TECHNICAL REPORT

ERL-0136-TR

THE ADAPTATION AND INSTALLATION OF THE  
RESOURCE ACCESS CONTROL FACILITY(RACF)

J.L. Roughan and J.C. Gwatking

S U M M A R Y

The Resource Access Control Facility (RACF) is a software package designed to control access by users to a computer system and to data stored on the system. This report describes the modifications and additions to the functions of RACF which were made during its installation in the computing centre at the Defence Research Centre. RACF is described in sufficient detail to allow the operation of the modifications to be clearly explained. The report also summarizes the functions and standards of the computing centre and lists the actions taken to accommodate users with non-standard requirements.

## 1. ENVIRONMENT OF THE COMPUTING CENTRE

This report discusses the installation of the Resource Access Control Facility (RACF), an IBM program product, in the central computer of the Defence Research Centre, Salisbury, South Australia. RACF is designed to control access to resources of the computer system such as data stored in the system(ref.1,2).

The Defence Research Centre, Salisbury, is engaged on a wide variety of scientific and engineering research and development for the defence forces of Australia. Substantial computing resources are required in this work for activities such as simulation, scientific data processing and engineering design. The central computer of the Defence Research Centre supplies a general computing service to the Centre. Many computer terminals are connected to the central computer via a private physically secure network in a secure area. Some terminals are installed at remote sites and connected via the telephone service but the data transmission is encrypted. Nearly all the users of the computer are cleared to access classified material but are only permitted access to material for which they have established a "need-to-know". Groups of users within the Defence Research Centre have separate interests and are administered separately. In all there are about 500 active users, most of whom are engaged on scientific and engineering projects; very few have substantial formal training in computer programming.

Data owned by users of the computer system are stored on disks attached to the system and on magnetic tapes which are stored in a physically secure area adjacent to the computer room. Many disk data sets are archived to magnetic tape to provide adequate free space on the disks. The archival is regular and automatic but commands are provided so that users can easily retrieve and manipulate archived data sets. The archives contain many more data sets than can be stored on the disks(ref.3,4,5).

Various software packages such as IMS, STAIRS and GIS allow users of the system to access data bases. TSO, a time sharing system, is used by a majority of the users to enter and edit data and programs, test new programs, and run programs and inspect their output.

A number of requirements must be met by a security package such as RACF in this environment. Most of the actions of the security system should be automatic and transparent to the user, to reduce inconvenience and to lower the possibility of user error. In particular all data stored on the computer, whether on disk, on magnetic tape or in the archives should be automatically protected as it is created. While access to this data should be restricted to its owner as a default, it should be relatively easy for the owner to share his data with other users on a need-to-know basis. It should be possible to specify that some users may only read the data while others may both read and alter it. It is important that the sharing of data should be readily controlled by the owners of the data and not by a central administrator. In order to control access to data and provide reliable privacy and integrity the security system must be able to identify users and monitor their activities. It should provide data to enable the production of user and management reports describing these activities. The overhead of providing protection for a large amount of data should be low and the security software must be properly integrated with the normal computer software so that full integrity of the system is maintained.

The basic RACF product fulfills most of these requirements for the control of access to data. This report describes the work which has been done in this computing centre to obtain these facilities using RACF. Appendix II describes the use of RACF procedures for users of the computer system.

## 2. HISTORY OF THE COMPUTING CENTRE

The table below gives a brief history of the size of the computer system(ref.6,7,8).

Year	Machine	Online storage	Terminals	Users
1961-1976	IBM 7090	-	-	200
1975	IBM 370/168	800 MB	15	7090(150),168(100)
1976	IBM 370/168	1400 MB	40	7090(50),168(250)
1977	IBM 370/168	1600 MB	60	300
1978	IBM 370/168	4000 MB	80	350
1979	IBM 370/3033	6000 MB	110	400

The growth and diversity of the user population and the increase in online storage and the number of interactive terminals implied a need for a comprehensive means of controlling the use of data. The technique used before the installation of RACF was password protection. Password protection had the disadvantages that it was not automatic and it was cumbersome to use because each protected data set required a password. Security exposures were possible since all the users who needed to use a data set had to know the password to that data set. It was difficult to regularly change passwords because of the difficulty of informing all the users of the data.

The installation of RACF has overcome these problems and provided a very flexible and powerful method of controlling the access to data.

### 3. CURRENT SECURITY MEASURES IN THE COMPUTING CENTRE

#### 3.1 Physical security measures

The building housing the computing centre is located in a secure area to which entry is controlled by an identifying pass. Access to the computer room is further restricted. The main communications' network is private and physically located within the secure area. Links to terminals in other secure areas are encrypted because they use the public telephone network.

Adequate fire detection and prevention equipment is installed in the computer room and tape storage area.

Backup tapes of all the disks and duplicate copies of all archive tapes are kept in a separate building. (The archives contain disk data sets which have been transferred to tape to provide adequate unused disk space).

#### 3.2 Procedural security measures

Nearly all the users of the system are cleared for access to classified material and owners of data may allow such users to access their data on a 'need-to-know' basis. Users of the system not cleared for access to classified material are restricted by the security software (RACF) to their own data plus essential system data even if another user tries to allow them access to his data.

All disk data sets which are changed during a day are backed up on to tape during the evening(ref.9). Data sets can readily be restored from the backup tapes or entire disks can be reconstructed. The operational housekeeping procedures are designed so that recovery of data is always possible(ref.10).

#### 3.3 Software security measures

A record of accesses by users to data sets is maintained and reports are distributed to users each fortnight showing which other users

accessed their data sets and what the types of access were (e.g. read or write).

Each user is personally identified when running a batch job or when logging on to a time sharing terminal by a user identification and password. Each user's password is known only to the user and can be changed by the user at any time; users are in any case forced to change their passwords every three months.

RACF controls the access to all data on the basis of information provided by the individual owners of the data.

#### 4. FUNCTIONS PROVIDED BY RACF

##### 4.1 RACF functions

RACF conveniently supports most of the requirements of this computing centre for controlling access to data. In addition, RACF has been designed so that it is easy to modify or extend its functions. Consequently the work described in this report was undertaken to extend RACF to provide the extra functions required in this computing centre.

There are certain fundamental requirements of a security system and RACF meets these:

- (a) the security system must be fully supported by and integrated with the operating system of the computer,
- (b) there must be no loopholes or exposures by which the access control may be bypassed except by a hardware failure; even this should not result in a general exposure,
- (c) it must be possible for all data to be protected automatically - without specific user action, and without severe overhead,
- (d) it must be possible for the owners of data to control the access to their data,
- (e) reliable reports of successful and failed accesses to data must be available to the owners of the data,
- (f) users of the system must be reliably identified so that access to the system can be controlled,
- (g) it must be possible to limit the type of access to data to input only or to input and output,
- (h) it must be possible to control the access to data by different users independently.

RACF allows individual users, groups of users, or all users to be given access to a data set. Different users or groups of users may be allowed different types of access (e.g. input only or input and output).

The types of access controlled by RACF are READ, UPDATE, CONTROL, and ALTER. READ allows input while UPDATE allows input and output. CONTROL is of specialised interest and may be considered as being equivalent to UPDATE. ALTER allows input, output and deletion of data sets.

##### 4.2 Major problems in this computing centre

There are several major areas where the standard functions of RACF do not meet the requirements of this computing centre. These problems have been solved by a variety of techniques, including modifying and extending

RACF. The solutions are discussed in Section 7.

- (a) A RACF definition or profile must exist in the RACF data set for every protected disk data set. In our case, since our archives are in effect an extension of the disks, a profile would also need to exist for every data set in the archives. The RACF data set would in our case become rather large and access to a profile would involve greater overhead.

When data sets are created it is possible to create the RACF profile automatically by copying some model profile. However if the user alters his model, the previously created data set profiles will not change.

- (b) The use of RACF to control access to data sets stored on magnetic tape is very awkward. No provision is made for erasing tapes when data sets are deleted.
- (c) In this computing centre, access to data sets in the archives must be controlled by RACF in a similar way to the control of access to disk data sets.
- (d) Disk space which has been freed by deleting, moving or compressing data sets can easily be used for input by any user, without first writing on the space. This is a major privacy exposure.
- (e) In this computing centre, operator started tasks are used extensively to submit batch jobs to perform operational housekeeping functions on the computer system. These submitted jobs require passwords on the job cards but it is not possible for a started task to obtain the password corresponding to its userid.
- (f) RACF does not provide any means for printing the security classification on printed output. The RACF LEVEL parameter could perhaps be used to maintain the security classification of a data set but it would require major changes to the JES2 job entry system software to cause automatic printing of the classification on a job output.

#### 4.3 Minor problems in this computing centre

Many other problems or inadequacies exist in the operation of RACF which do not have a major impact. Most of these problems, which are described below, have been solved by the work described in Section 8 of this report. The problems as yet unsolved do not cause any security exposures but cause minor inconveniences for the users.

- (a) FORTRAN programs open a data set for INOUT processing even when only READ statements appear in the program. READ access authority is therefore not sufficient to be able to use a data set for input to a FORTRAN program. At least UPDATE access authority is required.
- (b) The access available to each generation of a generation data group (GDG) must be defined to RACF when the generation is created. This could become tedious and induce errors with the frequent creation of new generations.
- (c) No provision has been made in RACF for an access authority of execute only, which should be a more restricted access type than READ. Presumably it would be difficult to make the MVS operating system properly support such a RACF access level.

- (d) The user's password on a batch job is checked at the time the job begins execution, not at the time the job is submitted. Thus, if the password is changed by the user after a job is submitted but before it begins execution, then the job will fail.

The RACF password command to change the password during a time sharing session does not change the password in the TSB (a system control block). Since the TSO SUBMIT command obtains the password for submitted batch jobs from the TSB, any job submitted after the password is changed in a session will fail.

If a job card is included in the JCL (job control statements) of a batch job submitted using the TSO SUBMIT command, then the password is not inserted in the job card. However, any job cards built entirely by the SUBMIT command do include the password.

The need to include the password in a batch job submitted as a card deck is a major security exposure for the password, but this is not logically a RACF problem.

- (e) The RACF manuals(ref.1,2) and the numerous RACF commands are too complicated for users who are not primarily programmers.

In issuing RACF commands to define the access available to a VSAM data set, the commands have to be issued separately for the components of the data set (cluster, index and data).

RACF only issues write-to-operator(WTO) error messages which normally would appear on the SYSLOG printout of a batch job but not at a time sharing terminal where required by most users.

- (f) The use of DD DATA JCL statements is an exposure since a job could read the JCL of other jobs following it in a card reader's input stream.

- (g) RACF does not allow any user to create a data set in the name of another user.

- (h) Data set access statistics can be recorded in the RACF profiles of data sets. However only a count of accesses by each user in the access list is recorded. The actual level of access (rather than that allowed) or the date of access is not recorded. The count of accesses cannot be reset to zero.

## 5. EXPLANATION OF THE OPERATION OF RACF

This explanation should not be regarded as a complete, or even fully accurate description of RACF. Some knowledge of general IBM 370 operating system functions has been assumed (however a number of definitions appear in the glossary).

RACF stores in a special data set a record or profile for every entity or resource to which it controls access. The profile for a resource contains a description of the level of access permitted to the resource. A data set is an example of a resource.

RACF is installed as an integral part of an operating system, MVS, which controls the operation of an IBM 370 computer and provides user services such as job management and data management. The installation of RACF includes the modification of certain parts of MVS. The modifications involve the insertion of code to invoke RACF to perform three broad functions :- to check whether a user has the authority to access a resource (known as the RACHECK function), to verify the identify of a user entering the system (RACINIT) and to manipulate the profiles of protected resources (RACDEF).

For instance, RACHECK macros have been inserted in the MVS OPEN routines and in the MVS routines which delete or rename data sets. The macro is executed before any access to a disk data set which is RACF protected, as

indicated by a protection flag set in the control block (DSCB) pointing to the data set in the directory of contents (VTOC) of a disk. The RACHECK macro is also executed before any access to a standard labelled magnetic tape if the RACF option for protection of tapes is enabled. Execution of the RACHECK macro causes an SVC interrupt which invokes the RACF RACHECK SVC routine. This SVC routine checks the authorization of the user to access the resource at the requested level, for example READ or UPDATE. The SVC routine returns a code to the calling routine indicating whether the user may access the resource. Messages may be issued by the SVC routine and if access is denied the routine which executed the RACHECK macro usually causes an ABEND (abnormal termination of the user program).

MVS has been modified to execute a RACINIT macro when a batch job or started task begins execution, when a time sharing user logs on or when a user logs on to the data base management system. The RACINIT macro causes the RACF RACINIT SVC routine to be invoked which checks whether the user's password is correct and sets up an MVS control block (ACEE) defining the characteristics of the user. The characteristics of the user are defined in a user's profile in the RACF data set, where his password is also stored. The security administrator may alter the user's profile. An important parameter that can be set in the profile specifies that all disk data sets created by the user are to be automatically protected by RACF: that is, the flag is to be turned on in the DSCB and a RACF profile is to be defined for each new data set.

Profiles in the RACF data set for disk data sets or tape volumes can be created, modified or deleted by executing a RACDEF macro. The RACDEF macro invokes the RACF RACDEF SVC routine to perform the required operation on the profile. RACDEF macros have been inserted in MVS routines which create, move, rename, extend or delete disk data sets so that corresponding creation, modification or deletion of the RACF profiles of the data sets will occur automatically.

Unfortunately similar provisions have not been made in the case of magnetic tape data sets. Specific action needs to be taken to create, modify or delete RACF profiles for magnetic tape volumes. Note that RACF only protects magnetic tapes by volume, not by data set, recognizing that once a data set is opened on a volume, other data sets can be accessed on that volume without repeating the open. Thus it is sensible to only protect volumes.

It is possible for "authorized programs" to use the various RACF macros to enhance the functions available from RACF. An authorized program is a program permitted to perform supervisor functions.

RACF provides commands for users to allow access by other users to their disk data sets and tape volumes. Specific users can be given access or all users can be given access. The level of access granted may be NONE, READ, UPDATE, CONTROL or ALTER. The first three are self explanatory, CONTROL is not usually required, and ALTER allows all forms of access to a data set, including the ability to delete or rename. Specific users can be given any of these levels of access and all other users can be given any one of these levels of access to a data set or magnetic tape volume.

Under RACF, users can be connected to a RACF Group. RACF Groups are designed to simplify data set creation and sharing for a project oriented group of users. A Group data set is identified by prefixing the data set name by the Group identifier, just as the owner of a user data set is identified by prefixing the data set name by the user identifier. Users connected to a RACF Group may use and optionally create Group data sets. This reduces the impact of the RACF restriction that one user may not create a data set for another.

The definition of which users are permitted to access a data set may be simplified by including a Group name in the list. Then any users connected to the Group may access the data set.

## 6. MODIFYING THE FUNCTIONS OF RACF

As previously mentioned, RACF incorporates several features designed to enable individual computing centres to modify or extend its function. Those features relevant to the work described in this report are explained in detail below. Other features are mentioned only briefly.

### 6.1 Performance

RACF contains a number of facilities to change its performance, that is to reduce overhead or to make it more efficient. Facilities for recovery are also supplied. However this description will concentrate on those facilities which allow the functional behaviour of RACF to be changed.

### 6.2 New resource classes

New classes of resources to be protected may be defined to RACF. This feature has not been used at this computing centre.

### 6.3 RACF macros

The RACF macros RACHECK, RACDEF and RACINIT execute the respective SVCs and can be used by programs written by an computing centre to add additional functions to RACF. The RACDEF and RACHECK macros are used by the archiving programs used in this computing centre since these programs bypass normal RACF processing. The RACDEF macro is also used in this computing centre to provide automatic RACF protection for a pool of magnetic tapes available to all users for the storage of large catalogued data sets. The RACHECK macro is used to authorize certain RACF commands and the creation of data sets that would normally be prohibited.

### 6.4 RACF exits

RACF provides flexible exit facilities to allow a computing centre to add or alter many functions. An exit is a program (subroutine), written and installed by the computing centre, which is called by RACF at a certain stage when processing a request to RACF. The exit is able to modify parameters of the request and supply a return code to cause the request to fail, to be repeated, to ignore validity checks or to terminate but return a successful completion code.

The exits supported by RACF are given access in a flexible manner to most of the parameters used in processing the respective requests.

#### 6.4.1 RACDEF exit

The RACDEF SVC is used to define, alter or delete RACF profiles for protected resources. RACDEF is executed by MVS routines which create, alter or delete DASD data sets.

The RACDEF pre-processing exit is called by the RACDEF SVC before any RACDEF processing has occurred. The return codes from the exit may bypass normal RACDEF authorization checking, terminate RACDEF processing, or refuse authorization for the RACDEF. The main functions of the exit in this computing centre are to prevent the creation of a RACF profile for every disk data set which is created (see Section 7.1 for more details), to prevent attempts to delete RACF profiles when data sets without profiles are deleted, and to allow users to create data sets for other users who have given them ALTER authority in their default profiles.

#### 6.4.2 RACHECK exits

The RACHECK SVC is used to check the authorization of a user to use a resource. RACHECK is executed by MVS routines such as OPEN to check whether a user is authorized to open a data set with the requested level of access.

The RACHECK pre-processing exit is called by the RACHECK SVC before any RACHECK processing occurs. The return codes from the exit may cause RACHECK to fail, allow authorization without further processing, or allow authorization but with further processing, such as logging. The main functions of the exit in this computing centre are to provide a fast path for a user's own data sets (that is provide access with no further checking), to detect disk GDGs and cause the check to be made on the GDG base name instead, and to simulate expiry date protection for all system data sets by requiring an operator authorization even when access is permitted.

The RACHECK post-processing exit is called by the RACHECK SVC after most RACHECK processing (except the issuance of error messages) has occurred. The return codes from the exit may cause the RACHECK to be repeated (including the execution of the pre-processing exit). Obviously some of the parameters for the RACHECK would have been changed by the exit before this retry. The exit may also modify the completion code to be supplied by the RACHECK SVC. The main functions of the exit in this computing centre are to issue a RACDEF to define a tape profile if one does not exist, and to retry RACHECK with a user's default data set profile for data sets which are not defined to RACF.

#### 6.4.3 RACINIT exits

The RACINIT SVC is executed when a user accesses the computer system or at the end of a job or session. RACINIT is issued by MVS at job start and end, TSO logon and logoff or IMS logon and logoff.

The RACINIT pre-processing exit is called before much RACINIT SVC processing has occurred. The exit may set a return code to cause the RACINIT to fail or to be accepted without further RACINIT processing. The exit is mainly used in this computing centre to supply userids for batch jobs from the first three characters of the jobname and to prompt the operator for the userids of started tasks not already defined to RACF. Started tasks (that is, jobs started by operator START commands) can be defined to RACF in a table which indicates the userid and Group associated with them. The userid and Group of a started task not in the table can be entered by the operator when prompted.

The RACINIT post-processing exit is called after most RACINIT SVC processing has occurred. The exit may set a return code to cause the entire RACINIT request to be retried with parameters changed by the exit. The exit may also alter the completion code which will be returned by the RACINIT SVC routine to the program which executed the RACINIT macro. The exit is mainly used in this computing centre to request permission from the operator for special users to log on and to store the password of the user in an area of main storage. (The password can then be obtained by a job which needs to submit another job, and included on the generated JOB card).

#### 6.4.4 RACF command exit

The RACF command pre-processing exit is called from various RACF commands before any command processing has occurred. The exit may set return codes to cause a command to fail with or without an error message, or to be accepted without any authorization checking. The exit is used in this computing centre to allow certain commands to be authorized which are normally forbidden. The commands are necessary because not all data sets have RACF profiles in this computing centre. Sections 7.1, 7.3, 8.5 and 8.6 supply more information and the Appendix gives full details.

### 7. EXTENSIONS TO RACF FUNCTIONS

Most of the problems described in Section 4.2 have been solved in this computing centre. This section describes the solutions, which required the development of a number of exits and TSO command procedures (CLISTs).

#### 7.1 Default definition of access to disk data sets

To simplify the use of RACF, and to reduce the size of the RACF data set, most disk data sets are not given a RACF profile but instead are defined by a single default profile for each user or Group. Each user may easily modify his default profile so that the access available to all his data sets (except those specifically defined to RACF with profiles) may be easily altered.

RACF normally expects a profile to exist for each data set and so several RACF exits are used to allow the default profiles to be used when data sets do not have profiles of their own.

For instance, a RACHECK (to check the authorization to access a data set) may discover that no profile exists for the data set. The RACHECK post-processing exit routine detects that no profile was found and modifies the data set name to be checked to the name of the default profile of the user or Group owning the data set. The exit then returns a code causing the RACHECK to be repeated. The exit also sets a flag which can be tested by other exits indicating that no profile was found. When the RACHECK is repeated the default profile is found and used to provide the access list for the data set.

When a RACDEF macro is executed by a system module responsible for deleting, renaming, moving or extending a data set, a RACHECK is first performed by the system module to test the authorization for the action. Therefore the RACDEF pre-processing exit may test the flag set by the RACHECK post-processing exit indicating whether a profile exists for the data set. If a profile does not exist then the RACDEF pre-processing exit returns a code to cause the RACDEF to be aborted but with a successful completion code. Thus deletion etc. of the data set continues successfully without errors being caused by an attempt to delete a nonexistent RACF profile.

When a data set is created, a RACDEF is executed to create a profile for the data set (assuming that data set protection is automatic - a RACF option). In this computing centre, the RACDEF pre-processing exit returns a code to cause the RACDEF to be aborted but with a successful completion code. Thus all newly created data sets do not have a specific definition or profile in the RACF data set but the RACF protect flag is switched on in the control block (DSCB) pointing to the data set in the disk directory (VTOC).

A RACF command can be executed to create or modify a profile for a data set. That is, data sets can be specifically defined to RACF, overriding the access list defined in the default profile. A data set

profile can also be deleted, thus causing the access to the data set to revert to that defined by the default profile. The versions of the RACF commands to add or delete RACF profiles without switching on or off the RACF protect flag in the DSCB are non-standard since RACF normally expects all protected data sets to have a profile. RACF normally prohibits the use of these commands except under very restricted conditions. The RACF command pre-processing exit is used to allow wider use of the above commands. The exit executes a RACHECK for the data set. If the user has ALTER authority, then the exit returns a code causing the command to be accepted without any authorization checking. (ALTER is the highest level of access authority to resources available in RACF).

A CLIST has been designed to simplify the use of the RACF commands. The CLIST executes a TSO command designed to search the catalog or archive catalog for the data set, discover the data set type and location, and issue a RACHECK to detect whether the data set has a profile or not. Then the appropriate RACF commands are built and executed by the CLIST.

Another CLIST to display the access available to data sets has been designed. The CLIST displays the default profile if a profile does not exist for the data set.

Disk Generation Data Groups (GDGs) may be defined by the GDG base name. The RACHECK pre-processing exit modifies a GDG generation name to the basename. If a profile does not exist for the base name, then the RACHECK is retried using the default profile just as for an ordinary disk data set (see Section 8.2).

## 7.2 Automatic protection of magnetic tape data sets

RACDEF macros are not automatically executed by MVS to create tape volume profiles during the creation of a data set on a tape volume which is not already defined to RACF. Also, tape profiles are not normally deleted when all the data sets on a volume are uncatalogued.

RACF exits and other programs are used in this computing centre to automatically define and delete tape profiles and to allow access to tape data sets to be defined by the default profile or by a specific definition just as for disk data sets. All standard labelled tape volumes containing catalogued data sets in this computing centre are defined to RACF and have profiles in the RACF data set. However a flag in the installation data of each profile is used to indicate whether the owner's default profile or the actual volume profile is to be used to define the access available to a volume.

The RACHECK post-processing exit checks the flag in a tape profile and causes the RACHECK to be retried with the owner's default profile if indicated. Otherwise the exit allows the RACHECK to complete using the actual tape profile. If no profile for the tape volume exists, then the RACHECK post-processing exit executes a RACDEF macro to create a volume profile. Note that if RACF tape protection is active, then a RACHECK macro is executed by MVS during the creation of a new data set on a standard labelled tape, thus ensuring that profiles will exist for all tapes containing data sets.

The RACDEF pre-processing exit sets the flag in the tape volume profile it is creating to indicate that the owner's default profile should be used to define the access available to the tape. Subsequent RACHECK requests therefore must be able to determine who the owner of the data set on the tape is. However the data set name is not available to the RACHECK exits as it is for a disk data set, and it would be too complicated to modify every MVS module that issues a RACHECK for a tape volume to make it available. The compromise adopted is to modify only the MVS OPEN module (Appendix VIII) that handles the creation and extension of tape data sets and to pass the data set name to the RACHECK SVC by way of an installation parameter. Whenever the RACHECK post-

processing routine determines that the tape volume does not already have a profile it issues a RACDEF macro to create one, again passing the data set name. The RACDEF pre-processing exit then stores the owner, as derived from the data set name prefix, in the installation data field of the profile, thereby making it available to subsequent RACHECK requests. This technique does mean that each protected tape volume must have a profile, whether the protection is defined by the owner's default profile or not.

In this computing centre, a program is run regularly to determine which standard labelled tapes do not contain catalogued data sets. The program causes all such tapes to be erased (except for the internal volume label) and to be placed back in the scratch pool. The program which erases a tape executes a RACDEF macro to delete the RACF tape volume profile. Thus when a new data set is subsequently created on the tape, a profile defining its new owner can be created as described above.

The CLISTs (time sharing command procedures) referred to in Section 7.1 above, which modify or display the access available to disk data sets, also modify or display the access available to tape data sets in an identical manner. The CLISTs execute a TSO command which searches the catalog to discover whether the data set is stored on tape. A RACHECK is issued by the command to detect whether the flag in the installation data indicates that the actual volume profile or the default profile is used to define the access available to the tape. Then the CLISTs execute appropriate RACF commands to modify or display the tape profile or display the default profile.

From a user's viewpoint the same technique is used to define specific access to a tape data set or to cause the definition of access to revert to the default profile as for a disk dataset. However, since the same tape volume profile applies to all data sets on the volume, then altering the access available to any one of the data sets will obviously have the same effect on the others.

Tape Generation Data Groups (GDGs) cannot be treated in the same way as disk GDGs since the RACHECK exits cannot detect that a data set is a GDG - the exits have no access to the data set name for tapes. Thus if the GDG requires a different level of access from that provided by the default profile for the user or Group, then each generation must be defined specifically when created.

### 7.3 Protection for datasets in the archives

This computing centre operates an archiving scheme(ref.3,4,5) that removes infrequently used data sets from the disks allocated for the storage of user data. These data sets are either written to tape (there may be several hundred per tape) or are compacted and stored as part of a special data set on another disk.

Since the archives are really an extension of the disks, the data sets in them must be afforded the same protection they would have if they were still on disk. The archive tapes and the special disk data set are therefore protected by RACF against all accesses, since they contain data belonging to many users. The programs of the archiving scheme that access these resources use a special MVS feature that enables them to bypass all RACF processing. Given this privilege, the programs must ensure that the users invoking them have the necessary authority to perform the desired action on the requested data sets. To accomplish this the programs issue their own RACHECK macros. ALTER access is required to perform any operation except for the RETRIEVE or RELOAD functions, which require READ access.

When transferring data sets between the archives and disk and vice versa, or when deleting data sets from the archives or disk, the programs must also perform the appropriate operations on the profiles of those data sets that are specifically defined to RACF. The programs issue

RACDEF macros to perform this function. The RACDEF pre-processing exit allows all processing requested by any program of the archiving scheme to proceed without authorization checking.

When a data set is transferred to the archives it may or may not be deleted from disk, depending on whether the operation is ARCHIVE or BACKUP, respectively. If the data set is specifically defined to RACF then its profile is copied and the volume field in the copy changed to 'ARCHIV'. This profile then protects the copy of the data set in the archives. If the disk data set is deleted then the original profile will also be deleted. The reverse processing is performed when a data set with a specific profile is returned to disk by the RETRIEVE facility, which also deletes the copy in the archives, or the RELOAD facility, which does not. In these cases the volume field of the profile that is created for the disk data set is changed from 'ARCHIV' to the serial number of the disk volume chosen to receive the data set.

Other features of the archiving scheme, such as the deletion or renaming of data sets, similarly manipulate the profiles of those that are specifically protected.

The command procedures (CLISTs) created to define access to disk data sets and list the access available to them (see Section 7.1) also operate identically on data sets in the archives. The default profile associated with each user protects all data sets in the archives that are not specifically defined to RACF, just as it would if those data sets were still on disk.

To enable the archiving programs to issue RACDEF macros to define profiles for data sets in the archives a modification to the RACDEF SVC was necessary. These profiles specify 'ARCHIV' in the volume field. This is a fictitious volume that simply indicates that this profile applies to a data set in the archives, rather than to another copy of the data set that might exist on disk. However the RACDEF SVC rejects attempts to create profiles for data sets on volumes not currently online. This restriction has been removed by this computing centre when the volume is 'ARCHIV'. It still applies to all other volume serial numbers. The modification was made to CSECT ICHRDF00 of the module IGC0012C (see Appendix VII).

#### 7.4 Erasing released disk space

It is easy for any user to access and read information in disk space which has been released by deleting, compressing or moving a data set.

Several solutions to this problem may be proposed:

- (i) Erase all disk tracks during or subsequent to the release of the space - possibly unacceptable because of the overhead incurred by the extra channel and disk activity.
- (ii) Encrypt all data which is protected by RACF against general inspection except perhaps by a specific list of users. The overhead in this computing centre would be great since all our default profiles have this characteristic - we do not allow a user to provide even READ access by all users to all his data sets.
- (iii) Use the RACF Level concept to indicate which data sets need erasing and erase these during the release of the disk space. This would be unacceptable because it is likely that users would forget to set the Level.
- (iv) Erase all data which is protected by RACF against general inspection. The decision would depend on the result of an RACHECK which would involve more overhead for the average sized data set than simply erasing the data set.

The most feasible solution is the first. However, even this may introduce an unacceptable increase in channel and disk activity. We have implemented this method (Appendix X) and intend to measure the consequent change in performance. The channel command used to erase each track will not cause the channel or control unit to be busy during the erasure. Only the actual disk drive will be occupied and even it will be available to other tasks between tracks.

A satisfying solution would involve a hardware addition to a disk drive which allowed a flag to be set (with low overhead) which would prevent a track from being read until it had been rewritten. If a track was only partly rewritten, the remainder of the track should be unreadable.

#### 7.5 Accessing the password in a started task

It is useful for a program to be able to obtain the user's password so that it can build the job control statements (JCL) for another job and then submit the job so constructed for execution. (The password must appear on the JOB card of each job).

An interactive program (run using TSO at a terminal) can obtain the user's password from the TSB (an MVS system control block). In this computing centre, the RACINIT post-processing exit has been used to place the password of the user for a batch job in a region of storage accessible to the user. Thus batch programs can also obtain the user's password.

Since a password is not needed to run a started task (a job run by an operator START command), the RACINIT exits do not have access to the password. Also there is no standard way for even an authorized program to gain access to a user's password from the RACF data set.

In this computing centre a task has been set up which executes at every IPL (system initialization) and generates a random password once per day for the userid associated with operations jobs. The password and date are stored in a data set only accessible by operations jobs and a PASSWORD command (a RACF command) is issued to reset the password for the operations user.

A started task, if defined as owned by the operations user, can then obtain the password from the data set in which it is stored. It is not normally possible to log on to time sharing (TSO) with the operations userid since the password is unknown.

#### 7.6 Printing the security classification

A modification to JES2 (a job entry subsystem of MVS) has been designed to print RESTRICTED, CONFIDENTIAL or SECRET on each printed page of a data set in SYSOUT classes R, C or S respectively. This security classification is also repeated on the separator pages.

The number of lines per page available to a user for SYSOUT classes R, C and S has been reduced from 66 to 60.

Another modification to JES2 causes the operator to be warned on the separator pages that a job contains classified output if a certain character appears in the job name. This is useful when the classification is included as part of a text data set, for example, and is not inserted on the output by JES2.

### 8. SOLUTIONS TO RACF PROBLEMS

This section addresses the problems described in section 4.3. Circumventions and solutions to some of the problems have been found and implemented by this computing centre, while solutions to others have not yet been implemented due to their difficulty.

## 8.1 FORTRAN I/O

FORTRAN programs open data sets INOUT or OUTIN, depending on whether the first statement issued for the dataset is READ or WRITE, respectively. Thus a FORTRAN program needs at least UPDATE access for all data sets, even though only READ statements may be used. This can be reduced to READ access by using the IN subparameter of the LABEL parameter on a DD job control statement, or by using the INPUT parameter of the time sharing (TSO) ATTRIB command in conjunction with the ALLOCATE command. Both these techniques are fairly awkward, particularly the latter.

In addition, the ATTRIB command cannot be used when allocating concatenated data sets under TSO, so that under these circumstances UPDATE access must be available to each of the data sets in the concatenation.

A reasonable solution to the problem would involve modifying an INOUT OPEN request to INPUT if only READ access is available to the data set. The modification could be performed by the RACHECK exits during OPEN processing and restricted to FORTRAN programs by examining the form of the DDNAME. However if the program later attempted to write to a dataset that had been only opened for INPUT the resulting diagnostic error message would not be particularly simple to understand (contrasting with the RACF error messages which are very lucid). Techniques for modifying the OPEN as suggested above are not known and grave difficulties have been predicted.

Alternatively the FORTRAN library routines that handle OPEN requests could be modified to intercept INOUT requests and, if the RACHECK denies UPDATE access to the data set, to reissue the RACHECK for READ access. If this check succeeds the routines could then modify the OPEN to INPUT and resume processing. However existing load modules would need to be relinked to incorporate the new version of the library routines.

We believe that the latter solution, although not ideal, offers the better chance of success.

## 8.2 GDGs

The obvious requirement is to automatically protect all generations of a GDG in the same way. This is accomplished for disk GDGs by detecting the form of a GDG data set name in the RACHECK pre-processing exit and modifying the name to the GDG base name. The RACHECK is then carried out on the GDG base. If the base has been defined specifically to RACF, then access is authorized accordingly. If not the default profile is used to determine authorization. The commands to provide access to data sets include provision for defining GDG bases to RACF and listing the profile.

Unfortunately, it is difficult to manage tape GDGs in the same way since the data set name is not available to the RACHECK exits. The result is that each generation must be specifically defined or the default profile will be used. No satisfactory solution to this has been found.

## 8.3 Execute only access

It is difficult to see how this could be provided given the structure of MVS. However, it is highly desirable and MVS should be modified to allow this additional level of access to be controlled by RACF. Obviously the level EXEC would fall between NONE and READ in the hierarchy of levels of access.

#### 8.4 Passwords

##### (a) Add password to JOB card in SUBMIT

With the TSO Command Package (IBM program number 5740-XT6) installed, the password is inserted on JOB cards created by the TSO SUBMIT command. However if a job processed by the SUBMIT command includes a JOB card, then the SUBMIT command does not add the password to this JOB card.

A SUBMIT exit has been written by this computing centre to perform this function. The exit also changes the userid field in the jobname (the first three characters) to the userid of the submitter (the RACINIT exits allow the RACF USER parameter to be omitted and obtain the userid of a batch job from the jobname).

##### (b) Passwords in card decks

The need to include a password in card jobs creates a risk of compromise of the secrecy of the password. DRCS practice is for all card decks in the Centre to be stored in locked cabinets. The password must be punched using print inhibit on a JOB card continuation which is destroyed by the operator whenever the job is submitted.

##### (c) Checking batch job password at submission time

The password should be checked at job submission time rather than at initiation of execution, because the user could have changed it in the intervening period. The modification required is to issue a RACINIT macro in the IEFUJV SMF exit at JOB submission time to check the password on the job. The caller will be identified by an installation parameter in the macro parameter list. When the RACINIT is issued at job initiation, the RACINIT exits will bypass the need for a correct password on the job.

##### (d) Password changes during a session

If the password is changed using the PASSWORD command during a TSO session, the change is not reflected in the TSB (an MVS control block). The SUBMIT command obtains the password for batch jobs from the TSB and thus batch jobs would fail if submitted after the change. This problem has been circumvented at this computing centre by not supplying users with documentation on using the PASSWORD command to change passwords. Passwords are only changed at logon or in a batch job.

#### 8.5 Simplifying the use of RACF

##### (a) Simplified commands

Standard RACF has over twenty rather complicated commands. In this computing centre command procedures (CLISTs) have been designed to simplify the commands which have to be used and reduce their number. Only two commands are needed by most users, and administrators of RACF Groups need to use one or two more. The two main commands define the access available to a data set and display the access available to a data set. Disk, tape and archived data sets are treated identically as far as the user is concerned. Thus the disk data set commands of RACF and the RACF commands for tape resources are amalgamated. As well as this the effect of the RACF PERMIT command is included. The ability to

specifically define a data set to RACF or cause it to revert to the definition of the default implies inclusion of the effect of the RACF ADDSD and DELDSD commands.

The CLISTS execute a specially designed command which issues various macros to search the catalog and the archive catalog for the data set name. The volume and type of the data set are identified. The RACHECK macro is executed to discover the owner of the data set for tape data sets and whether the default profile is to be used. The results of this special command are passed back to the CLISTS.

If a VSAM data set is identified, the cluster, index and data entries are automatically and identically defined to RACF. (VSAM stands for Virtual Storage Access Method).

The CLISTS allow easy revision or display of the default profile, which defines the access available to all data sets not specifically defined to RACF. If the access available to a data set not specifically defined to RACF is requested, the default profile is displayed with an explanation.

The CLIST used to define access to data sets causes various RACF commands to be executed. Some forms of these commands would not be allowed by RACF but for the action of the exits described in Section 6.3.

The command exit authorizes the use of ADDSD and DELDSD commands with the NOSET parameter for any data set to which the user has ALTER authority rather than only to his own data sets. (The NOSET parameter is necessary because disk data set profiles in this computing centre must be created and deleted without affecting the RACF protect flag in the DSCB).

Unfortunately no way has yet been found of overcoming problems in authorizing users to execute commands to alter profiles for tapes. Only the owner or the creator of such profiles may execute the commands as long as the profile indicates that access to the data set is controlled by the default profile. The difficulty in overcoming the problem exists because no exit is entered when a command to alter a tape profile is executed. The problem could be overcome by coding the CLISTS as commands.

#### (b) Error messages

At this computing centre, the TSO command PROFILE WTPMSG has been included in a CLIST executed at every LOGON to cause operator messages to be displayed at time sharing terminals. Normally RACF messages would not be displayed since they are write-to-operator (WTO) messages.

### 8.6 The DD DATA JCL statement

The DD DATA statement creates a security exposure for the passwords of batch jobs read through a card reader (that is, jobs in the form of card decks). This computing centre uses the SMF job validation exit (IEFUJV) to prohibit the use of the DD DATA statement in such jobs, except under special circumstances. However, this has not presented a problem for users.

### 8.7 Creating data sets for other users

The existence of a default profile for each RACF user in this computing centre allows a slight relaxation of the rule that no user may create a data set for another user. The RACDEF exit allows such requests if a user has ALTER access authority in the default profile of the future owner of the data set to be created.

Even without this, the future owner may rename or copy a data set with appropriate authority or pre-allocate a data set to be loaded by the originator of the data.

The relaxation of the data set creation rules has removed the need for establishing large numbers of artificial RACF Groups in this computing centre, thereby reducing administrative and user education requirements.

## 8.8 Data set statistics

The data set statistics maintained by RACF have not been exploited in this computing centre because to find out when a particular user accessed another user's data set the second user would have to notice when the access count was incremented. The SMF record of access is more useful because the time and date and actual level of access are recorded, not just the maximum permitted level.

If part of the reason for producing reports on access to data sets is to monitor the reliable operation of RACF, then it is doubtful whether the RACF SMF records that identify accesses should be used. MVS also can produce SMF records describing data set accesses but these records are not complete for concatenated data sets.

In this computing centre, SMF records for concatenated partitioned data sets are produced by an SMF job validation exit (IEFUJV) which scans the JCL of batch jobs. This means that the records are always produced, whether the data sets are opened or not. Currently records are not produced for dynamically allocated concatenated data sets, although the dynamic allocation validation exit could be used for this purpose. As with the IEFUJV exit, the records would be produced whether the data sets were opened or not.

## 9. EXCEPTIONS IN THE USE OF RACF

There are several users at the Defence Research Centre that have special requirements not consistent with the security philosophy of RACF. Code has been included in various RACF exits to isolate these users from the remainder of the user population, and to restrict the functions they may perform, thereby maintaining the high level of security demanded by the Centre.

### 9.1 External users

Certain users should not be allowed even READ access to data sets owned by other users in spite of such access being granted, for example by setting the universal access (UACC).

This has been achieved by creating a RACF Group, XTN, to which these users are connected. The RACHECK exits have been modified so that when a user connected to this Group attempts access to a data set the access is never allowed unless it is his own or a system data set. The normal access available to system data sets is provided.

### 9.2 Special purpose terminals

A number of terminals are used for particular applications where each individual user is not identified to the system. For instance a terminal may remain permanently logged on although various people use it.

A special RACF Group, NOL, has been created to accommodate applications of this kind. The RACHECK exits prevent access to data sets other than their own and system data sets for users connected to the Group NOL. The RACINIT exits allow logon for the users without entering a password and prevent the execution of batch jobs. RACF terminal protection is defined so that any user may normally access any terminal but users connected to the Group NOL may only access a terminal if

specifically permitted to do so by a RACF definition.

### 9.3 Mini-computer simulating an RJE terminal

A mini-computer is used for engineering design by several workshops and drawing offices. Many terminals are connected to the mini-computer and jobs are submitted to the central computer by the users to transfer data sets between the mini-computer and the central computer. Complete security or privacy is not provided in the mini-computer so that users could find out each others' passwords by inspecting the jobs which are built to be transmitted to the central computer.

Since data security in the mini-computer is incomplete, it is illogical to provide data security between users of the mini-computer for the data stored by them on the central computer. However normal security protection is required for their data relative to other users of the central computer.

The solution which has been evolved is to assign all such data sets to the special user WMD. WMD jobs will not require a password but it will only be possible to submit them from the identifiable mini-computer, not from any other terminal.

The implementation technique involves modifying JES2 to place the reader name in columns 73 to 80 of the job card image of a job (these columns previously contained the JES2 job number). The IEFUJV SMF exit (job validation) checks the terminal name for the userid WMD and cancels the job if it came from the wrong terminal. Appendix IX contains the details of the JES2 modification.

The user WMD is connected to the RACF Group NOL and thus does not require a password on jobs, may only access WMD data sets plus system data sets and is not permitted by RACF to logon at any terminal. The RACINIT exits have been extended to allow batch jobs from the user WMD even though connected to the Group NOL.

### 9.4 Service group processing data for many other users

One section of the Defence Research Centre processes data from trials conducted by many other sections. Various members of the above section need to create and modify data sets for these other users. A large number of processing programs, JCL, and CLISTs is maintained. Previously a number of userids were used to store the programs and submit processing jobs.

The solution has been to give each member of the section a personal userid and to change the userids used to prefix data sets containing programs, JCL or CLISTs into RACF Group identifiers. Personnel responsible for program maintenance are given appropriate access to the various Group data sets.

As well as this, all members of the section are connected to some of the RACF Groups. When data for another section is to be processed, that section will give the necessary level of access to the appropriate RACF Group, thus ensuring that any user connected to the Group will have the ability to process the data. Users connected to the Groups are given READ access to the data sets containing processing programs and procedures.

### 9.5 Special purpose data base enquiry terminal

A dedicated terminal is used to make enquiries into and also update a particular data base (using interactive programs under TSO). The terminal is sometimes unattended and is used by a large number of people who are not registered as users of the central computer.

The solution to this problem is to provide a userid, SUP, which is connected to the RACF group NOL and therefore is not allowed to log on at

a terminal unless specifically permitted, may not submit batch jobs, and does not require a password to log on. The RACHECK exits have been extended to prevent SUP from gaining greater than READ access to any data sets including its own. Access is limited to SUP and system data sets plus the data sets of another RACF Group (ADP). RACF prevents attempts by SUP to log on to any terminal other than the single dedicated one. All updates to the data base are now done by users connected to the ADP Group with the appropriate level of RACF authority.

#### 9.6 Typing pools

Several typing pools exist and their supervisors need to control text data sets which are being created.

A RACF group has been created for each typing pool and each typist has been registered as a computer user and connected to the appropriate Group. The supervisors have been given ALTER access to Group data sets but individual typists may only access data sets which they need to update. The supervisor will allocate any new data set and give the typist concerned UPDATE access to the data set.

#### 9.7 Simulation task with several unidentified users logged on

A section of the Defence Research Centre runs a task which involves several users logged on to TSO who interact with each other and with a model via a number of data sets. The users of the model are not defined as users of the central computer.

The solution is to make either a RACF Group or one of the members of the modelling section the owner of the data sets. The person who supervises the use of the model will own an appropriate number of extra userids which he will use to log on for the users of the model. These extra userids will be given appropriate access to the data sets which they need to access - for example READ access to all the programs and UPDATE access to data sets which are modified. More than one person in the section will need a set of the extra userids because of possible illnesses or vacations.

### 10. STANDARDS THAT SIMPLIFIED THE RACF IMPLEMENTATION

Standards adopted by this computing centre when it first obtained an IBM 370 computer system helped in the implementation of RACF.

#### 10.1 Userids

All userids are three characters long. This standard has been extended to RACF Group identifiers and has helped simplify the coding in the RACF exits.

#### 10.2 Data set names

All non-VSAM data sets are prefixed by the userid or groupid of their owner. This is the naming convention assumed by RACF and therefore avoided the need for complex coding in the RACF exits to simulate it.

VSAM data sets are prefixed by a four character qualifier - the three character userid plus the character 'V' (indicating VSAM). However the RACF exits use only the first three characters of the dataset name to establish the userid of the owner, so these names still appear to conform to the naming conventions. This feature was extended as part of the RACF implementation to allow certain users and Groups to use qualifiers of three or more characters to prefix their dataset names, as long as the first three indicate the userid or groupid. For example, the RACF Group

IMS has data sets with several different prefixes, each representing a different component of the IBM IMS (Information Management System) product. Some of these are IMSVS (IMS system libraries), IMSLOG (log tapes), IMSDICT (IMS Data Dictionary), and so on. Datasets prefixed by any one of these qualifiers which are not specifically defined to RACF are all protected by the default profile that applies to the entire IMS Group.

This feature is particularly useful to RACF Groups, such as IMS, which have a large number of data sets that can be categorized into different areas of responsibility or function, for example. It enables the personnel responsible for these data sets to more easily recognize and therefore maintain them.

The names of the data and index components of a VSAM data set are also governed by a computing centre naming convention. The names must be the same as the cluster name of the associated data set, but with '.DATA' or '.INDEX' appended, respectively. This convention is used by RACF in two places. The first is in the CLIST that modifies the access available to data sets. Whenever a VSAM cluster name is processed the CLIST performs the same action on the data and index components, thereby avoiding the need for separate commands to be issued. Secondly, whenever one of the programs of the archiving scheme processes a VSAM data set through the RACHECK or RACDEF macro, they also perform the same action on its components, thereby ensuring that integrity is maintained.

### 10.3 Jobnames

The names of all batch jobs must be from four to eight characters long, and the first three characters must indicate the userid of the submitter. This information is used by the RACINIT exits to avoid the need for the USER parameter on the JCL JOB statement.

## 11. HISTORY OF THE DESIGN AND TESTING OF THE EXTENSIONS TO RACF

The concepts described in the implementation plan (Appendix I) were developed during August through October 1978.

The RACF exits were designed in November 1978 and three users were defined to RACF for tests. The exits were coded, tested and installed in December, 1978 and thirty users were defined to RACF to allow more extensive tests. However data set protection was not invoked. The design of CLISTS to replace the RACF commands was commenced (Appendix II).

The RACINIT return code and abend code had to be reset in the post-processing exit for batch jobs from users not defined to RACF for which the SUBMIT command generated the USER parameter on the JOB card. Otherwise RACF did not allow the job to execute.

During January and February 1979 disk data set protection was activated for three users and most of the problems in the exits were resolved. The CLISTS were coded and tested and all users were defined to RACF.

In March 1979 disk data set protection was activated for thirty users and tape protection for five users. At this stage care had to be taken that other users were not affected since they had not yet been informed that RACF was being installed - access to data sets had to be provided as required.

Protection for system data sets was activated in April 1979 - appropriate access had to be provided for users.

During May 1979 users were trained and were able to set up access authorities to their data sets in advance of activation of protection. All disk and tape data sets were protected in June 1979 and most problems of access had been resolved in advance.

A minor problem was caused by allowing the commands to be issued in advance. Because the RACF protection was not yet turned on in the DSCBs of data sets belonging to these users, the deletion or renaming of a data set did

not cause the deletion or alteration of the RACF profile of a specifically defined data set. (Obviously no problem existed in the case of a data set not specifically defined). To overcome this, a program was written to check for occurrences of data set profiles in the RACF data set for which no data set existed on disk or in the archives. Exceptions, of which there were few, were repaired manually after consulting the users.

Few problems existed in the extensions to RACF because of the extensive testing which had been done. Also RACF has shown very few bugs and none of these has resulted in a security exposure.

Some peculiar effects were observed due to the way RACF maintains the duplicate data set backing up the primary RACF data set. A code can be set to ensure that all changes to the primary data set are copied to the backup. However, the physical organization of the data sets can change because of differences in timing of different changes while preserving the same logical content. Also the data sets are only enqueued SHARE while updating statistics so that statistics may not be maintained correctly.

## 12. HISTORY OF THE USE OF RACF

Presentations were made to all users in May 1979 to explain the use of RACF. Users were encouraged to set up access authority to their data sets in advance by using the commands provided. This was made possible by the way the commands were designed. A data set access report was presented to each user together with a description of how to use the commands. Each user's access report showed the data sets owned by other users which he had accessed during the previous six months, and the level of access to each. It was then the responsibility of each user to make sure that the owners of the data sets arranged appropriate access authority for him.

Protection was turned on for all disk and tape data sets plus those in the archives in June 1979. Users encountered few problems because most had already set up access authorities to their data sets. No cases have been reported where failure of protection occurred.

The impact on performance has not been measurable even though all data sets are protected. The inconvenience to most users has been minor because of the basic transparency of RACF for a user's own data sets. The uniform treatment of tape, disk and archive data sets and the use of the default profiles have also simplified the use of RACF.

The operational and administrative maintenance of RACF occupies trivial human resources.

## 13. CONCLUSIONS AND RECOMMENDATIONS

RACF would in its standard form satisfy most of the requirements of this computing centre for a software security package. RACF with the extensions and other security measures described in this report fulfills all the requirements. In addition, RACF has caused no system problems and no security exposures have occurred due to the failure of RACF.

We believe that IBM should address the problems in the use of RACF that are described in this report. Three possible improvements which are thought to be most important are summarized below. Disk tracks which are written on by a user and then freed for allocation to other users should be automatically made unreadable until written on again. The method of invoking RACF for controlling access to data sets stored on magnetic tape should be made as similar as possible to the method used for disk data sets. It should be possible, as a standard feature, to use a default RACF profile to control the access to a user's data sets and avoid the need to define a RACF profile for every data set.

## GLOSSARY

access -	used to indicate the use of a resource.
access authority -	the type of access which a user may have to a resource.
archives -	in this computing centre, disk data sets are regularly copied or archived to magnetic tape to provide free disk space. The archived data sets are managed by software which allows them to be retrieved to disk or deleted from the archives.
authorized program -	a program authorized to perform any supervisor function.
audit trail -	record of data set usage.
batch job -	program executed by being scheduled from a queue of jobs which have been submitted at some previous time.
BPP -	bypass password protection - allows a program to access protected data sets without authorization checking.
CLIST -	TSO command procedure - a list of TSO commands which can be executed by entering a single command.
default profile -	in this computing centre access to data sets is controlled by a default profile for each user unless the user defines a specific profile for the data set.
disk data set -	a data file uniquely named (within this computer system) and stored on a direct access storage device (disk). All data sets stored on a disk are directly accessible by the computer system.
DSCB -	record in the VTOC of a disk describing the location of a data set or of free space.
exit -	a computing centre written routine called under defined conditions by a component of the operating system.
GDG -	generation data group - automatic control and labelling of generations of data sets relative to the latest version.
GIS -	query and report generation system.
Group -	RACF facility to allow users to own common data sets.
Groupid -	identifier of the Group data sets.
IMS -	Information Management System - a data base management system.

INOUT -	an OPEN parameter requesting that a data set be opened for input and output.
JCL -	job control language - control statements used to describe the data sets, running options and programs required in a batch job.
JES2 -	job entry system - controls the submission, scheduling of execution, and output of batch jobs.
JFCB -	MVS control block describing the characteristics of an allocated data set and including the data set name.
macro -	an assembler statement expanded by the assembler to include a number of machine instructions in a program.
magnetic tape -	a data set may be stored on a magnetic tape which must be mounted on a tape drive by the operator to use the data.
MVS -	the operating system used in the DRCS computing centre.
OPEN -	the operation performed by the operating system before a data set can be used for input or output.
password -	several alphanumeric characters known only to a user and the system which validates his identity.
profile -	definition to RACF of the level of access available to a resource controlled by RACF.
RACF -	Resource Access Control Facility - software package used to control access to data and to the computer system.
RACF Level -	a RACF parameter available for use by a computing centre to further classify resources.
SMF -	System Measurement Facility - records information about processes occurring in the computer system.
STAIRS -	library information retrieval system.
started task -	program executed by an operator start command.
SUBMIT -	TSO command used to cause batch jobs to be queued for execution.
SVC -	an SVC machine instruction causes an interrupt which is handled by the operating system to give control to the supervisor routine requested in the SVC instruction. SVC routines are the part of the operating system used to perform functions for users.

SYSLOG - system log - a record of operator console messages and commands.

TSO - the time sharing system - supplies editing and program checkout facilities to interactive terminals.

universal access authority - the type of access to a resource which is permitted to all users.

userid - string of alphanumeric characters that uniquely identifies a user.

VSAM - virtual storage access method - the current IBM access method for indexed data sets.

VTOC - volume table of contents of a disk - each disk contains a VTOC which contains DSCB records describing the locations of data sets and free space on the disk.

## APPENDIX I

### PLAN FOR RACF IMPLEMENTATION AT DRCS

This Appendix contains a document prepared in September 1978 as a preliminary specification of the requirements and implementation of RACF at DRCS. Many of the ideas were later refined and modified during the detailed design and development phases of the project, as greater familiarity with RACF was obtained.

The Appendix is included in this report partly as a record of the complete documentation of the project and partly because it is interesting to compare the preliminary design with the final.

#### I.1 Principles in order of priority

- (a) Ensure full IBM support and responsibility for security and integrity.
- (b) Supply an effective level of security and integrity.
- (c) Minimum impact should be caused to users.
- (d) Implementation should be as simple as possible.

#### I.2 Specification of functional requirements

- (a) Disk and tape data sets should appear to be treated identically by RACF (accepting that all data sets on a single tape volume will in effect have the same protection as that given to the last data set specifically protected on that volume). If the tape data sets are not specifically protected then they should have a default level of protection set by the user for all his data sets. Multivolume tape data sets should be protected as for single volume data sets. It should be possible to protect GDG data sets using just the GDG base name. (This is not feasible for tape GDGs).
- (b) All data sets (tape and disk) should be automatically protected by RACF initially at a default level specified by the owner in his default data set protection profile. Any data set can optionally be given its own different protection attributes. The default profile should be easily altered by the user and the protection attributes of any data set which is not specifically protected should follow the change in the default. The default profile for each user should initially be set up to allow no access to his datasets by all other users. Prior to actual protection of the data sets, each user should be given a report showing which data sets owned by other users he has been accessing. It will be up to him to make sure the owner authorizes future accesses to these data sets. GDGs should get the default protection profile if the GDG base is not specifically protected.
- (c) The archiving system should function without a significant increase in restrictions and with an archived data set having the same protection as it would have if it were still on disk. A retrieved data set should have the same protection as it previously had if specifically protected. Otherwise it should change its protection if the default profile has changed. ASCRATCH (deletes an archived data set) should only be possible with appropriate access authority for the data set.

- (d) Job submission from TSO should remain simple except that specification of a user's Group will be necessary if the Group for the job is different from the Group to which he connected during LOGON.

Job submission on cards will require the addition of the PASSWORD and possibly GROUP to the job card unless the default Group is satisfactory.

LOGON will require specification of the GROUP if the user's default Group is not appropriate.

When all the passwords are in the RACF data set instead of the UADS data set, then we may allow user access to UADS only to add account numbers (to remove the need for them to be entered at LOGON).

- (e) Operational maintenance programs should function normally (but it should be possible to subsequently reduce the authorization of each of these systems to the maximum which it requires). Inconsistencies in the RACF data set should not occur due to the activities of operational maintenance programs. In particular bypass password protection would cause the RACF data set not to be updated when programs running with this attribute cause additions, deletions and relocations of data sets.
- (f) FORTRAN may have to be modified to only OPEN INOUT for a data set which is not write protected. OPEN INPUT would have to be used for a data set for which only read access is allowed. (FORTRAN now opens all data sets INOUT which would cause problems with read only data sets).
- (g) The RACF command language reference manual contains descriptions of too many forbidden commands and operands to be suitable for even Group administrators, let alone ordinary users. An edited version of this manual should be produced at DRCS and additional features provided here should also be described in the new manual. The main addition should describe the use of default profiles to gain default protection for all data sets not individually protected.
- (h) IMS data sets should initially be protected against access by other programs and when release 1.1.5 is installed the full protection features should be usable.
- (i) Definition of project oriented groups of users should be done by CS Group. Each of these groups should be able to have a default profile to give data sets default protection attributes just as occurs for individual users. The Group administrator should have CONNECT authority for the Group and should be the only person able to change the access attributes for the default profile. The members of a Group should be given appropriate access authorities to Group data sets by the Group administrator.
- (j) Sufficient backups of the RACF data set should exist so that complete recovery is possible under all eventualities. It is postulated that we will only run without RACF under very unusual circumstances.
- (k) User reports should be generated to list accesses and attempted accesses to data sets.

### I.3 Specification of implementation

#### (a) Users

Each user will be defined to RACF:

```
ADDUSER(userid) NAME(username) PASSWORD(current psswrđ) GRPACC  
ADSP DATA('address and tel.no.')
```

The userid and password will be obtained from UADS and the username, address and telephone number will be obtained from the data set containing names and addresses. The ADDUSER commands will be automatically generated by a CLIST.

PROFILE WTPMSG will be issued for each user in the system LOGON CLIST to cause RACF error messages to be issued to TSO terminals.

Each user will be given a default data set profile:

```
ADDSD 'userid.RACF.MODEL.PROFILE' UACC(NONE) NOSET AUDIT(FAILURES)  
UNIT(DISK) VOLUME(DUMMY)
```

The user may change the profile e.g.

```
ALTDSD 'userid.RACF.MODEL.PROFILE' UACC(ALTER)  
or PERMIT 'userid.RACF.MODEL.PROFILE' ID(XYZ ABC) ACCESS(READ)
```

#### (b) Disk data sets

When an attempted access to a data set occurs the RACHECK pre-processing exit will bypass further checking if the userid is the same as the first level qualifier of the data set name. Otherwise if a disk data set is defined to RACF normal checking will be done. If the disk data set is not defined to RACF, then the RACHECK post-processing exit will substitute the name of the default profile for the data set to be checked and cause RACHECK to be reinvoked. Then the default profile will be used to provide the default access authority for the data set. If a profile for a GDG base exists then it will be used, (caused by the RACHECK pre-processing exit) otherwise the default profile will be used.

The RACF commands ADDSD, ALTDSD, DELDSD, LISTSD may be used directly to create specific protection profiles for individual data sets, modify them, delete them, or list them. The command exit will have to be used to allow the NOSET operand of these commands to be used for group data sets or for other data sets to which ALTER access is available since all data sets will have the RACF DSCB indicator turned on.

The PERMIT command will not work for a data set which is not specifically defined to RACF unless a definition is created by an exit in this case. It is probably unnecessary to do this as a user can easily define the data set to RACF using ADDSD or a CLIST that we might provide to perform the same function which would merge the new attributes and the default attributes.

A CLIST could be created to combine the functions of all the RACF commands and deal with the problems when profiles do not exist for data sets.

The SEARCH command will only list those RACF protected disk data sets which have been specifically defined to RACF. This should be reasonable since only the more sophisticated users will use the SEARCH command.

## NOTE

It has been decided not to use RACF statistics since the SMF type 14 and 15 records are currently produced for the backup system, tape management system, archiving system, and access list reports. It would involve a great deal of work to modify these systems and the equivalent of or better than the RACF statistics are currently produced. However the RACF audit records indicating changes to the RACF data set and unsuccessful access attempts will be produced.

Since statistics are not to be used it does not matter that RACHECK will be bypassed in some cases or that every data set does not have a RACF definition - either of these conditions prevents the recording of statistics.

Ultimately it will be desirable to use RACF audit records instead of SMF type 14 and 15 records since IBM is more likely to support the RACF records properly.

## (c) Tape data sets

The introduction of protection for tape data sets may be delayed until a later stage.

Tape data sets which are not specifically protected will use the default profile for disk data sets.

When a data set on a standard label tape is created the RACHECK post processing exit will determine if a profile already exists for the volume or volumes. If not, the exit will create one for each volume by issuing a RACDEF macro and then place the userid and a one-byte flag in the installation data field. The UACC will allow any access. If a profile already exists for the volume and the userids match, the request will be allowed. If the userids do not match and the flag byte in the user field is set (which means the default profile should be used), then the check will be repeated against the default data set profile.

The checks performed for a read access are the same as those for a write access when the profile already exists.

Thus a tape data set will use the disk data set default access authority if no specific access authority has been defined for the tape.

The CLIST mentioned above in (b) will also execute RALTER and PERMIT commands for tape volumes where the user specifies the data set name. A catalog search will provide the CLIST with the volume serial number and the flag in the installation data will be set by the CLIST to indicate whether or not the default profile is to be used.

Specific protection of a GDG base where the data sets are on tape will not be possible. Either the default profile will have to be used or each generation will have to be specifically protected.

Note that since there is never a RACF definition for a tape data set but only for a tape volume, each data set on a tape (if there is more than one) will have the same access authority, namely that last defined. This is consistent with the fact that access to all of a tape is possible once access to one data set on the tape has been achieved.

When all the datasets on a tape have been deleted it will be erased and returned to the scratch pool for reuse, as now. The erase program will be authorized and will delete the profile associated with the tape volume.

## (d) Archiving

All archive tape volumes will be RACF protected with universal

access authority of NONE and owner OPS. When a data set with a specific definition in the RACF data set is archived, the archiving program will modify the volume serial number in the definition to ARCHIV. The reverse will happen on retrieval. If a data set is backed up, a duplicate definition will be created with ARCHIV as the volume serial. Reload will operate in a similar manner.

If a data set is scratched from the archives, then a specific definition for volume ARCHIV in the RACF data set will be deleted. The archiving software will be privileged and thus will bypass the protection of the RACF tapes and the normal checks performed for protected data sets. Each program will therefore have to perform its own authorization checking to ensure that the user is permitted to perform the requested function on the data sets. The user will need ALTER authority for any deletion, which includes ASCRATCH, ARENAME, as well as when another version of a data set must first be deleted in order to carry out a RETRIEVE, RELOAD, ARCHIVE or BACKUP request. These four commands will also require READ authority for the version of the data set they are to transfer between the archives and disk. The EXPIRY and MIGRATE commands will require no authorization.

(e) Batch job validation

The RACINIT exit will get the userid from the first 3 characters of the jobname so that the USER field on the job card will be unnecessary. The PASSWORD will have to be added to all job cards but TSO submit will add this to submitted jobs. RACF will use the default Group of a user if GROUP is not specified. TSO submit will add the logon GROUP to a job card. The logon GROUP will be the user's default Group if unspecified.

The command package will add PASSWORD, USER and GROUP to jobs with no job card. We may need to modify our SUBMIT exit to do this for jobs which have a job card included.

(f) TSO LOGON

The logon will be the same as now except for the addition of GROUP if other than the user's default Group is required, and the requirement to change the password at intervals. The maximum interval between password changes will be set at 90 days.

Since logon passwords will be in the RACF data set, the UADS data set will no longer be important for system security. Thus it may be possible to allow users access to the UADS data set to insert accounting information, thus avoiding the need to enter it at every logon. Simple CLISTS could be provided to add, change and delete accounting information. It would be a good idea to remove information on the ACCOUNT command from HELP so that users would not be able to find out how to modify other aspects of their user attributes.

(g) Operational maintenance programs

The started task which is used to submit maintenance programs to the internal reader will not need a password, and does not normally have access to any password. However the submitted jobs must have passwords on their job cards so that some way must be found to get the password for a userid out of the RACF data set. Of course this could only be done by a job with authorization to read the RACF data set.

An alternative might be to mark such submitted jobs in a way

which would allow the RACINIT exit to recognize that there was no need for a password. Such a method could be a security loophole since any user who knew the technique could submit jobs without supplying the correct password and thus gain access to any part of the system without detection.

Another method which is both practical and secure would be to only allow logon or job start for users who have higher than the normal authorization if confirmed by the operator. Thus a password for such jobs would not be required.

Another solution would be to store the OPS password in a protected data set and automatically and randomly change it every day at IPL. OPS tasks would be able to read it from the data set to submit other jobs.

Assuming that the above problem can be resolved, either by implementing one of the suggested solutions or inventing a better one, it is proposed that initially the userids of the submitted maintenance programs be given the highest authorization possible to ensure that they work. Later the authorization will be reduced to the maximum required. If bypass password protection is required the program concerned will have to update the RACF data set appropriately since this will also be bypassed.

Some maintenance programs, running as batch jobs, also generate and submit other jobs to the internal reader. Batch jobs therefore also need a means to determine their own password dynamically so they can insert it on the generated job cards. One solution would be to provide a routine which a program could call and which would return the password and userid of the caller. During RACINIT processing the password could be stored in the user's address space for later reference by the routine. There is no reason why such a routine could not be made generally available to all users.

It is proposed that password protection and not RACF protection be retained for SYS1.OPSAUTH (the library containing authorized and privileged utilities) since the operator should continue to be involved whenever this data set is accessed.

In the future, this case, and the expiry date protection mechanism which requires operator authorization for modifications, could be simulated by additions to a RACHECK exit. Any attempted modification to a SYS1 data set or read access to OPSAUTH could require an operator reply to authorize the access. The user would also need to be authorized within RACF to access such a data set. It is not intended to implement this proposal initially.

The cleanup program should list the names of any data sets which are not RACF protected (the DSCB indicator is off).

It is possible for any user to prevent access by specific other users e.g. operations. This would be a nuisance but the most sensible way to overcome it should be by administrative methods if it ever occurs.

A CSECT has to be built with the names of all the started procedures.

#### (h) Operational precautions

The use of BLP (bypass label processing) for tape will have to be carefully controlled, as it is now.

The use of DD DATA in a job read from a card reader presents an exposure as a user might gain access to all jobs following his on the reader if he omits the end of file delimiter. The IEFUJV exit will have to be modified to convert DD DATA to DD \*. This will prevent any subsequent jobs from being destroyed as well as prevent a privacy exposure.

A data security exposure exists now because anybody can delete a data set catalog entry even if the data set is password protected. With RACF it is possible to protect the catalogs (with UACC of UPDATE) and RACF prevents users from manipulating, changing, or creating catalog entries for which they do not have ALTER authority. This is not documented in any RACF manual.

(i) FORTRAN

Most users will probably require default protection of READ but no WRITE. This allows other users to read their data sets. FORTRAN always opens a data set for INOUT, even when only input is to be performed. This would cause an access failure to a WRITE protected data set. The users can solve the problem by specifying input only on DD statements or in ALLOC-ATTR but this is rather cumbersome. It is proposed that the FORTRAN OPEN routine be modified to only open INOUT when there is no write protection. Otherwise it would open for input only. The RACHECK macro would be used to check the access authority. IBM are investigating whether this has been done elsewhere. For tape data sets the check will have to be performed against the tape volume on which the dataset resides.

(j) IMS

All data bases will be RACF protected against use by other than their owners and the normal IMS programs which support the use of the data bases. Full security will be attained with the installation of IMS release 1.1.5.

(k) Existing data sets

Existing data sets, tape, disk and archived, will initially be given the default access authority of their owners' default profiles which allow no access by any users. Users will be able to modify the access available to their data sets before the date on which they will become protected.

(l) RACF Groups

The exits will treat Group disk or tape data sets just as they do individual data sets i.e. each Group will have a default profile data set and a Group data set will acquire the attributes of the default data set if not defined explicitly to RACF. Normally only the Group administrator will be able to change the characteristics of the default data set. (Note that it is not possible to logon with a Group name as a userid).

User Groups will be added using the command:

ADDGROUP (group name) SUPGROUP(CSGROUP) OWNER(OPS)

A Group administrator will be appointed by the commands:

ALTUSER userid GROUP(group name) AUTHORITY(CONNECT)  
ALTUSER userid DFLTGRP(group name)

Group administrators will add and delete members of groups:

CONNECT userid GROUP(groupname) AUTHORITY((CREATE)) GRPACC ADSP  
((USE ))

REMOVE userid GROUP(groupname) OWNER(userid)

(m) RACF data set recovery

It is possible to maintain a duplicate RACF data set so that a hardware failure allows processing to continue without interruption. However, a logical failure would presumably affect both data sets similarly and an alternate form of recovery would be necessary. It is proposed that the RACF data sets be backed up every night using the normal backup system. It seems that activity on the secondary RACF data set should be low since only changes need to be recorded and most data sets will not have an entry in the RACF data set. The primary RACF data set will be much more active since a search for an entry will be necessary for each data set accessed which does not belong to the user performing the access.

A sample RACHECK exit to allow access to protected data sets with RACF inactive has been obtained. This will be installed so that it can be optionally included with MLPA in an IPL to allow recovery procedures on RACF data sets with RACF inactive.

(n) User data set access reports

A report of accesses to data sets will continue to be generated from SMF record types 14, 15, 17, 18 and so on. The RACF audit records describing unsuccessful accesses will be added to the access reports.

(o) RACF options

The RACF system wide options will be specified by the SETROPTS command:

```
SETROPTS CLASSACT(TAPEVOL) TAPE DASD NOTERMINAL INTERVAL (90)
        NOSTATISTICS(*) NOINITSTATS AUDIT(*) SAUDIT CMDVIOL LIST
```

giving tape and disk volume protection, no terminal checking, a maximum of 90 days between user password changes, no RACF statistics, AUDIT SMF records of all changes to the RACF data set, and a list of command failures due to inadequate authority.

(p) Creating data sets on behalf of other users

The procedure will be to create a user or Group data set in the creator's userid or Group and then authorize the new owner of the data set to access the data set, e.g. to copy it he will need READ authority or to rename it he would need ALTER authority.

In reloading an unloaded data set from a distribution tape, it will be necessary in some cases to use the RENAME parameter of IEHMOVE to change the data set name to one's own dataset.

(q) Error message

The IEFU83 exit can supplement the 913 abend code with a TPUT message. This may be more acceptable than changing all the user profiles to get WTP messages. A sample exit has been obtained.

#### I.4 RACF installation program

October	install RACF design the implementation write exits, programs and CLISTs define the education required write the documentation define the operational policy
November	test the implementation educate the operators who will administer RACF define all users as inactive RACF users
December	test the implementation on CS Group educate duty programmers and the groups to be involved in the January tests
January	test the implementation on two other DRCS groups educate all users
February	introduce RACF for all users
March	introduce tape data set protection if delayed

## APPENDIX II

COMPUTER BULLETIN NO. 122  
NEW SECURITY AND PRIVACY FACILITIES (RACF)

This Appendix contains the DRCS Computer Bulletin sent to users to introduce RACF and related security measures. Included are descriptions of the TSO CLISTs SHARE (to define access to a data set) and LISTP (to list access to a data set).

## II.1 Introduction and background

A new facility has been added to the IBM 370 computer operating system software which provides a much more powerful means of controlling access to data stored on the computer. It is known as RACF (Resource Access Control Facility) and is a fully supported IBM product. As more users and particularly as terminals from other laboratories and establishments are connected to the 370 system it becomes increasingly important to employ rigorous but flexible security techniques.

The new facility is very different from the existing arrangements and every effort has been made by Computing Services Group to minimise the number of commands that need to be understood and used. In fact, if you only wish to access your own datasets no change is involved. It is however important that you read at least the first 3 sections of this bulletin.

Until now all data sets were accessible to every user unless they had been individually password protected. Under the RACF system access to every data set is confined to its owner unless arrangements are made otherwise. The existing facility of password protection for individual data sets will be removed, since RACF provides equivalent function.

Since many users share data sets, it will be necessary to establish sharing arrangements before RACF is brought into effect. TSO commands have been provided to make this simple and users who access data sets belonging to others will be provided with a list of the data sets they have accessed during the last six months.

The system has been designed so that access to disk, tape and archived data sets will be controlled in the same way. Only the standard range of labelled magnetic tapes which are stored in the computer centre will be protected.

The security of all data sets under RACF depends on each user being positively identified when he logs on to the system. Therefore, logon passwords will be classified SECRET. The practice of sharing userids and passwords will not be allowed. If you have any suspicion that your password is known to others it must be changed immediately. It is now possible for you to change your own logon password easily at any time and in any case, to ensure its secrecy, you will have to change it every 3 months. To maintain a satisfactory level of security, a terminal at which you are logged on must not be left unattended.

In addition to the protection of data sets by RACF, a facility to print security classifications on job output has been provided. This facility is described in Section 6. The distribution of classified output is discussed in Section 7.

## II.2 Implementation of RACF

The implementation has been planned to provide total protection for all data sets while causing the minimum of disruption. Protection for all your data sets will commence on 11/6/79, and this level of protection will prevent any shared access (either read or write) to your data sets unless you have previously taken action. The action must take the form of issuing commands to RACF declaring which data sets are to be

shared with which users. The commands to set up access authorities to your data sets can be issued from 1/5/79, so that when protection is introduced no disruption will be caused to other users who need to access your data sets.

Your data sets can be shared in two ways. First, all your data sets can be shared with specified users (see example (c) below). Second, an individual data set can be shared with as many users as you like (see examples (a) and (b) below). If an individual data set is not specifically defined to be shared in this way then it is shared according to a default (for example as defined in example (c)). A default list of users to share data sets should be adequate for the majority of data sets owned by most users. We recommend that you attempt to create a default list of users to share all your data sets since this is simple and easy to maintain. The ways in which your data can be accessed can be displayed by a command (see examples (e) and (f) below).

Some examples of commands to give various levels of access are described below and a more comprehensive description is given in Section 5.

- (a) to allow all users READ access to one of your data sets (READ access allows a data set to be input, copied or listed but not updated or deleted):

```
SHARE dsn UACC(READ)
```

(the data set name must include the type - for example .CNTL)

- (b) to allow several users update access to one of your data sets (UPDATE access allows a data set to be written or updated but not deleted. UPDATE includes READ access - READ access is defined in (a) above):

```
SHARE dsn ID('userid1 userid2 ....') ACCESS(UPDATE)
```

(the data set name must include the type - for example .FORT)

- (c) to allow several specific users a default access authority of ALTER to all of your data sets except those which are defined specifically by the SHARE command as in (a), (b) and (d). (ALTER access allows a data set to be read, updated and deleted. ALTER access includes UPDATE access and READ access):

```
SHARE * ID('userid1 userid2 ....') ACCESS(ALTER)
```

- (d) to allow several users READ access to one of your datasets:

```
SHARE dsn ID('userid1 userid2 ....') ACCESS(READ)
```

- (e) to display the default access available to all datasets not defined specifically as in (d):

```
LISTP *
```

- (f) to display the access available to a specific data set:

```
LISTP dsn
```

To ensure that appropriate access to data sets is available, a list of the data sets owned by other users which you have accessed during the past 6 months is attached. It will be necessary for you to approach

these users so that they may arrange access to their data sets.

### II.3 Consequences of the installation of RACF

The rigorous application by RACF of the principle of only sharing data with authorized users will conflict with procedures that were previously legitimate. Also some features of the implementation of RACF need explanation even though great efforts have been made to design it in a consistent manner. Some consequences of the implementation of RACF are described in the following paragraphs.

#### (i) Archiving

RACF will prevent you from retrieving another user's data set from the archives unless you have READ authority to that data set. Other commands of the archiving system require ALTER authority.

#### (ii) Creating data sets for other users

To create a data set for another user, the data set is given a prefix equal to that other user's userid. For tape data sets, this is readily done, but should be followed by a SHARE dsn OWNER(userid) command to make the other user the owner of the data set. For disk data sets, you will need to be on the other user's default access list with ALTER authority. Alternatively, the other user can make a copy of your data set (for which he will need READ authority).

CLISTS should be checked to ensure that they do not use &SYSPREF as the prefix of any data set which they create. JCL should also be examined to ensure that data sets for other users are not created.

RACF does allow for the definition of Group data sets. This may be of interest to some groups of users - for example those associated with a project or task. All users connected to a RACF Group are allowed to create Group data sets and access the data sets. The groupid is the prefix of Group data sets but it is not a userid so it is not possible to logon with the groupid.

#### (iii) FORTRAN I/O

FORTRAN programs open all data sets FOR INPUT and OUTPUT so that a FORTRAN program which merely READs a data set normally requires UPDATE access authority to that data set. If the data set is yours, there is no problem, but if you have only READ access to another user's data set you will have to use the IN parameter of the FILE command or the IN subparameter of the LABEL parameter on a JCL DD statement. The IN parameter causes the data set to be opened for INPUT only so if a WRITE is attempted it will fail with an I/O error.

#### (iv) Batch jobs

All batch jobs will require your logon password on the JOB card but the SUBMIT command will add this automatically to jobs submitted from TSO. If the jobname contains another userid, SUBMIT will change it to your userid instead of rejecting the job as it does currently.

Card jobs will require the logon password on the JOB card in the format:

.....,PASSWORD=password

The password must be coded on a continuation card of the JOB card with printing suppressed. All card decks should be treated as if classified SECRET, since the security of all data sets will depend on the security of the logon password. To ensure the privacy of the password and to avoid accidental disclosure, the card containing the password will be destroyed by the operator as soon as a job has been read in at the central computer. A new card will have to be punched and inserted every time the job is submitted. The password will be printed as XXXXXXXX on the job printout so that the listing need not be protected.

(v) Password changes

Your password will have to be changed regularly, but this is very easy to do. If you wish to change your password at any time it may be changed at LOGON to TSO or in a batch job (see below). At LOGON, enter:

oldpassword/newpassword

when prompted for the password.

If you have not changed it often enough, TSO will prompt you to enter the new password. The sequence of prompting is given here:

```
logon userid acct(nnnnnn/nnn)
ENTER CURRENT PASSWORD FOR USERID
old password
CURRENT PASSWORD HAS EXPIRED AND NO NEW PASSWORD ENTERED
REENTER
new password
```

If your first activity on the day the password needs changing is to submit a batch job on cards then the job will be rejected because the password needs to be changed. The job can be resubmitted with the old and new passwords in the format:

.....,PASSWORD=(oldpassword,newpassword)

If a job is not run on the day it is submitted (for example there is too much work) and the password is due to be changed on the next day then the job will fail because the password is no longer current. The job will need to be resubmitted.

(vi) GDG data sets

Disk generation data group (GDG) data sets may not be given different levels of access for different generations. All generations will have the same default level of protection as all other disk data sets which are not defined individually to RACF. On the other hand the GDG collection of data sets may be protected differently from the default by protecting the GDG base name. Note that if the GDG base is deleted the definition to RACF will not be automatically deleted and must be deleted using the command:

## SHARE gdgbase DEFAULT GDG

GDG data sets stored on tape must either be defined to RACF for each generation using the full data set name (name.GnnnnVnn) or will be protected according to the user's default for all data sets not defined specifically to RACF.

## (vii) DD DATA statement

The JCL statement DD DATA causes a security exposure, and therefore its use will, with the introduction of RACF, be prohibited. The DD DATA statement was used to process JCL statements as an instream data set. Therefore if you wish to enter JCL into a data set it will now have to be entered at a terminal by you or by the punch room staff.

## (viii) Magnetic tape data sets

RACF protection of tape data sets is by tape volume so that different levels of access cannot be defined for multiple data sets on a single volume. All data sets on a volume are protected identically so that a definition to RACF of an access authority to any data set on a volume applies to all the data sets on the volume. Only the standard range of labelled tapes which are stored in the computer centre will be protected.

## (ix) Partitioned data sets

The members of a partitioned data set cannot be given different access authorities since only the partitioned data set can be defined to RACF - not the members.

## (x) Creation of sensitive data

Since a data set, when first created, is protected by the default access list defined by you, it may be necessary (for sensitive data) to preallocate a data set and specifically define no access to it before loading data into the data set.

## (vi) Data set access reports

Every fortnight, a report is distributed to you showing which users accessed your data sets. The report shows the level of access, for example READ or UPDATE, and the number of times it occurred. After RACF becomes active, you should regularly check this report to make sure that accesses are consistent with your definition to RACF of how your datasets are to be shared with other users.

The content of the data set access report will be enhanced with a list of users who tried to access your data sets and failed because of RACF protection. In cases where this is not simply because of your omission to provide appropriate access to your data sets, you may wish to investigate why such an attempt was made. You can find out another user's name and address with the TSO command:

USER userid

## II.4 Submitting batch jobs to the internal reader from a batch job

A small number of users have programs which submit jobs to the internal reader. The following subroutine and utility program assist in creating a job to be submitted to the internal reader by supplying the user's own password (needed for the JOB card of the submitted job).

### (i) Subroutine PASSWRD

This subroutine may be called from a PL/I program to return a user's own password.

Calling sequence

```
DCL    PASSWRD ENTRY OPTIONS (ASM, INTER);
DCL    USERID CHAR(3),
        PASSWORD CHAR(8),
        LENGTH BINARY FIXED(31);
CALL    PASSWRD (USERID, PASSWORD, LENGTH);
```

The user's userid, password and the number of characters in the password are obtained.

### (ii) Program OPSEEDIT

This program is a replacement for IEBEDIT for submitting jobs through the internal reader. It finds any JOB cards in the input stream and adds the user's PASSWORD to them.

The JCL required is exactly the same as that required for the IBM utility IEBEDIT (see the OS/VS Utilities Manual, GC35-0005).

## II.5 TSO commands for RACF

A user will control the access to his data sets by a default access list or by specifically defining to RACF which users may access an individual data set. Access to each data set on disk or tape will be controlled by the default access list when the data set is created. The user may modify the default access list or define the level of access to a specific data set by a TSO command.

The level of access available to any data set which may be defined specifically to RACF (differently from the default), consists of a universal access authority (UACC) and a list of specific users who are permitted access different from the UACC. The levels of access which can be defined are:

NONE - the user may not access the data set either to read, update or delete.

READ - the user may read or inspect the data set but not update or delete it.

UPDATE - the user may read or update the data set but not delete it.

CONTROL - equivalent to the VSAM control password.

ALTER - the user may gain any access to the data set (read, update or delete).

A default list of users and corresponding access authorities may be defined. Any user not on this list will have a default access authority of NONE to any data sets not defined specifically to RACF. This is

equivalent to saying that the default universal access authority (UACC) is NONE.

When any data set is deleted, a specific definition to RACF of the level of access to the data set is also deleted. The definition will not automatically carry over to a data set of the same name that might subsequently be created.

A user not wishing to use TSO at a terminal may execute TSO commands in a batch job to authorize sharing of his data sets. See Computer Bulletin No. 100 for a description of how to execute TSO commands in a batch job.

## SHARE command

The SHARE command is used to alter the access authority of all users or specific users to datasets or to provide a default access authority for datasets not defined specifically using the SHARE command. Most of the parameters of the SHARE command can be abbreviated.

---

```
SHARE {dsn | * } [DEFAULT] [UACC(uacc)]
SH
[ID(userid) {ACCESS(access)|DELETE}] [GDG]
[FROM(dsn2)|FROMDEFAULT] [OWNER(userid)] [ARCHIVE]
[REPEAT]
```

---

- dsn - data set for which protection is to be altered. The data set name must include the type qualifier - for example .FORT etc. (for VSAM data sets, the cluster, index and data components are dealt with automatically and identically - the dsn must be the cluster name).
- \* - alter default protection for all your data sets for which SHARE is not used to protect specifically. The parameter UACC is not permitted in conjunction with this parameter.
- DEFAULT - remove specific protection from the data set - it will be protected according to your default.
- UACC(uacc) - access authority to the data set for all users not specifically identified using the ID parameter. See the list of possible access authorities defined below. The UACC parameter is not allowed with dsn=\* (the default).
- ID(userid) - a user to be given a different access authority from the universal access authority (UACC). (A list of userids may be entered in quotes). The ACCESS or DELETE parameter must be used with the ID parameter.
- ACCESS(access) - access authority for the user defined in the ID parameter. See the list of possible access authorities defined below. (If the ID parameter is omitted then the ACCESS parameter is changed to UACC by the SHARE command).
- DELETE - the user defined by the ID parameter is to be removed from the list of users with specifically defined access authorities.
- GDG - the dsn is a disk generation data computing centre base name.
- FROM(dsn2) - copy the access list of users and authorities defined

specifically for dsn2 into the access list for the data set. Note that the UACC defined for dsn2 is not copied so that the UACC for the dataset will be NONE unless it is explicitly specified.

- FROMDEFAULT - copy your default access list of users and authorities into the access list for the data set. Note that the UACC defaults to NONE unless explicitly specified and also note that if you are protecting another users data set, it is his default access list which is copied, not yours.
- OWNER(ownerid) - change the owner of the data set (only relevant for a Group data set). The owner of a data set is normally the creator.
- ARCHIVE - the data set is in the archives (only necessary if another data set with the same name exists either on disk or tape).
- REPEAT - if this parameter is specified the command will prompt for further data set names and add identical protection for each after they are entered.

Access authorities:-

- NONE - no access allowed
- READ - only read access
- UPDATE - the data set may be updated but not deleted and the SHARE command may not be used.
- CONTROL - the same as UPDATE for non-VSAM data sets - equivalent to VSAM CONTROL password for VSAM data sets.
- ALTER - all forms of access permitted, including the use of the SHARE command.

## LISTP command

The LISTP command is used to display the access authority of other users to datasets. Most of the parameters of the LISTP command may be abbreviated.

---

```
LISTP {dsn | * | (DISK) | (ALL)} [ID(prefix)]  
LP
```

```
[PREFIX(prefix)] [ARCHIVE] [GDG]
```

---

- dsn - defines the data set whose protection attributes are to be listed. The data set name must include the type qualifier - for example .FORT.
- \* - the default protection attributes to be used for all data sets not specifically defined using the SHARE command are listed.
- (DISK) - the protection attributes of all specifically protected disk data sets are to be listed. Tape data sets and data sets with the default protection are omitted. The command executes much faster with this option than with (ALL) - see below.
- (ALL) - the protection attributes of all specifically protected data sets are to be listed. Data sets with the default protection are omitted. The LISTP command is very slow for this option.
- ID(prefix) - the protection attributes of specifically protected data sets to which you have access and which begin with the indicated prefix are listed. The prefix may include the userid plus one or more qualifiers of the data set names to be selected.
- PREFIX(prefix)
- ARCHIVE - indicates that the data set specified is in the archives. This is unnecessary unless a data set of the same name also exists on disk or tape.
- GDG - the dsn is a disk generation data group base name.

An example of the output of the LISTP command follows:

```
listp name.text
INFORMATION FOR DATASET XYZ.NAME.TEXT

LEVEL  OWNER   AUDITING  UNIVERSAL ACCESS
-----
   00    XYZ    FAILURES      NONE

YOUR ACCESS  CREATION GROUP  DATASET TYPE
-----
NONE GIVEN      DRCS          NON-VSAM

VOLUMES ON WHICH DATASET RESIDES  UNIT
-----
STOREA                                DISK

  USER   ACCESS  ACCESS COUNT
-----
ABC      ALTER   00000
QRS      READ    00000
```

Universal Access is equivalent to UACC in the SHARE command and indicates the access authority which all users have except those in the access list. The access list appears last and contains specific userids and access authorities. This list corresponds to the ID and ACCESS parameters of the SHARE command.

#### LISTUSER Command

---

LISTUSER

---

The details of your RACF user profile are listed.

#### PASSWORD Command

---

PASSWORD [INTERVAL(change interval)]

---

The command can be used to alter the maximum interval allowed between password changes. The interval between password changes may not be increased to a period greater than the computing centre standard which is currently 90 days.

## II.6 Printing the security classification on listings

A facility now exists on the IBM 370 computer system for automatically printing the security level of classified computer printouts at the top and bottom of each page.

The security level can be selected individually for each output dataset produced by a job, and is indicated by the choice of output class for the printout. No other action is necessary. The three new output classes available are R for Restricted output, C for Confidential and S for Secret. All other classes are assumed to be unclassified, unless the user produces his own security messages.

In most respects classes C, R and S are treated the same as class A output. However, several lines per page are required for the security messages when using these three classes, leaving users with a maximum of 60 lines per page for their own output. Other output classes allow up to 66 lines per page (see TM 1662(AP)).

Users should be aware that the security classification messages are not incorporated into the output until it is selected for printing on a local or remote printer. Therefore, if the TSO OUTPUT command is used to scan the output at a TSO terminal prior to printing, the messages will not be present.

Several examples of using the new output classes follow.

- (a) Userid ABC requires a batch job to compile and execute a FORTRAN program and produce printed results on logical unit 6. These results are restricted, but all other output produced by the job is unclassified. The job will be submitted from TSO and the results are to be held for scanning on TSO prior to printing. The JCL could be -

```
//ABCJOB JOB , ,CLASS=X,MSGCLASS=A
// EXEC FTG1CG
//FORT.SYSIN DD *
      FORTRAN program
//GO.FT06F001 DD SYSOUT=R,HOLD=YES
```

- (b) A user runs a FORTRAN program interactively from TSO, and the job produces printed output that is confidential and is to be sent to remote printer RMT14.

The TSO commands to allocate FORTRAN logical unit 6 could be -

```
ALLOCATE FILE(FT06F001) SYSOUT(C) DEST(RMT14)
or
FILE FI(6) PRINT(C) DEST(RMT14)
```

- (c) Userid ABC has a dataset named ABC.SECRET.DATA that contains data classified as Secret. He wishes to use the TSO PRINTOFF command to obtain a listing of the dataset at the central printer. The command could be -

```
PRINTOFF SECRET.DATA CLASS(S)
```

## II.7 Distribution of classified output

Distribution of classified output from the Computing Office will be controlled.

A log of classified jobs will be kept in the Computing Office and anyone collecting the output will have to sign for it. If someone other than the owner wishes to collect the output, they will need written authorisation which they can present to the Computing Office, e.g.

"I authorise A. Brown to collect 6 jobs CXDA - CXDF submitted  
at 11 a.m. on 27/4/79.

C. Dale"

The listed job names plus date and time must give sufficient

information to allow Computing Office staff to identify the output. The authorisation must be signed either by the owner or by the head of the section. The collector will be asked to sign for the output and should display his DRCS pass as identification.

Classified output directed to a remote terminal is the responsibility of the user creating it.

Unclassified output is not affected by the new arrangements.

## APPENDIX III

## INSTRUCTIONS ON THE MANAGEMENT OF RACF GROUPS

This Appendix contains a document distributed to administrators of RACF Groups at DRCS.

## III.1 Defining the group

When a RACF group is established one user must accept responsibility for its administration. This user must approach L. Binns or G. Owen of the Operations Section of CS Group to define the necessary RACF environment. The definition includes the following functions :-

- (a) creation of the group, with a mutually agreed three character name,
- (b) creation of an initial RACF default profile for the group's datasets that are not specifically protected. This profile will include UACC(NONE), which cannot be altered, and will nominate the administrator as its owner,
- (c) connection of the administrator to the group with CONNECT authority, which allows him to connect other users to the group.

## III.2 Connecting users to the group

A user does not have to be a member of a group in order to access or create datasets belonging to that group (i.e. datasets having the group name as their first level qualifier). These functions are controlled solely by the access authorities granted in the group's default profile and those of any specifically protected datasets. The only advantage in being connected to a group is that it may be necessary in order to access certain datasets. This is because the access lists in dataset and default profiles may include group names as well as userids. Either may be specified in the ID parameter of the SHARE command. If a group name is included then any user executing under control of that group is granted access to the dataset, without the need for his userid also being in the list.

Before a user can gain access to a group he must first be connected to it by the administrator. The format of the command to do this is -

CONNECT userid GROUP(group-name) AUTHORITY(group-authority)

The group authority defines what functions the user may perform in the group and must be USE or CONNECT:

## (a) USE

A user with this authority can access group datasets. The level of access available is that granted to the user in the RACF profile of a specifically protected dataset or in the group's default profile for one not so protected. The level may be NONE, READ, UPDATE or ALTER, which also allows creation when specified in the default profile. As already mentioned, these functions are also available to users who are not members of the group. The extra privilege granted to group members is that they can access datasets to which the group itself is authorized, under the circumstances described in Section 4.

(b) CONNECT

This authority is the highest available and is normally assigned only to the group administrator. It includes the functions of USE and in addition allows the holder to connect other users to the group and remove them from it. CONNECT authority could be assigned temporarily to another group member while the administrator is on leave, for instance, and revoked on his return.

For example, to connect user ABC to group XYZ with USE authority the command would be -

CONNECT ABC GROUP(XYZ) AUTHORITY(USE)

III.3 Altering the group activity

The administrator may alter the group authority (USE or CONNECT) of a user already connected to a group by simply re-issuing the CONNECT command.

III.4 Gaining access to the group

Under RACF each user must be connected to one or more groups, one of which must be designated his default group. In our group all users are in fact connected to the group DRCS, which is also the default, when they are initially defined to RACF. Being connected to a group does not automatically grant the user authority to datasets that mention the group name in their access lists. The user must also be executing under control of that group. All TSO sessions and batch jobs initiated by a user execute under his default group unless another group to which he is connected is specified in the GROUP parameter of the TSO LOGON command or the GROUP parameter of the JCL JOB statement. For example, for userid ABC to logon to group XYZ (not his default), the command would be -

LOGON ABC GROUP(XYZ) ACCT(123456/789)

This technique is obviously inconvenient for a user who normally wishes to access a group other than DRCS (the standard default group). Accordingly a TSO command is provided for any user to change his own default group, provided he has already been connected to the group. The format of the command is

DEFGROUP group-name

For example, to change the default group to XYZ the command would be -

DEFGROUP XYZ

The output from the LISTUSER COMMAND (see Computer Bulletin 122) indicates a user's current default group.

### III.5 The group's default profile

When a group is first established the administrator is nominated as the owner of the default profile. He must assign ALTER access authority to all users who are permitted to create group datasets. The administrator and any other user with ALTER authority is then permitted to change the default profile as required. The sequence of commands necessary to achieve a change to the group's default is -

```
PROFILE PREFIX(group-name)
SHARE * other parameters
PROFILE PREFIX(userid)
```

The access list for the default may include group names (including the default's group), userids connected to the group and even userids not in the group. For example, suppose user ABC is the administrator of group XYZ and that all members of the group require ALTER authority in the default profile. In addition user LMN, not a group member, requires READ authority. The commands to achieve this could be -

```
PROFILE PREFIX(XYZ)
SHARE * ID(XYZ) ACCESS(ALTER)
SHARE * ID(LMN) ACCESS(READ)
PROFILE PREFIX(ABC)
```

This example illustrates that the group name, or alternatively the individual userids of the group members, must be mentioned in the group's default profile and the profiles of specifically protected datasets (see below). Access authorities to group datasets must be implicitly stated, even for group members. There is no feature similar to the explicit ALTER authority granted to each user over his own datasets.

### III.6 Specifically protected group datasets

When all group datasets are initially created they are protected by the group's default profile. Any user with ALTER access authority in the default may specifically protect a group dataset, and that user becomes its owner. The specific protection may be changed or even deleted by the dataset owner or by any other user who currently has ALTER access authority to the dataset.

### III.7 Listing users connected to the group

The group administrator may obtain a list of the userids connected to the group using the command -

```
LISTGRP group-name
```

### III.8 Removing users from the group

The group administrator may also remove, or disconnect, users from a group when they no longer have a requirement to be associated with it. The format of the command is -

```
REMOVE userid1 GROUP(group-name) OWNER(userid2)
```

The OWNER parameter identifies another member of the group (userid2) who is to be assigned ownership of all specifically protected group datasets still owned by the user being removed (userid1). This parameter is not required if no such group datasets exist.

Note that the owner of each specifically protected group dataset is indicated in the output of the LISTP command and can also be changed by the current owner using the SHARE command.

If a user is disconnected from a group it may also be appropriate to remove his userid from the access list of the group's default profile and those of any specifically protected group datasets.

If the group administrator is being disconnected he must first nominate another member as the new administrator, by giving him CONNECT group authority. In addition he must assign ownership of the group's default profile to the new administrator using the SHARE command.

Before a user can be disconnected from a group he must ensure that it is not his current default group. If it is, the default must be set to some other group the user is connected to, say DRCS. The command to achieve this would be -

DEFGROUP DRCS

HIPO-DIAGRAM B1

Define the access available to a data set - SHAPE command

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 The parameters specified by the user are analyzed to determine which RACF profile is to be altered, created or deleted, and what alterations are to be made to the profiles. If DEFAULT, ARCHIVE or GDG was specified then the profile can immediately be altered, since no further information is needed.	LISTP			2 Execute the CATFIND command which creates a CLIST to be executed by the calling CLIST to obtain information derived by CATFIND.			
				3 Execute the appropriate RACF commands to make the desired changes in the RACF profile for the disk data set or tape volume.			
				4 Prompting for additional data sets can be requested by a parameter of the SHAPE CLIST.			

HIPO-DIAGRAM B1

Analyze SHAPE command parameters and modify default, ARCHIVE or GDG data set profile

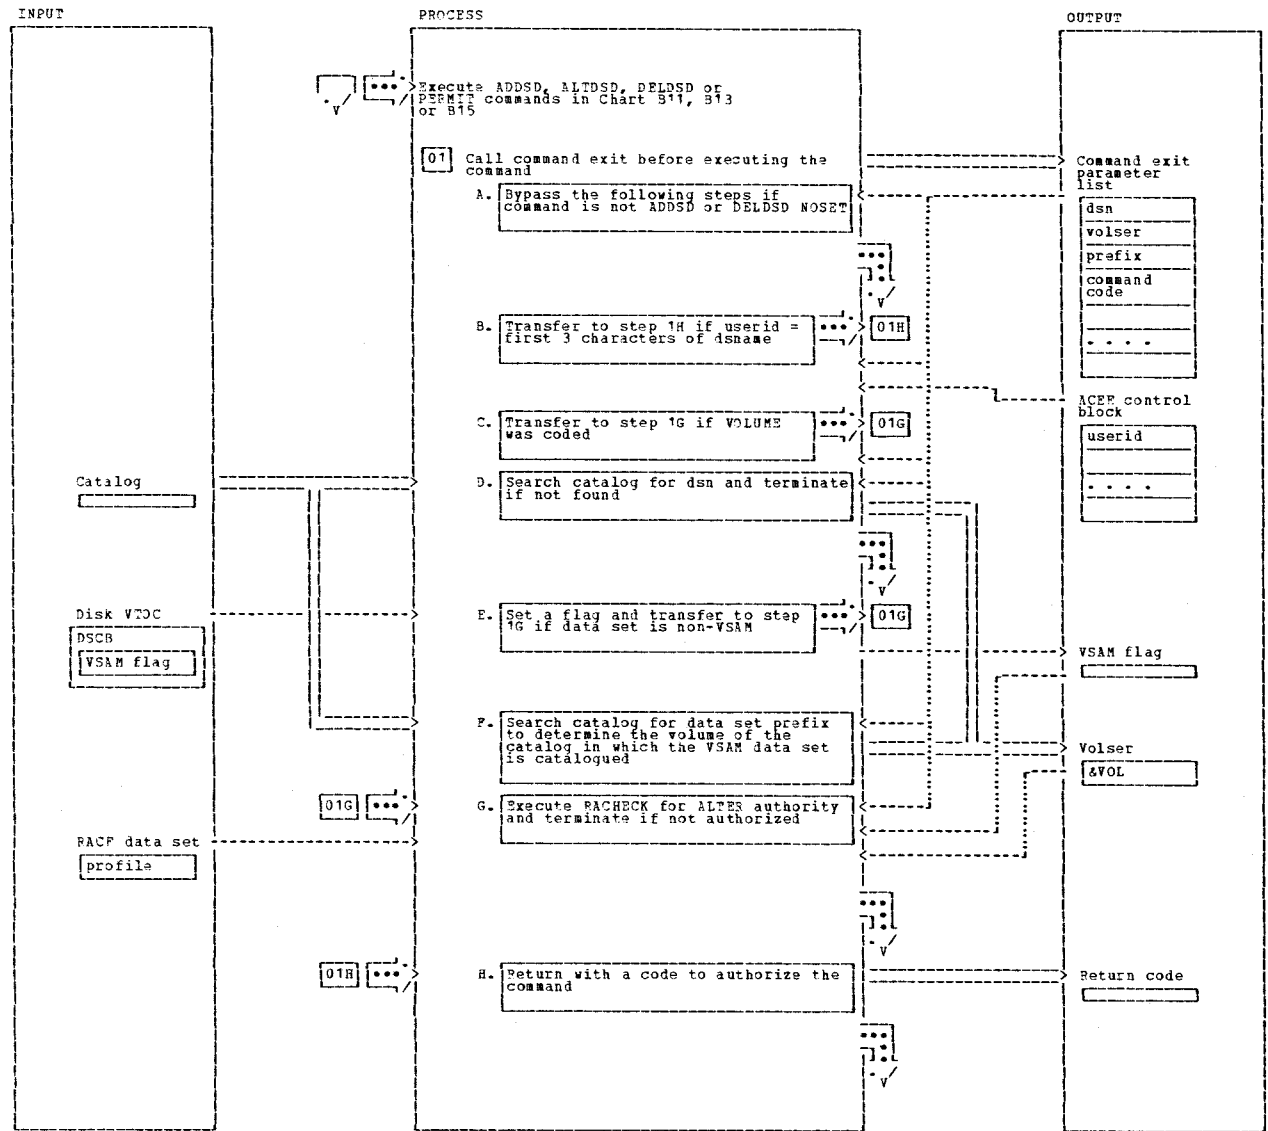

HIPO-DIAGRAM B11

Analyze SHAPE command parameters and modify default, ARCHIVE or GDG data set profile

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 Error if Command parameters are not sufficient to cause any change to a RACF profile.				4 Prevent the user from specifying UICC for the default profile since it is banned in this installation.			
2 The type of FROM dataset is determined and the FROM and PCLASS parameters are set up for use in a PERMIT command in step 4 or 5.				5 If AVOLUME has been set, then it must be a disk data set profile - either for archives or GDG base. The normal reason for a command (ALDSO or PERMIT) to fail is that a profile does not exist - i.e. the default applied. In this case an ADDSO NOSET command must first be issued to create the profile. This will fail if the user does not have ALTER access in the default profile.			
3 ARCHIVE only has to be coded if a data set of the same name is catalogued on tape or disk and the one in the archives is being referred to. GDG is coded for a disk GDG base name - all generations are SHAPE'd in the same way.				6 The request is complete if step 4 or 5 was executed.			

HIPO-DIAGRAM B11

Execute ADDSD, ALTDSD and DELDSD commands

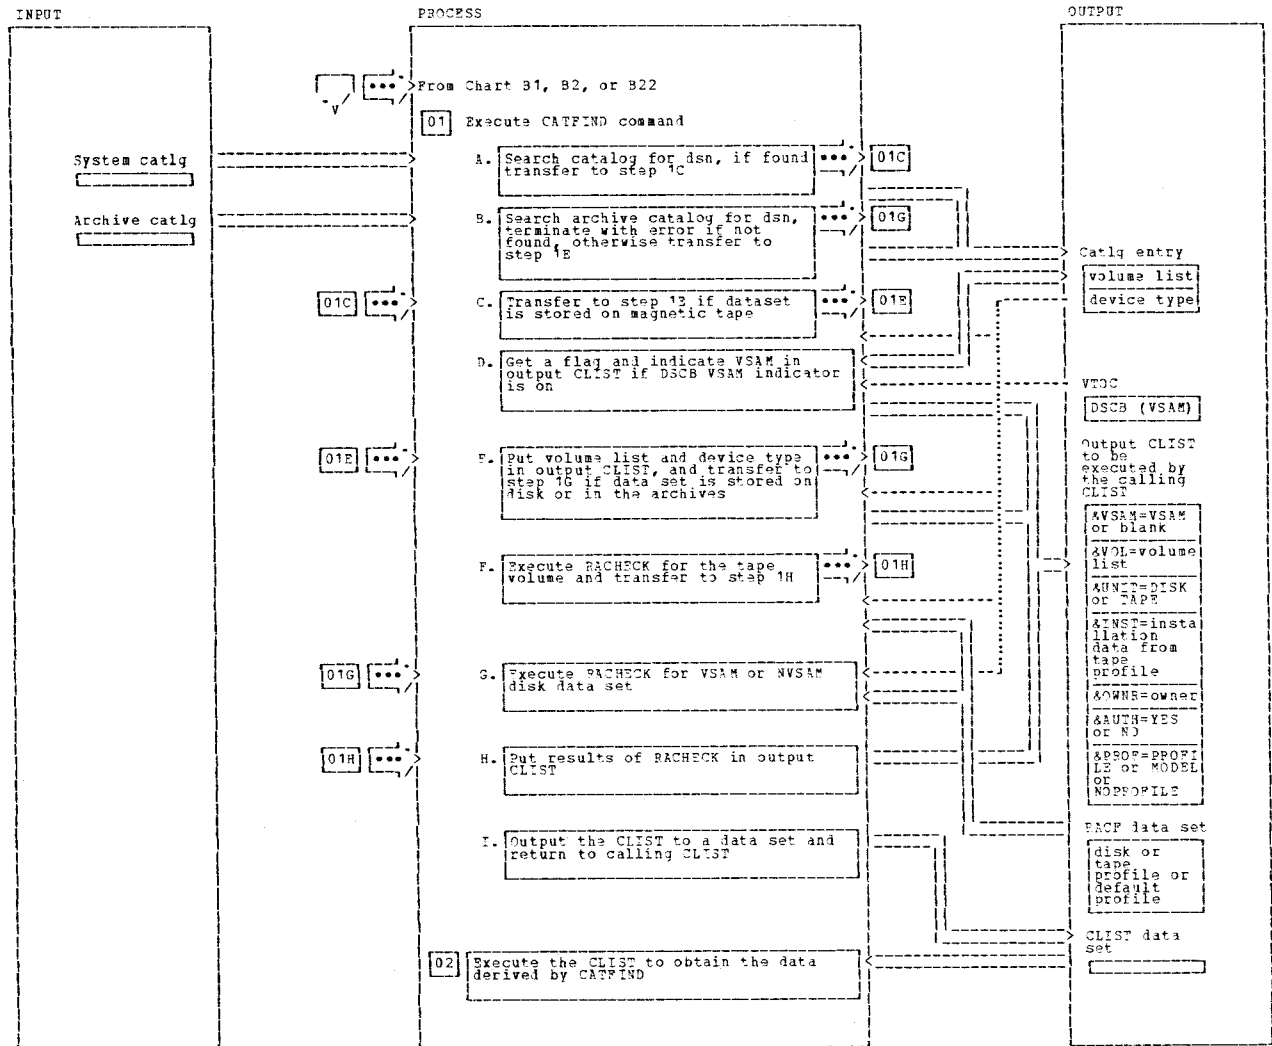

HIPO-DIAGRAM B111

Execute ADDSD, ALTDSD and DELDSD commands

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 The RACF command processor calls the installation coded command exit before executing the RACF command	ICHCNX00			1B In this installation userids are 3 characters but data sets owned by a user may have more than 3 characters in the prefix as long as the first 3 equal the userid.			
1C The normal checks on commands other than the NOSET commands are satisfactory - NOSET commands are only allowed for the data set owner in standard RACF.				1F RACHECK for a VSAM data set requires the volume of the catalog to be specified.

Determine data set characteristics

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 The SHARE or LISTP CLISTS execute the CATFIND command to determine the characteristics of the data set.				1P The RACHECK macro is executed with the CSI option which causes a copy of the profile to be placed in storage so that the command may access fields in the profile.			
1A The volume list and unit type are obtained.	CATFIND			1H The CATFIND command creates a CLIST which the calling CLIST may execute to obtain the results of the CATFIND command.			
1B The data set may be in the archives if it is not catalogued.							
1D If data set is VSAM, search the catalog for the data set prefix - the volume of the catalog in which the data set is catalogued is obtained.							

HIPO-DIAGRAM B12

Alter RACF profile for disk or archive data set

Alter RACF profile for disk or archive data set

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
RACF normally only allows the DELDSD and ADDSD commands with the NOSST parameter to be executed by the user whose userid prefixes a data set, or a SPECIAL user. However in this installation a command exit executes a RACHECK to determine whether the user has ALTER access authority and if so, authorizes these commands. In the case of ADDSD the user must have ALTER authority in the default profile.							

HIPO-DIAGRAM B13

Alter the RACF profile for tape volumes

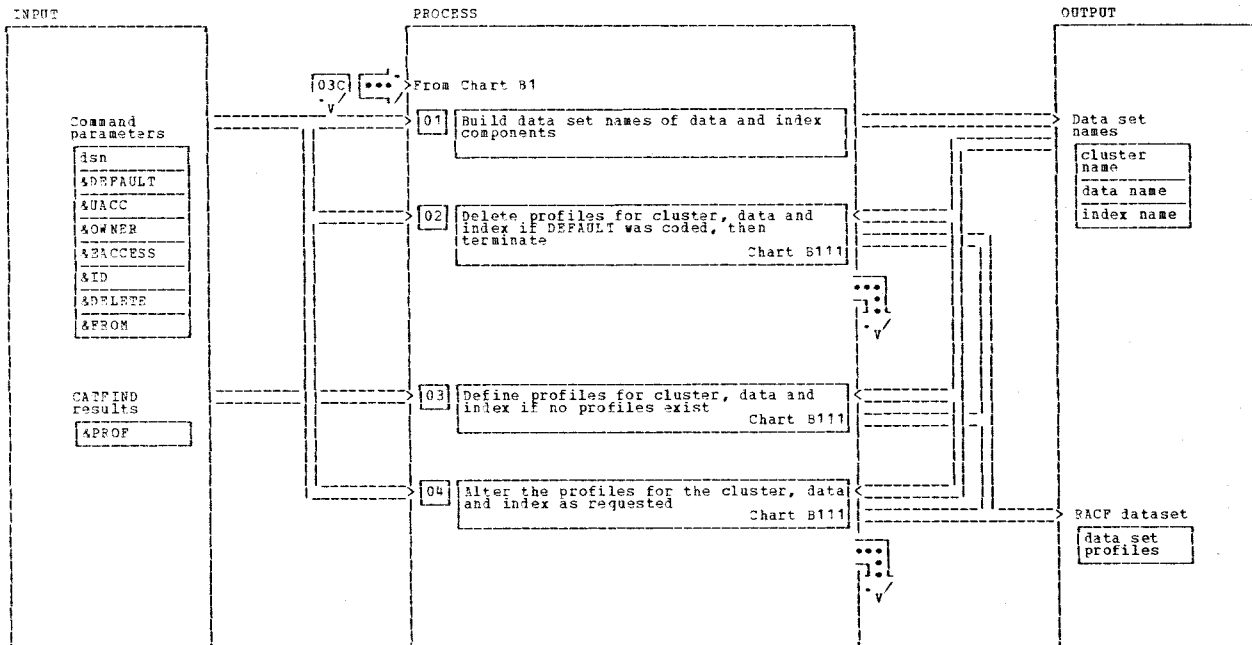

## Alter the RACP profile for tape volumes

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
2 The ownerid in the installation data is the first 3 characters of the data set name. If the first character of the installation data is blank it indicates that the default profile should be used to determine the access available to the data set. In this case, the data set name is not available to the RACHECK exits to determine whose default profile should be used. Therefore the first 3 characters of the data set name are also stored in the installation data (all default profiles have 3 character prefixes).				3 In this installation all tape volumes which contain a catalogued data set will have a profile, except momentarily when the SHARE CLIST deletes a profile preparatory to redefining it to indicate the default. Therefore it is safe to allow all users to define a profile for any tape volume.			

HIPO-DIAGRAM B14

## Alter RACP profiles for VSAM data sets

HIPO-DIAGRAM B15

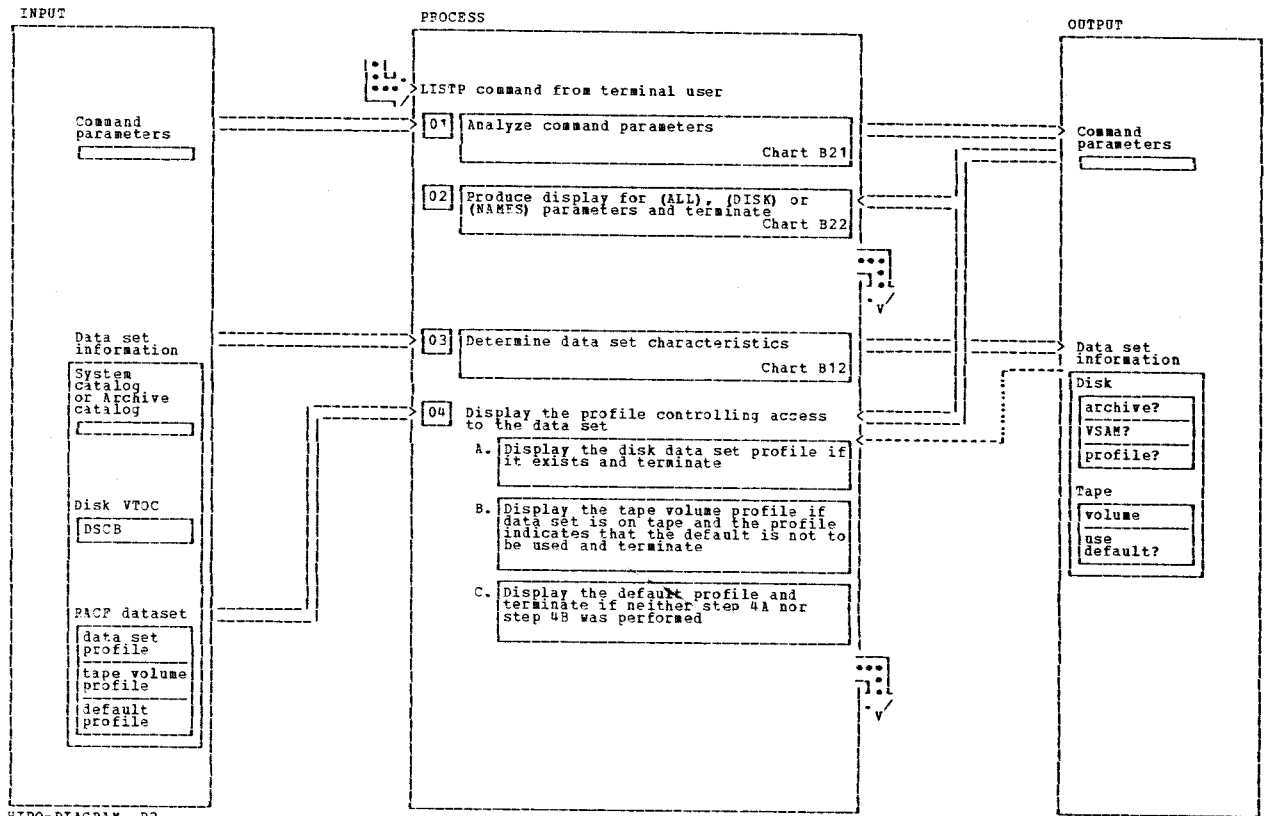

## Alter RACP profiles for VSAM data sets

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 In this installation, all VSAM data set names standardly have clustername.DATA and clustername.INDEX as the names of the data and index components respectively.				2 The default profile is used to define the access available to a disk data set if no RACP profile exists for the data set.			
				3 The ADDSD command is used.			
				4 The ALTDSD and PERMIT commands are used.			

HIPO-DIAGRAM B15

Display the access available to a data set

Display the access available to a data set

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
4A The access to a disk data set is controlled by the owner's default profile unless a specific profile exists for the data set.				4B The access to a tape data set is controlled by the default profile unless the first character of the installation data in the tape profile is non-blank.

Produce displays for the LISTP parameters (ALL), (DISK) and (NAMES)

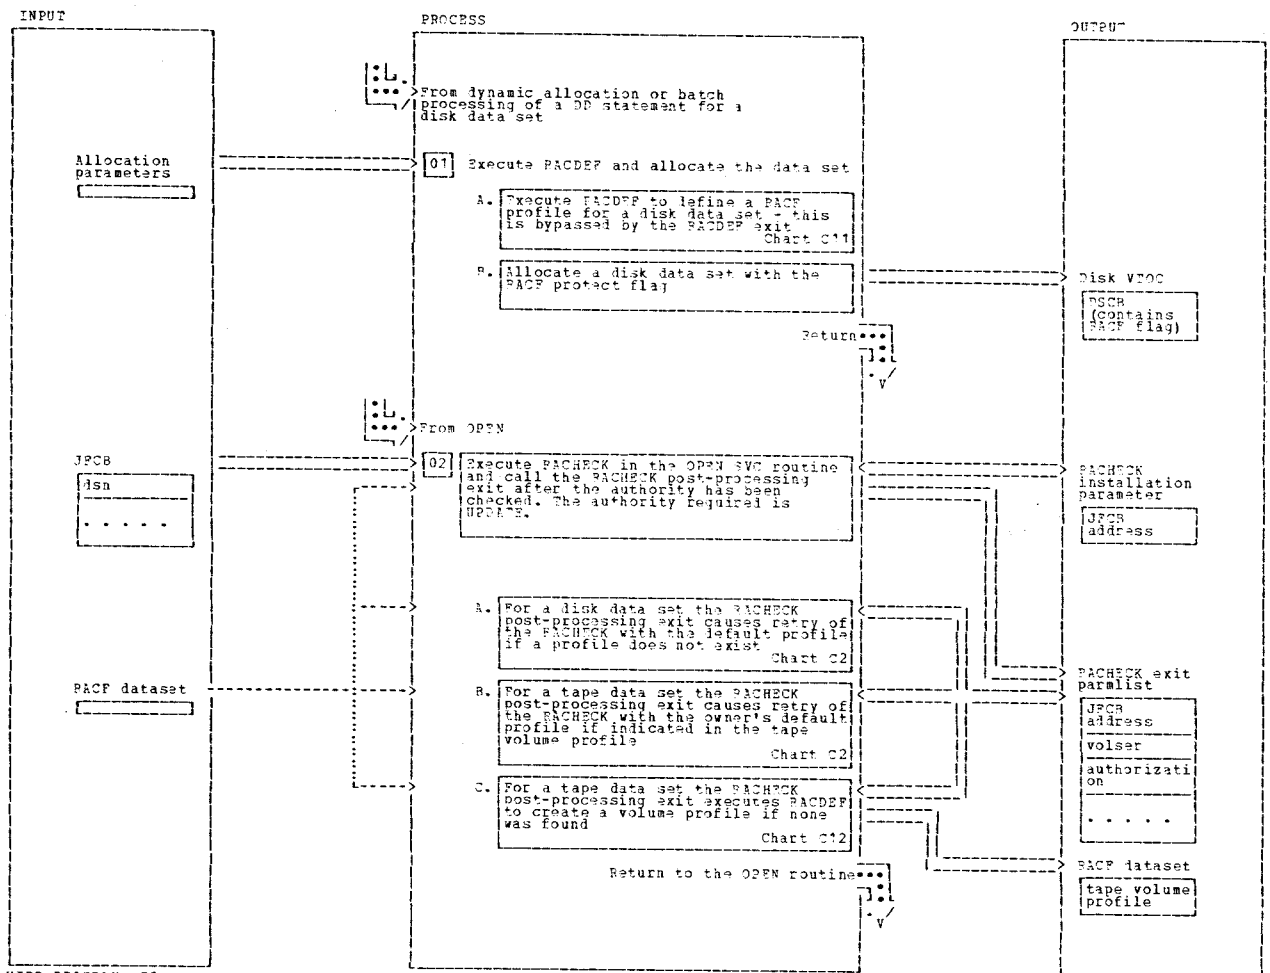

HIPO-DIAGRAM B22

Produce displays for the LISTP parameters (ALL), (DISK) and (NAMES)

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
3B The default profile determines the access to a tape data set unless the first character of the installation data in the tape volume profile is non-blank.				5 A single PACF command can be used to display specifically defined disk data sets since profiles exist only for these but the complications of step 3 are necessary for tape since a profile exists for each tape volume.			
4 Several data sets are used during the above steps.				6 A PACF SEARCH command can be used since a profile only exists for each specifically defined data set.			

HIPO-DIAGRAM B22

Create a data set

Create a data set

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1* In this installation, access to a disk data set is controlled by a default profile unless a profile is specifically defined for the data set. Therefore a profile is not created when a data set is created.				2A Since the data set is just being created it will not have a specific profile - see step 01A above.			
1B All users are given ADSP so all data sets are automatically protected when created.				2B If the tape volume already contains one or more data sets it will have a profile.			
2 The OPEN routines have been modified to pass the JPCB as an installation parameter to PACHECK and thence to the PACHECK exits in the case of a new tape data set. The data set name prefix is needed to establish the ownership of the tape in the case where a user creates a tape data set not his own. (The JPCB contains the data set name).				2C If the tape has come from the scratch pool it will not have a profile, and one must be created when the first data set is written to it. This is done by executing a PACDEF in the PACHECK post-processing exit.			

HIPO-DIAGRAM C1

RACDEF DEFINE a new disk data set

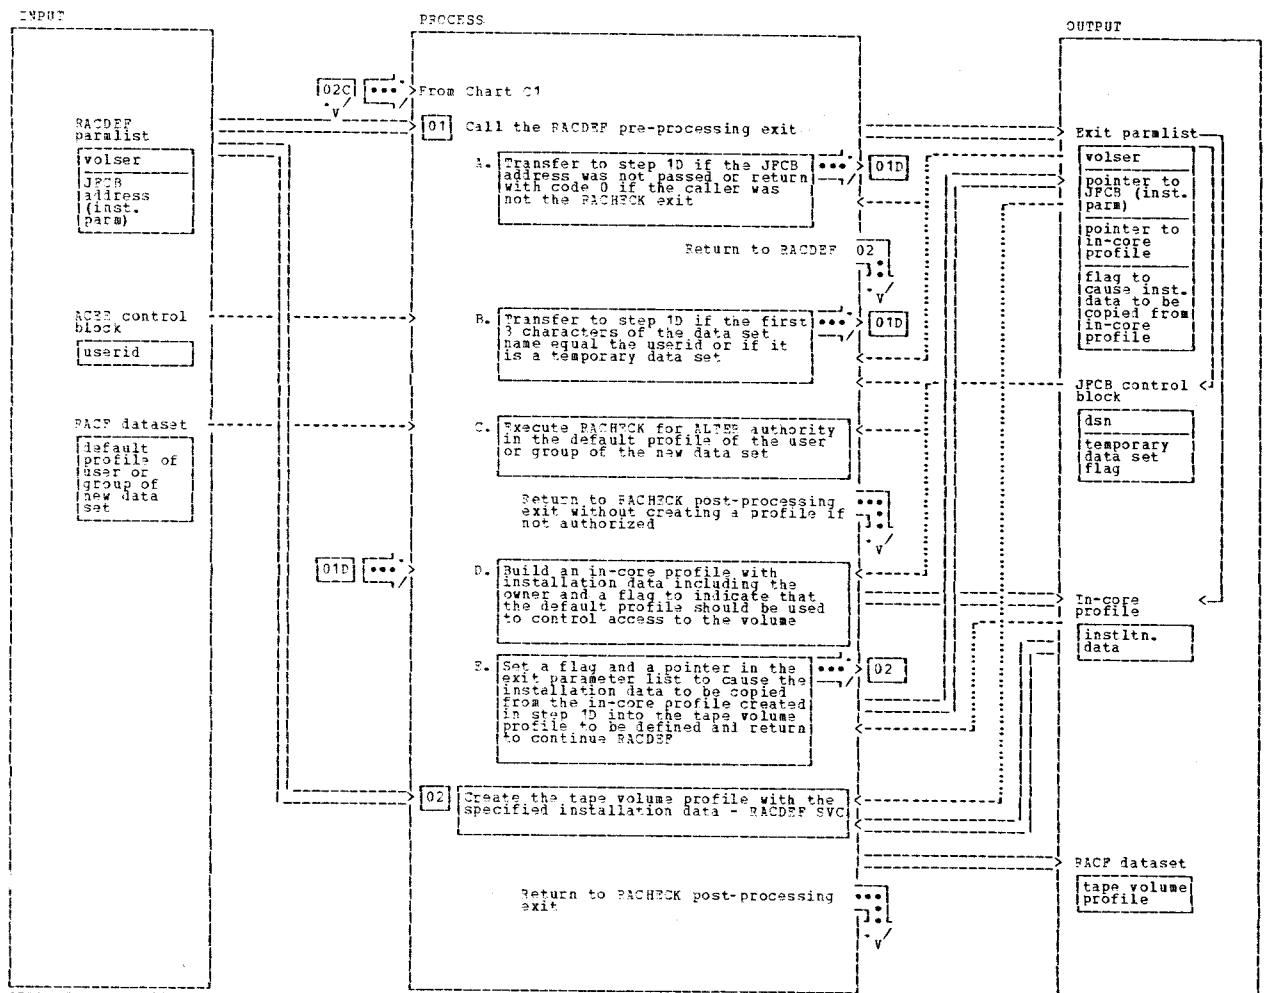

HIPO-DIAGRAM C11

RACDEF DEFINE a new disk data set

NOTES	MODULE	LABEL	PEP	NOTES	MODULE	LABEL	PEP
1A All userids and groupids in this installation are ? characters and users may own data sets with a longer prefix as long as the first ? characters equal their userids.	ICHREDX01			10 Data sets in this installation only have profiles if defined specifically. Access is normally controlled by a default profile for each user or group.			
1C A data set may be created for another user only if ALTER authority is available in the other user's default profile. A return code of 0 from the exit causes RACDEF to continue normally in which case RACDEF will fail the request since RACF normally does not allow users to create data sets for others.							

HIPO-DIAGRAM C11

Define a tape volume profile

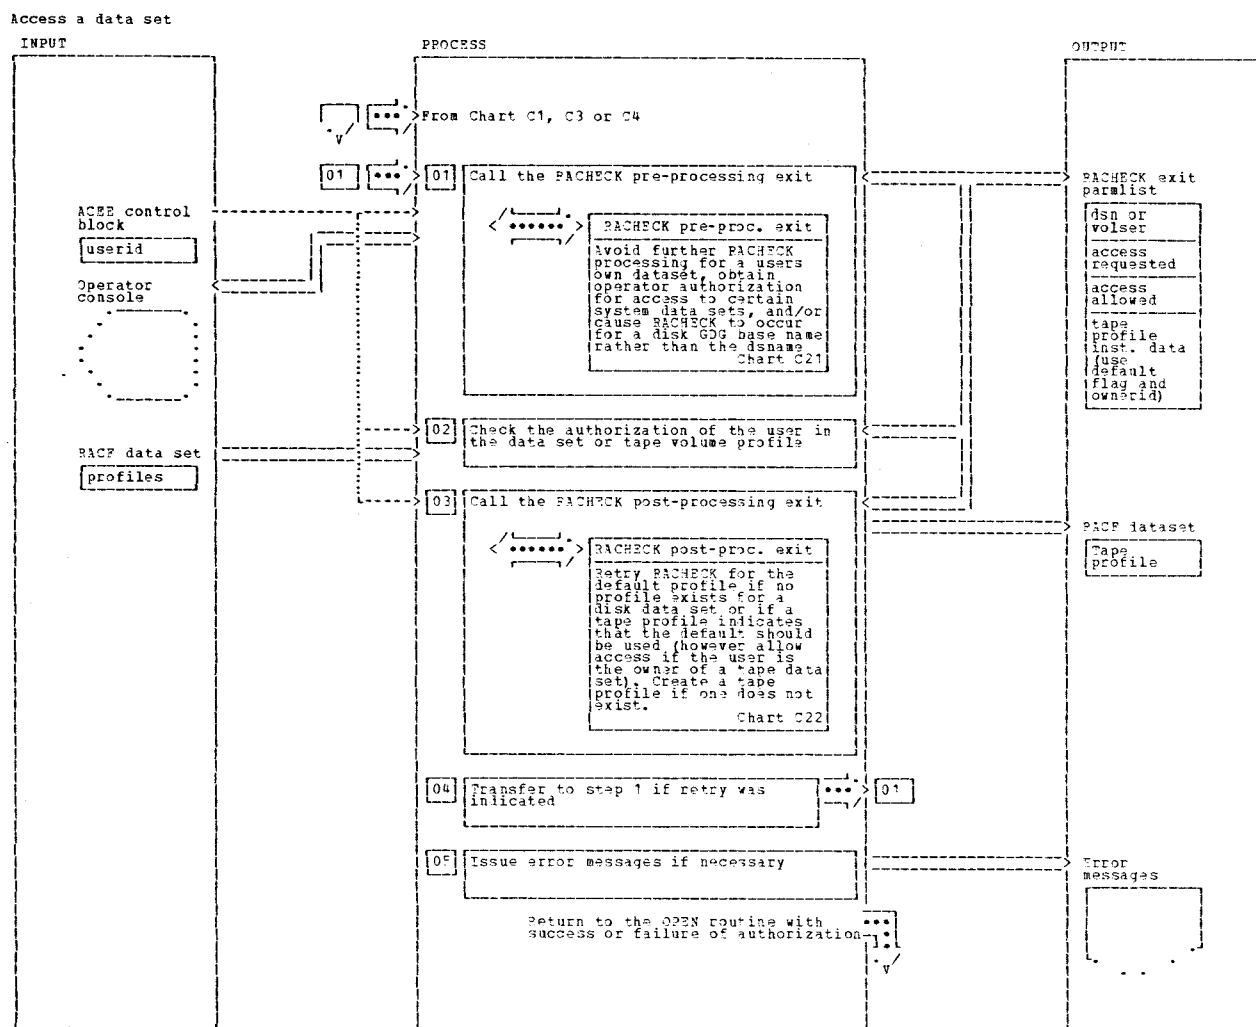

HIPO-DIAGRAM C12

Define a tape volume profile

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1C In this installation, a data set may be created for another user only if ALTF authority is available in the other user's default profile.				1E When RACDEF subsequently creates the tape profile, it will copy the installation data from the in-core profile into the created profile. A pointer to the in-core profile and a flag in the exit parameters cause this to happen.			

HIPO-DIAGRAM C12

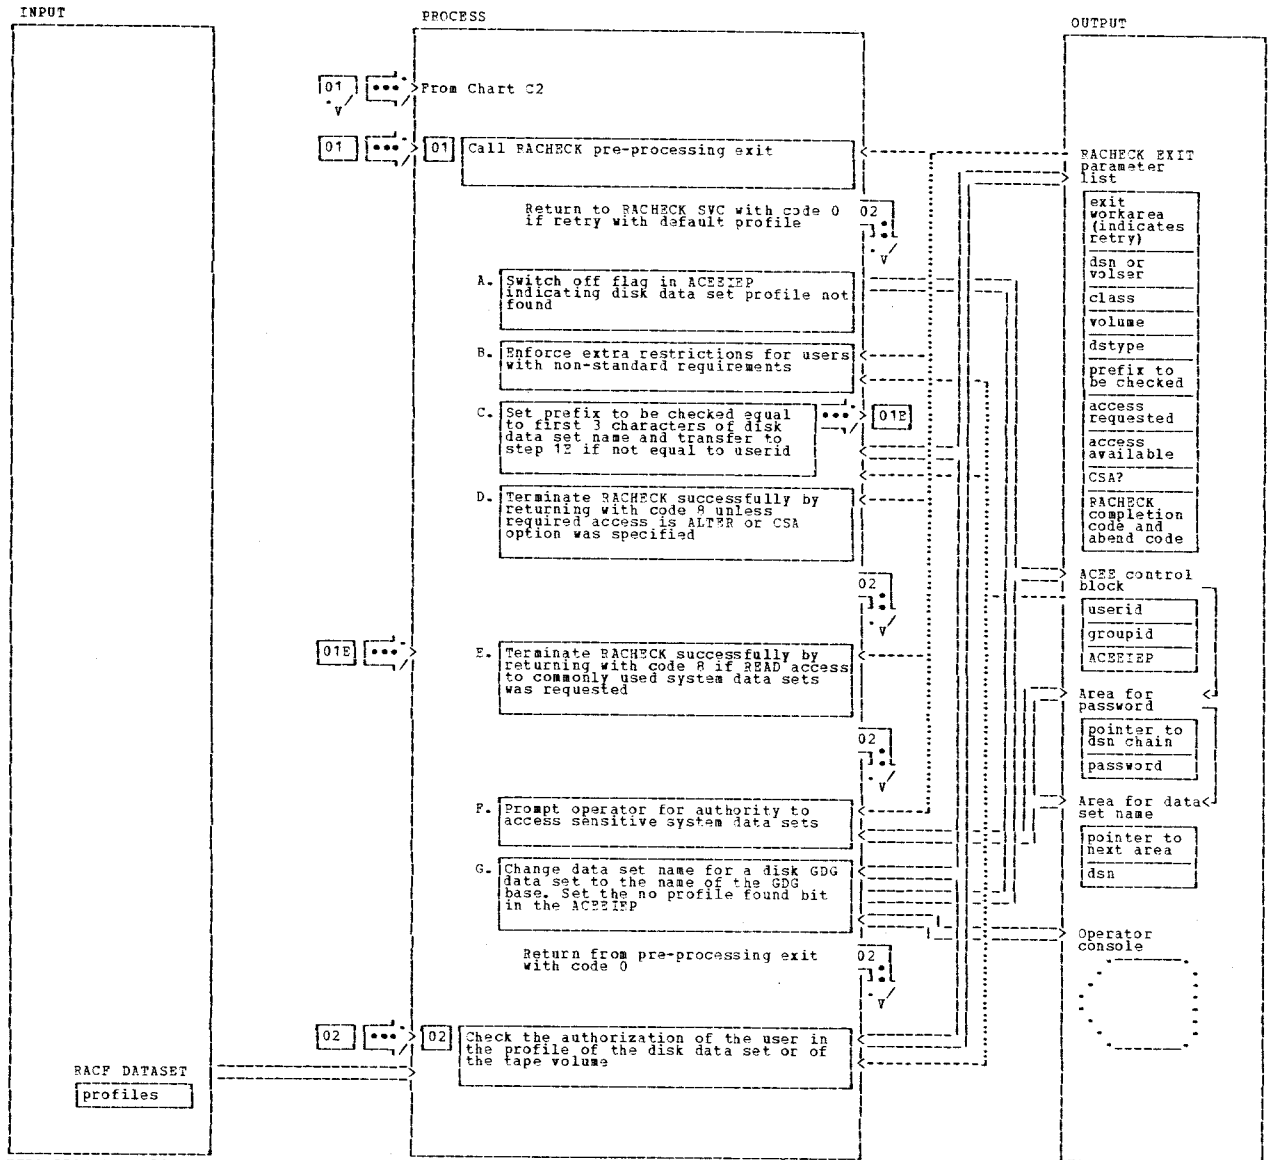

HIPO-DIAGRAM C2

## Access a data set

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 A return code from the exit can prevent further processing of RACHECK.	ICHSCX01			3 A return code from the exit can cause the RACHECK to be repeated with the resource to be checked altered to the default profile. A flag has to be set to prevent loops.	ICHSCX02		

HIPO-DIAGRAM C2

Detailed actions of the RACHECK pre-processing exit for for data set access

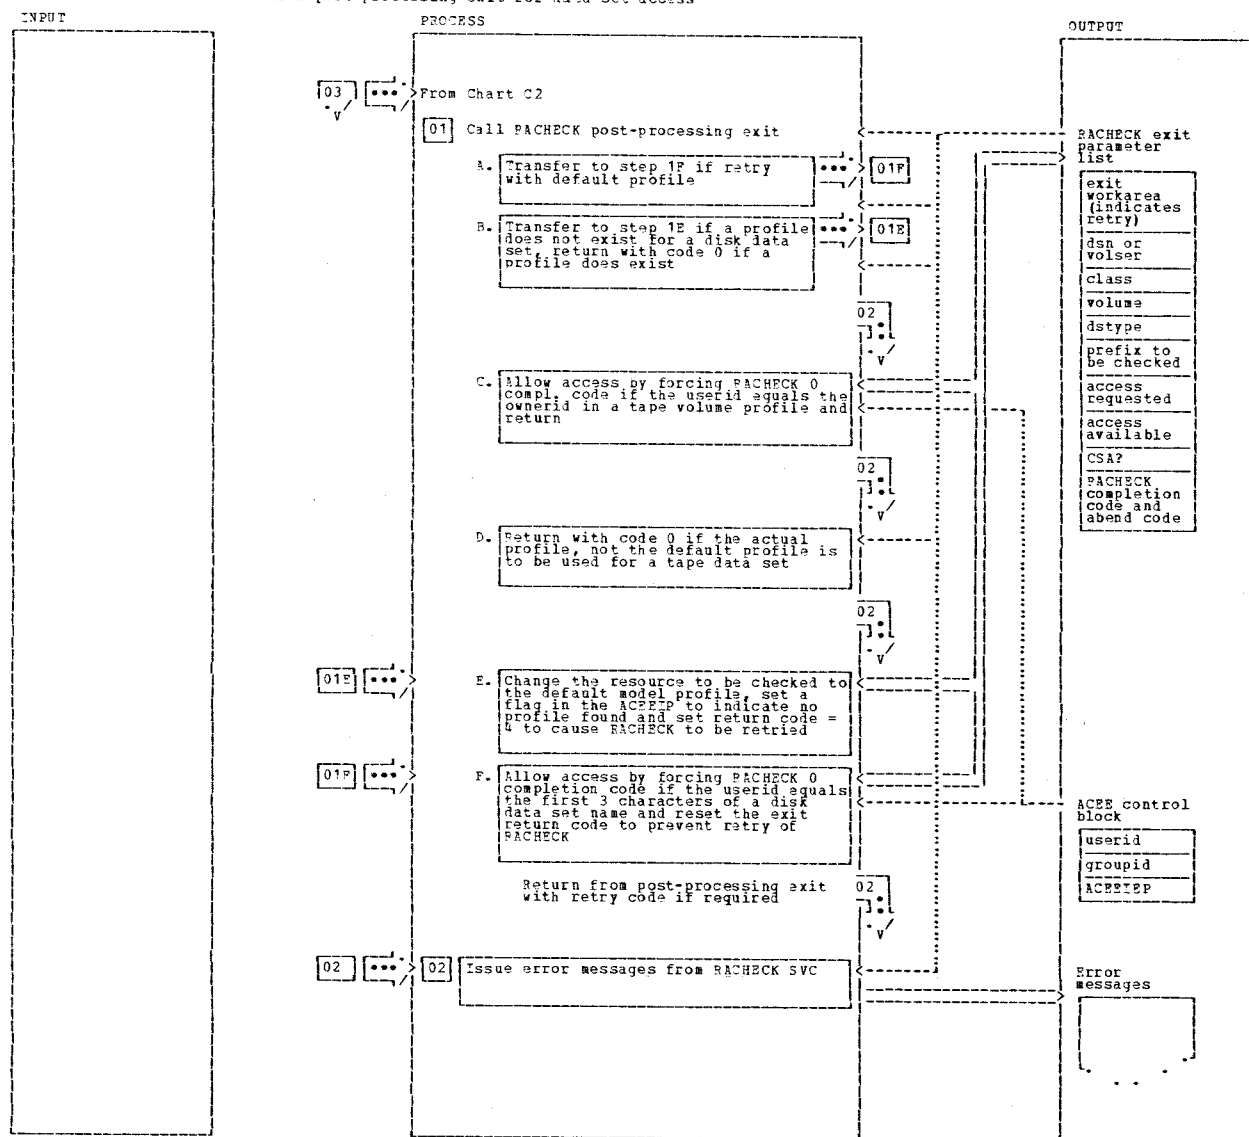

HIPO-DIAGRAM C21

Detailed actions of the RACHECK pre-processing exit for for data set access

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 Return code 0 allows the RACHECK to proceed normally	ICHECKX01			1E This is a fast-path for RACHECK.			
1A The flag is used by the RACDEF pre-processing exit to avoid attempts by RACDEF to delete or alter profiles for disk data sets which do not have profiles.				1F Authority is required for greater than READ access for most system data sets and for READ access to several. To avoid multiple operator replies in the same job for the same data set, the data set names are chained in storage areas connected to the password area pointed to by the ACCEZEP (the password area is created by the RACINIT exit). The list of data set names is searched every time to avoid an operator reply if possible.			
1B Users attached to certain groups are not permitted to access data sets other than their own and system data sets.				1G The volume is changed to dummy. Disk GDG data sets have access controlled by a profile defined for the GDG base or, if this is not defined, by the default profile. The no profile found flag must be set on since the GDG base profile must not be deleted if a generation is deleted.			
1C A user in this installation may own data sets with a prefix longer than his 3 character userid as long as the first 3 characters of the prefix equal the userid.							
1D This is a fast path for RACHECK for a user's own data set. However the full RACHECK must be performed for the CSA option since a copy of the profile is required in storage. Since the no profile flag must be set for data set delete or rename the full RACHECK must be performed for ALTER access (needed for delete or rename). To avoid fast path within the RACHECK SVC for a user's own data set, the prefix to be checked is changed to blank.							

HIPO-DIAGRAM C21

Detailed actions of the PACHECK post-processing exit for data set access

HIPO-DIAGRAM C22

Detailed actions of the PACHECK post-processing exit for data set access

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1A A return code of 0 is supplied for the subsequent return from the exit to prevent any further attempts at retry by the PACHECK exits i.e. loops are prevented.	ICHECK02			1D The installation data contains a flag which indicates whether access to the tape is controlled by the default profile of the tape owner or by the actual tape volume profile.			
1B Return code 0 allows normal PACHECK to continue. Most disk data sets do not have profiles but are controlled by a default profile for each user.				1E The volume is changed to DUMMY, the class to DATASET, the data set type to non-VSAM.			
1C The userid is stored in the installation data of a tape profile by the PACDEF exit when the profile is created. Profiles exist for all OLD tape data sets since the exit issues a PACDEF to create a tape profile if one does not exist for any tape data set - this happens when PACHECK occurs during creation of the tape data set. The return code and abend code which would be issued by the PACHECK SVC are altered to 0.				1F This step allows access if the prefix was set to blank in step 1D, Chart C21 (see note) and prevents retry with the model profile in this case for a user's own data set.			
				2 No error messages are issued by the PACHECK SVC when the disk data set profile is not found, because the retry finds the default profile before entering this step.			

HIPO-DIAGRAM C22

Delete a data set

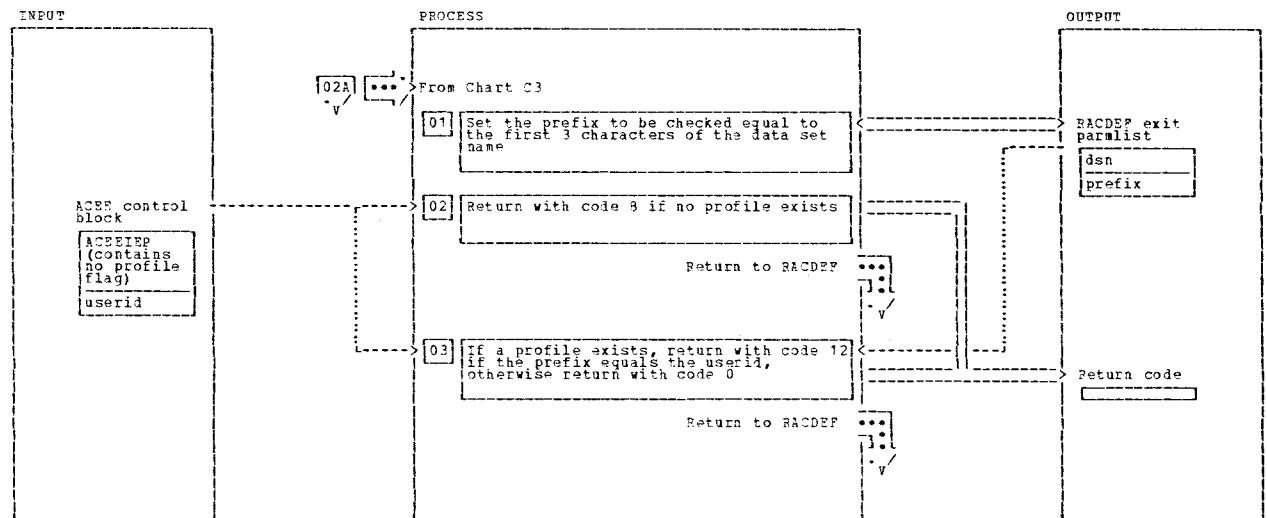

HIPO-DIAGRAM C3

Delete a data set

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1A In this installation most disk data sets do not have profiles and access to these data sets is controlled by a default profile defined for each user.				3B The tape erase and volume profile delete are carried out later by a house-keeping program.			
2A The attempt to delete a non-existent profile would cause a failure of the delete program.							

HIPO-DIAGRAM C3

Prevent attempt to delete non-existent data set profile

HIPO-DIAGRAM C31

Prevent attempt to delete non-existent data set profile

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 In this installation, a user may own datasets with a longer prefix than his 3 character userid as long as the first 3 characters equal the userid.	ICHPDX01			3 Return code 12 causes authorization checking in the RACDEF to be bypassed. Thus users who own datasets with longer prefixes than 3 characters are able to delete them.			
2 The return code 8 causes the RACDEF to terminate without attempting to delete the profile. The RACDEF issues a zero completion code to its caller.							

HIPO-DIAGRAM C31

# Delete a tape volume profile and erase the tape

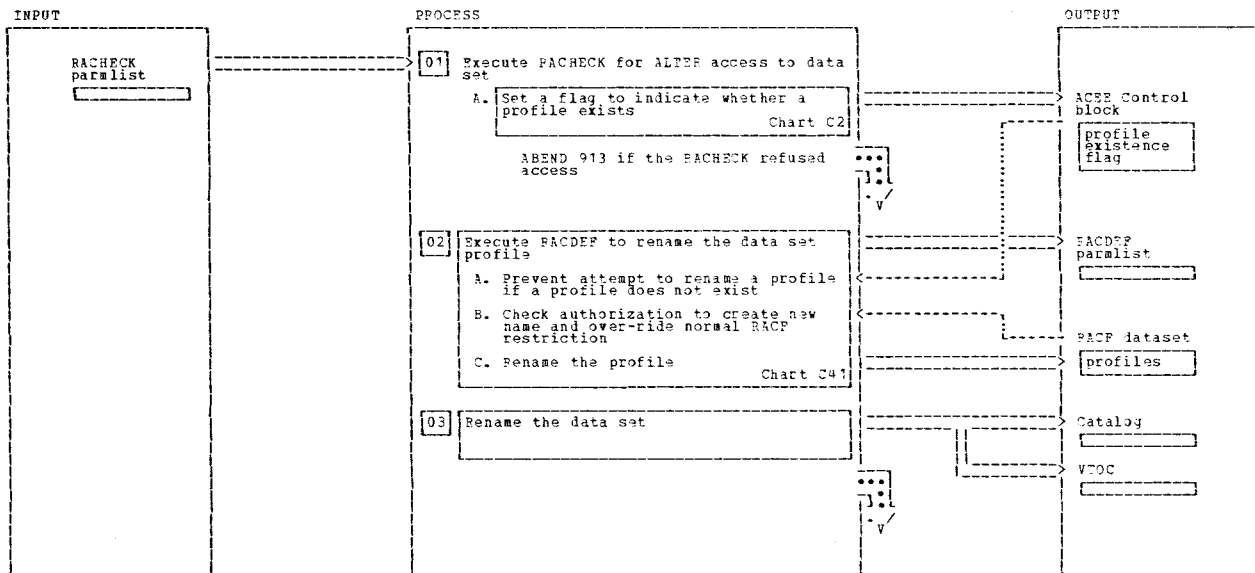

HIPO-DIAGRAM C32

# Delete a tape volume profile and erase the tape

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 All tape data sets stored on the standard range of volumes are catalogued.				3A BLP allows the label to be processed as a data file.			
2 A list of tapes in the scratch pool - i.e. with no data stored on them is maintained. The tapes considered are a standard range of tapes stored near the computer room which can be used for scratch or to store permanent data sets. The list of volumes with catalogued data sets is compared with the list of volumes not in the scratch pool.				3B Since normal label checking is bypassed by BLP, the program checks the label.			
				3C "Erase write" only involves the tape drive, not the control unit or channel.			
				3D The RACDEF exit allows the RACDEF to proceed (the erase program must be authorized to be able to execute RACDEF).			

HIPO-DIAGRAM C32

# Rename a disk data set

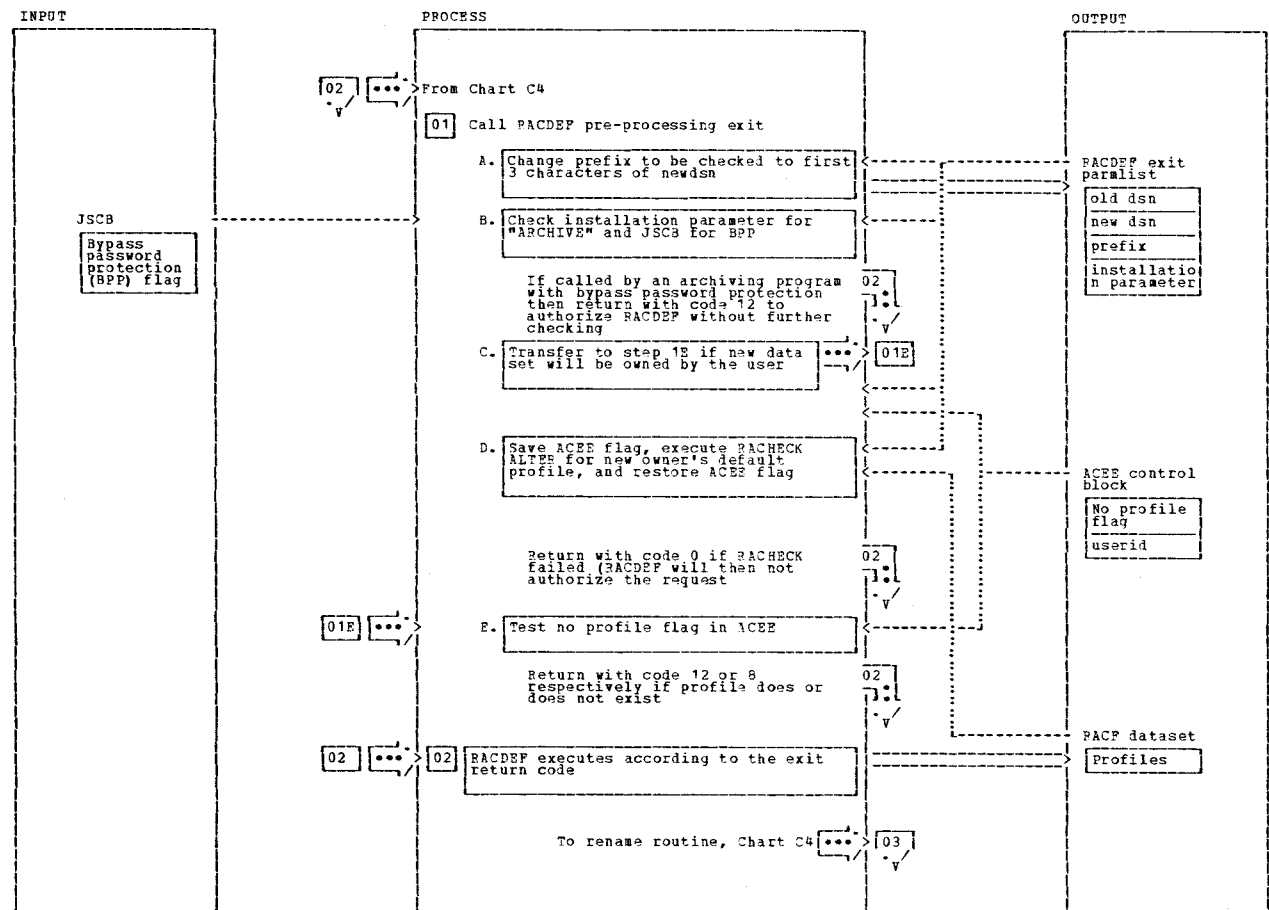

HIPO-DIAGRAM C4

Rename a disk data set

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1A Most data sets in this installation do not have profiles but access to them is controlled by a default profile for each user.				2A The attempt to rename a non-existent profile would cause the entire rename to fail if it was allowed to be attempted.			
2B RACF normally does not allow a user to create a data set for another user. The existence of a default profile for each user in this installation allows this rule to be relaxed so that users may create data sets for other users if they are given ALTER access authority in the other users default profile.							

HIPO-DIAGRAM C4

RACDEF rename for a disk data set profile

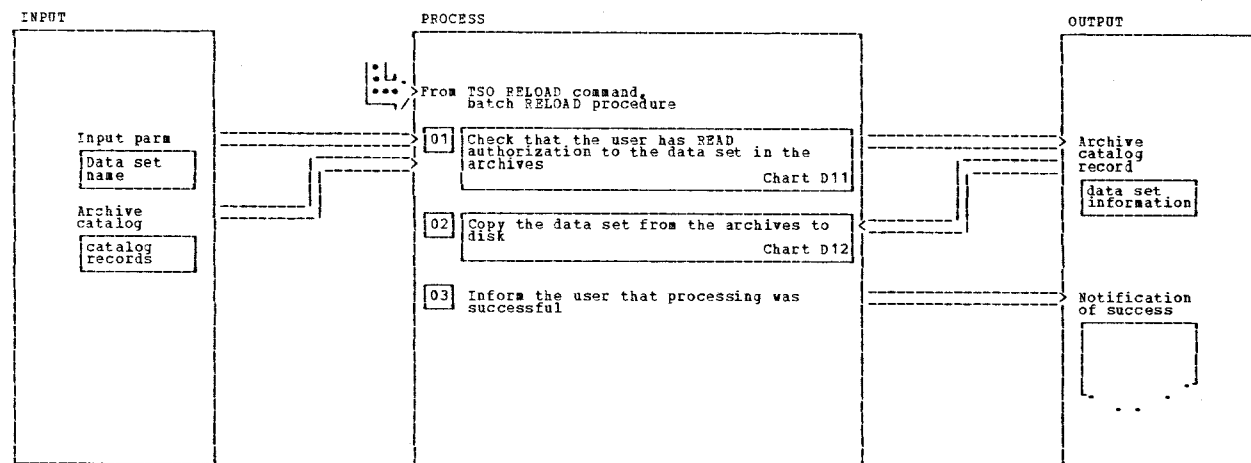

HIPO-DIAGRAM C41

RACDEF rename for a disk data set profile

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1A Users in this installation may own data sets prefixed by longer than 3 characters as long as the first 3 characters equal their 3 character userid.	ICHRDX01			1E The no profile flag in the ACEE is set by a RACHECK exit in the RACHECK executed prior to the execution of the RACDEF. It indicates whether the data set has a profile. Data sets without profiles in this installation have access controlled by a default profile for each user.			C4
1B Archive programs are authorized and use RACHECK to determine if a profile exists before executing RACDEF.				2 Return code 3 from the exit prevents any further action by RACDEF but causes RACDEF to appear to complete successfully. It is used to avoid problems when a profile is not defined for a data set. Return code 12 from the exit causes the RACDEF to continue normally except that it's normal authorization checking is bypassed.			
1C The RACDEF may be allowed to proceed if the user will own the new data set since an RACHECK has already determined that he has ALTER access to the old data set.			C4				
1D The ACEE flag has to be saved and restored because the RACHECK will destroy it. RACHECK ALTER for the new owner's default profile is appropriate since no specific definition of the data set by the new owner can exist at this stage.							

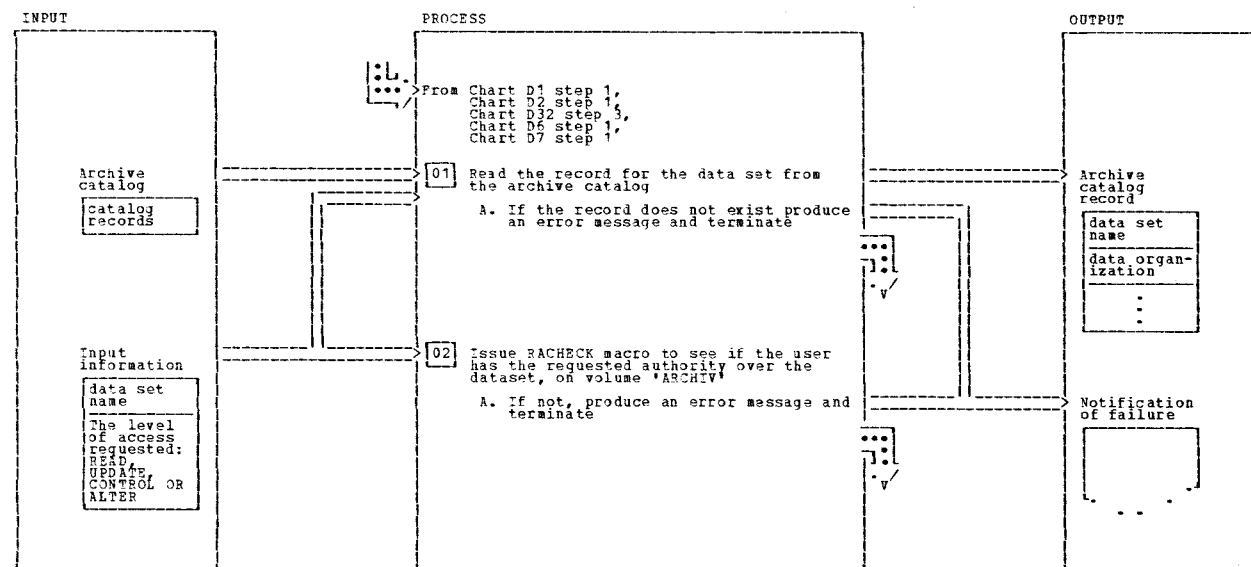

HIPO-DIAGRAM C41

## Reload a Data Set from the Archives

HIPO-DIAGRAM D1

## Check Authorization to a Data Set in the Archives

HIPO-DIAGRAM D11

## Check Authorization to a Data Set in the Archives

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
2 Specific profiles for all data sets in the archives have 'ARCHIV' in the volume field. This imaginary volume just serves to distinguish between data sets of the same name in archives and on disk.							

HIPO-DIAGRAM D11

## Copy a Data Set from the Archives to Disk

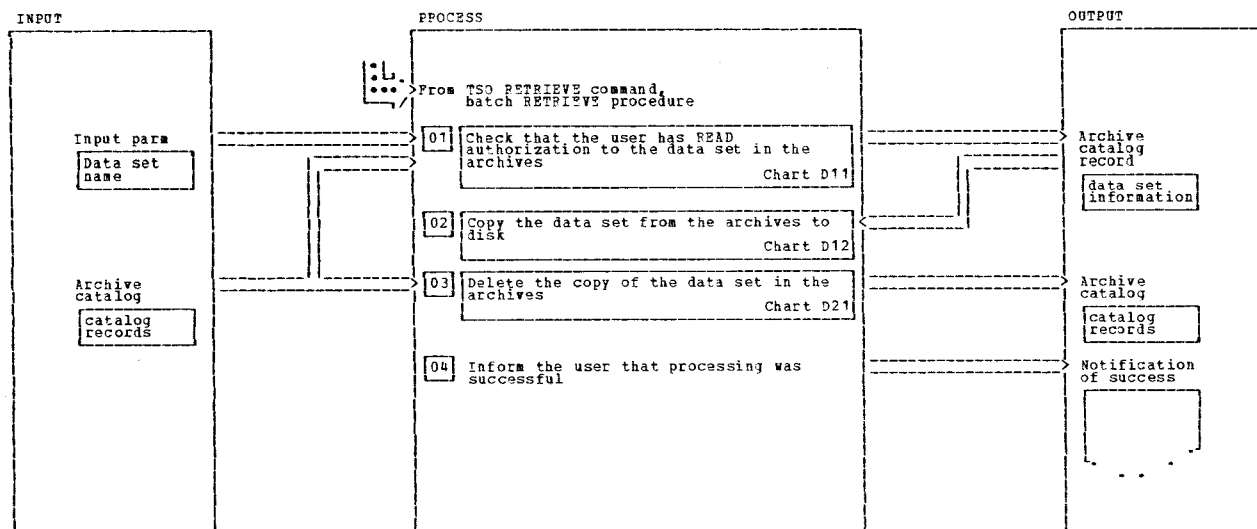

## Copy a Data Set from the Archives to Disk

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 The data set will be returned to the disk volume it came from if it occupies 1 cylinder or less. Otherwise the volume with the largest amount of free space will be selected.				7 The RACDEF attempts to model the profile of the archived data set. If the archived data set doesn't have a specific profile (it is protected by the user's default profile) then the RACDEF will fail and will not create a profile for the disk data set, causing it to be protected by the user's default as well.			
2 An existing data set of the same name may have to be deleted first.				8 VSAM data sets may have DATA and INDEX components which have the same protection requirements as the cluster. Their names are governed by an installation standard.			
4 If an existing data set is being deleted or uncatalogued the user must have ALTER authority to this version.							
6 The main attribute is the data set type - sequential, partitioned, direct access or VSAM.							
6 Some archived data sets reside on tape and some in a special partitioned data set on disk. Different programs are required for the various data set type/storage medium combinations.							

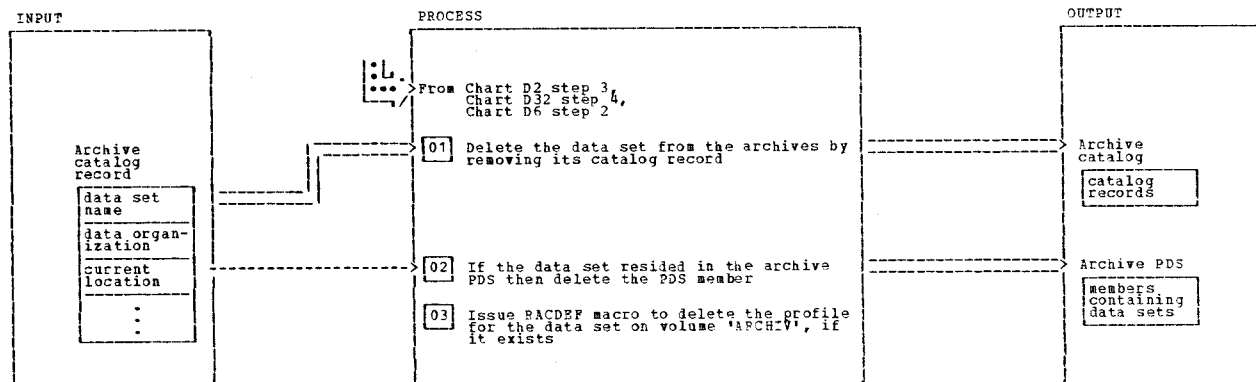

HIPO-DIAGRAM D12

# Retrieve a Data Set from the Archives

HIPO-DIAGRAM D2

# Delete a Data Set from the Archives

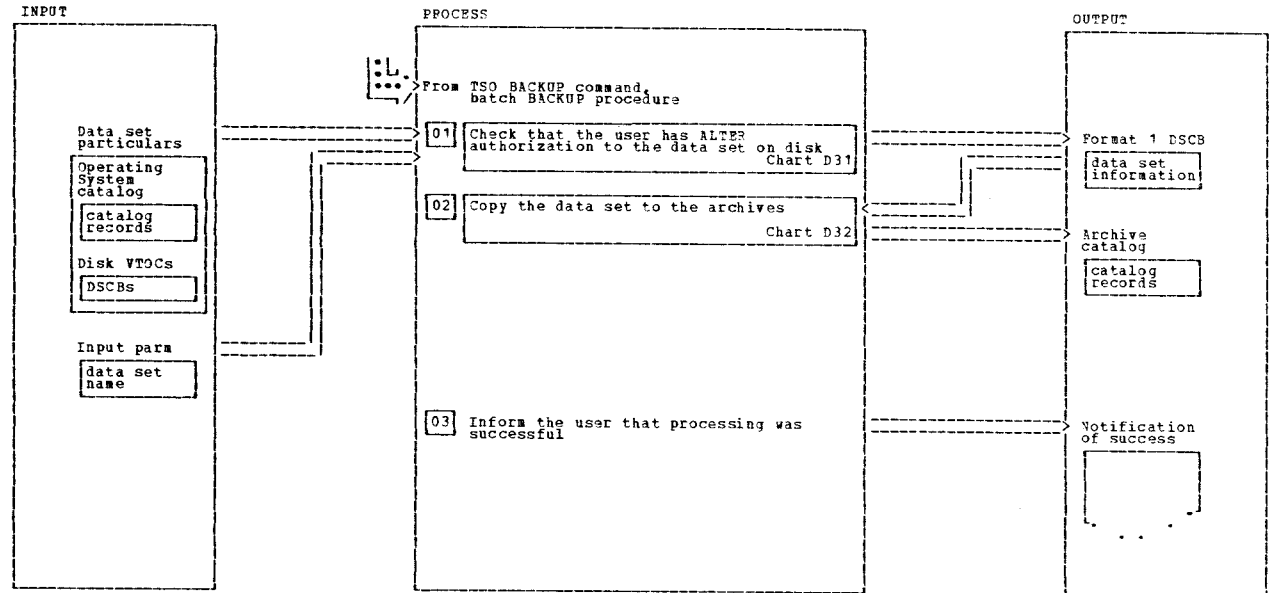

HIPO-DIAGRAM D21

# Delete a Data Set from the Archives

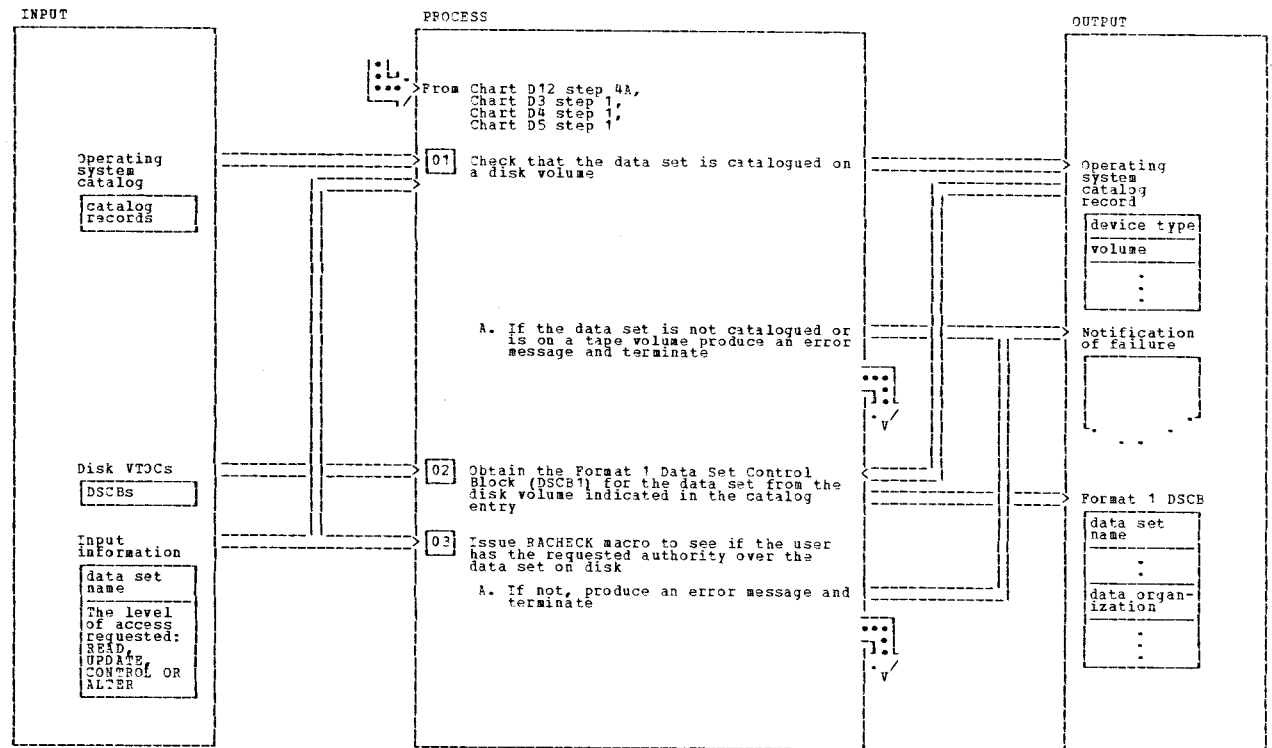

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 A data set is deleted from the archives by simply removing reference to it from the Archive catalog.				3 If entered from Chart D2 then the RACDEF issued at step 3 of Chart D12 will have already indicated whether a specific profile exists or not and an associated return code is available for testing. This RACDEF is bypassed if the return code is non-zero.			
2 If the data set is in the special archive PDS the associated member is also deleted, primarily to enable the disk space to be reclaimed.				If entered from Chart D32 then the RACDEF issued at step 3 of Chart D31 will have set the appropriate value in the flag in ACDEF indicating whether the profile exists or not. In this case this RACDEF is always issued and the pre-processing exit will bypass SVC processing if the flag is set. A similar situation exists if entered from Chart 6.			

HIPO-DIAGRAM D21

# Backup a Data Set to the Archives

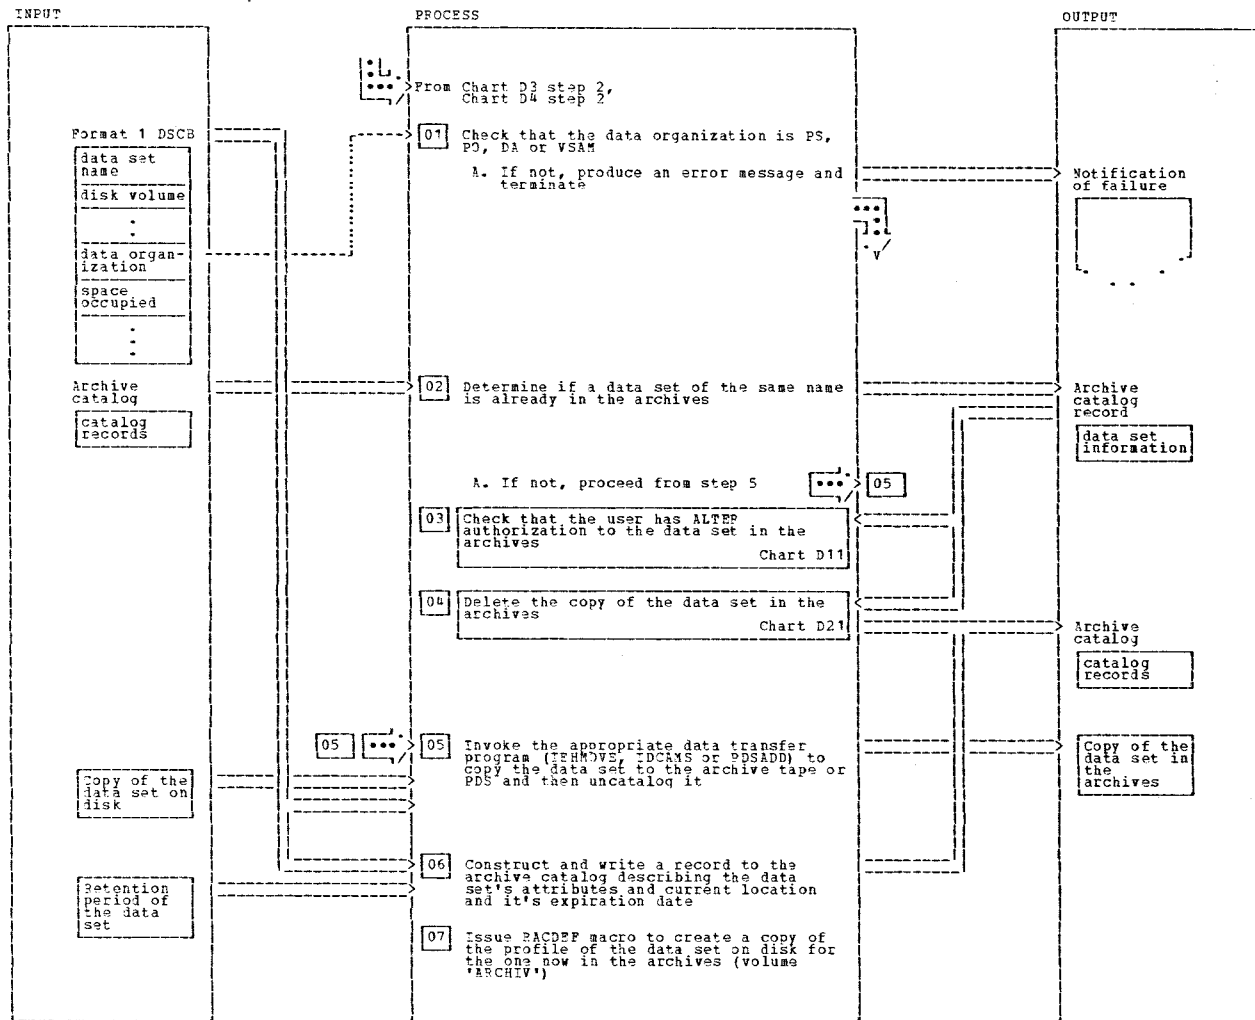

# Check Authorization to a Data Set on Disk

# Check Authorization to a Data Set on Disk

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 Only catalogued, disk data sets can be archived.				3 For a VSAM data set the volume containing the catalog entry must be determined and used in the RACHECK, rather than the volume containing the data set.			
2 For a VSAM data set the DSCB1 will be incomplete, but will at least indicate that the data set is VSAM.							

Copy a Data Set from Disk to the Archives

HIPO-DIAGRAM D32

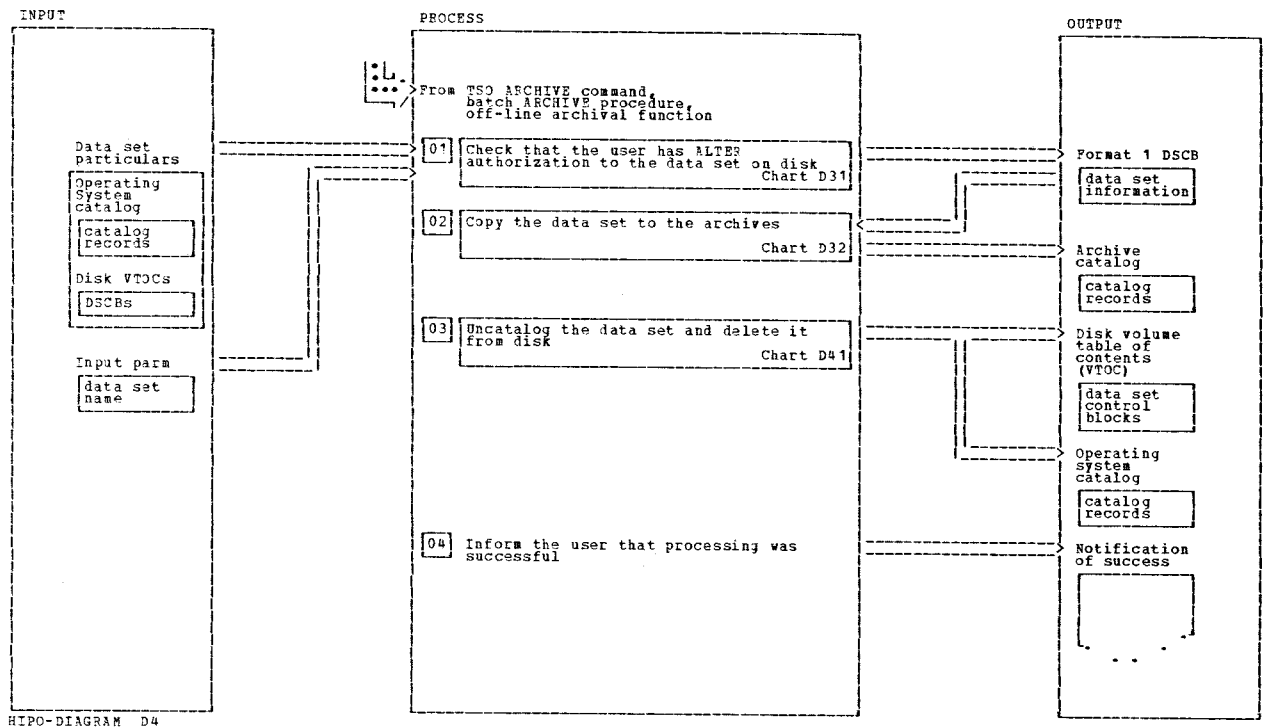

Copy a Data Set from Disk to the Archives

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 These are the only data set types currently supported.				6 The archive catalog record contains all information necessary to return the data set to disk if later required.			
2 If a data set of the same name already exists in the archives it must be deleted first.				7 The PACDEF attempts to model the profile of the disk data set. If the disk data set doesn't have a specific profile (it is protected by the user's default profile) then the PACDEF will fail and will not create a profile for the archived data set, causing it to be protected by the user's default as well.			
3 ALTEP authorization is required to delete the copy in the archives.							
5 Some archived data sets reside on tape and some in a special partitioned data set on disk. Different programs are required for the various data set type/storage medium combinations.

NOTES				NOTES			
	MODULE	LABEL	REF		MODULE	LABEL	REF
1	IPCAMS is the IBM utility program that performs a variety of functions for VSAM data sets.			5	The DATA and INDEX component names are governed by an installation standard.		
4	For a VSAM data set the volume containing the catalog entry must be determined and used in the RACDPF, rather than the volume containing the data set. If entered from Chart D4 then the RACDPF issued at step 7 of Chart D32 will have already indicated whether a specific profile exists or not and an associated return code is available for testing. This RACDPF is bypassed if the return code is non-zero. If entered from Chart D12 then the RACDPF issued at step 3 of Chart D31 will have set the appropriate value in the flag in ACBDEFP indicating whether the profile exists or not. In this case this RACDPF is always issued and the pre-processing exit will bypass SVC processing if the flag is set.						

HYPO-DIAGRAM D41

Migrate a Data Set to the Archives

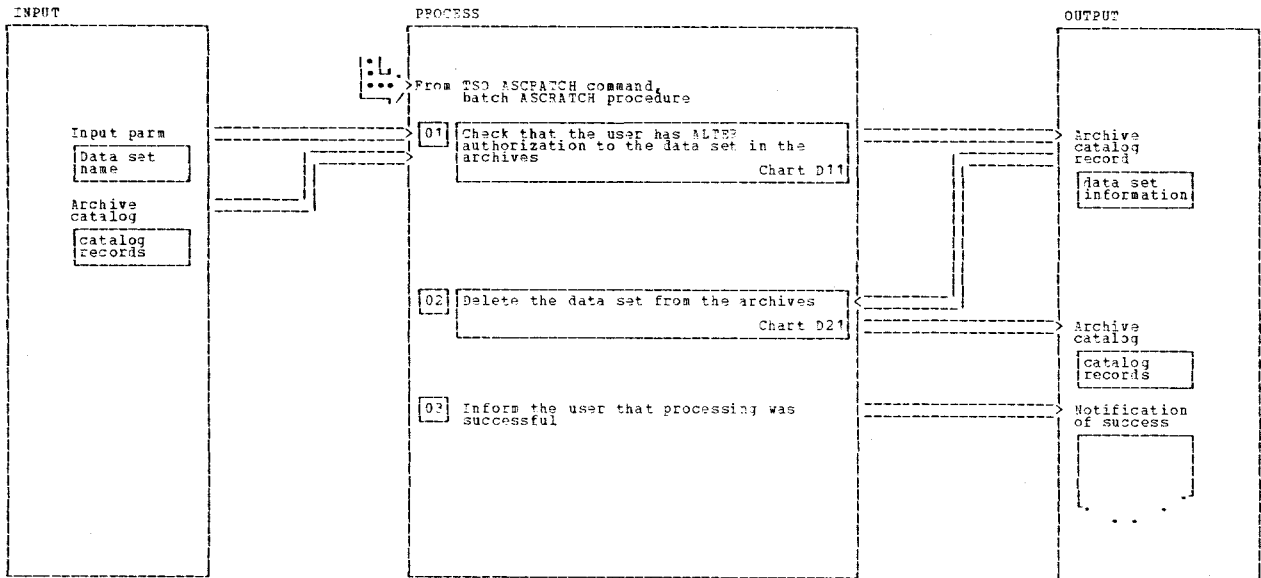

HIPO-DIAGRAM D5

Migrate a Data Set to the Archives

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
1 Although no data access is involved in the MIGRATE operation ALTR access is implied by its function.				2 The 'migration' data set contains an entry for each data set that has been migrated (flagged for off-line archival). The entry contains the data set name and an initial retention period for it.			

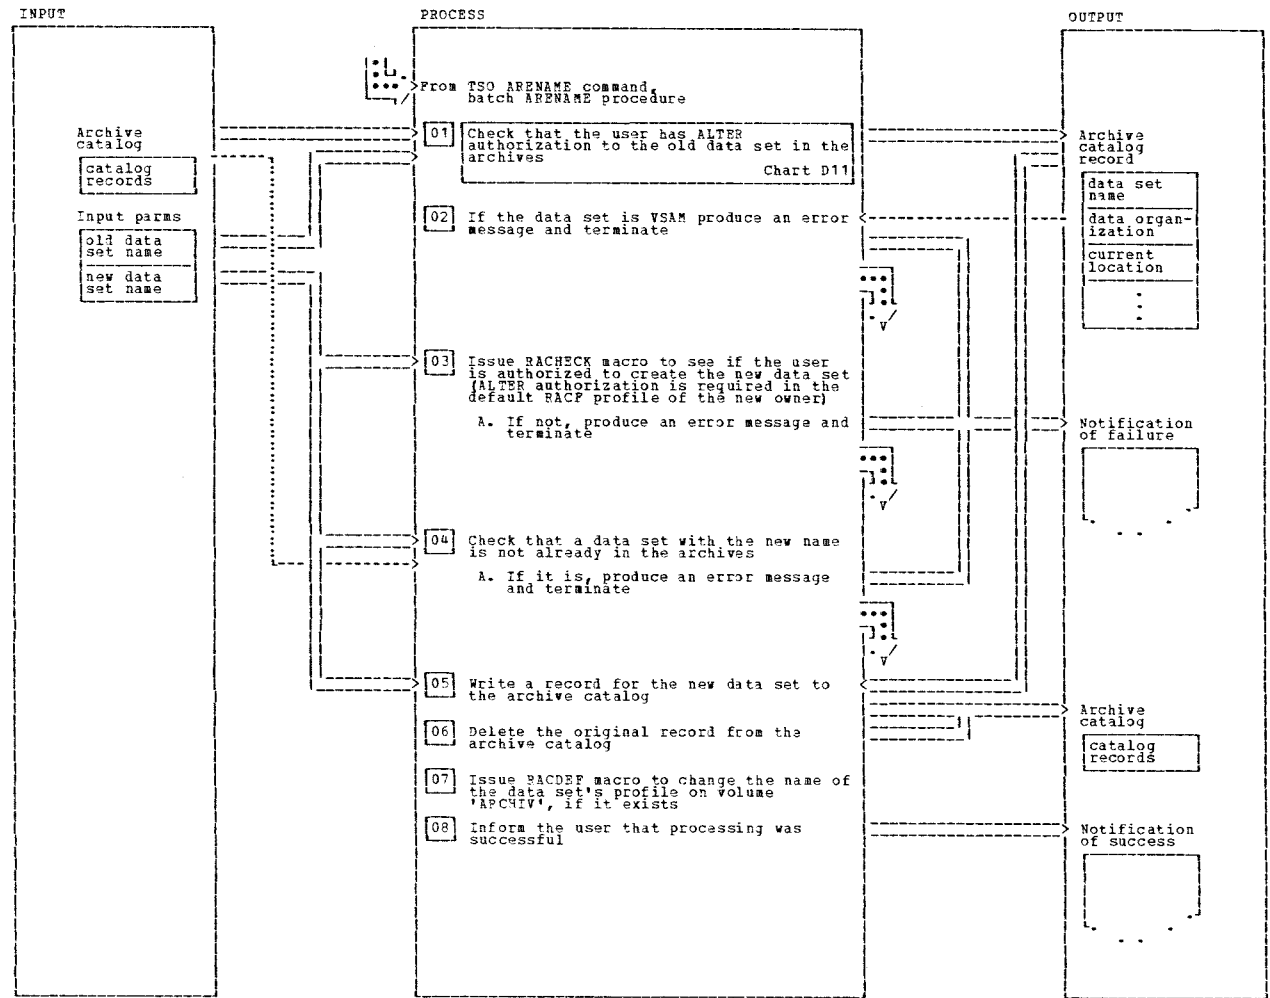

HIPO-DIAGRAM D5

Scratch a Data Set from the Archives

HIPO-DIAGRAM D6

Rename a Data Set in the Archives

HIPO-DIAGRAM D7

Rename a Data Set in the Archives

NOTES	MODULE	LABEL	REF	NOTES	MODULE	LABEL	REF
2 VSAM data sets cannot be renamed while in the archives due to VSAM catalog volume ownership implications.				7 The RACDEF NEWNAME option is used for this function. If the old name doesn't have a specific profile (it is protected by the user's default profile), then the RACDEF will fail and will not create a profile for the new data set, causing it to be protected by the default as well.			
3 This function is provided for consistency with the ability to create a disk data set for another user - see Charts C1 and C4.							

HIPO-DIAGRAM D7

# APPENDIX V

## LISTINGS OF RACF EXITS AND OTHER PROGRAMS

### Definitions of the flags used in the RACF exits

Control block	Displacement	Size	Bit	Exit	
ACEE	+12(ACEEIEP)	1	x0000000	ICHRCX02 ICHRDX01	indicates no profile exists for a disk data set
ACEE	+13(ACEEIEP)	3		ICHRIX01 ICHRCX01 ICHRIX02	points to an area containing the password and pointing to areas containing data set names
exit work area	+0	1	x0000000	ICHRIX01 ICHRIX02	indicates that password should not be checked
exit work area	+1	1	x0000000	ICHRIX01 ICHRIX02	indicates retry in progress
exit work area	+2	1	x0000000	ICHRIX01 ICHRIX02	indicates that RACINIT should be failed
exit work area	+0	1	x0000000	ICHRCX01 ICHRCX02	access allowed by pre-processing exit
exit work area	+1	1	x0000000	ICHRCX01 ICHRCX02	indicates retry of RACHECK with default profile

### Definitions of installation parameters used in exits

SVC	Parameter content	Use
RACDEF	'ARCHIVE'	indicates that SVC was issued by an archive program
RACDEF	dsn	RACHECK post-processing exit has issued RACDEF to create a profile for a new tape data set
RACHECK	dsn	OPEN has issued a RACHECK during the creation of a new tape data set

## APPENDIX VI

## INSTALLATION OF THE MODIFICATIONS TO RACF

The full implications should be understood if any of the following instructions are not carried out as defined.

- (1) Install RACF according to IBM documentation.
- (2) Identify and create all necessary RACF groups. These will include one or more groups for system data sets (in particular group SYS for all SYS1, SYS2 etc. data sets) as well as those groups required for users.
- (3) Define all users in the UADS data set to RACF using the CLISTs supplied in Appendix V. Create RACF user definitions for any other users not defined in UADS. Batch jobs submitted from TSO will include the USER parameter on any generated job cards and will fail if the users are not defined to RACF. The ADDUSER command below is suitable for adding users:-

```
ADDUSER userid PASSWORD(password) DFLTGRP(group-name)
CLAUTH(TAPEVOL) GRPACC
```

However note that this command will set the password expired, and it will have to be changed the next time the user accesses the system. If this is considered acceptable then the users will have to be warned that it is going to happen, and instructed on how to change the password. At DRCS this was circumvented by initially setting each user's password to a dummy value and generating and running a batch job for each user that changed the dummy password to his current password in UADS. The jobs consisted simply of a job card with the USER and PASSWORD parameters (the latter nominating the dummy and current passwords) and an EXEC statement to execute IEFBR14.

- (4) Modify the RACF exits as required. For example, the exits assume 3 character userids and groupids and contain code to control unusual users at DRCS. In addition tape volume protection is defined only for a range of volume serial numbers.
- (5) Install the RACF exits, the SUBMIT exit and the RACF CLISTs and CATFIND command.
- (6) Install the RACDEF modification if archive functions will be used with RACF in the same manner as at DRCS.
- (7) Install the OPEN modification if tape access control will be used.
- (8) Install the SCRIBBLE modifications if privacy control for disk data sets is critical.
- (9) Define default profiles for all users and groups, e.g.

```
ADDSD 'userid.RACF.MODEL.PROFILE' NOSET
VOLUME(DUMMY) UNIT(DISK) UACC(ALTER)
```

(The SEARCH command can be used to generate the commands).

- (10) Define RACF options including tape volume protection, e.g.

```
SETROPTS CLASSACT(*) TERMINAL(READ) INTERVAL(90)
NOSTATISTICS(*) INITSTATS AUDIT(*) SAUDIT
CMDVIOL LIST
```

- (11) Create profiles for all existing tape volumes. A suitable command to define a tape profile is:-

```
RDEFINE TAPEVOL(volser) OWNER(ownerid)
DATA(' userid ')
```

The DATA parameter must include the userid or groupid of the first data set on the volume with one blank on the left and padded with blanks on the right to a total of 9 characters. The OWNER parameter is the same as the userid if it is a user data set, or identifies the group administrator if it is a group data set. The owner is the only user who can issue the first SHARE command to specifically protect any data set on the volume.

The RDEFINE commands can be automatically created by a program or CLIST that reads and interprets information from the catalogs.

- (12) Protect VSAM catalogs and CVOLs e.g.

```
ADDSD 'SYS1.CATALOGA' UACC(UPDATE)
```

The VSAM catalog names must be prefixed by a valid RACF userid or groupid to do this, or the RACF exits must be changed to bypass the naming conventions. It is possible to rename a VSAM catalog by appropriate internal modifications.

- (13) Test RACF for selected users by turning on the DSCB protect flag for their DISK data sets e.g.

```
ADDSD dsn
DELDSD dsn NOSET
```

A program or CLIST to automatically generate these commands from catalog or VTOC information greatly reduces the effort involved. Specify automatic data set protection, e.g.

```
ALTUSER userid ADSP
```

Alter the default profile, e.g.

```
ALTDSD 'userid.RACF.MODEL.PROFILE' NOSET UACC(NONE)
```

Enter SHARE commands to define the levels of access to be authorized.

- (14) After testing RACF successfully with the selected users, protect all system data sets, again using ADDSD and DELDSD commands. Issue the appropriate ALTDSD commands to define the access available to the default profiles of the groups or users associated with the system data sets and use SHARE commands to specifically protect any individual data sets that require a different level of access. For example, most SYS1 data sets can be read by users. The default profile for group SYS at DRCS therefore specifies UACC(READ). However certain data sets required a higher level of access, such as SYS1.BROADCAST, and must have their own profiles.

- (15) Educate users and induce them to define access authorities to their data sets, (e.g. by providing access reports to owners and users of data sets).
- (16) Educate the group administrators and have them check and correct the users connected to the groups and their group authorities.
- (17) When an appropriate period has elapsed, turn on the DSCB protect flags for all disk data sets. This can be done by generating commands as in (13) by processing a VTOC listing or catalog listing. Alter user profiles for automatic data set protection (the SEARCH command can be used to generate a CLIST). Alter the default profiles to specify UACC(NONE), again using the SEARCH command.  
Delete any disk data set profiles for which no data set exists (caused during the period when specifically defined data sets did not have the DSCB bits on and therefore the profiles were not deleted when the data sets were).

## MODIFICATION TO THE RACDEF SVC

The modification is to CSECT ICHRDF00, which is at MVS Rel 3.8A base level and is expressed in SMP4 format.

[illegible]

## APPENDIX VIII

## MODIFICATION TO OPEN FOR CREATION OF TAPE DATA SETS

This modification passes the JFCB and therefore the data set name to the RACFDEF SVC whenever a new tape data set is defined or a new volume added to an existing one.

The modification is to CSECT IFG1094F, which is at PTF UZ22357 level, and is expressed in SMP4 format.

```

++USERMOD(LOCZ014) .

# APPENDIX IX

## MODIFICATION TO JES2

The purpose of this modification is to place the name of the JES reader that processed a job in columns 73 to 80 of the JOB card. The information is then available to SMF exit IEFUJV for validity checking. It can be used, for instance, to prevent certain users from accessing TSO, or to place constraints on which users may submit batch jobs from particular RJE's.

The modification is to module HASPRDR, which is at PTF UZ24623 level, and is expressed in SMP4 format.

```

++USERMOD(LOCSU03) .
++VER(Z038) FMID(EJE1102) PRE(UZ24623) .

          DROP  R1          DROP DCT ADDRESSABILITY      LOCSU03 92738005
./ ENDUP

```

## APPENDIX X

## MODIFICATIONS TO DADSM DURING RELEASE OF DISK SPACE

## X.1 Aim

The aim of the modification is to ensure that all disk space is erased as it is freed, thereby overcoming the security problems created by residual data. The erasure is automatic and is performed as a result of a scratch request (SVC 29) and a partial release request.

## X.2 Method

Both functions of DADSM have been modified to pass control to a module located in the link pack area (SCRIBBLE) to perform the actual erasure. In addition, DASDM has been altered to ensure that the disk volume is not reserved (enqueued) while the erasure is in progress, which could be for a considerable time, depending on the size of the data set.

The relevant steps currently performed by partial release are:-

- (1) reserve the disk
- (2) read the format 4 DSCB
- (3) set the DIRF bit and rewrite the format 4 DSCB
- (4) enqueue on the data set and process its format 1 DSCB, building a table of extents to be freed
- (5) read and process the format 3 DSCB, if necessary, adding to the extent table
- (6) delete the format 3 DSCB, if necessary, or
- (7) rewrite the format 3 DSCB, if necessary
- (8) rewrite the format 1 DSCB
- (9) update the format 5 DSCB free space chain if no previous VTOC error
- (10) reset the DIRF bit and rewrite format 4 DSCB
- (11) release the disk

This logic has been changed to the following:-

- (1) read the format 4 DSCB
- (2) enqueue on the data set and process its format 1 DSCB, building the extent table
- (3) read and process the format 3 DSCB, if necessary, adding to the extent table
- (4) invoke SCRIBBLE to erase the space
- (5) reserve the disk
- (6) reread the format 4 DSCB

- (7) set the DIRF bit and rewrite the format 4 DSCB
- (8) delete the format 3 DSCB, if necessary, or
- (9) rewrite the format 3 DSCB, if necessary
- (10) rewrite the format 1 DSCB
- (11) update the format 5 DSCB chain if no previous VTOC error
- (12) reset the DIRF bit and rewrite the format 4 DSCB
- (13) release the disk

This sequence ensures that the disk is not reserved during the possibly lengthy erasure while maintaining full integrity for the VTOC. In addition the erasure is performed even if the DIRF bit was originally set in the format 4 DSCB, indicating a previous VTOC error. This ensures that all unallocated areas on the disk will be clear when the VTOC is rebuilt.

A similar reorganization was made to the scratch logic. It currently is:-

- (1) enqueue on the data set
- (2) reserve the VTOC
- (3) read the format 1 DSCB and format 4 DSCB
- (4) set the DIRF bit and rewrite the format 4 DSCB
- (5) process the format 1 DSCB, building a table of extents to be freed
- (6) delete the format 1 DSCB by overwriting with a format 0 DSCB, reread it and then read the next DSCB in the chain (format 2 or 3 DSCB, or format 5 DSCB at the end of the chain)
- (7) repeat steps (5) and (6), processing the current DSCB, overwriting it and reading the next, until the end of the chain, when the first format 5 DSCB is read instead
- (8) update the format 5 DSCB free space chain if no previous VTOC error
- (9) reset the DIRF bit and rewrite format 4 DSCB
- (10) release the disk

This logic has been changed to the following:-

- (1) enqueue on data set
- (2) read the format 1 DSCB and format 4 DSCB
- (3) process the format 1 DSCB, building the extent table
- (4) save the address of the format 1 DSCB, read the next DSCB in the chain, if any
- (5) repeat steps (3) and (4), processing the current DSCB, saving its address and reading the next, until the end of the chain
- (6) invoke SCRIBBLE to erase the space

- (7) reserve the disk
- (8) reread the format 4 DSCB
- (9) set the DIRF bit and rewrite the format 4 DSCB
- (10) delete the DSCBs whose addresses have been saved, if any (by overwriting with a format 0 DSCB and read checking)
- (11) delete the last DSCB in the chain and read the first format 5 DSCB
- (12) update the format 5 DSCB free space chain if no previous VTOC error
- (13) reset the DIRF bit and rewrite the format 4 DSCB
- (14) release the disk

### X.3 The SCRIBBLE program

The input to the program is documented in the listing below. The program builds its own DEB, DCB etc and uses the erase channel command to erase the data. On conclusion it writes a user GTF record (ID=100) describing the request it has just processed. For efficiency SCRIBBLE tries to avoid erasing space that is already clear. For data set types except ISAM (where all the space is erased) only the space indicated by the last TTR field of the format 1 DSCB, plus one extra track, is erased initially. The next track is then read to see if it is clear. If so, the erasure is terminated. Otherwise a further 30 tracks are erased, another read performed, and so on. (There is nothing magic about the figure of 30 tracks, and no tests have been made to determine an optimum value.) During this process the DEB protects space belonging to other users.

In addition SCRIBBLE addresses the problem of catalog contention during erasure. An Access Method Services deletion invokes SVC 29 with the catalog containing the data set held exclusively. To avoid prolonged lockouts to the catalog in such a case SCRIBBLE frees it if more than 5 tracks are being erased and re-enqueues prior to returning to SVC 29. Standard catalog management routines IGGPRPLF and IGGPRPLM are used for this. However they must be link-edited as aliases of module IGG0CLA1.

### X.4 Operating characteristics

Tests indicate that about 30 tracks per second can be erased on a 3350 disk in a 'stand-alone' environment. The channel utilization in achieving this is quite small (about 3-4%), as is the CPU utilization (about 1.5 secs per 100 cylinders of 3350 space on a 3033). In practice we find that the average elapsed time per cylinder erased on a heavily loaded system (40+ TSO users, IMS, 5 or 6 batch jobs) is about 1.4 seconds. However the average time for a deletion initiated from TSO is only 0.4 seconds, and this increase in response time is not perceptible.

Only about 30% of space deleted in this installation is actually erased. The remainder is already clear. (We delete about 19000 tracks per hour, erasing about 5700 of them). The erase load is distributed fairly evenly over 17 disk drives and 4 channels. The overload is only 0.05% of the total capacity of each channel (assuming it can achieve 100%), and 0.33% of the capacity of each disk drive (again assuming a possible 100%).

### X.5 Modifications to partial release

The modifications are expressed in SMP4 format. They apply to MVS Release 3.8 at PTF level 7908. PTF UZ23177 has been applied to CSECT IGG020P1. CSECTs IGG202P2 and IGG020P3 are at 3.8A base level.

## X.7 SCRIBBLE program listing

SCRIBBLE START 0

\*

\* THIS ROUTINE IS CALLED FROM DASDM PARTIAL RELEASE (IGG020P2) AND  
 \* DASDM SCRATCH (IGG0299A) TO ERASE SPACE BEING FREED BEFORE IT IS  
 \* PUT BACK ON THE FMT5 FREE SPACE LIST.  
 \* ON ENTRY THE FOLLOWING INFORMATION IS AVAILABLE -  
 \* REG 6 HAS THE ADDRESS OF A SAVE AREA  
 \* REG 7 HAS THE ADDRESS OF THE DASDM EXTENT TABLE  
 \* REG 8 HAS THE NUMBER OF TRACKS PER CYLINDER FOR THE DEVICE IN  
 \* BYTE 0 AND THE UCB ADDRESS IN BYTES 1 TO 3  
 \* REG 10 HAS 'S' IN BYTE 0 IF CALLED FROM SCRATCH OR 'R' IF CALLED  
 \* FROM PARTIAL RELEASE AND HAS THE DATASET NAME ADDRESS IN  
 \* BYTES 1 TO 3  
 \* REG 11 HAS THE DATASET ORGANIZATION FROM THE DS1DSORG FIELD IN  
 \* BYTE 0 AND THE TTR OF THE LAST BLOCK FROM THE DS1LSTAR  
 \* FIELD IN BYTES 1 TO 3 (FOR A SCRATCH REQUEST ONLY)

\* DELETIONS OCCURING AS A RESULT OF A REQUEST TO ACCESS METHOD  
 \* SERVICES (AMS) ENTER SCRIBBLE WITH THE OS VSAM CATALOG HELD WITH AN  
 \* EXCLUSIVE ENQ. TO AVOID PROLONGED LOCKOUTS OF THE CATALOG FOR LARGE  
 \* DELETIONS IT IS DEQ'ED PRIOR TO THE ERASURE AND RE-ENQ'D AFTER.  
 \* THE CATALOG MANAGEMENT ROUTINES IGGPRPLF AND IGGPRPLM ARE USED TO  
 \* DEQ AND ENQ THE CATALOG RESPECTIVELY. THEY ALSO CAUSE EXTRA OVERHEAD  
 \* RELATED TO FREEING AND REACQUIRING BUFFERS ETC.  
 \* BOTH ROUTINES EXPECT THE ADDRESS OF THE CATALOG COMMUNICATIONS AREA  
 \* TO BE IN REG 11 AND THE ADDRESS OF THE NEXT AVAILABLE 3 WORD SAVE  
 \* AREA FROM THE CCA IN REG 13 AND THEY DESTROY ALL REGISTERS EXCEPT  
 \* 11 TO 14.  
 \* TO DETERMINE IF THIS IS AN AMS REQUEST WE NEED TO SEE IF SVC 29  
 \* (DADSM SCRATCH) WAS INVOKED BY SVC 26 (CATALOG MANAGEMENT). IF SO  
 \* THE REGS REQUIRED (11 AND 13) CAN BE OBTAINED FROM THE SAVE AREA OF  
 \* THE APPROPRIATE SVRB. TO DO THIS THE RB CHAIN MUST BE TRACED. THE  
 \* INTERRUPT CODE THAT CAUSED THE CREATION OF THE CURRENT RB IS STORED  
 \* IN THE NEXT RB IN THE CHAIN, WHILE THE REGISTER CONTENTS WHEN IT  
 \* RELINQUISHED CONTROL ARE IN THE PREVIOUS RB IN THE CHAIN.  
 \* THE LINK SVC IS USED TO TRANSFER CONTROL TO IGGPRPLF AND IGGPRPLM  
 \* AND THIS REQUIRES BOTH TO BE DEFINED AS ALIASES OF IGGCLA1.

## 17 SUMMARY OR ABSTRACT:

(if this is security classified, the announcement of this report will be similarly classified)

The Resource Access Control Facility (RACF) is a software package designed to control access by users to a computer system and to data stored on the system. This report describes the modifications and additions to the functions of RACF which were made during its installation in the computing centre at the Defence Research Centre. RACF is described in sufficient detail to allow the operation of the modifications to be clearly explained. The report also summarizes the functions and standards of the computing centre and lists the actions taken to accommodate users with non-standard requirements.
