EVALUATION

Northrop Corporation, addressed six technical topics that received special analysis during the Phase I study to establish the DHRS baseline configuration. These topics are:

- 1. Overall System Design
- 2. Cache Storage
- 3. Mass Storage
- 4. Displays
- 5. Target Screeners
- 6. Compression/Expansion Techniques

The parameters which drove the preliminary architectural design of the DHRS were that (for the DHRS to operate without delays), the Image Interpreter must finish his exploitation/reporting tasks in less than 4.8 to 120 seconds. For worst case, as many as 6 exploitation stations would be required to process target data in real-time if each processing task took (on the average) only 30 seconds. Due to the high cost of multiple exploitation stations, Northrop decided on only one exploitation station, and thus the baseline architecture was designed.

ABSTRACT

The following document constitutes the final technical report on Contract F30602-79-C-0269, Data Handling/Recording System - Phase I. The work was performed in the Image Systems Branch of Northrop Corp., by Messrs Gary Wycoff, William Baker, J. Sekiguchi, and Dr. Gerry Haas.

CDRL A002

DHRS TECHNICAL REPORT

1.0 INTRODUCTION

The Data Handling and Recording System is a system of personnel, equipment, computer software and procedures capable of receiving and exploiting tactical reconnaissance information in near real time. The reconnaissance information is infrared imagery and location data from the AN/AAQ-9 forward-looking infrared (FLIR) and AN/AAD-5 downward-looking infrared (DLIR) multiplexed with AN/ARN-101 computer inertial navigation information. After demultiplexing, data is routed to the data processing and video and display consoles. Exploitation equipment is housed in a 20by-8 by 8-foot shelter. The shelter contains computer and peripherals (magnetic tape units and disks) and conversion, and target/intelligence report writing. The shelter is modular, mobile, air transportable and capable of global deployment.

The DHRS technical report addresses six topics that received special analysis during the DHRS Phase I study to establish the baseline configuration submitted as CDRL A003, Technical Proposal/ Program Plan. These topics are discussed under the following subsections: Overall System, Cache Storage, Mass Storage, Displays, Target Screeners and Compression-Expansion.

2.0 OVERALL SYSTEM

2.1 Technical Problem

A significant difference exists between an operational future DHRS and the Advanced Development Model used to evaluate target screeners and to evaluate system response timeliness. Specifically, target input rates dramatically impact the size of the DHRS exploitation station, since Image Interpreter (II) exploitation time limits the DHRS throughput. It also affects the size of the cache memory (which functions as a buffer between the target input rate and the II exploitation rate). And finally, it determines a fundamental system parameter, throughput timeliness, and thus the requirements for real time and near real time target processing.

2.2 General Methodology

To bound the target input rates, two mission scenarios were developed (see Figure 1). The minimum is the surveillance mission. It is a low-altitude, wide-field-of-view updating of already located targets and consists of a 2 hour flight with 6 imaging segments each yielding one formation target and new targets in

three out of four such segments. This mission is depicted in Figure 2. The maximum mission, called reconnaissance, is used to find new targets in an unsurveyed region. It consists of a high altitude flight with continuous sensor imaging and will collect images of 3 formation targets, thirty individual targets and 60 man made objects that are not targets. These figures are based on battlefield target densities described by General Stubblebein for the BETA program.

Within these bounds on target thougput rates, table 1 was constructed for both the AN/AAD-5 and the AN/AAQ-9 sensor in three scenarios; the present ADVISOR-62 data, during tests of the DHRS, and operationally as in a Reforger Exercise.

2.3 Technical Results

The critical parameters that impact the DHRS timelines and cache size are the average target frame rate and the average targets per target frame. For the DHRS to operate without delays, the II must finish his exploitation/reporting tasks in less than 4.8 to 120 seconds. Therefore, for worst case, as many as 6 exploitation stations would be required to process target data in realtime if each processing task took on the average of only 30 seconds. These parameters drove the preliminary architectural design of DHRS (see figure 3). It was obvious that the cost of multiple exploitation stations was prohibitive and unnecessary to the purpose of an Advanced Development Model (ADM). The project managers made a decision that only one exploitation station would be procured for the ADM and thus the baseline as shown in figure 4 was defined.

Before leaving this section, a time compression in the collected versus inputted target data must be mentioned as illustrated in figure 2. Although the sensor collects the image data over sixfour minute segments in two hours, the Advisor-62 tape input to the DHRS plays back this data as if a continuous twenty-four minute image was collected, thus speeding up the target data rate by, at most, a factor of 5. The program managers made a decision that the Advisory-62 could be played back in segments that would simulate the actual target image collection rate.

3.0 CACHE STORAGE

3.1 Technical Problem

As mentioned in paragraph 2.1, the cache memory is simply a buffer that stores target input images when the input rate exceeds the exploitation output rate. The questions are then; How Large must the cache memory be? How does the difference in input versus output rate affect the system timelines?, and How should the cache be implemented?

FIGURE 4

•

3.2 General Methodology

The assumed DHRS inputs are defined in figure 5. Figure 6 examines each of three ways that this data rate affects the system throughput based on an exploitation output rate of one target frame per minute. In case one an unlimited cache is available and the twenty-four minutes of Advisor-62 is input continuously. In case 2 either a 20 or 30 frame cache is available and when either is filled (10 minutes for 20 frame cache and 15 minutes for 30 frame cache), the input from the Advisor-62 is interrupted until the cache is emptied (30 minutes and 45 minutes respectively). It is then restarted and in case of the 20 frame cache stopped again at 40 minutes and restarted at 60 minutes. The third case has no cache and the Advisor-62 input is stopped after each target image is received. In all cases, all processing of 72 target images is completed in 72 minutes. Figure 7 shows the number of images stored in the cache at any time. These data were developed without simulating the timeline of the data collection. Figure 8 shows the input when a realistic mission timeline is simulated and Figure 9 shows the cache loading for both 1 and 2 minute exploitation times. Table 2 shows how frame storage is performed by the cache. Finally, regardless of the cache size, delays in the system will occur because of exploitation/reporting time. Figure 10 examines these delays.

A final concern is the cost of the cache and the cost associated with exceeding the cache capacity. The cost of implementing the cache in RAM memory is two orders of magnitude more expensive per target frame than that of a disk memory. Second, the cost of storing the retrieving target frames that exceed the cache capacity in another memory device has associated with it a considerable cost in software and computer overhead.

3.3 Technical Results

The fundamental delay cause by the assumed target input rate exceeding the exploitation output rate cannot be improved upon except by employing additional exploitation stations or by assuming a faster exploitation time. A disk cache with virtually unlimited capacity costs about the same as a RAM cache of 7.5 target frame capacity. In addition, it will save all the software and computer costs associated with storing excess target images in another storage device. Finally, as shown in the Technical Proposal, the delays cause by implementing the cache in disk versus RAM will not exceed 2 seconds worst case, and thereby will not be objectional to the II. The disk cache was included in the baseline DHRS configuration.

FIGURE 10

4.1 Technical Problem

Figure 11 summarizes the mass storage requirement of the DHRS. The characteristics of candidate technologies that might satisfy these requirements are shown in Figure 12. Included in the optical disk technology survey were those under development by RCA, MCA and the GE Advanced Archival Storage System (BEAMOS extension). Although these devices have been demonstrated in laboratory environments, no prospective manufacturer would commit to a production model delivery to support the DHRS schedule. Figure 13 tabulates the characteristics of instrumentation tape unit technology selected for the baseline DHRS configuration. The minimum cost for 10^{12} bits on line of 500 thousand dollars is considered excessive.

4.2 General Methodology

Figure 14 summarizes the conclusions of the technology trade off in selecting a mass storage device. With the characteristic defined for the mass storage, a request for proposal was prepared and sent to the following vendors:

> Honeywell Ampex Bell and Howell Sangamo RCA (no bid)

4.3 Technical Results

With the mass storage device relieved of storing any cache overload (see paragraph 3.3) and with data compression, (see paragraph 7.3) a single reel of 28 track tape can store an entire 24 minutes of digitized Advisor-62 tape. It was selected as the most cost effective method of providing the required mass storage. Of the tape units, the Ampex HBR-3000 was selected for its match to the mass storage requirements and its cost, and is included in the DHRS baseline configuration.

5.0 DISPLAYS

5.1 Technical Problem

The AN/AAD-5 produces imagery of very large extent. How can this imagery be presented on a limited extent CRT, cost effectively?

5.2 General Methodology

A simply linear relationship exist between number of displayed pixels and cost, i.e. a 2048 line by 2048 pixel display costs approximately 4 times a 1024 line by 1024 pixel display and 16

STORAGE AND RETRIEVAL MODULE (S/RM) RFP REQUIREMENTS

CAPACITY: 10¹² BITS EQUIVALENT (4.1.1.2.1)

OPERATING MODES: SIMULTANEOUS RECORD AND/OR PLAYBACK (4.1.1.3.3.1) DATA TRANSFER RATES: 4.1.1.1.6: "... PRESENT BANDWIDTHS OF 6 TO 7 MH2..."

17

4.1.1.1.3: "... 100 MEGABITS/SEC."

4.1.1.2.5: "... SHALL STORE BOTH THE ... RTPM OUTPUT

AND THE INPUT IMAGE."

FIGURE 11

S/RM VIEW

- SYSTEM PERFORMANCE/COST TRADE-OFF WILL ULTIMATELY PROVIDE A BASIS FOR S/RM **CONFIGURATION CHOICE**
- THE 28 TRACK SYSTEMS OFFER ADEQUATE DATA RATE CAPABILITY AND THE OPPORTUNITY TO **MINIMIZE COST**
- THE 84 TRACK SYSTEMS OFFER SUPERIOR PERFORMANCE
- OPTICAL DISC SYSTEMS OFFER PROMISE FOR THE FUTURE
- SYSTEM USAGE OF DATA COMPRESSION COULD SAVE COST

FIGURE 14

times more than a conventional 512 line by 512 pixel display. However, from a utility point of view, the 2K x 2K display is more effective than 4 and 16 times, respectively. This results from requiring overlap to avoid cutting targets in half when segmenting an image into smaller subdivisions. If 20% overlap is provided then a 2K x 2K display will require 5.8-1K x 1K and $33.2-5K \times 5K$ displays. Therefore the cost benefit of a 2K x 2K display is 44% better than a 1K x 1K display and 101% better than .5K x .5K. These calculations imply that the largest display that supports the DHRS schedule, and is within DHRS budget limitation, should be utilized.

5.3 Technical Results

The cost and developmental risk associated with a 2K by 2K display eliminated it from further consideration at this time. A survey of ten companies that produce lower resolution image displays was conducted. The results of this survey is shown in tables 3-5. The Comtal Vision one/20 was selected for inclusion in the DHRS baseline since it provides 1K by 1K display with versatility and reasonable cost and delivery.

6.0 TARGET SCREENER

6.1 Technical Problem

Figure 15 is the objective of the effort assigned to MC^2 under a subcontract agreement. Specific evaluation criteria are shown in Figure 16.

6.2 General Methodology

A preliminary survey was made of 13 potential target screeners for which data was available. These target screeners were subsequently categorized as shown in Figure 18. All screeners used a basic algorithm generalized in Figure 19. The specific details used in the NEMD "ATC" are diagrammed in Figure 20.

6.3 Technical Results

The three previous mentioned screeners as well as the Rockwell International "ISA" target screener were considered equivalent, in that they all performed similarly and all equally failed to meet the evaluation criteria. Therefore, to evaluate availability in meeting the DHRS schedule and cost, request for proposal was sent to Westinghouse, Honeywell, Rockwell International and Northrop Electro-Mechanical Division. The responses received from the last two companies are included as Appendix B and C to CDRL A003 Technical Proposal/Program plan. DISPLAY SYSTEM COMPARISON

OBJECTIVE

DEFINE THE OPTIMUM TARGET SCREENER FOR DHRS

-- OVERRIDING CONSTRAINT --

25

ONE OF THOSE ALREADY DEVELOPED AND FIELDABLE DURING OR BEFORE NO MAJOR DEVELOPMENT. THE TARGET SCREENER WILL BE BASED UPON DHRS PHASE II. ENHANCEMENTS REQUIRING MINIMAL DEVELOPMENT COST WILL BE CONSIDERED.

FIGURE 15

EVALUATION CRITERIA

FLEXIBILITY AND EXPANDABILITY TO PROVIDE FOR:

- ACCOMMODATION TO NEW SENSORS
- INTRODUCTION OF NEW ALGORITHMS
 INTRODUCTION OF NEW TARGET CLASSES
 - INTEGRATION INTO DHRS

AVAILABILITY/MATURITY

FUNCTIONAL AND OPERATIONAL REQUIREMENTS

- 100 Mbps INPUT RATES
- EIGHT CLASSES OF TARGETS
 - **EFFECTIVENESS:**
- 90% DETECTION
- 80% CORRECT CLASSIFICATION 10% OR LESS MISCLASSIFICATION
 - VAN ENVIRONMENT

COMPATIBILITY WITH OVERALL DHRS **RELIABILITY/MAINTAINABILITY** COST

FIGURE 18

A

7.0 COMPRESSION-EXPANSION

7.1 Technical Problem

The DHRS requires considerable amounts of expensive memory in the FIFO Buffer and Formatter of the SIM, the MTU's of the SRM, and Delay Buffer, Overview Buffer, Cache and Output Buffer of the RPTM. See Figure 4.

7.2 General Methodology

The literature on image data compression was surveyed to find a method of reducing the dynamic range of the image data while retaining its fidelity.

7.3 Technical Results

Differential Pulse Code Modulation (DPCM) was selected for inclusion in the DHRS baseline. DPCM was employed because: it exploits the signal statistics of digital imagery and the visual properties of the observer, it is simple to implement and it halves required memory and its attendent costs. (1)

Rome Air Development Center

RADC plans and executes research, development, test and selected acquisition programs in support of Command, Control Communications and Intelligence $\{C^3I\}$ activities. Technical and engineering support within areas of technical competence is provided to ESD Program Offices (POs) and other ESD elements. The principal technical mission areas are communications, electromagnetic guidance and control, surveillance of ground and aerospace objects, intelligence data collection and handling, information system technology, ionospheric propagation, solid state sciences, microwave physics and electronic reliability, maintainability and compatibility.
