

SUSQUEHANNA RIVER BASIN, FALLS CREEK, LUZERNE COUNTY GNational Dam Inspection Program. LAKE CATALPA DAM NDSHD NO_PA-560 Number DER-ID 40-57 A. C. NESBIT III PHASE I INSPECTION REPORT Kim ba 500 8¢ acw31-89-C-0029 Prepared By L. ROBERT KIMBALL & ASSOCIATES CONSULTING ENGINEERS & ARCHITECTS EBENSBURG, PENNSYLVANIA 15931 FOR DEPARTMENT OF THE ARMY BALTIMORE DISTRICT CORPS OF ENGINEERS BALTIMORE, MARYLAND 21203 411 \$ 59 SEPTEMBER, 1980 Hit to an

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through frequent inspections can unsafe conditions be detected and only through continued care and maintenance can these conditions be prevented or corrected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the spillway design flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. The spillway design flood provides a measure of relative spillway capacity and serves as an aid in detemining the need for more detailed hydrologic and hydraulic studies, consistent damage, go of the dam, its general condition and the downstream damage, go the dam, its general condition and the downstream damage, go the damage of the dama noucel AVCIL 5

in the set of the set of the set of the set of the set

Lake Catalpa Dam Pennsylvania Luzerne Falls Creek Lat: 41° 23.6' Long: 75° 59.6' May 20, 1980 and July 30, 1980

ASSESSMENT

The assessment of Lake Catalpa Dam is based upon visual observations made at the time of inspection, review of available records and data, hydraulic and hydrologic computations and past operational performance. The inspection and review of the data of Lake Catalpa Dam did not reveal any immediate problems which require emergency action. The dam appears to be in good condition and adequately maintained.

Lake Catalpa Dam is a high hazard-intermediate size dam. The spillway design flood (SDF) for a dam of this size and classifications is the PMF. \neg The spillway and reservoir are capable of controlling approximately 33% of the PMF. Based on criteria established by the Corps of Engineers, the spillway is termed inadequate.

The following recommendations and remedial measures should be instituted immediately.

1. A detailed hydrologic and hydraulic analysis should be conducted by a registered professional engineer knowledgeable in dam design and construction to increase the spillway capacity of the dam. Recommendations resulting from this study should be implemented immediately.

2 The maintenance schedule and procedures presently in use should be continued. The existing crack in the concrete on the downstream face of the dam should be monitored on a regular basis and repaired if the monitoring program indicates that the crack is enlarging.

3. The rigid fish screen which spans the spillway crest blocks free access of flow to the spillway. The screen should be removed. A method should be developed to stop debris from blocking the spillway culvert and one which does not effect free discharge at the spillway.

4. Develop a warning system to warn downstream residents in event of large spillway discharges or imminent failure of the dam. LAKE CATALPA DAM PA 560

5. A safety inspection program should be implemented with inspections at regular intervals by qualified personnel.

L. ROBERT KIMBALL & ASSOCIATES CONSULTING ENGINEERS AND ARCHITECTS

PHASE I NATIONAL DAM INSPECTION PROGRAM LAKE CATALPA DAM NDI. I.D. NO. PA 560 DER I.D. NO. 40-57

SECTION 1 PROJECT INFORMATION

1.1 General.

a. <u>Authority</u>. The National Dam Inspection Act, Public Law 92-367, authorized the Secretary of the Army, through the Corps of Engineers, to initiate a program of inspection of dams throughout the United States.

b. <u>Purpose</u>. The purpose of the inspection is to determine if the dam constitutes a hazard to human life or property.

1.2 Description of Project.

a. Dam and Appurtenances. Lake Catalpa Dam is an earthen embankment with dry masonry walls on both the upstream and downstream sides. Portions of the downstream slope have been replaced with concrete walls. The maximum height is 23 feet. The crest width ranges from 27.5 feet to 30 feet, the crest length is 160 feet. A paved road passes over the crest of the dam. Parapet walls are present both upstream and downstream above the roadway elevation. The reservoir drain is operated by a sluice gate located in the valve house and consists of a 30" pipe of unknown material. The sluice gate is operated and lubricated both in the spring and fall of each year. The sluice gate controls flow through the drainline which passes through the embankment.

The spillway is a three sided weir structure placed against the upstream wall with a total crest length of 26 feet. The weir crest is formed by an ogee crest with fish screens along the entire length. The ogee slopes to the entrance of a tunnel through the dam. The tunnel is 6 feet wide and 8.1 feet to 12.7 feet high. The tunnel discharges into an open rectangular shaped channel, at the downstream end of the structure. This rectangular channel continues for about 20 feet where it discharges into a tributary of Leonard Creek.

Concrete buttresses were added to the structure and portions of the downstream slope masonry was replaced with concrete in 1966.

b. Location. The dam is located on Falls Creek, a tributary to Leonard's Creek, Luzerne County, Pennsylvania. Lake Catalpa Dam can be located on the Center Moreland, U.S.G.S. 7.5 minute quadrangle.

c. <u>Size Classification</u>. Lake Catalpa Dam is an intermediate size structure (23 feet high, 1031 acre-feet).

d. <u>Hazard Classification</u>. The hazard classification for Lake Catalpa Dam was determined to be high. Downstream conditions at the time of inspection indicated that loss of more than a few lives is probable should the structure fail. Several homes are located approximately one mile downstream of the dam.

e. <u>Ownership</u>. Lake Catalpa Dam is owned by Abraham Nesbitt, III. Correspondence should be addressed to:

Abraham Nesbitt, III R.D. #1 Dallas, Pennsylvania 18612 717-639-5492

f. <u>Purpose of Dam</u>. The dam was originally constructed to furnish mill power for a small saw mill and as a private ice supply. Currently the dam is used for fishing and recreation.

g. Design and Construction History. The dam was originally constructed in 1860 by Elijah Harris. The dam was rebuilt in the fall of 1929. The roadway across the crest of the dam was constructed at this time. According to information in the PennDER files the upstream masonry wall was continued down into the old fill material as a corewall and tied into rock for most of its length. Concrete buttresses and concrete walls were added to the structure in 1966 by the Sardoni Construction Company. The repairs to the dam were designed by Mr. John M. Coon an architect from Luzerne, Pennsylvania.

h. Normal Operating Procedures. The owner of the dam accompanied the inspection team on the inspection of the dam and stated that regular maintenance is conducted on the dam. It was determined that the fish screens are cleaned daily in the spring and every 10 days in the summer. Maintenance on the concrete walls is completed on an unscheduled basis. In 1979 epoxy was applied to the upstream wall. The reservoir drainline is reportedly operated and lubricated in the spring and fall of each year.

SECTION 2 ENGINEERING DATA

2.1 <u>Design</u>. Some correspondence and inspection reports were available for review in the PennDER files. No construction plans or structural details were available.

2.2 <u>Construction</u>. Very little information was available on the construction of the dam. Several inspection reports exist in the PennDER files. These indicate that the structure was built in 1860 and rebuilt in 1927. According to information in the files the upstream concrete wall extends through the original embankment to a rock foundation to provide an impervious cutoff. The owner indicated that maintenance construction was completed in 1966, including installation of concrete buttresses and concrete walls. This construction was done by Sardoni Construction Company. The design work relative to the 1966 modifications was completed by John M. Coon an architect from Luzerne, Pennsylvania.

2.3 <u>Operation</u>. No operating records are known to exist. The owner indicates that the fish screens are cleaned daily in the spring and approximately every ten days during the summer months. The owner also lubricates and operates the sluice gate valves in the spring and fall of each year.

2.4 Evaluation.

Sec. Star Office in

a. <u>Availability</u>. Engineering data was provided by PennDER, Bureau of Dams and Waterway Management. The owner was available for interview and he informed the inspection team of current maintenance and operating procedures. The owner also indicated that maintenance construction was done in 1966.

b. <u>Adequacy</u>. No design data was available for review for the purposes of this report. Minimal information was available concerning the upkeep of the dam, and overall history. This Phase I report is based on visual inspections, hydrologic and hydraulic analysis. Sufficient information exists to complete a Phase I report.

SECTION 3 VISUAL INSPECTION

3.1 Findings.

٦

a. <u>General</u>. The onsite inspection of Lake Catalpa Dam was conducted by personnel of L. Robert Kimball and Associates on May 20, 1980 and August 30,1980. The inspection consisted of:

- 1. Visual inspection of the retaining structure, abutments and toe.
- 2. Examination of the spillway facilities, exposed portion of any outlet works and other appurtenant works.
- 3. Observations affecting the runoff potential of the drainage basin.
- 4. Evaluation of the downstream area hazard potential.

b. Dam. The dam appeared to be in good condition. From a brief survey conducted during the inspection it was noted that the crest elevation of the structure is generally consistent. A low spot exists on the right abutment and was considered the top of dam for our analysis. The crest width was measured to be between 27.5 and 30 feet. The dam length is approximately 160 feet. An earth core is supported by vertical masonry wall on both the upstream and downstream sides. The most recent inspection of the structure was in 1944. That inspection report noted slight settlement and cracking of the upstream wall about 20 feet left of the spillway. Also noted in that inspection report was some seepage through the masonry structure. This inspection noted some cracking near the center of the dam.

c. <u>Appurtenant Structures</u>. The water level at the time of inspection was estimated to be 1270. The spillway appears to be in good condition. The entire crest of the spillway was topped with a rigid steel frame fish screen two feet high. This fish screen is reportedly cleaned and maintained on a regular basis. However in the event of major flooding the screen would become clogged, therefore in our analysis of the spillway the crest was considered to be the top of the screen.

The drainline for the reservoir consists of a 30" pipe of unknown material operated by a sluice gate located in the valve house. This gate is reportedly lubricated and operated in the spring and fall of each year.

ð

A.

d. <u>Reservoir Area</u>. Most of the hillside slopes surrounding the pond are wooded and are moderately steep and rise to an elevation of 100 to 200 feet above the surface of the pond. The area seems to be fairly stable and not susceptible to massive landslides which would affect the storage volume or cause overtopping of the dam by displacing water.

e. <u>Downstream Channel</u>. Lake Catalpa Dam empties into Falls Creek. Falls Creek flows through a fairly steep and narrow valley for a distance of approximately 1 mile at which point it enters Leonard Creek. Leonard Creek then flows for approximately 4 miles and empties into Bowmans Creek, which in turn enters the North Branch of the Susquehanna River.

3.2 <u>Evaluation</u>. In general, the structure and outlet works appear to be in good condition. The drainline was not observed during the inspection.

7

ŧ

SECTION 4 OPERATIONAL PROCEDURES

11 M

4.1 <u>Procedures</u>. Water level is maintained at an approximate elevation of 1270.0. The fish screen is reportedly maintained and cleaned on a regular basis. However in the event of major flooding, it could be assumed that this screen would clog with debris and that the effective spillway crest would be at elevation 1271.5.

4.2 <u>Maintenance of the Dam</u>. The concrete walls are maintained and repaired on an unscheduled basis. An epoxy mixture was applied to the upstream walls in 1979. The maintenance of the dam appears to be good.

4.3 <u>Maintenance of Operating Facilities</u>. The operating procedures for the dam and its facilities consist of regular cleaning and maintenance of the fish screens obstructing the spillway and the semi-annual maintenance and operation of the sluice gate. The overall condition of the facilities appeared good, although the gate was not operated at the time of inspection.

4.4 <u>Warning System in Effect</u>. There is no known warning system in effect to warn any downstream residents of large spillway discharges or imminent failure of the dam.

4.5 <u>Evaluation</u>. In general the maintenance of the operating facilities and dam appears to be good, however there is no known warning system in effect to warn downstream residents of large spillway discharges or imminent failure.

1

Contraction and and

SECTION 5 HYDRAULICS AND HYDROLOGY

5.1 Evaluation of Features.

a. <u>Design Data</u>. PennDER files contained no information concerning hydrologic and hydraulic design for these facilities. However, there exists a 1930 inspection report which sugests that the spillway without the fish screen would discharge some 1360 cfs, or about 650 cfs per square mile. The report continues and notes that it is doubtful that the tunnel entrance will take much more than half that quantity.

b. <u>Experience Data</u>. No rainfall, runoff or reservoir level data was available. It was indicated that the maximum waterlevel experienced was in 1972 during hurricane Agnes and that the water level reached the top of the fish screens. The spillway reportedly has functioned adequately in the past.

c. <u>Visual Observations</u>. The spillway appeared to be in good condition, although along the entire crest of the spillway there exists a rigid fish screen. In the event of a major flood this screen could become clogged with debris and the effective spillway crest elevation would be the top of the screens at an elevation of 1271.5.

d. <u>Overtopping Potential</u>. Overtopping potential was investigated through the development of the probable maximum flood (PMF) for the watershed and the subsequent routing of the PMF and fractions of the PMF through the reservoir and spillway.

The Corps of Engineers, Baltimore District, has directed that the HEC-1 Dam Safety Version systemized computer program be utilized. The program was prepared by the Hydrologic Engineering Center (HEC), U.S. Army Corps of Engineers, Davis, California, July, 1978. The major methodologies or key input data for this program are discussed briefly in Appendix D.

5.2 <u>Evaluation Assumptions</u>. To enable us to complete the hydraulic and hydrologic analysis for this structure, it was necessary to make the following assumptions.

1. Pool elevation prior to the storm was at the top of the fish screen structure at elevation 1271.5.

2. Top of dam was considered to be the low spot elevation at the right abutment, 1275.4. The top of the parapet walls would generally be considered the top of dam.

3. Discharge through the drainline was not considered.

9

in the second

Bern Bernet Hilling

5.3 <u>Summary of Overtopping Analysis</u>. Complete summary sheets for the computer output are presented in Appendix D.

Peak inflow (PMF)	5740 cfs
Spillway capacity	723 cfs (top of screen
	normal pool)
Storage capacity	1031 ac-ft

a. <u>Spillway Adequacy Rating</u>. The Spillway Design Flood (SDF) for a dam of this size and classification is the PMF. Based on the following definition provided by the Corps of Engineers, the spillway is rated as inadequate.

Inadequate - All intermediate high hazard dams which do not pass the spillway design flood (PMF).

The spillway and reservoir are capable of controlling 33% of the PMF storm without overtopping the dam.

5.4 <u>Summary of Dam Breach Analysis</u>. The subject dam cannot satisfactorily pass 50% of the PMF based on our analysis therefore it was necessary to perform the dam breach analysis and downstream routing of the flood wave. This analysis determined the degree of increased flooding due to dam failure.

A reservoir pool elevation of 1275.75 was considered sufficient to cause failure of the Lake Catalpa Dam. This elevation represents a depth of overtopping of approximately 0.35 foot over the low spot of the dam for a duration of approximately 4 hours.

The resulting flood wave was routed downstream with and without failure considerations. Downstream potential for loss of life and property damage is not significantly increased by dam failure. Therefore, the spillway is rated as inadequate. A detailed printout of the breach analysis is included in Appendix D.

SECTION 6 STRUCTURAL STABILITY

6.1 Evaluation of Structural Stability.

a. <u>Visual Observations</u>. Minor concrete cracking was evident near the center of the dam in the masonry. The concrete and concrete buttresses appeared to be in good condition. No seepage was observed through the dam or at the toe of dam.

b. <u>Design and Construction Data</u>. No design or construction data existed in the PennDER files. There was a note in the DER files that some deterioration of the concrete did exist. This problem however has been repaired in the past and the present concrete is in good condition.

c. Operating Records. No operating records are known to exist. However, the owner indicated that regular cleaning and maintenance is done to the fish screen on the spillway crest, and that the sluice gate is operated and lubricated on a semiannual basis.

d. <u>Post Construction Changes</u>. The dam was originally constructed in 1860. It was rebuilt in 1929 and additional concrete buttresses were added in 1966.

e. <u>Seismic Stability</u>. The dam is located in seismic zone 1. No seismic stability analyses has been performed. Normally, it can be considered that if a dam in this zone is stable under static loading conditions, it can be assumed safe for any expected earthquake loading. No visual deficiencies were observed which would affect the stability of the dam. No stability analysis have been completed to date on this structure to document long-term stability.

11

Sec.15

SECTION 7 ASSESSMENT AND RECOMMENDATIONS/REMEDIAL MEASURES

7.1 Dam Assessment.

a. <u>Safety</u>. The dam appears to be in good condition. No signs of immediate instability were observed during the inspection. Minor cracking is occurring near the center of the dam in the masonry on the downstream face of the dam. No seepage or erosion was noted at the time of inspection, however past inspections reports indicate that seepage and concrete deterioration existed. Lake Catalpa is capable of controlling approximately 33% of the PMF. The spillway is rated as inadequate but not seriously inadequate.

b. <u>Adeqacy of Information</u>. This Phase I report is based on the visual inspection and a hydrologic and hydraulic analysis. Sufficient information is available to complete a Phase I Report.

c. <u>Urgency</u>. The recommendations suggested below should be implemented immediately.

d. <u>Necessity for Further Investigation</u>. In order to accomplish some of the recommendations/remedial measures outlined below, further investigations will be required.

7.2 Recommendations/Remedial Measures.

1. A detailed hydrologic and hydraulic analysis should be conducted by a registered professional engineer knowledgeable in dam design and construction to increase the spillway capacity of the dam. Recommendations resulting from this study should be implemented immediately.

2 The maintenance schedule and procedures presently in use should be continued. The existing crack in the concrete on the downstream face of the dam should be monitored on a regular basis and repaired if the monitoring program indicates that the crack is enlarging.

3. The rigid fish screen which spans the spillway crest blocks free access of flow to the spillway. The screen should be removed. A method should be developed to stop debris from blocking the spillway culvert and one which does not effect free discharge at the spillway.

4. Develop a warning system to warn downstream residents in event of large spillway discharges or imminent failure of the dam.

5. A safety inspection program should be implemented with inspections at regular intervals by qualified personnel.

POST CONSTRUCTION ENGINEERING STUDIES AND REPORTS	Several inspection reports available in DER files.
PRIOR ACCIDENTS OR FAILURE OF DAM Description Reports	Unknown.
MA INTENANCE OPERATION RECORDS	Concrete walls drainline gate operated and lubricated semi-annually. Fish screens are cleaned on a regular basis.

APPENDIX D HYDROLOGY AND HYDRAULICS

<u>Methodology</u>. The dam overtopping and breach analyses were accomplished using the systemized computer program HEC-1 (Dam Safety Investigation), September, 1978, prepared by the Hydrologic Engineering Center, U.S. Army Corps of Engineers, Davis, California. A brief description of the methodology used in the analysis is presented below.

1. <u>Precipitation</u>. The Probable Maximum Precipitation (PMP) is derived and determined from regional charts prepared from past rainfall records including "Hydrometeorological Report No. 40" prepared by the U.S. Weather Bureau.

The index rainfall is reduced from 10% to 20% depending on watershed size by utilization of what is termed the HOP Brook adjustment factor. Distribution of the total rainfall is made by the computer program using distribution methods developed by the Corps.

2. <u>Inflow Hydrograph</u>. The hydrologic analysis used in development of the overtopping potential is based on applying a hypothetical storm to a unit hydrograph to obtain the inflow hydrograph for reservoir routing.

The unit hydrograph is developed using the Snyder method. This method requires calculation of several key parameters. The following list gives these parameters their definition and how they were obtained for these analysis.

Parameter	Definition	Where Obtained
Ct	Coefficient representing variations of watershed	From Corps of Engineers*
L	Length of main stream channel miles	From U.S.G.S. 7.5 minute topgraphic
Lca	Length on main stream to centroid of watershed	From U.S.G.S. 7.5 minute topographic
Cp	Peaking coefficient	From Corps of Engineers*
A	Watershed size	From U.S.G.S. 7.5 minute topographic

*Developed by the Corps of Engineers on a regional basis for Pennsylvania.

D-1

è

R

3. <u>Routing</u>. Reservoir routing is accomplished by using Modified Plus routing techniques where the flood hydrograph is routed through reservoir storage. Hydraulic capacities of the outlet works, spillways and the crest of the dam are used as outlet controls in the routing.

The hydraulic capacity of the outlet works can either be calculated and input or sufficient dimensions input and the program will calculate an elevation discharge relationship.

Storage in the pool area is defined by an area - elevation relationship from which the computer calculates storage. Surface areas are either planimetered from available mapping or U.S.G.S. 7.5 minute series topographic maps or taken from reasonably accurate design data.

4. <u>Dam Overtopping</u>. Using given percentages of the PMF the computer program will calculate the percentage of the PMF which can be controlled by the reservoir and spillway without the dam overtopping.

5. Dam Breach and Downstream Routing. The computer program is equipped to determine the increase in downstream flooding due to failure of the dam caused by overtopping. This is accomplished by routing both the pre-failure peak flow and the peak flow through the breach (calculated by the computer with given input assumptions) at a given point in time and determining the water depth in the downstream channel. Channel cross-sections taken from U.S.G.S. 7.5 minute topographic maps were used in the downstream flood wave routing. Pre and post failure water depths are calculated at locations where crosssections are input.

Lake Catalpa and its dam lie within the (Glaciated) Low Plateaus Section of the Appalachian Plateaus Physiographic Province. This area is characterized by broad anticlines and synclines and little, it any, faulting. There are no known faults in the vicinity of the dam.

The rocks underlying the lake and dam consists of the Devonian aged Susquehanna Group. This is a complex unit of conglomerate, sandstone, siltstone and shale. The usually well developed bedding ranges in thickness from less than one to over fifteen feet. The well developed joints are regular and closely spaced in the shales and siltstones. They are vertical or steeply dipping and usually form a blocky or platy pattern. The shales disintegrate rapidly, but the siltstone, sandstone and conglomerate are fairly resistant to weathering. The rocks of the Susquehanna Group form a good foundation for heavy structures if excavated to sound material and the shales and siltstones are kept water-free. The interstitial porosity of the coarser rocks is low, but joint development has created a medium level of total effective porosity.
