#### PREFACE

This report is prepared under guidance contained in the <u>Recommended</u> <u>Guidelines for Safety Inspection of Dams</u>, for Phase I Investigations. Copies of these guidelines may be obtained from the Department of the Army, Office of Chief of Engineers, Washington, D.C. 20314.

The purpose of a Phase I investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon visual observations and review of available data. Detailed investigations and analyses involving topographic mapping, subsurface investigations, material testing, and detailed computational evaluations are beyond the scope of a Phase I investigation; however, the inspection is intended to identify any need for such studies which should be performed by the owner.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of the dam depends on numerous and constantly changing internal and external factors which are evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through frequent inspections can unsafe conditions be detected and only through continued care and maintenance can these conditions be prevented or corrected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the spillway design flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. The spillway design flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

The assessment of the conditions and recommendations was made by the consulting engineer in accordance with generally and currently accepted engineering principles and practices.

#### PHASE I INSPECTION REPORT NATIONAL DAM INSPECTION PROGRAM

#### BRIEF ASSESSMENT OF GENERAL CONDITION AND RECOMMENDED ACTION

Name of Dam:	Johnson's Pond
	NDI ID NO. MD-11
Size:	Intermediate (1930 acre-feet, 16.5 feet high
Hazard Classification:	High
Owner:	City of Salisbury
	P.O. Box 791
	Salisbury, Maryland 21801
State Located:	Maryland
County Located:	Wicomico
Stream:	Wicomico River
Date of Inspections:	July 10, 1980 and August 5, 1980

Based on the visual inspection, available records, past operational performance, and in accordance with the guideline criteria established for these studies, Johnson's Pond dam is judged to be in good condition.

The dam is constructed across the full width of the North Prong of the Wicomico River in Salisbury, Maryland. The dam consists of a concrete and steel ogee spillway, wingwalls, and a clay fill enbankment constructed on either side of the spillway. Including the lengths of clay fill embankments shown on the contract drawings of the dam, the total length of the dam is 580+ feet. The concrete and steel structure is comprised of a 300 foot long ogee spillway with wingwalls at the left and right abutments. According to the dam crest survey, the lowest point along the clay fill is elevation 14.5 and is located adjacent to the right wingwall. The crest elevation of the ogee spillway is +11.1, and a 30 foot long notch with a crest elevation of 10.6 is located in the middle of the spillway. Three sluice gates are located in the spillway directly below the notch.

The water level in Johnson's Pond is normally maintained at elevation +11, the crest elevation of the ogee spillway. The water level can be controlled by opening any of the three manually operated sluice gates. The gates are normally opened once a year during the winter to lower the water level by approximately 6 feet. This is done to expose and kill plants growing on the bottom of the pond. The water level was lowered one foot below the crest elevation for this inspection so that the condition of the ogee spillway could be checked.

Several cracks were noted in the concrete of the ogee spillway and the wingwalls, but the cracks are not considered large enough to adversely affect the structural stability of the dam at this time. The two largest cracks were noted on the wingwalls, extending through the

JOHNSON'S POND NDI ID NO. MD-11

walls from the spillway crest to the top of the wingwall. The crack in the left wingwall is approximately 0.25 inch wide and the crack in the right wingwall is approximately 0.5 inch wide. Cracking is responsible for a piece of concrete being displaced on the upstream side of the spillway along a joint located 20+' left of the spillway notch. No displacement was noted along any other cracks in the spillway, and no water was noted seeping through the cracks on the downstream side of the spillway. Minor spalling of the concrete was noted on the crest of spillway near the left wingwall.

According to the hydrologic and hydraulic analyses, the Johnson's Pond embankment will overtop by 0.4 foot for a duration of 10 hours during a flood equaling 50 percent of the Probable Maximum Flood (PMF). The analyses indicate that the Johnson's Pond spillway can pass approximately 43% of the PMF before overtopping commences. Dam breech analyses suggest that failure of the Johnson's Pond dam would raise water levels in the industrialized area between Isabella Street and U.S. Route 50 by less than one foot over the water surface that would have existed just prior to failure. It is judged that this nominal rise in flood levels would not significantly increase the hazard to loss of life than that already existing prior to dam failure. Therefore, the spillway of the Johnson's Pond dam is rated as inadequate, but not seriously inadequate.

The following remedial measures are recommended to be accomplished by the Owner:

- 1. Conduct a hydrologic and hydraulic study to determine what remedial measures are necessary to provide adequate capacity of the spillway.
- 2. Repair the cracks which extend through the right and left wingwalls from the crest of the ogee spillway to the top of each wingwall.
- 3. Repair the cracks noted in the ogee spillway before the cracks enlarge.
- 4. Raise the embankment to the design elevation.
- 5. Carefully inspect the ogee spillway for additional cracks, seepage through cracks or displacement of concrete along the cracks at least once a year while the water level is down.
- 6. Develop a formal warning system to alert downstream residents in the event of emergencies.

JOHNSON'S POND

A. OVERVIEW

#### PHASE I INSPECTION REPORT NATIONAL DAM INSPECTION PROGRAM

#### JOHNSON'S POND NDI ID NO. MD-11

#### SECTION 1 PROJECT INFORMATION

- 1.1 General.
  - a. <u>Authority.</u> The Dam Inspection Act, Public Law 92-367, authorized the Secretary of the Army, through the Corps of Engineers, to initiate a program of inspection of dams throughout the United States.
  - b. <u>Purpose</u>. The purpose of the dam inspection program is to determine if the dam constitutes a hazard to human life or property.
- 1.2 Description of Project.
  - Dam and Appurtenances. Johnson's Pond dam consists of a 8. concrete and steel ogee spillway, wingwalls, and a clay fill embankment constructed on either side of the spillway. According to the profile of the dam shown on the contract drawings, the total length of the dam, including the clay fill embankments, is 580+ feet. The concrete and steel ogee spillway is 300 feet long. The low point elevation along the clay fill, noted adjacent to the right wingwall, is 14.5; the elevation of the wingwalls is 16; the crest elevation of the ogee spillway is 11.1; and the elevation of a 30 foot long notch located in the center of the ogee spillway is 10.6. The water level in Johnson's Pond is normally maintained at the crest elevation of the ogee spillway. The water level can be lowered by opening three manually operated sluice gates located below the notch in the ogee spillway.
  - Location. The dam is constructed across the North Prong of the Wicomico River in Salisbury, Maryland approximately 0.6 mile upstream of the Route 50 bridge. Johnson's Pond is shown on U.S.G.S. Quadrangle, Salisbury, Maryland, at latitude N 38° 22' 24" and longitude W 75° 36' 6". A location map is included as Plate E-1.
  - c. <u>Size Classification</u>. Intermediate (1930 acre-feet, 16.5 feet high).

-1-

- d. <u>Hazard Classification</u>. High Hazard. There are businesses and residences along the Wicomico River downstream of the dam which could be damaged in a flood resulting from a dam failure. The embankment and bridge carrying Isabella Street over the Wicomico River 700 feet downstream of the dam could also sustain damage from a flood.
- e. <u>Ownership</u>. City of Salisbury, P.O. Box 791, Salisbury, Maryland 21801
- f. Purpose of Dam. Recreation.
- g. Design and Construction History. The dam was constructed in 1936 by the Federally funded Works Progress Administration. According to profiles and typical sections of the dam shown on the contract drawings, the dam is 580+ feet long, including the 300 foot long ogee spillway, wingwalls, and clay fill embankments on either side of the spillway. The ogee spillway is 20 feet wide at the base and is constructed in between two lines of steel sheet piles. The steel sheet piles extend 100 feet outside the wingwalls on either side of the spillway.
- h. <u>Normal Operating Procedure</u>. Johnson's Pond is normally maintained at the spillway crest elevation of +11. The sluice gates are usually opened during the winter to lower the water level enough to expose and kill plants growing on the bottom of the pond.
- 1.3 Pertinent Data.

#### SECTION 2 DESIGN DATA

- 2.1 Design.
  - a. <u>Data Available</u>. The available information was provided by the State of Maryland, Water Resources Administration. The information consists of a revised set of contract drawings dated August 1, 1936 and a limited amount of design computations and correspondence relative to design of the dam.
    - (1) Hydrology and Hydraulics. A limited amount of hydrologic and hydraulic computations are available.
    - (2) <u>Embankment</u>. The only information available is shown on the contract drawings.
    - (3) <u>Appurtement Structure</u>. The only information available is shown on the contract drawings.
  - b. Design Features.
    - (1) Embankment. According to the contract drawings, the embankment on either side of the ogee spillway is comprised of clay fill. Steel sheet piling which was driven for the upstream side of the ogee spillway extends approximately 100'+ from the wingwalls into the embankments on either side of the spillway. The top elevation of the sheet piling is +5 and the bottom elevation ranges from -2 to -15. The fill cannot be differentiated from natural ground, but based on the contract drawings, the clay fill extends approximately 140 feet from the wingwalls on either side of the spillway.
    - (2) <u>Appurtenant Structures.</u> The appurtenant structures of the dam consist of the ogee spillway and the outlet works. The concrete and steel ogee spillway is 300 feet long and has a 30 foot long notch at its center. The ogee spillway is constructed in between two lines of steel sheet piling having a top elevation of +5 on the upstream side and a top elevation of 0 on the downstream side. The outlet works consist of three, 48 inch square openings equi-spaced below the spillway notch and three 48 inch square sluice gates. The gate stems are located on a deck constructed above the spillway notch. The water level in Johnson's Pond can be lowered by opening the gates.
  - c. Design Data.
    - (1) <u>Hydrology and Hydraulics</u>. Limited design data are included in the available design computations.

- (2) Embankment and Appurtenant Structures. The only design data available are shown on the contract drawings.
- 2.2 <u>Construction</u>. Construction of the dam was completed in 1936. No dam construction records are available.
- 2.3 Operation. No records are kept of the operation of the dam or appurtenant structures.
- 2.4 Other Investigations. No records of other investigations are available.
- 2.5 Evaluation.
  - a. <u>Availability</u>. The contract drawings, the limited design computations, and the correspondence provided by the State of Maryland, Water Resource Administration are the only data available.
  - b. <u>Adequacy</u>. The available data, not including any construction records or detailed design calculations, is considered insufficent to evaluate the design and construction of the dam.

-5-

#### SECTION 3 VISUAL INSPECTION

- 3.1 Findings.
  - a. <u>General.</u> The on site inspection of Johnson's Pond consisted of:
    - (1) Visual inspection of the embankment, abutments, and embankment toe.
    - (2) Visual examination of the appurtement structures.
    - (3) Evaluation of the downstream area hazard potential.
    - The specific observations are shown on Plate A-1.
  - b. <u>Embankment.</u> The general inspection of the embankment consisted of searching for indications of structural distress, such as cracks, subsidence, bulging, wet areas, seeps and boils, and observing general maintenance conditions, vegetative cover, erosion. and other surficial features. The contract drawings indicate that the clay fill extends approximately 140 feet from the wingwalls on either side of the ogee spillway. Other than the noticeable projection of the fill into the river on the left side of the dam the clay fill cannot be differentiated from natural ground. The fill on the left side of the dam is covered primarily with grass, and trees grow along the bank. The fill on the right side is covered with grass and trees.

The crest of the clay fill embankment was surveyed and the variance in elevation was 10 inches between the high and low point on the left side, and was 36 inches between the high and low point on the right side. It should be noted that the contract drawings show that the clay fill on both sides of the ogee spillway was to be constructed even with the top of the wingwalls, or to elevation 16. The low point of the fill was elevation 14.5 noted adjacent to the right wingwall. The crest elevations measured on the left side of the dam ranged from 15.1 to 15.8. Since there is no evidence that any fill was removed from the crest by natural processes, it is presumed that either the fill was not constructed in accordance with the contract drawings, or regrading of the fill has been accomplished since construction of the dam.

Datum for the crest survey was based on a reference elevation on the crest of the ogee spillway provided by the chief surveyor for the City of Salisbury. The dam crest profile is included on Plate A-2.

-6-

Appurtenant Structures. Generally, the appurtenant structures were found to be in good condition. Several cracks were noted in the concrete of the ogee spillway and the wingwalls, but the cracks are not considered large enough to adversely affect the structural stability of the dam at this The two largest cracks were noted on the wingwalls. time. extending through the walls from the spillway crest to the top of the wingwall. The crack in the left wingwall is approximately 0.25 inches wide and the crack in the right wingwall is approximately 0.5 inches wide. Cracking is responsible for a piece of concrete being displaced on the upstream side of the ogee spillway along a joint located 20+ feet left of the spillway notch. No displacement was noted along any other cracks in the spillway, and no water was noted seeping through the cracks on the downstream side of the spillway. Minor spalling of the concrete was noted on the spillway crest near the left wingwall.

с.

To expose the spillway for our inspection, the pond level was lowered approximately 1 foot by opening the sluice gates the day before our visit.

During our inspection, personnel of the City of Salisbury manually closed all three sluice gates, and the gates appeared to function satisfactorily. The gates are normally opened at least once a year, and usually during the winter, to lower the water level in order to expose and kill plants growing on the bottom of the pond.

The crest of the ogee spillway was surveyed and the variance in elevation was 1 inch between the high and low point, not including the spillway notch at the center of the spillway. The low point elevation was 11.1, which is equal to the design crest elevation of the spillway. The Dam Crest Profile is included on Plate A-2.

- d. <u>Reservoir Area.</u> An urban residential area surrounds the impoundment. A community beach and recreational area is located along the left shoreline of Johnson's Pond approximately 800 feet upstream from the dam. No significant amount of shore erosion was noted.
- e. <u>Downstream Channel</u>. The downstream channel is the North Prong of the Wicomico River. Its confluence with the South Prong is 0.75 miles downstream of the dam. A railroad trestle bridge is located 400+ downstream of the dam, and the bridge opening at Isabella Street is 700+ feet downstream. Approximately 25 feet upstream of Isabella Street is a wooden weir which extends across the river and controls the tailwater level of Johnson's Pond. The floodplain downstream from the

-7-

dam is highly industrialized, particularly between the Isabella Street bridge and the Maryland Route 50 bridge, located approximately 0.6 miles downstream of the dam. A few residences were noted in the floodplain downstream of the Route 50 bridge.

3.2 <u>Evaluation</u>. The visual examination and observations of the Johnson's Pond dam indicated that the structure is in good condition. We recommend that the cracks in the wingwalls be repaired the next time the sluice gates are open for an extended period of time.

#### SECTION 4 OPERATIONAL FEATURES

- 4.1 <u>Procedure.</u> There are no formal operating prodecures for the dam. The pond level is normally maintained at the crest elevation of the ogee spillway. During the winter, personnel of the City of Salisbury open the sluice gates to lower the water level approximately 6 feet to expose and kill plants growing on the bottom of Johnson's Pond.
- 4.2 <u>Maintenance of the Dam.</u> Maintenance of the dam is considered to be satisfactory.
- 4.3 <u>Maintenance of Operating Facilities</u>. Maintenance of the Operating Facilities is considered to be satisfactory.
- 4.4 <u>Warning System.</u> No formal warning system exists for the dam. Telephone communication facilities are available from the residences along the shoreline upstream from the dam.
- 4.5 <u>Evaluation</u>. The overall maintenance condition of the dam and its appurtenant structures is considered to be good.

والالكرز وورياته

1. S. 1. P. 1. 19. 14.

#### SECTION 5 HYDRAULICS AND HYDROLOGY

#### 5.1 Evaluation of Features.

- a. <u>Design Data.</u> Correspondence dated January 30, 1936 and addressed to the Water Resources Commission of Maryland by the City of Salisbury indicates that the spillway for Johnson's Pond was designed to carry a peak discharge of 8400 cubic feet per second (cfs) or 200 cfs per square mile from a 42-square mile Wicomico River drainage area. Subsequent review computations by the State of Maryland suggests that the design depth of flow over the spillway crest was approximately 4 feet. Based upon the final spillway crest elevation shown on August 1, 1936 contract drawings, the apparent design high water level for Johnson's Pond was about 15 feet above mean sea level when passing 8400 cfs.
- b. <u>Experience Data.</u> No records of maximum pool levels are available.

In August, 1933, prior to construction of the dam for Johnson's Pond at its present site, a major flood overtopped the existing bridge and embankment which formed the original dam for Johnson's Pond at Isabella Street some 700 feet downstream from the present dam site. It is reported that this flood event washed out the eastern bridge approach rendering the dam useless.

Tide data for the Wicomico River indicates a mean high tide of 2.07 feet above m.s.l. and a mean low tide of 0.93 feet below mean sea level. Driven timber sheeting forming a sharp crested weir across the Wicomico River just upstream from Isabella Street eliminates the affect of normal tidal fluctuations upon tailwater levels at the present dam for Johnson's Pond since its crest elevation exceeds mean high tide events. However, during record high tide events, the weir becomes submerged and tidewaters extend to the spillway apron at Johnson's Pond. Available data indicates that the August 1933 flood produced a record high tide of 8.07 feet above m.s.l.

c. <u>Visual Observations</u>. Several observations made during the visual inspection of the Johnson's Pond impoundment are particularly relevant to the hydraulic and hydrological evaluations.

-10-

- (1) Embankment. The field survey of the embankments or nonoverflow sections of the dam adjacent to the left and right wingwalls of the ogee spillway indicates that the crests of the existing non-overflow sections are lower than their design elevation of 16 feet above m.s.l. The low points for the left and right non-overflow sections are 15.1 and 14.5 feet above m.s.l., respectively. The data for the existing crests of the non-overflow sections was employed in subsequent hydraulic analyses.
- (2) Ogee Spillway and Appurtenant Structures. The spillway crest has been constructed in accordance with the record contract drawings. The three 48-inch by 48-inch sluice gates which control discharges through openings in the ogee spillway below its crest were demonstrated during the visual inspection and operated as designed. These gates are normally closed except for a short period in the winter when the pool level is lowered to implement vegetation control measures. Subsequent hydraulic analyses assumes that these gates are in a closed position during the occurrence of a major flood event.
- (3) Downstream Conditions. Failure of the dam impounding Johnson's Pond could cause significant damage to the intensely developed industrialized area downstream between Isabella Street and U.S. Route 50. Large fuel oil storage depots serving the Maryland Eastern Shore characterize the major type of industrial development in Other facilities situated in this reach this area. include a brickyard, feed supply center, automotive parts warehouse, concrete plant, and state highway maintenance yard. Because of the constricted opening at the Isabella Street bridge, a dam failure could also result in overtopping of the Isabella Street bridge approaches and severing Isabella Street, a Salisbury thoroughfare. Several shore residences situated just upstream from the dam but adjacent to and just slightly above the crest elevation of the left dam abutment could also be damaged if the dam abutments were overtopped. In keeping with the potential hazard classification criteria established by the Office of the Chief of Engineers (OCE), the downstream conditions suggest that a high hazard classification be assigned to the dam impounding Johnson's Pond.
- d. <u>Overtopping Potential</u>. According to the criteria promulgated by the Office of the Chief of Engineers, the recommended Spillway Design Flood (SDF) for a dam classified as "intermediate" with a "high" hazard potential is 100 percent of the Probable Maximum Flood (PMF).

-11-

The Probable Maximum Precipitation (PMP) index as adjusted for the Johnson's Pond drainage area is 21.1 inches in 24 hours. Employing criteria established by the Corps of Engineers, Baltimore District, 100 percent and 50 percent PMF inflow hydrographs developed using the HEC-1 computer program have peaks of 15,800 and 7,900 cfs, respectively. The 8400 cfs discharge rate employed in the original spillway design would occur during a flood event equivalent to 54 percent of the Probable Maximum Flood.

PMF inflow hydrographs were routed through Johnson's Pond for percentages ranging from 10 to 100 percent of the PMF with each routing starting at the normal pool level of 11.1 feet above m.s.l. These initial analyses employ ogee spillway discharge ratings which neglect the affect of spillway submergence caused by downstream conditions. . Spillway submergence resulting from backwater may occur as a result of the severe downstream channel constriction caused by the approaches to the Isabella Street bridge. The initial analyses suggest that the Johnson's Pond spillway can pass approximately 43 percent of the PMF without overtopping the adjacent non-overflow sections of the dam. However, for the 50 percent PMF routing, the reservoir water level reached an elevation of 14.9 feet above m.s.1. overtopping the low point in the right dam embankment by 0.4 feet. For the 100 percent PMF routing, the reservoir water level reached an elevation of 16.9 feet above m.s.l. overtopping the embankment low point by 2.5 feet. Additional results for the initial routing analyses are found in Appendix D.

Downstream channel routings of outflow hydrographs generated by the above reservoir routings indicate that the barrier caused by the approaches to the Isabella Street bridge will produce backwater conditions extending upstream to the Johnson's Pond spillway. In addition these analyses indicate that these approaches will be overtopped if the flood event exceeds 10 percent of the PMF. If these bridge approaches fail upon overtopping, the results from the initial reservoir routing analyses for Johnson's Pond can be considered valid since backwater conditions caused by the bridge embankment would not materialize for the 50 and 100 percent PMF events. If it is assumed that the bridge approaches do not fail, this affect or resultant backwater conditions upon the spillway discharge must be considered.

Additional analyses, which consider these potential backwater conditions, were performed for Johnson's Pond using inflow hydrographs ranging from 10 to 100 percent of the PMF. Under these conditions the additional analyses suggest that the Johnson's Pond spillway can pass only approximately 11 percent of the PMF without overtopping the non-overflow sections of the dam. For the 50 percent PMF routing the reservoir water level reached an elevation of 16.9 feet

-12-

above m.s.l. overtopping the embankment low point by 2.4 feet. For the 100 percent PMF routing, the corresponding water level and overtopping depth are 18.2 feet above m.s.l. and 3.7 feet, respectively. Results for intermediate routings of the alternate analyses are found in Appendix D.

- Spillway Adequacy. It is probable that the approaches to the Isabella Street bridge would fail prior to any failure of embankments adjacent to the Johnson's Pond spillway. For this reason, the initial reservoir routing analyses, which neglect tailwater conditions caused by the constriction at Isabella Street, have been employed in evaluating the spillway adequacy. These analyses indicate that overtopping of the Johnson's Pond embankment during the occurence of a 50 percent PMF event would have a duration of 10.0 hours. It is judged that a 0.4 foot maximum overtopping depth and 10.0hour duration could be sufficient to result in failure of the dam embankment. Dam failure analyses have been performed for two different failure configurations for a 50-percent PMF event assuming each failure begins when the dam first starts to be overtopped. (Failure configurations are identified in Appendix D). On the basis of these analyses, routing of the resultant flood wave downstream suggests that failure of the Johnson's Pond dam would raise water levels in the industrialized area between Isabella Street and U.S. 50 by only 0.5 feet to 0.7 feet over the water surface that existed failure, depending upon the just prior to breach configuration employed. It is important to note, however, that flood levels produced by passage of a 50 percent PMF flood event through this industrialized reach, assuming no dam failure, would exceed the top of the adjacent seawalls by approximately 5 feet. Such levels could cause serious damage to the industrialized development in this area and would undoubtedly pose a hazard to loss of life. It is judged that an increase of less than one foot over this flood level by a concurrent failure of Johnson's Pond would not significantly increase the hazard to loss of life already existing prior to Therefore the spillway is rated as the dam failure. inadequate but not seriously inadequate in accordance with Office of the Chief of Engineers guidelines.
- f. <u>Additional Considerations.</u> In evaluating the overtopping potential and spillway adequacy of Johnson's Pond, it was assumed that the peak spillway discharge resulting from a 50 percent probable maximum flood event occurred when the water level in the downstream reaches was at a mean high tide level of 2.1 feet above m.s.l. Should the occurrence of such an event coincide with a high tide equal in magnitude to the 8.1 high tide of record for the Salisbury area, it follows from the previous analyses that failure of the Johnson's Pond dam would not significantly increase the hazards associated with the flood and record high tide event over those hazards already existing prior to the failure.

# STRUCTURAL STABILITY

### 6.1 Evaluation of Structural Stability

- Visual Observations.
  - (1) Embankment. No deficiencies were noted for the clay fill embankment on either side of the ogee crest which could adversely affect the structural stability of the dam.
  - (2) Appurtenant Structures. At this time, the cracks noted in the wingwalls and in the ogee spillway are not considered large enough to adversely affect the structural stability of the dam. However, the existing cracks should be repaired so that they do not enlarge and pose a potential threat to the stability of the dam.
- b. Design and Construction Data.
  - (1) Embankment. The stability of the clay fill embankment cannot be adequately evaluated because of insufficient construction records and design calculations.
  - (2) <u>Appurtenant Structures.</u> The contract drawings include the structural details of the appurtenant structures and are sufficient to assess the adequacy of the ogee spillway, wingwalls, and sluice gates.
- c. <u>Operating Records</u>. The structural stability of the dam is not considered to be affected adversely by its operational features of the dam.
- d. <u>Seismic Stability</u>. Johnson's Pond dam is located in Seismic Zone 1. Based on our visual observations, the static stability of the dam appears to be adequate. Consequently, the structure should present no hazard from earthquakes.

above the same the same the same the

#### SECTON 7 ASSESSMENT AND RECOMMENDATIONS/REMEDIAL MEASURES

- 7.1 Dam Assessment.
  - a. <u>Assessment.</u> Johnson's Pond is an intermediate, high hazard impoundment. Failure of the dam embankment could cause significant damage to the intensely developed industrialized area downstream between Isabella Street and U.S. Route 50. The visual observations indicate that the embankment of Johnson's Pond is in good condition. At this time, the cracks noted in the wingwalls and the ogee spillway are not large enough to adversely affect the structural stability of the dam. However, the cracks should be repaired before they enlarge and pose a threat to the structural stability.

Hydrologic and hydraulic analyses indicate that the Johnson's Pond dam would be overtopped during a flood equaling 50 percent of the Probable Maximum Flood (PMF), but would not be overtopped by a flood event equal to or less than 48 percent of the PMF. Dam breech analyses suggest that failure of the Johnson's Pond dam would raise water levels in the industrialized area between Isabella Street and U.S. Route 50 by less than one foot over the water surface that would have existed just prior to failure. It is judged that this nominal rise in flood levels would not significantly increase the hazard to loss of life than that already existing prior to dam failure. Therefore, the spillway of the Johnson's Pond dam is rated as inadequate, but not seriously inadequate.

- b. <u>Adequacy of Information</u>. Coupled with the visual observations, the available information, even though it does not include construction records or design calculations for the clay fill embankments, is considered to be sufficient to make the recommendations that are given below.
- c. <u>Urgency</u>. Although there is no urgency in instituting the remedial measures recommended below, the measures should be accomplished in a timely manner.
- d. <u>Necessity for Additional Information</u>. No additional information is needed.

#### 7.2 Recommendations/Remedial Measures.

It is recommended that the following remedial measures be implemented by the Owner:

a. Conduct a hydrologic and hydraulic study to determine what remedial measures are necessary to provide adequate capacity of the spillway.

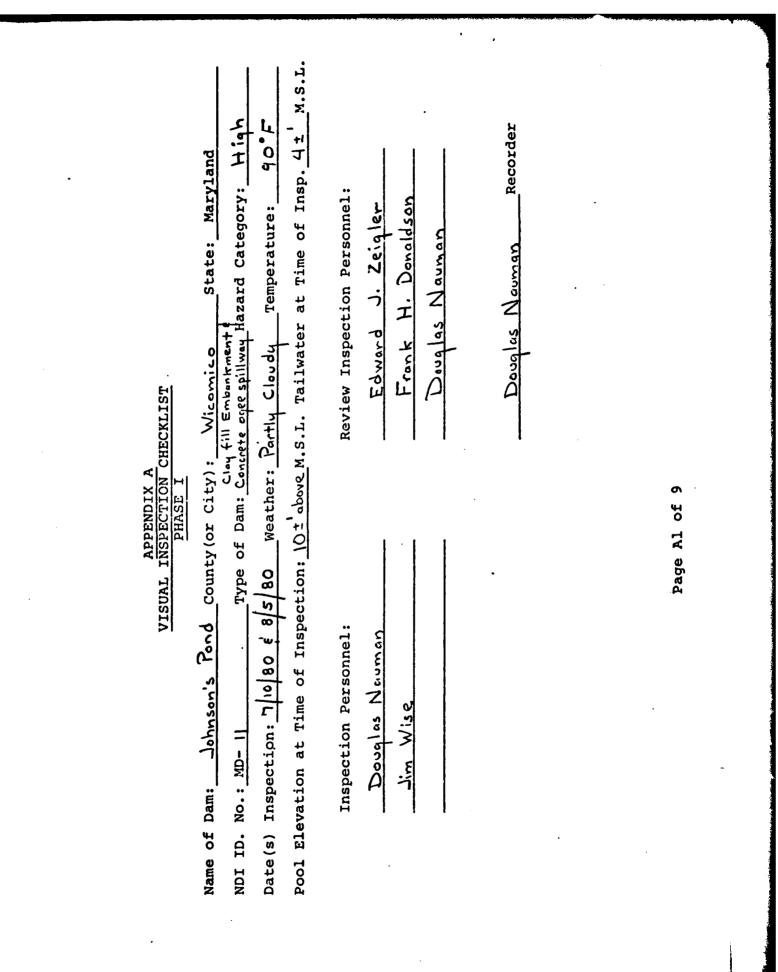

-15-

- b. Repair the cracks which extend through the right and left wingwalls from the crest of the ogee spillway to the top of each wingwall.
- c. Repair the cracks noted in the ogee spillway before the cracks enlarge.
- d. Raise the embankment to the design elevation.
- e. Carefully inspect the ogee spillway for additional cracks, seepage through cracks, or displacement of concrete along the cracks at least once a year while the water level is down.
- f. Develop a formal warning system to alert downstream residents in the event of emergencies.

### JOHNSON'S POND

## APPENDIX F

## REGIONAL GEOLOGY

The Johnson's Pond dam is situated on the sediments of the Pliocene Beaverdam Sand and the Pleistocene Parsonsburg Sand, which include sand and silty sand which is locally interbedded with gravelly sand and clayey silt. These sediments of the Coastal Plain Provience lie unconformably on the Upper Miocene deposits of the Yorktown Cohansey and the Pensaulken Formations. The Parsonsburg Sand is a relatively thin deposit in the area, rarely exceeding a depth of 10 feet. The thickness of the Beaverdam Sand is approximatley 30 feet, and the deposits generally thicken to the northwest and to the southeast.

### A CALLER CONTRACTOR CONTRACTOR

Qai

ALLUVIUM (HOLOCENE) - Largely sand, gravelly sand or clay. Narrow deposits fill most stream valleys, particularly in the eastern haif of the County; generally thin and poorly exposed. The headward part of a typical valley is swampy and underlain by peaty sand or clay. Downstream, the alluvium is mainly sand or gravelly sand, depending upon the texture of the formation traversed by any given stream.

Qtm

TIDAL MARSH DEPOSITS (HOLOCENE) - Silty clay to fine sand, dark gray to gray-brown, largely muck. Woody debris and finely comminuted organic matter abundant.

PARSONSBURG SAND (UPPER WISCONSIN) - Mostly sand, loose and light colored; pale yellow, yellowish orange, pale red-brown, or white. Locally at base where peaty, the sands are dark gray-brown. Most of the sand is medium-grained, although coarse sand and sand containing granules is locally common. Sorting varies in vertical cuts from good to poor. In outcrop the upper few meters of the Formation are red-brown, slightly clayey, and appear to be extensively burrowed. The material is laced with numerous cylindrical burrows about 3 cm (1 in) in diameter and 5-15 cm (2-6 in) long. Below the massive redened zone, thin bands of red-brown clayey sand are common in the thicker sections to a depth of as much as 3 m (10 ft). In some of the thickest sections, the lower part of the Parsonsburg Sand is well stratified with small scale cross beds. Concentrations of black minerals are common in the cross-bedded portion.

Qk

KENT ISLAND FORMATION (MIDDLE WISCONSIN OR UPPER SANGAMON) - Predominantly sand, white, yellow, brown, or pale to medium gray, interstratified with thin beds of dark-gray silt or silty fine-grained sand. Light-gray to white gravelly sands common at the base of the Formation. Underlies a broad lowland in the western part of the County between hilly topography of the Parsonsburg Sand along the east side of the Nanticoke River and a sandy terrain about 5 miles east of the river along a highly dissected northwest-trending scarp extending from Crows Nest on the southeast to Mardela Springs on the northwest. Most of the land surface here is at elevations ranging from 3.0-7.6 m (10 to 25 ft). Small dune-shaped sand bodies which rise above this general level are scattered across the lowland. North of Mardela Springs, a small area of lowland deposits flanks the east side of the lower Nanticoke River as far as the northern part of the County.
