated from a hydrothermal fluid of sea water origin (Spooner and Bray, 1977; Heaton and Sheppard, 1977; Chapman and Spooner, 1977):-

- e.g. 1 Fluid inclusion studies on ore material from Cyprus have shown that samples of the ore forming fluid trapped in small cavities in quartz intergrown with sulphides have a freezing point indistinguishable from that of sea water  $(-1.9^{\circ}C \pm 0.4^{\circ}C; 205 \text{ measurements}; \text{Spooner and}$ Bray, 1977). Since the freezing point of a solution is a reflection of its salinity this information indicates a close bulk compositional similarity between the hydrothermal fluid, which was at temperatures between  $\sim 300^{\circ}C$  and  $\sim 350^{\circ}C$  (Spooner and Bray, 1977), and sea water.
- e.g. 2 Mineralized material from 4 deposits in Cyprus is significantly enriched in <sup>87</sup>Sr (Chapman and Spooner, 1977).Initial <sup>87</sup>Sr/<sup>86</sup>Sr ratios as high as upper Cretaceous sea water have been recorded (e.g. 0.7075 ± 0.0002).

e.g. 3 The hydrogen isotope composition of the hydrothermal fluid has been shown to be close to that of sea water (Heaton and Sheppard, 1977). Hence, this evidence completes successful identification of the complete cycle of sea water circulation. The following points can now be made about the nature of the convective process which occurred in the ophiolitic rocks of the Troodos

430 SPOONER

Massif, Cyprus (summarized from Spooner, 1977 and, particularly, from Parmentier and Spooner, 1978):-(a) The flow geometry appears to have consisted of axially symmetric cells containing a central plume of hot ascending fluid which was positionally fixed through time with respect to enclosing rock. This is, perhaps, a rather unexpected result. (b) Strong hydrothermal metamorphism does not significantly affect the middle and lower parts of the gabbroic sequence on Cyprus. This suggests that strong sea water penetration and circulation occurred in a permeable layer  $\sim$  2-3 km thick. (c) The mean half-spacing between ore deposits along the northern pillow lava outcrop in Cyprus is 2.6  $\pm$  1.4 km (1 $\sigma$ ). This suggests that the original rising plumes were separated by a disstance comparable to the thickness of the permable layer -- an observation consistent with a convective model.

(d) In Cyprus, ore deposits are frequently crosscut by unmineralized dykes and/or overlain by unmineralized pillow lavas. This suggests that formation of the ore deposits occurred within the volcanically active zone at a spreading ridge. For a half-width of  $\sim$  6 km and a spreading rate of  $\sim$  5 cm/yr the ore deposits may have formed in a time on the order of  $10^5$  years. The mean internal upward flow rate may have been  $\sim 10^{-6} g$  cm<sup>-2</sup>s<sup>-1</sup> (Spooner, 1977) -- a flux which has been shown to be reasonable by later finite difference calculations (Parmentier and Spooner, 1978). (e) Homogenisation temperatures of fluid inclusions in three mineralized stockworks in Cyprus indicate that the temperature of the plume of rising hydro-thermal fluid was  $300^{\circ}C - 350^{\circ}C$  (Spooner and Bray, 1977). This range is in good agreement with a value of  $\sim 300^{\circ}$ C estimated for the temperature of last equilibrium with quartz of end-member hydrothermal fluid from the Galapagos Ridge axis (Edmond, 1978), and is consistent with a value of ∿ 285°C (max.) estimated by Crane and Normark(1977) for hydrothermal activity on the East Pacific Rise

at 21°N. (f) Parmentier and Spooner (1978) have modelled hydrothermal circulation relevant to the origin of the Cyprus deposits by finite difference approximations, and have found that diffus: plumes of rising fluid contain hot core zones which are comparable in size to stockworks in Cyprus. Such hot core zones remain approximately isothermal to within  $\checkmark$  300 m of the ocean floor, where they cool abruptly to ocean bottom water temperatures. In the model, conductive cooling alone was considered. In the real situation cooling by mixing with cool sea water in a near surfice zone is probably more important (e.g. Edmond, 1978).

A larger scale implication of the possible presence of sulphide deposits in oceanic crust, which could be comparable in gize and density of occurrence to those in Cyprus, is suggested by the isotopic composition of contained sulphur. It appears to indicate that the ore sulphide is largely of reduced sea water sulphate origin (Bachinski, 1977; Spooner, 1977; Heaton and Sheepard, 1977). Hence, large quantities of sulphide, in association with hydroxyl and chloride, could be added to oceanic crust. Release of water from the descending slab at subduction zones may cause wet melting of mentle material, and could produce volatile rich siliceous magmas enriched in chlorine and sulphur. Such a simple model could explain the amounts of magmatically released water, chlorine and sulphur required for the formation of porphyry Cu  $\pm$  Mo  $\pm$  Au deposits. Water is needed as the transport medium, chloride for metal complexing and sulphur for fixing the metals as solid phases.

Finally, it should be re-emphasized that it is uncertain how representative of oceanic crust the Troodos Complex, in particular, and ophiolitic sequences, in general, might be. The general nature of the findings discussed above is, therefore, likewise subject to uncertainty.

Acknowledgements. I am very grateful to Dr. Manik Talwani for inviting me to attend. The Second Maurice Ewing Memorial Symposium, and would also like to thank Drs. R.N. Anderson and S.R. Hart for helpfully reviewing this abstract.
