Abstract

-Asynchronous multitask processes occur in a wide variety of control
applications ranging from industrial control to computer operating systems,
yet no analytical methods are available for studying their detailed behavior.
The preliminary results reported here illustrate that a very general class
of such processes can be represented by discontinuous hybrid-state discrete-
time systems.

## Background and Motivation

A multitask process is characterized by a number of tasks which operate concurrently or sequentially, on an external resource or data base. The timing of the tasks is generally asynchronous in that new task execution is initiated by the completion of previous tasks. If necessary, synchrony and sequential ordering of tasks can be enforced in a number of ways through the task definitions themselves. However in this research no such constraints are imposed: rather, the general qualitative behaviors which may arise in such systems are analyzed. Only two basic assumptions are imposed: (1) a task requires a finite amount of time and storage to execute, and (2) task descriptions are fixed, in that the execution of a task cannot alter its own nature nor the number or nature of any other tasks.

The range of possible behavior of such systems is so large that the problem of conceptualizing, analyzing and "debugging" multitask processes is very common and enormously complex. Two approaches are presently in use: stochastic queueing analysis [1],[2] and simulation [3],[4]. Queueing analysis is most useful for evaluating the average performance properties of an operational multitasking system, while simulation allows certain undesirable properties of a planned system to be discovered and corrected during the design process. Neither of these methods provides very much insight about generic problems in the design of such systems, nor do they provide ideas about how to remedy or detect flaws. The results reported here constitute a modest step in that direction.

## Model Development

Let $t \varepsilon [t_o, \infty)$ denote time. Three sets of state variables will be identified:

$x^1$ - those states which vary continuously with time and take on real values.

$x^2$ - those states which are real-valued but change only at discrete instants of time

$x^3$ - those states which are discrete-valued and (necessarily) change only at discrete instants of time.

The state set is denoted $X = \{x^1, x^2, x^3\}$. For present purposes, it will be assumed that these sub sets of states are finite-dimensional and recognizable; an example will be provided below. Let the increasing sequence $\{t_k\}$ denote the set of all values of t for which changes in at least one element of $x^2$ or $x^3$ occur, and let the values of the states prior to and following $t_k$ be denoted $x_k^{i^-}$, $x_k^{i^+}$, respectively, for i = 1,2,3. In the sequel, $x_k^{i^+}$ will be identified with $x_k^i$.

The instants $\{t_k\}$ will be identified with task initiation or termination times. Let the set of tasks in the system be denoted $G \overset{\bullet}{=} \{G_1 \ldots G_n\}$. Associated with each task is an iniation function, a termination function and a state-update function[1]:

$g_j^I$: $X \to \{0,1\}$     -     initiation function for task j

$g_j^T$: $X \to \{0,1\}$     -     termination function for task j

$f_j$: $X \to X$     -     state-update function for task j

Each task is either "on" or "off": let $\hat{G}$ denote those tasks which are "on" and $\check{G}$ denote those which are off, so that $G = \hat{G} \cup \check{G}$ and $\hat{G} \cup \check{G} = \varphi$ (the null set). The subscript $\hat{j}$ will be used to denote tasks which are "on" and $\check{j}$

---

[1] To simplify this exposition, these are assumed to be time-invariant; however, this assumption may be relaxed.

to denote tasks which are "off". The task succession rule is as follows:
A transition time, $t_k$, is declared whenever

    (a)  For some $j\epsilon\{\check{j}\}$, $g_j^I(x^1,x^2,x^3)$ undergoes a $0\rightarrow1$ transition

or

    (b)  For some $j\epsilon\{\hat{j}\}$, $g_j^T(x^1,x^2,x^3)$ undergoes a $0\rightarrow1$ transition

Between task transition times, only the states $x^1$ can change, according to
a state equation

$$\dot{x}^1(t) = f(x^1(t), x_k^{2^+}, x_k^{3^+}) \tag{1}$$

with $x^1(t_k) = x_k^{1^+}$. At the completion time $t_k^-$ of a task $j$, the transformation

$$\begin{bmatrix} x_k^{1^+} \\ x_k^{2^+} \\ x_k^{3^+} \end{bmatrix} = f_j \left( \begin{bmatrix} x_k^{1-} \\ x_k^{2-} \\ x_k^{3-} \end{bmatrix} \right) \tag{2}$$

is applied, with $x_k^{2-} = x_{k-1}^{2^+}$ and $x_k^{3-} \doteq x_{k-1}^{3^+}$.

    At a transition time, it is possible that more than one task terminates
and/or more than one task is initiated. This produces an inherent conflict
situation which must be resolved in a consistent manner. For instance, if
tasks $j_1$ and $j_2$ terminate together, it is not necessarily true that
$f_{j1} \circ f_{j2} = f_{j2} \circ f_{j1}$ (functional composition may not be commutative). Or
if task $j_1$ is initiated when $j_2$ terminates, then up-dating with $f_{j2}$ may
turn off $j_1$, while terminating $j_1$ may turn on $j_2$ again, etc. In this pre-
liminary abstract, it will be assumed that

    • there is a fixed priority among task completions (e.g. $1 > 2 > 3 >$
$j > \ldots > n$)

• all completions are performed first according to priority, and then

   initiation functions are re-evaluated to redetermine which tasks (if

   any) should be initiated at the transition times.

Other conflict-resolution methods, such as imposed sequential orderings, are

also possible.

Let $\hat{j}_k \epsilon\ 2^n$ be the set of tasks active at $t_k^+$. Let the transition map-

ping of (1) be given by $\phi$: $[0,\infty) \times X^1 \rightarrow X^1$, so that the solution of

$$\dot{x}^1(t) = f(x^1, x_k^2, x_k^3) \ ; \ x^1(t_k) = x_k^1 \tag{3}$$

is

$$x^1(t) = \phi(t-t_k, x_k^1; x_k^2, x_k^3) \tag{4}$$

where $x_k^2, x_k^3$ are viewed as parameters. Define the function $\tau$: $2^n \times X \rightarrow R^+$

to be the first transition-time encountered with processes $\hat{j}\ \epsilon 2^n$ active at

$t = t_o$, with initial state $x = (x^1, x^2, x^3) \epsilon X$. This can be tabulated by

integrating (1) and applying rules (a) and (b). Let the function

$\sigma$: $2^n \times X \rightarrow 2^n$ define the next set of active tasks, determined from the

preceding priority rules, at the transition time defined by . In other

words,

$$t_{k+1} = t_k + \tau(\hat{j}_k, x_k^1, x_k^2, x_k^3) \tag{5}$$

$$\hat{j}_{k+1} = (\hat{j}_k, x_k^1, x_k^2, x_k^3) \tag{6}$$

The important point to observe is that, in principle, it is not necessary

to include the continuous-time part of the dynamics, since $\tau$ and $\sigma$ can be

pre-computed from f, $\{g_j^I\}$, and $\{g_j^T\}$.

In summary, the dynamics of the asynchonous multitask system can always

be represented in the form

$$t_{k+1} = t_k + \tau(\hat{j}_k, x_k)$$
$$x_{k+1} = f_{\hat{j}_k}(x_k) \qquad\qquad (7)$$
$$j_{k+1} = \sigma(\hat{j}_k, x_k)$$

where $f_{\hat{j}_k}$ is the composition, according to priority, of the transition functions (2) of the tasks completing at $t_{k+1}^-$. It is then clear that $t_{k+1}$ may be combined with $x^1$ and $x^2$, and that $x^3$ may be combined with $\hat{j}$ to yield a general discontinuous hybrid discrete-time system. Extensions to stochastic behavior of $f, \{f_j\}, \{g_j^I\}$ and $\{g_j^T\}$ are readily accomodated.

## Qualitative Properties

The finite-state part of (7) may be further aggregated to produce an equivalent real-state discrete-time system with discontinuous transition function. Systems of this general class have been discussed by Johnson [5] and Kaliski and Lemone [6]. Their behavior may roughly approximate the behavior of discontinuous systems discussed in Utkin [7] and Johnson [8]. The pertinent properties of such systems will be described more fully in the final version of this paper. Here it is merely noted that problems may arise if $\lim_{k \to \infty} t_k$ is finite. A possible behavior in this situation is an approximation to sliding mode behavior, which is closely akin to the phenomenon of "thrashing" observed in heavily-loaded multitasking systems.
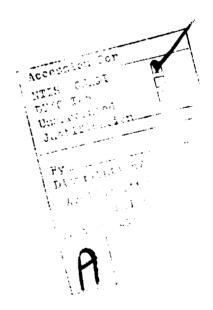

## Examples

Realistic examples will be provided in the conference version of this paper.
