SECURITY CLASSIFICATION OF THIS PAGE(When Data Entered)

Using the Corps of Engineers screening criteria for review of spillway adequacy, it has been determined that concrete gravity section of the dam would be overcopped for all storms enceeding approximately 12 percent of the Probable Maximum Flood (PMF). Although the spillway capacity is inadequate from a hydraulic and hydrologic point of view, the hydraulic inadequacy will not affect the safety of the dam because the concrete dam is supported on the sound rock and overtopping of the dam will cause neither significant erosion at the toe or abutment nor undermine the foundation of the dam. In addition, the stability of the concrete dam section is adequate during overtopping.

The following remedial and maintenance actions should be completed within one year.

- a. Establish a systematic program to observe changes of seepage occuring at the monoliths and the construction joints.
- b. "Remove all trees and brush growth on the slopes of the embankment. Provide a program of periodic cutting and mowing of the embankment surfaces.
- c. Provide a program of periodic inspection and maintenance of the dam and appurtenances including yearly operation and lubrication of the reservoir
 drain. Document this information for future references. Also develop an emergency action plan.

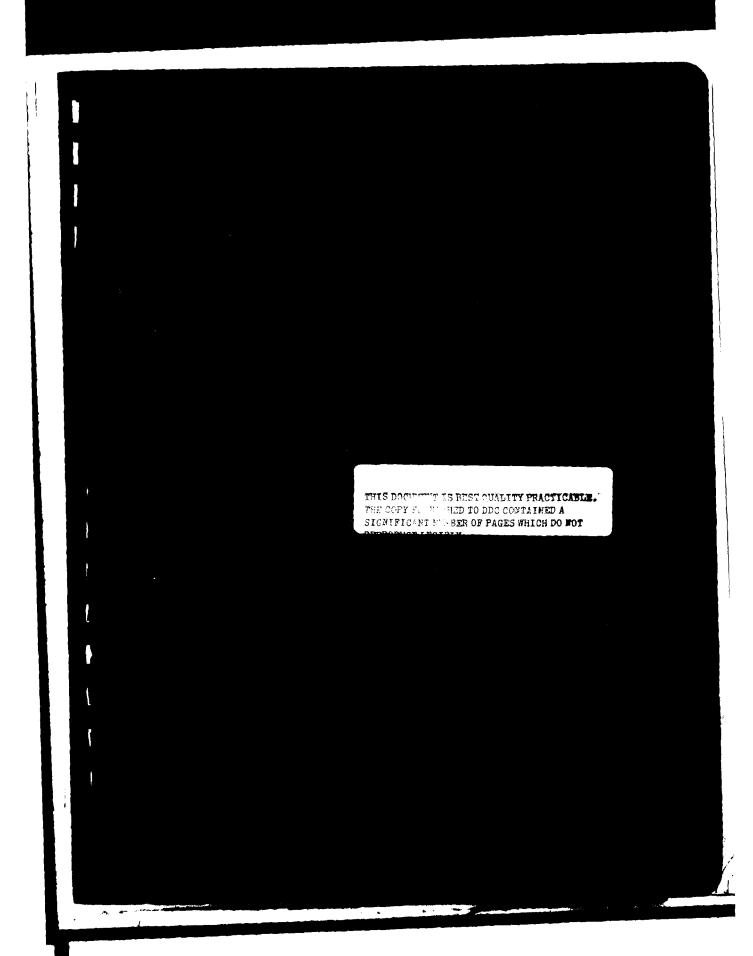

In addition to above remedial and maintenance action the following should be considered:

a. Resurface the downstream face to the original geometry.

DISCLAIMER NOTICE

THIS DOCUMENT IS BEST QUALITY PRACTICABLE. THE COPY FURNISHED TO DTIC CONTAINED A SIGNIFICANT NUMBER OF PAGES WHICH DO NOT REPRODUCE LEGIBLY.

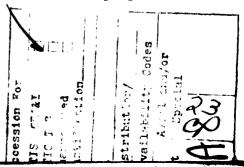

PREFACE

This report is prepared under guidance containted in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C., 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigations, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I Investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through frequent inspections can unsafe conditions be detected and only through continued care and maintenance can these conditions be prevented or corrected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the Spillway Test flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. Because of the magnitude and rarity of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as necessarily posing a highly inadequate condition. The test flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

PHASE I REPORT

NATIONAL DAM SAFETY PROGRAM

Name of Dam:	Lake Welch Dam (I.D. No.N.Y. 283)
State Located:	New York
County Located:	Orange
Stream:	Minisceongo Creek
Basin:	Hudson River
Date of Inspection:	April 24, 1980

ASSESSMENT

Examination of the available documents and visual inspection of the Lake Welch Dam did not reveal conditions which constitute a hazard to human life or property.

Using the Corps of Engineers screening criteria for review of spillway adequacy, it has been determined that concrete gravity section of the dam would be overcopped for all storms enceeding approximately 12 percent of the Probable Maximum Flood (PMF). Although the spillway capacity is inadequate from a hydraulic and hydrologic point of view, the hydraulic inadequacy will not affect the safety of the dam because the concrete dam is supported on the sound rock and overtopping of the dam will cause neither significant erosion at the toe or abutment nor undermine the foundation of the dam. In addition, the stability of the concrete dam section is adequate during overtopping.

The following remedial and maintenance actions should be completed within one year.

- a. Establish a systematic program to observe changes of seepage occuring at the monoliths and the construction joints.
- b. Remove all trees and brush growth on the slopes of the embankment. Provide a program of periodic cutting and mowing of the embankment surfaces.

A PART OF

 c. Provide a program of periodic inspection and maintenance of the dam and appurtenances including yearly operation and lubrication of the reservoir drain. Document this information for future references. Also develop an emergency action plan.

In addition to above remedial and maintenance action the following should be considered:

- a. Resurface the downstream face to the original geometry.
- b. High level outlet made operable.

PHASE I INSPECTION REPORT NATIONAL DAM SAFETY PROGRAM LAKE WELCH DAM I.D. NO. N.Y. 283 DEC #196-854 HUDSON RIVER BASIN ROCKLAND COUNTY, NEW YORK

SECTION 1 - PROJECT INFORMATION

1.1 GENERAL

a. Authority

The Phase I inspection reported herein was authorized by the State of New York, Department of Environmental Conservation by a letter dated 7 January 1980, in fulfilment of the requirements of the National Dam Inspection, Public Law 92-367, 8 August 1972.

b. Purpose of Inspection

This inspection was conducted to evaluate the existing conditions of the dam, to identify deficiencies and hazardous conditions, to determine if these deficiencies constitute hazards to life and property, and to recommend remedial measures where required.

1.2 DESCRIPTION OF PROJECT

a. Description of Dam and Appurtenant Structures

Lake Welch Dam, formerly known as Beaver Pond Dam is located on the east side of Lake Welch. The maximum height of dam is 32 feet. The dam is 788 feet long and consists of a concrete gravity section (563 feet) and an earth embankment (right of gravity section) with a central concrete core wall (225 feet). The concrete dam, supported on a rock foundation consists of 18 monoliths which are anchored to the rock by 25-ton post-tensioned rock anchors. According to available drawings the rock anchors are spaced along the crest 10 feet center to center and are embedded 10 feet into rock. (See drawings given in the Appendix A). The gravity section has a maximum height of 32 feet and a crest width of 3.5 feet. The upstream slope is vertical and downstream slope is 1.6V to 1H. The concrete includes a 152 foot-long spillway portion, the crest of which is one foot below the top of the dam.

The earth embankment at the left side of the concrete dam is about 10 feet wide at the crest and has a maximum height of 19 feet. The upstream slope is about 1V on 2.5H and covered with riprap. The downstream slope is 1V on 3H. A central corewall extends 2 feet from dam crest to the rock.and is about 1.6 feet wide at the top. The slope of the upstream face of the wall is vertical; the downstream face is battered downstream at 4V on 1H from the top of wall to a depth of about 6 feet, and vertical to the remainder of the depth.

There are two regulating outlet pipes located through the concrete dam. The high level outlet is a 12 inch diameter cast iron pipe which discharges water from a square concrete intake structure located at the upstream face of the concrete section, about 210 feet from the left abutment. Water discharges from the reservoir into the intake structure over two 3.3-foot long by 4-inch wide slot openings, located on two walls of the structure. The sill of the openings is at El. 1010, about 6 feet below the top of the concrete dam. Discharge through the pipe may be controlled by a gate valve which is operated from the top of the structure. According to available documents, the outlet once served as a service spillway maintaining the pool at El. 1010 during low flows.

The low level outlet is a 3-foot square sluiceway located through the concrete dam, about 180 feet from the left abutment. Discharge through the sluiceway is controlled by a manually operated sluice gate located at the upstream face of the dam, the control of which is located at the crest of the dam.

The two outlets and the spillway discharge into the natural channel of Minisceongo Creek.

b. Location

The dam is located within the Palisades Interstate Park. Harriman Section, about 2 miles west of the Town of Willow Grove, in Rockland County, New York.

c. Size Classification

The dam is 32 feet high, and has a lake storage capacity of 4,750 acre-feet (1,000 and to 50,000 acre-feet). Therefore, the dam is classified as "Intermediate".

d. Hazard Classification

The dam is in the high hazard potential category because a campsite, several homes along the creek and in the Town of Willor Grove, state Route 210 and the Palisades Interstate Parkway are all located within 1.5 miles downstream from the dam.

e. Ownership

Lake Welch Dam is owned, operated and maintained by the Palisades Interstate Park Commission of the New York State Department of Parks and Recreation, Administration Building, Bear Mountain, New York 10911, Tel. No. (914)786-2701.

f. Purpose of Dam

The impoundment provided by the dam is used mainly for recreation. This lake also supplies water via pipelines to campsites at the lake.

g. Design and Construction History

Original design and construction records are not available. It is reported the construction of the dam was completed in 1937. The designer of the original dam was Mr. W.A.Welch, Chief Engineer, Palisades Park Commission. The name of the Contractor is unknown. The concrete dam was rehabilitated in 1959 and 1979. Because of leakage the entire concrete dam was resurfaced in 1959 by applying a 3-inch "gunite" layer. In 1979, the concrete dam was again repaired because of leakage problems; in addition, the stability of the dam was improved. According to available documents, the entire concrete dam was strengthened by installing post-tensioned rock anchors from the crest of dam into the foundation. The post-tensioned rock anchors were installed and grouted in drill holes spaced at 10 feet center to center along the Additional holes were drilled through the dam crest. from the crest and pressure grouted. The design and supervision of the repairs were carried out by the engineering firm of Charles T. Main, Boston. In addition, the existing gunite surface of the downstream face was partially removed and the original concrete exposed in preparation for resurfacing later this year.

h. Normal Operating Procedure

Sur - La

The USGS map and available drawings show that the normal pool level once was maintained at El 1010, the level of the sill at the high level regulating outlet. Since the high level outlet pipe is now inoperative and the gate in the closed position, the lake level is maintained at the crest of the ungated principal spillway, El. 1015, about 1.3 feet below the top of the concrete dam.

I

SECTION 2 - ENGINEERING DATA

2.1 GEOLOGY

Lake Welch Dam is located in the New England Upland physiographic province of New York State. These uplands, with relief ranging from 500 to 1,300 feet above sea level, trend northeast-southwest; folds striking northeasterly and plunging slightly to the north are characteristic of the province. Fault lines throughout the New England uplands are generally parallel to the strike of the rocks. Bedrock in the vicinity of Lake Welch includes crystalline metasedimentary hornblende gneisses and leucogranitic gneisses of Precambrian Age.

2.2 SUBSURFACE INVESTIGATION

No subsurface investigation could be located for the project. However, the "General Soil Map of New York State" prepared by the Cornell University Experiment Station (1963) indicates that the surficial soils around Lake Welch Dam are of the Rockland-Chatfield Association. The Rockland, about 70% of the area, is steep slopes, gneiss rock outcrop with shallow, stony soil developed from glacial till. The remaining area is predominantly Chatfield soils that are moderately deep (less than 30 inches to bedrock), very stony and well drained, developed from glacial till derived from gneiss.

2.3 DESIGN RECORDS

The original dam was designed by Mr.W.A.Welch, Chief Engineer of the Palisades Interstate Park Commission. The dam is reported built in 1937. There are no design data or specific design memoranda available for the project features. Two contract drawings dated February 1928 were obtained from the New York State Department of Environmental Conservation and are given in Appendix A. The drawings show the plan, profile and details of the dam.

The concrete dam was resurfaced in 1959 by applying a 3 inch thick gunite surface. The details of modifications are shown on a drawing entitled "Details of Dam Repairs"dated July 17, 1958, prepared by the Palisades Interstate Park Commission and given in Appendix A.

Because of excessive seepage at the concrete dam, major modifications were made in 1979 in accordance with recommendations by Charles T. Main, Consulting Engineers, Boston, Massachusetts. The recommendations included chemical and cement grouting to control seepage through horizontal and construction joints and strengthening of the dam by installing rock anchors. The details of the modifications, shown on a construction drawing entitled "Lake Welch Dam Repairs", dated April 4, 1978 and prepared by Charles T. Main, Inc., Boston, Massachusetts, are given in the Appendix A.

2.4 CONSTRUCTION RECORDS

No detailed construction records of the original dam and the subsequent modifications are available; however, photographs and daily narratives of the 1979 repairs are available.

2.5 OPERATION RECORDS

There is no formal operation and maintenance manual for the project. There are no records of rainfall and operation of the gates and the sluiceways.

2.6 EVALUATION OF DATA

Existing information was made available by the New York State Department of Environmental Conservation, Albany, New York, and the owner.

The information obtained from the available data, the personal interviews and the visual inspection are considered adequate for the Phase I inspection and evaluation. Reviews of the original and subsequent drawings indicate some discrepancies, as follow:

- a. Crest elevation of the concrete dam is incorrectly shown on 1978 repair drawings.
- b. The length of spillway shown on the original drawing shows about 89.5 feet, whereas repair drawings of 1978 show about 152 feet. There are no construction records of the spillway modifications available; however, the spillway length of 152 feet was confirmed during the inspection.
- c. Geometry of the downstream face of the dam is in accordance with 1978 repair drawings and not as shown on the 1929 drawings.

SECTION 3 - VISUAL INSPECTION

3.1 FINDINGS

a. General

The visual inspection of the Lake Welch Dam was made on 24 April 1980. The weather was sunny with the temperature at about 60°F. The reservoir level was El.1015.4 at the time of inspection, about 3 inches above spillway crest.

b. Dam

(i) The Gravity Section Including Spillway:

The concrete gravity section appears to be in generally good condition. The horizontal and vertical alignment are uniform and there is no indication of movement. The crest and the upstream face above the waterline appears to be in good condition. At the crest there are grouted holes which were drilled during the recent repairs.

The gunite surface at the downstream face of the dam has been removed and the original concrete exposed. The exposed concrete surface appears in good condition. There is minor seepage through several construction and monolith joints. Several construction joints are packed with oakum to prevent seepage.

(ii) <u>Embankment</u>: The earth embankment appears to be in generally good condition. The horizontal and vertical alignment of the crest are uniform.

The downstream slope does not exhibit any evidence of subsidence, erosion and sloughing. The slope is covered with ground cover, seedlings, shrubs and trees. There are no signs of seepage at the slope, toe and downstream from the toe. There is heavy vegetation, including large trees, downstream of the toe area.

The upstream slope does not show any sloughing or erosion. The slope is covered with ground cover and shrubs and trees.

c. Appurtenant Structure

The concrete surface of the low level sluiceway is in good condition. The physical condition of the downstream face of the sluice gate appears in good condition except for minor rusting. Although the gate is closed there is minor discharge emerging from the sluiceway. The operating control for the gates located at the crest appears to be in good condition. The gate was not operated during the inspection because

-8-

the owner's representative did not have the keys for a padlock; the owner reports that the gate is in operating condition.

The 12-inch cast iron outlet pipe is closed and reported to be inoperable. However, there was discharge of about 1 cfs through the pipe.

d. Downstream Channel

The channel downstream of the concrete dam is Minisceongo Creek. In the vicinity of the dam, the channel floor and the side slopes are in rock. There is some vegetation including bushes and large trees, which will not impede flows over the spillway.

e. Reservoir Area

In the vicinity upstream of the dam there was no evidence of sloughing, potentially unstable slopes, or other unusual conditions which would adversely affect the dam.

3.2 EVALUATION OF OBSERVATIONS

×_ - _ _

Visual observation made during the course of the investigation revealed several deficiencies which at present do not adversely affect the adequacy of the dam. However, these deficiencies do require attention and should be corrected.

The following is a summary of the problem areas encountered, in order of importance, with the appropriate recommended action:

- Establish a systematic program to observe and monitor changes in seepage occuring at the monoliths and construction joints.
- 2. Remove all trees and brush growth on the slopes of the embankment. Provide a program of periodic cutting and mowing of the embankment surfaces.
- 3. Provide a program of periodic inspection and maintenance of the dam and appurtenances including yearly operation and lubrication of the reservoir drain. Document this information for future references. Also develop an emergency action plan.

In addition to above remedial and maintenance the following should be considered:

- a. Resurface the downstream face to the original geometry.
- b. High level outlet made operable.

SECTION 4 - OPERATIONAL AND MAINTENANCE PROCEDURES

4.1 PROCEDURES

There is no specified required release of water from the lake. The lake level is maintained at the principal spillway crest level the entire year. The low level outlet which is a 3-foot square sluiceway, is usually kept closed. The 12-inch diameter cast iron pipe is closed and reported inoperative.

4.2 MAINTENANCE OF THE DAM

The dam is maintained by the owner, Palisades Interstate Park Commission. Maintenance of the dam is considered inadequate as evidenced by the seepage through the monolith joints; at the concrete section there is extensive vegetative growth on the earth embankment and an inoperable regulation gate at the high level outlet.

4.3 WARNING SYSTEM IN EFFECT

There is no warning system in effect or in preparation.

4.4 EVALUATION

*_ -_ -_ -

The dam and appurtenances have not been maintained in satisfactory condition as noted in Section 3: Visual Inspection.

SECTION 5 - HYDROLOGIC/HYDRAULIC

5.1 DRAINAGE BASIN CHARACTERISTICS

Lake Wlech Dam is located about 2 miles west of Willow Grove in Rockland County, New York. The total drainage area contributing to the lake is 2.87 square miles of which the lake occupies 234 acres or 13% of the area. The basin is a part of the Palisades Interstate Park and is mainly undeveloped except for a few campsites. Relief in the drainage area is fairly steep, varying from E. 1015 (lake surface) to ridges above El 1200.

5.2 ANALYSIS OF CRITERIA

The analysis of Lake Welch Dam was performed using the U.S. Army Corps of Engineers HEC-1 computer program 1/. The Probable Maximum Precipitation (PMP) was obtained from Hydrometeorological Report No. 51 4/. The unit hydrograph was computed using the Snyder method 6/ and average regional coefficients were 2 and 400 for Ct and 640 Cp, respectively. It was assumed that there would be an initial rainfall loss of 2 inches and that the constant loss rate would be 0.5 inches per hour. It was also assumed that both outlets were closed during the flood event. In accordance with the recommended guidelines of the Corps of Engineers 7/, the adequacy of the spillway was analyzed using the Probable Maximum Flood (PMF) and one-half the PMF.

5.3 SPILLWAY CAPACITY

The principal spillway is located at the concrete dam. The length of spillway is about 152 feet with a 3.5-foot wide concrete sill at El 1015. The maximum discharge capacity of the principal spillway is 591 cfs.

5.4 RESERVOIR CAPACITY

Normal capacity of Lake Welch at El 1010 (equivalent to the intake elevation of high level outlet) is reported to be about 3440 acre-feet $\frac{7}{}$. The computed storage between El 1010 and El 1015 (principal spillway crest) is about 1010 acre-feet. Total reservoir capacity to the top of the concrete dam (El 1016.3) is about 4750 acre-feet. The available surcharge storage between the spillway crest and the top of the dam is about 291 acre-feet which is equivalent to about 1.9 inches of runoff over the entire basin.

三派漢ない

5.5 FLOODS OF RECORD

There are no available records of floods or maximum lake elevations.

-11-

5.6 OVERTOPPING POTENTIAL

The potential of the dam being overtopped was investigated on the basis of the spillway discharge capacity and the available surcharge storage to meet the selected design flood inflows.

The Probable Maximum Flood routed through the lake caused the lake surface to rise to El 1018.41, 2.11 feet above the concrete dam, but does not overtop the embankment (El 1019.0). The one-half Probable Maximum Flood routed through the lake caused the lake surface to rise to El 1017.41, 1.11 feet above the concrete dam. The peak outflow discharge was 4765 cfs.

Using the Corps of Engineers criteria, the maximum spillway capacity without overtopping the dam is 12% of PMF outflow.

5.7 EVALUATION

The dam does not have sufficient spillway capacity to pass either the PMF or one-half the PMF without overtopping the dam. On the basis of this investigation the project discharge capacity is considered to be inadequate from a hydrologic and hydraulic point of view; however, overtopping of the dam under the PMF would cause neither significant erosion at the toe or abutment nor undermine the foundation of the dam.

SECTION 6 - STRUCTURAL STABILITY

6.1 EVALUATION OF STRUCTURAL STABILITY

a. Visual Observations

Visual observations did not indicate condition which would adversely affect the structural stability of the dam. The observed seepage through the monolith and construction joints of the concrete dam are not detrimental to the dam's stability or safety at the present time.

b. Design and Construction Data

The original preconstruction design computations regarding the structural stability of the dam or spillway are not available. Stability analysis of the concrete dam with the rock anchors was carried out by Charles T. Main, Inc., Consulting Engineers, Boston, Massachusetts, for the 1979 rehabilitation program; these are given in the Appendix F.

c. Operating Records

There are no available records of reservoir elevation and gate operation. No major operational problems which would affect the stability of the dam were reported.

d. Post Construction Changes

The concrete dam was resurfaced in 1959 by applying a 3 inch thick gunite surface. The details of modifications are shown on a drawing entitled "Details of Dam Repairs" dated July 17, 1958, prepared by the Palisades Interstate Park Commission and given in Appendix A.

Because of excessive seepage the concrete dam, major modifications were made in 1979 in accordance with recommendations by Charles T. Main, Consulting Engineers, Boston, Massachusetts. The recommedations included chemical and cement grouting to control seepage through horizontal and construction joints and strengthening of the dam by installing rock anchors. The details of the modifications, shown on a construction drawing entitled "Lake Welch Dam Repairs", dated April 4, 1978 and prepared by Charles T. Main, Inc., Boston, Massachusetts, are given in the Appendix A.

e. Seismic Stability

According to the recommended Corps guidelines, the dam is located in Seismic Zone No.1. However, based on past earthquake history, the New York State Geological Survey

-13-

considers the site to be in Zone 2. Based on this assessment the dam is considered in the Seismic Zone 2. The results of Seismic Stability are described in Section 6.2.

6.2 STRUCTURAL STABILITY ANALYSIS

The available structural stability analysis of the nonoverflow section of the concrete dam was reviewed. The method of analysis and stability criteria, except the values of sliding coefficients, were computed in accordance with EM 1110-2-2200 published by the Corps of Engineers, U.S. Army. The sliding coefficient values used were higher than recommended. The spacing of rock anchors used in the structural stability analysis is not the same as that shown on 1978 construction drawings. The analysis shows that rock anchors at the gravity section are spaced 5 feet center to center, whereas the 1978 drawings show a 10-foot spacing. The owner was unable to verify the discrepancy. Since a 10-foot spacing of the rockbolts at the gravity section would be more critical, additional analyses of structural stability using this anchor spacing were performed. These are included in the Appendix E, and summarized as follows:

	Loading Condition	Location of Resultant	Sliding F.S. (see Appendix E)
a.	Normal loading condition, reservoir level at spill- way crest, no ice load	Within middle third	1.53
b.	Normal loading condition, reservoir level at spill- way crest, with ice load	-3.09 feet outside middle third	1.30
c.	Unusual loading: flood level equal to 1/2 PMF at gravity section	Within middle half	1.17
d.	Extreme loading: flood level equal to PMF at the gravity section	Within middle half	1.06
e.	Unusual loading: reservoir level at spillway crest, and earthquake forces	Within the mid- dle half	1.30

The results of the stability analysis indicate that stability of the gravity section of the dam against overturning is inadequate for all loading conditions except normal loading.

-14-

The analysis indicates that in order for the resultant of the force to be within the middle third under the other loading cases, the rock bolts would have to be stressed 30.5 tons, which is above the working load(25 tons) and less than the ultimate limit (37 tons). Because of the additional force (5.5 tons) that can be developed in the anchors, the stability of the gravity section of the dam against overturning is considered adequate. The sliding stability is considered adequate for all cases.

6

......

SECTION 7 - ASSESSMENT/REMEDIAL MEASURES

7.1 DAM ASSESSMENT

a. Safety

Examination of available documents and the visual inspection of the Lake Welch Dam and appurtenant structures did not reveal any conditions which constitute a hazard to human or property. The dam (earth and concrete gravity sections) are not considered to be unsafe.

Using the Corps of Engineers screening criteria for review of spillway adequacy, it has been determined that the concrete gravity dam would be overtopped for all storms exceeding approximately 12 percent of the PMF. Although the spillway capacity is inadequate from a hydraulic and hydrologic point of view, the hydraulic inadequacy will not affect the safety of the dam because the concrete dam is supported on sound rock and overtopping of the dam will cause neither significant erosion at the toe or abutment, nor undermine the foundation of the dam. In addition, the concrete dam is stable under all loading conditions.

b. Adequacy of Information

The information and data available were adequate for performance of this investigation.

c. Necessity of Additional Investigations

No additional investigations are required.

d. Urgency

The recommended measures 1 through 3 as described below must be corrected within 1 year from notification.

7.2 RECOMMENDED MEASURES

The following are the recommended measures:

- Establish a systematic program to observe and monitor changes in seepage occuring at the monoliths and construction joints.
- 2. Remove all trees and brush growth on the slopes of the embankment. Provide a program of periodic cutting and mowing of the embankment surfaces.

-16-

3. Provide a program of periodic inspection and maintenance of the dam and appurtenances including yearly operation and lubrication of the reservoir drain. Document this information for future references. Also develop an emergency action plan.

In addition to above remedial and maintenance, the following should be considered:

- a. Resurface the downstream face to the original geometry.
- b. High level outlet made operable.

STABILITY ANALYSIS

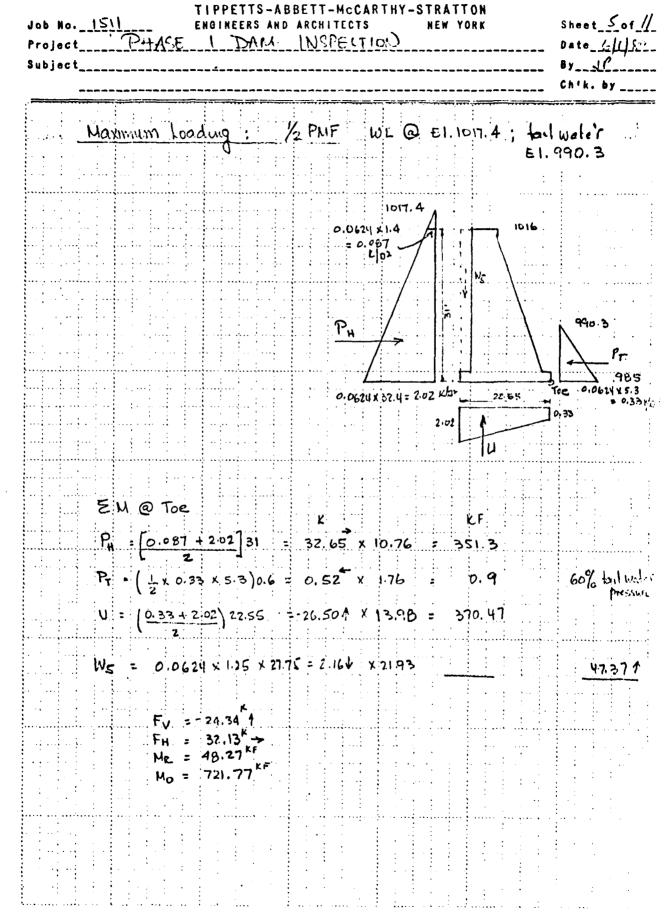

-ABBETT-MCCARTHY-STRATTON Job No. 1511 Sheet / of // NEW YORK PHASE I DAM INSPECTION Date 611/80 ect DAM STABILITY ANALYSIS. By JP LAKE WELCH Ch'k. by Assumptions : 1.) The limit weight of concrete is assumed to be 145 lbs / cu ft 2) Ice load of 5000 lbs/sgft acting about 1 foot from top of dawn, laccording to Corps of Engineers 3) Angle of Internal resistance of rock is assumed to be 45° based on Vunal examinations of the exposed rock at downstream the and its bedding planes. 4) Dans site is Seismic Zone 2 LOADING CONDITIONS Case I. Normal loading : Lake level at splany crest El 1615.0 no ce lead Normal londing: Lake ler (al Spilling Crest El 1045.0, wirth Loc lohd. Case T Case III Unusual loading; Lake level at 1/2 MAIF Case IV Extreme loading : Lake level at Prist Case J. Unuonal loading ; Lake level at Sullivary Court and earliginke forces of 0.05 g.

Stability Analysis of the Lake Welch Gravity Dam

The Lake Welch Dam was analyzed for both sliding and overturning stability. Three conditions of loading were considered:

- Case I Normal condition of dead hydrostatic forces, including uplift.
- Case II Extreme condition of normal loading plus ice forces of 3,000 pounds per lineal foot.
- Case III Extreme condition of normal loading plus earthquake forces of 0.05g.

The analysis showed that the ratio of the horizontal forces tending to cause sliding to the vertical forces are, for the three conditions respectively, 0.78, 0.86 and 0.97. While there are no codes, or universally accepted standards, mandating the design of gravity dams, these values are somewhat higher than modern practice would dictate. The analysis showed further that the corresponding ratios of moments resisting overturning to the moments tending to cause overturning are 1.36, 1.18 and 1.18. These values are lower than considered prudent

in modern practice.

These figures indicate that, while not in accordance with today's thinking, the dam is not approaching the point of incipient failure from either sliding or overturning. The factors found for Case I are conservative as the uplift forces applied in the analysis were determined in an accepted and conservative manner. Effects of ice in Case II can be mitigated to any degree desired by drawing down the lake in winter, either fully or partially. Regarding Case III, there has been little seismic activity in this area.

RECEIVED NPR 200 1000 SOILS SECTION

An Equal Opportunity Employer

REGION - Palisades PROJECT NAME - Repairs to the Lake Welch Dam

P. F. NO. -

THIS AGREEMENT made this ______ day of ______ 19, _____, by and between the State of New York, arting by and through the Office of Parks and Reviention, herrinafter referred to as "PARKS", whose office is at <u>Administration Building</u>

Bear Mountain, New York 10911

and ____Chas.T. Main of N.Y. Inc. with offices at 125 E. 38th Street. New York.

Bereinatier referred to as the " CONSULTANT."

WITNESSETH:

WHEREAS, PARKS is charged by the law with the construction, maintenance and operation of state parks, parkways, historic sites, marine facilities and other recreational facilities and desires to obtain behavial and protessional services therein as hereinafter specified, and is authorized to engage such services in accordance with the provisions of the Parks and Recreation Law of the State of New York.

NOW, THEREFORE, in consideration of the premises and the mutual covenants and conditions contained herein the parties hereto agree as follows:

1. SCOPE OF SERVICES - PARKS agrees to employ and hereby does employ the CONSULTANT for the services hereinafter described, and the CONSULTANT agrees to furnish and perform such services upon the fullowing described project:

Repairs to the Lake Welch Dam

The consultant will furnish services related to the repair of the Lake Welch Dam by means of chemical and cement grouting of horizontal construction joints and sealing of vertical expansion joints.

The method to be recommended by the consultant will enable the repair work to be carried out without the necessity of emptying the lake.

More specifically, the scope of the consultants' services shall consist of four parts, itemized as follows:

- Item 1 Inspection of the dam, attendance at meetings, and other work required to propose a solution to the leakage problems, all performed prior to January 1, 1978.
- Itcm.2 Performance and documentation of a stability analysis of the dam so as to determine the basic soundness and integrity of the dam.
- Item 3 Under the assumption that the results of the analysis described in Item 2 show the dam to be essentially sound and capable of repair, the consultant will prepare drawings and specifications for the drilling, grouting and sealing of the dam. If the results of the work performed under Item 2 indicate that the dam is not sound or that some other means of repair are indicative, this agreement may be terminated or amended as appropriate to the conditions at this point.
- Item 4 Field surveillance of the drilling, grouting and sealing workafter the award of the construction contract by Farks.

The Consultant will furnish contract drawings in reproducible form after approval of preliminary drawings by Parks.

The Consultant will also furnish five (5) copies each of detailed contract

Mr. Robert Santoro Palisades Interstate Park Commission Administration Building Bear Mountain, NY 10911

Dear Sir:

۰.

In compliance with your request we have undertaken a study of the leakage problem at Lake Welch Dam. The site was visited and we inspected the concrete cores obtained from the dam. We understand the need to reduce leakage through the dam and its foundation to a minimum and we appreciate the desirability of avoiding draining the lake. Considering both of these requirements, we offer the following solution:

- Sealing of the horizontal construction joints of the dam, and the foundation of the dam and its abutments, by a combination of cement and chemical grouting.
- Sealing of the vertical contraction joints by drilling a large (6") hole vertically through each joint and backfilling with a non-setting sealant.
- 3. The above procedures are to be performed in the early Spring of 1978 without the lake being drained.
- 4. Observation of the dam, foundation and sluice gate leakage through September 1978 when decisions can be made relative to:
 - Draining the lake to effect additional grouting or repairs, if indicated, to the upstream face of ' the dam.
 - b. The need for a new sluice gate, or the repair of the existing gate.
 - c. Refacing or repairing the downstream face of the dam for aesthetic reasons.
 - d. Performing other remedial work, also for aesthetic reasons.

It is our opinion that steps 1 and 2 above will successfully reduce leakage to a practicable minimum at the least cost. This solution has the further advantage of not requiring the draining of the lake during the recreation season. Should additional work

NEW YORK . LOWVILLE . MALONE . ORISKANY . POTSDAM . PRATTSVILLE

R. Santoro 5 October 1977 Page 2

> requiring the draining of the lake be necessary, such can be performed early next Fall and the lake refilled before the 1979 season. We estimate the cost of steps 1 and 2 to be not in excess of \$225,000.

> It is proposed that MAIN write the specification for the grouting program and provide a resident engineer for the surveillance of the field work. We estimate that the total cost of our services will not exceed \$30,000 up to and including steps 1 and 2. This figure is based on an estimate of 55 working days to perform steps 1 and 2.

> We will be happy to discuss this subject with you and are available to meet with you at your convenience.

Yours very truly, CHAS. T. MAIN OF NEW YORK, INC. Gustav A. Diezemann

Dear Mr. Santoro:

ENGINEERING

APR.

7 1978

3308-001-1

Further to the draft of the report on our stability analysis of the Lake Welch Dam, we wish to advise you that post-tensioned fock bolts, five feet on centers and ten feet into rock, placed in reamed grout holes through the top of the dam would produce the following ratios of forces:

| • | Sliding | Overturning |
|----------|---------|-------------|
| Case I | 1.64 | 1.69 |
| Case II | 1.33 | 1.47 |
| Case III | 1.49 | 1.47 |

The addition of the rock bolts improve the resistance to sliding and overturning significantly, as the above figures indicate. While there is nothing to assure that the dam would fail without the rock bolts, there is similarly no guarantee that the dam will never fail with the rock bolts installed. Considering the age and condition of the Lake Welch Dam, it is obviously prudent to install the bolts during the rehabilitation procedure. We estimate the cost of installation to be \$93,000.

Very truly yours,

T. MAIN OF NEW YORK, INC. HAS. Gustav A. Diczemann

Dear Mr. Santoro:

ENGINEERING P. I. P. C.

Reference is made to our letter of October 5, 1977 in which we stated that, if the recommended sealing of the horizontal and vertical joints and the foundation of the Lake Welch Dam did not satisfactorily stop the leakage, the lake could be drained to effect additional grouting or repairs.

We also stated in that letter that we believed that the recommended sealing would reduce the leakage to a practicable minimum. We are still of that opinion. We cannot, however, for obvious reasons, guarantee that it will.

Should additional repairs be necessary, and we repeat that we believe the recommended will be successful, it is not possible to estimate the cost of such repairs until the problem, if any, is known.

Very truly yours,

CHAS. T. MAIN OF NEW YORK, INC. $\pi \sim$ Gustav A. Diczema ńπ Vice President
