Tiffin, Ohio 44883

Dear County Farmer:

Improving the quality of water draining from agricultural areas is a big job, but one which must be done. Done right it does not need damage farm income. In fact, it may mean even more profit from your farm operation rather than less. Reduced tillage and no-till farming especially can improve water quality by reducing soil loss through erosion control. Soil retained in your fields means that expensive fertilizers, particularly phosphorus, and herbicides stay in place, too. Time and fuel savings help gain favorable returns from reduced tillage as well. Finally, taxpayer costs to clean ditches and dredge streams and lakes go down. All of these factors, most of which benefits farmers directly, also improve water quality.

Through the Honey Creek Project, you, in cooperation with local agricultural agency people and farm service dealers, can work with us in determining ways to do our share of helping improve Lake Erie water quality. Together, we should be able to demonstrate ways to do the water quality job - economically and practically.

This publication describes results of reduced tillage and no-till demonstration plots carried out within the Honey Creek watershed in 1979. These practices, when properly applied, not only reduce erosion, but also maintain or improve net farm income through economies of manpower, energy and machinery.

Please review the data presented. See how reduced tillage practices might fit into your farm operation. We feel that reduced tillage can directly benefit farmers while at the same time do the water quality job. What do you think? What is your solution? The job must be done!

Sincerely yours,

Lee E. Buckingham

Maurey Lewis, Technician

A special note of appreciation to Jean
Knoblauch who typed and retyped the
various portions of this manuscript.

SPECIAL ACKNOWLEDGEMENTS

Successful accomplishment of tillage demonstration plots this year resulted from the combined efforts of farmers, agri-business interests and agricultural agency people, Without the support of these people, there would have been no demonstration plots. Special thanks and appreciation to the following people for their part in the demonstration effort:

CRAWFORD COUNTY

Farmer Cooperators:

Don Crum	Dick and Ed Harer
Ross Eckstein	Jason Kalb
Gary Green	Tom Niese
Don Phenicie	Jim and Gerald Nedolast

Task Force Members:

Bill Kleman, County Agent, Chairman
Floyd Reinhart, Atricultural Stabilization & Conservation Service
Bob Smith, Soil Conservation Service
Burton Geissman
Howard Von Stein
Randy Strauch, County Engineer

SENECA COUNTY

Farmer Cooperators:

Harry Hoffert	Richard Willman
Bill Smith	Rich Reichert
Paul Price	

Task Force Members:

Bill Stuckey, County Agent, Chairman
Bill Bernard, Agricultural Stabilization & Conservation Service
Bill Smith, Seneca Soil and Water Conservation District
Gene Baltes, Soil Conservation Service
Sam Spitler
Phil Dunn
Rich Reichert
Delbert Morter

HURON COUNTY

Farmer Cooperator:

Mark Fritz

Task Force Members:

Lloyd Young, Soil Conservation Service
John Metz, Huron Soil and Water Conservation District
Jerry Beck, Agricultural Stabilization & Conservation Service
Carlos Tucker, County Agent

OTHERS

Richard Heimlich, Seneca East FFA, Attica, Ohio
Paul Young, Chevron Chemical Co., Lima, Ohio
Paul Price, Silver Valley Agricultural Services, Bloomville, Ohio
Melvin Speece, Landmark Crop Services, New Washington, Ohio
Mike Grapevine, Danville Feed & Supply Co., Danville, Ohio

INTRODUCTION

As a result of 1972 Federal legislation, Congress has given the U. S. Army Corps of Engineers responsibility for developing by 1982, a plan to "restore and repair" Lake Erie water quality. Since receiving this responsibility, the Army Corps has worked with other Federal agencies, Canadian officials, States, and numerous universities to develop a plan. Early work identified phosphorus as the element contributing to overenrichment of Lake waters. Plans were made to address significant "point" sources of phosphorus such as waste effluent from major cities. Reductions here, though, could not do the whole job. Treatment of diffuse or "nonpoint" phosphorus sources would be required if the Lake were to return to previous levels of water quality. Of these nonpoint sources, nutrient runoff from agricultural watersheds is most significant.

How, though, was the Corps, experienced as civil engineers, to address nutrient runoff and erosion control in farm areas? Their answer to this question was to ask the agricultural community for help. In November, 1978, this was done contractually through the Joint Board of Supervisors in the Honey Creek watershed.

The Honey Creek Watershed Management Program is a pilot demonstration project. Its purpose is to demonstrate on agricultural lands practices designed primarily for the purpose of improving water quality (Best Management Practices or BMP's). It is to also demonstrate approaches or ways to get practices on the ground. Finally, it is to inform people about agricultural activities - water quality relationships and how they can help develop workable ways to carry out erosion or nutrient control practices (BMP's).

With these goals in mind the Joint Board, with help from Cooperative Extension Service, Soil Conservation Service, and Agricultural Stabilization and Conservation Service, and numerous farm service representatives, began working with farmers to carry out BMP's. Engineering practices such as grassed waterways and erosion control structures were planned as well as numerous plots demonstrating reduced tillage and no-till methods.

This publication reports results of 1979 tillage demonstration plots within the Honey Creek watershed. Plot histories from planting to harvest, economic data and soil erosion information are reported. The publication is not a research document, rather a compilation of data and information gathered while working with landowners to perform tillage demonstration practices. Main effort was "hands on" demonstrations that people could see and judge. Plot results, too, represent data from one year only. Consider this fact when comparing among plots or from plot data to your own experiences.

RAINFALL AND TEMPERATURE - 1979

Cold and wet weather prior to May, 1979, delayed corn planting in demonstration plots until the first and second week of May. Above normal rainfall in May and June, particularly in Crawford County and southeast Seneca County (Table 1) caused bean planting to extend through the end of May and into early June.

During the growing season (May - August), rainfall was 5.71" and 7.08" above normal in Seneca and Crawford Counties, respectively. In Seneca County rainfall was above normal in both June and August, 2.85" and 3.05", respectively. Greatest rainfall amounts were recorded in June after planting, with heaviest distributions in Crawford County and Venice Township of Seneca County. Intense storm activity was also greatest at this time, causing severe erosion and crop replanting in many areas of the watershed.

In fall (September - October) rainfall was near or somewhat below normal for most of the watershed. Lesser amounts of rain at this time did aid harvesting after a very wet summer.

Using records at Tiffin, temperatures were 1 to 3 degrees above normal during the first half of the growing season, but 1 to 2 degrees below normal during the second half. Below normal temperatures in August combined with above normal precipitation produced exceedingly cool and wet conditions during this portion of the growing season. Delayed maturation of corn, lodging of beans and continued erosion were common observations by farmers during August.

PERFORMING DEMONSTRATION PLOTS

Plot Selection

Tentative plot locations were initially suggested by county task force members in January. Major factor influencing selection was availability of fields that had not been tilled the previous fall. Other factors considered were potential cooperators, soil suitability for reduced tillage, drainage, known problem erosion areas, field histories (weed pressure, insecticide problems, fertility) and availability of reduced tillage equipment and no-till planters. Demonstration plots were also to be adjacent to roads and accessible for viewing by the public. Using these factors as guidelines, landowners were contacted in February and March to determine final plot locations. While reduced tillage demonstration efforts were directed to more erosive areas of the watershed, factors such as equipment availability, plot accessibility and previous crop residue suitability were significant determinants of plot location. As a result many plots were in erosive areas, but others were not. In final analysis, plots selected tended to represent a variety of conditions (drainage, soils, crop residues, etc.) commonly found throughout the watershed. NOTE: Based on this initial work, the Honey Creek Joint Board did lease a Buffalo no-till slot planter for use in the watershed.

Planning

After plot locations had been selected, cooperating landowners were contacted in late March to plan demonstration plot details. Recommendations were made regarding fertility, herbicide-insecticide usage, seed varieties, and equipment to be used. (Where current soil test data was not available, fertilizer recommendations were based on previous yields, expected yields and past fertility programs.) It was further determined exactly who was to do what job and when. For example, it may have been determined that the farmer would have herbicides custom applied following planting. If necessary, times were also set to assist landowners in planter calibration. Finally, all cooperators were asked to contact project personnel before planting so that one of them or an agency representative could be present to view planting and/or assist the planting operation. Through all planning discussions, management steps required to insure a successful reduced tillage operation were emphasized. Extension Service representatives reviewed final recommendations to insure technical correctness. Extension personnel, farm service dealers/representatives and others with current information on reduced tillage also provided assistance during final plot planning.

Planting - Spraying

Upon receiving notification from a cooperator that he was ready to plant, project or other agency personnel went to the plot to assist planting and to check seeding rate and depth. In some cases project personnel drove planting equipment so farmers could observe proper operation of no-till planting units.

Most plots were custom sprayed after planting. To help insure proper herbicide application, local custom sprayers, where possible, were informed about the plots and provided written herbicide recommendations several weeks before planting.

Monitoring

Following planting, plots were checked for emergent plant populations. Amounts of past crop residues on the surface were also estimated. Throughout the growing season, insect, weed and disease conditions were checked 2 to 3 times weekly by either project staff or Extension Service representatives. Where pest problems were detected, recommendations were made to eliminate or reduce damage encountered. Near the end of the growing season, final stand populations were recorded. Photo documentation of most plots was also done.

Harvest

In order to uniformly determine net return to farmers from corn plots, yield checks were done using the method employed by Chevron Chemical Co. in their state-wide (Ohio) no-till yield contest. With this method a representative acre or more is harvested. Based then on measurements of average row width, length, number of rows, corn moisture at harvest, and total weight harvested, corn yields were calculated to 15.5% moisture. Total harvest weights from demonstration plots were determined with a weigh wagon having an electronic scale with digital readout. For soybeans the method was modified to include measurements of combine header width as compared to row width for corn. Modifications were also made to calculate bean yields at 13% moisture.

TILLAGE PLOT ECONOMICS - GUIDELINES FOR COMPARISON

During 1979 tillage demonstrations, cooperators reported quantities of fertilizer, herbicides and insecticides used per acre, and noted the number and type of operations across the field. Tables 7 and 8 show 1979 spring unit prices of materials and custom rate charges used in determining production costs. The \$2.25 base price for corn was determined by averaging local elevator prices during the week of November 11, 1979. The \$6.25 base price for soybeans was determined by averaging local elevator prices during the week of October 14. Crop value for corn was calculated by taking yields at 15.5% moisture, multiplying by \$2.25 minus drying charges (local elevator schedule). Crop value for soybeans was calculated by taking yields at 13.0% moisture and multiplying by \$6.25 minus drying charges (local elevator schedule). Return to land management was then calculated as the difference between crop value and production costs. Pages 12 to 49 provide detailed explanation and breakdown of calculations for all tillage plots.

Guidelines

1. Due to limited planning time for demonstration plots, few economic comparisons between reduced tillage and conventional tillage operations were made. More emphasis was placed on demonstration of conservation tillage practices rather than comparisons with other tillage systems.
2. Material costs for corn plots varied greatly both within and among tillage categories (no-till, reduced till, and conventional). Variations are attributed to yield goals, build up of fertility rates, previous crops, and amounts of growing vegetation present at planting time (reduced till and no-till plots). As noted in the individual economic analyses, growing vegetation within reduced or no-till plots requires additional expense for a contact herbicide (\$5-\$10/A), and surfactant (\$.30-.90/A). Rates of residual herbicides are about the same, except higher rates were generally used to insure control under heavy residue conditions.
3. Machine costs for plots within a given tillage category were fairly consistent (Tables 5 and 6). For example, machine costs on corn plots averaged \$46.37 for no-till, \$53.49 for reduced tillage, and \$68.77 for conventional. Machine costs for soybean plots were similar since doubling back in no-till plots for 15" rows was an added \$10/acre cost. This cancelled cost benefits for reduced tillage passes. NOTE: Conventional plots on the Phenicie and Niese farms (Tables 5 and 6) are not traditional plow forms of conventional tillage, but are conventional systems compared to their normal tillage operations.
4. Nitrogen costs vary according to form in which N is applied. Anhydrous ammonia is cheaper per unit of N, but takes more time, fuel, equipment, and experienced labor to apply.
5. Cost of insecticides used in the no-till plots were slightly more than that of reduced or conventional plots. Seed treaters were used in all no-till plots but one, and higher rates of Furadan 10G were used in some plots to insure armyworm control.
6. The schedule of custom rates may differ from those in your area. The costs of owning and operating your own equipment may differ substantially. Machine custom rates includes overhead costs, machine operating costs, machine replacement, repairs, fuel, and time for the operator.

7. Timeliness of operation is not considered in any of the economic comparisons. Reduced tillage systems may enhance the timeliness of field operations. OSU Agronomists estimate that corn yields are reduced about 1 bushel per acre for every day that planting occurs after May 10. Thus reduced and no-till systems with their lower field time requirements may improve the timeliness and increase yields for your operations.

8. Costs of soil losses are not included but need important consideration. Soil loss may be a significant economic loss in your farm operation. One ton of medium textured soil is worth \$6-\$9 in N - P₂O₅ - K₂O alone and it's not uncommon for farms to be losing 5 tons or more soil per acre per year conventionally. Of course, this soil loss may also impose costs on others as sediment is deposited in drainage ditches, streams, and harbors, for example.

9. Fuel use was not measured in the plots or compared with other tillage systems. One must realize the tremendous fuel savings when tillage trips over a field are reduced. With the rising cost of fuel and energy, the farmer of the future will have to be an energy conservationist as well as a soil conservationist.

10. Yields will still be a main factor in determining profitability of different conservation tillage systems. With any tillage system, experience and years of practice with different growing seasons, will enable more reliable comparison of results and conclusions.

Main requirement for successful application of reduced tillage and no-till is following proper management steps. Knowledge of planting depth and seed placement in different crop residues is an important step leading to good stands.

Table 3, UNIT PRICES OF MATERIALS

Fertilizer:

Anhydrous ammonia (82%)	12¢/lb. actual N	
Nitrogen solution (28%)	19.5¢/ lb. actual N	
Urea (45%)	19.5¢/ lb. actual N

NOTE: Summary of production costs and yields taken from pages 12 to 41. See individual economic analysis pages for detailed explanation of cost differences. Material cost includes seed, lime, fertilizer, herbicides and interest on operation capital. Machinery costs includes tillage, planting, harvest, trucking, application of fertilizer, herbicides, insecticides, and time for operator.

1979 TILLAGE COMPARISON OF FURROW & ECONOMIC DATA

Harry Hoffert, 7648 N. Oak St., Blountville, Ohio 44818

PLOT DETAILS

Planted Gutwein 2140 on May 8 in 30 inch rows. Intended seed drop was 25,000; of which 23,100 plants emerged in the Tiro and Bennington silt loam soil. No tile drainage present. 1978 crop was soybeans. 350# of 6-24-24 was applied next to row and 100# of N was applied as 28% with a total N-P-K as follows: 121-84-84. 1 qt. Paraquat 4L w/16 oz. X-77 spreader/100 gal. 28%, 3 qt. Atrazine 4L and 2 qt. Lasso 4L were applied before planting with the 28%. Good weed control but some nut-sedge and foxtail not controlled. Some European corn borer damage. Harvested November 13.

No-till corn after soybeans. About 100 lbs. of bean residue per acre reduces erosion and corn stand establishment.

1979 TILLAGE COMPARISON CULTURAL & ECONOMIC DATA

Mark Fritz, Box 72, Rt. 2, Afton, Ohio 44207

PLOT DETAILS

Planted Pioneer 3780 on May 18 in 30 inch rows. Intended seed drop was 29,550; of which 21,500 plants emerged in the Cardington, Bennington silt loam, Marengo silty clay loam soil. Problem in getting good consistent seed coverage with the planter used in this type situation. 1978 crop was alfalfa-timothy sod. Tile drainage is systematic. 225# of a blended 10-21-31 was applied next to row. 178# N applied as 28%, with total N-P-K applied as follows: 201-47-71. 1/2# 2,4-D Amine and 1/8# Banvel D was applied 10 days prior to planting. 1 qt. Paraquat CL with 16 oz. X-77 spreader/100 gal. 28%, 2 qt. Bladex 4L, 2.5 qt. Axtrox 4L applied with the 28% just after planting. Grass control good except some breakthrough of nutsedge and fall panicum. Broadleaf control excellent. 14# Furadan 10G incorporated by planter above furrow and Isotox "F" seed treater used. No insect problems. Harvested November 3.

Planting no-till corn in alfalfa-timothy sod. Proper surface soil moisture at planting helps insure good stands under this cover condition.

/1 If 1 pt. Paraquat 2 CL and X-77 spreader could have been used for 2 qt. Roundup 4 EC, herbicide costs would be \$17.75. See plot details next page.

1979 TILLAGE COMPARISON CULTURAL & ECONOMIC

Paul Price, 6236 S. Fwp. Rd. 173, Bloomville, Ohio 44818

PLOT DETAILS

Planted Funks 4323 on May 18 in 30-inch rows. Intended seed drop was 30,200; of which 27,800 plants emerged in the Tiro, Randolph, Channahon silt loam soils. No tile drainage present. 1978 crop was corn. 600# of 7-26-26 was broadcasted after corn emerged, slightly burning the plants. 240# (21 gal.) of 9-27-3+2s was applied next to the row. 157# of N was applied as 28%, with total N-P-K applied as follows: 221-196-139+5s. 2 qt. Roundup 4EC was applied 8 days prior to planting to eradicate quackgrass and Canada thistle. 2 qt. Aatrex 4L and 3 qt. Bladex 4L were applied just after planting with the 28%. Grass and broadleaf control was excellent. 14# Furadan 10G applied in the furrow and Isotox "F" seed treater used. No insect problems. Harvested November 21.

Dave Wurm, Project Conservationist, checking no-till corn stand on the Paul Price farm. Special Honey Creek cost share monies through the Agricultural Stabilization and Conservation Service assisted completion of this plot.

1979 TILLAGE COMPARISON CULTURAL & ECONOMIC DATA

Dick Willman, 13974 E. TR 104, Attica, Ohio 44807

PLOT DETAILS

Planted Pioneer 3780 on May 11 in 30 inch rows. Intended seed drop was 27,700; of which 24,500 plants emerged in the Blount silt loam soil. Tile drainage is very random in lows. 1978 crop was wheat with a clover plowdown mixture seeded. Early in spring 400# of a blended 6-15-40 was broadcasted. Just before planting a blend of 300# 45-0-0 and 100# 0-0-60 was applied on the surface. 20 gal. 8-25-3 was applied next to row with a total N-P-K as follows: 177-126-227. 1 qt. Paraquat CL with X-77 spreader at 8 oz./100 gal. water, 2 qt. Bladex 4L, and 2.5 qt. Aatrex 4L were applied just after planting using 40 gal. water/acre as carrier. Throughout the growing season the effects of probable denitrification and/or volatilization of urea could be observed. These effects included: yellowing of the corn plants; the burning back of the leaves in a "V" shape; and very short ears pinched at the tips with very hard, round, small, shiny kernals. Factors related to this loss of nitrogen in this situation could have one or more of the following: warm weather above 55°F at time of urea application; soil surface with a high pH (above 6.5); the failure to get a rain soon after application; the physical obstruction of the clover residue not letting the urea get to the soil surface; and the chemical instability and volatility of urea. Excellent grass and broadleaf control. Isotox "F" seed treater and 15# Furadan 10G was applied in the furrow at planting. No insect problems. Harvested November 15.

No-till corn after wheat with clover. Good stands are the first thing a farmer wants to see when using no-till.

1979 YIELD COMPARISON CULTURAL & ECONOMIC DATA

Bill Smith, 10685 E. Esp. Rd., 106, Arcadia, Ohio 44807

PLOT DETAILS

Planted Dekalb XL92, Plot #1, and Pioneer 3780, Plot #2, in 30-inch rows. Intended seed drop was 29,900; of which 26,600 plants of the Dekalb and 27,300 plants of the Pioneer 3780 emerged in the Blount silt loam soil. Tile drainage is systematic. 1978 crop was wheat with a clover plowdown mixture seeded. A few days before planting 800# of a blended ratio 25-15-15 fertilizer was broadcasted on the surface. 10 gal. 9-27-3+2s were applied next to row with a total N-P-K as follows: 210-150-124. 1 qt. Paraquat CL w/8 oz. X-77 Spreader/100 gal. water, 1.5 qt. Aatrex 4L and 2.5 qt. Bladex 4L were applied just after planting using 40 gal. water/acre as carrier. Throughout the growing season the effects of probable denitrification and/or volatilization of urea could be observed. These effects included: yellowing of the corn plants; the burning back of the leaves in a "V" shape; and very short ears pinched at the tips with very hard, round, small, shiny kernels. Factors related to this loss of nitrogen in this situation could have been one or more of the following: warm weather above 55°F at time of urea application; soil surface with a high pH (above 6.5); the failure to get a rain soon after application; the physical obstruction of the clover residue not letting the urea get to the soil surface; and the chemical instability and volatility of urea. Excellent grass and broadleaf control except a few giant foxtail. Diazinon seed treater and 15# Furadan 10G were applied at planting in furrow. No insect problems. Harvested November 3.

No-till corn after wheat with clover. Here 1300 lbs. of crop residue covers 94% of the soil surface to reduce erosion.

1979 TILLAGE COMPARISON CULTURAL & ECONOMIC DATA

Jason Kalb, 6010 Vorndron Rd., New Washington, Ohio 44854

PLOT DETAILS

Planted Pioneer 3518 in plot #1 and Pioneer 3780 in plot #2 on May 9 in 30 inch rows. Except for seed variety both plots were the same. Intended seed drop was 30,000; of which 27,800 plants emerged in plot #1 and 27,000 emerged in plot #2, in the Shoals, Bennington, and Cardington silt loam soils. No tile drainage present. 1978 crop was corn. 100# 0-0-60 broadcasted in the fall. 285# (25 gal.) 9-27-3 applied next to the row. 210# N was applied as 28" for a total N-P-K as follows: 201-72-68. 1.5 pt. Paraquat CL with X-77 spreader at 16 oz./100 gal. 28%, 1.5 qt. Aatrex 4L and 2 qt. Dual 6E were applied with the 28% just after planting. Excellent grass and broadleaf control. Iso-tox "F" seed treater and 15# Furadan 10G applied in the furrow at planting. No insect problems. Harvested October 25.

No-till corn after corn. Only small bands of soil are tilled when using a "no-till" planter. This creates a good seedbed for corn and a poor one for weeds.

Jim & Gerald Nedolast, 6696 Kymberly, New Lexington, Ohio 44893

PLOT DETAILS

Planted Select Seeds 3100, 3300, and Pioneer 487 on May in 30 inch rows. Intended seed drop for the three plots was 28,900 at which 28,370, 28,660 and 28,760 plants emerged in the Iowa silt loam soil. (Seed drop greater than anticipated by planter manual.) Tile drainage is generally systematic on about 10' spacing. 1978 crop was wheat with clover plowdown mixture seeded. 1997 0-0-60 was broadcasted in the spring. 13 gal. 9-18-9 was applied in the row. 140# N was applied as 28%. Foliar application of 7 gal. 10-10-10 was applied on June 26. The total N-P-K applied as follows: 160, 5-33.5-80.5. 1 qt. Paraquat CL with 16 oz X-77 spreader/100 gal. 28%, 1.8 qt. Aatrix 4L, 2.4# Bladex 4L were applied with the 28% just after planting. 3/8 pt. Banvel D was applied post emergence for canada thistle. Grass and broadleaf control was excellent. 15# Furadan 100 banded and Isotox "F" seed treater used. No insect problems. Harvested October 31.

Proper planter adjustment before planting is a must when planting no-till. Consistent planting depth, adequate coverage, and good seed to soil contact are important ingredients for good stands.

1979 TILLAGE COMPARISON CULTURAL & ECONOMIC DATA

Donald Crum, 5473 New Haven Rd., Shelby, Ohio 44875

PLOT DETAILS

Planted Pioneer 3518 in plot #1 and Pioneer 3780 in plot #2, on May 7 in 30 inch rows. Except for seed variety both plots were the same. Intended seed drop was 29,950; of which 29,925 plants emerged in plot #1 and 29,050 in plot #2, in the Pewamo silty clay loam and Alexandria, Cardington, Bennington silt loam soils. Tile drainage is random in lows. 1978 crop was corn. 123#N, 28#P and 74#K were broadcast in the spring with a blended fertilizer. 200# 8-32-16 was applied next to row, and 25 gal. 28% was applied after planting, with a total N-P-K as follows: 214-92-106. 1 pt. Paraquat CL with X-77 spreader at 8 oz./100 gal. water, 1.5 qt. Aatrex 4L and 3 pt. Dual 6E were applied after planting using 40 gal. water/acre as carrier. Excellent grass and broadleaf control. Isotox "F" seed treater and 15# Furadan 10C incorporated above the furrow at planting. No insect problems. Harvested November 8.

No-till corn after corn. No-till corn looks just like any other corn once the stand begins maturing. Where storms have caused erosion after planting, no-till stands may appear better than conventional.

1979 TILLAGE COMPARISON CULTURAL & ECONOMIC DATA

Don Phenicie, 5661 Stevens Rd., New Washington, Ohio 44854

PLOT DETAILS

Planted no-till corn in three plots with the varieties as follows: Plot #1 was Pioneer 3518, plot #2 was Pioneer 3780, and plot #3 was Landmark 747X. Plot #4 was fall chiselled plus secondary tillage and planted to Pioneer 3780. All plots were planted on May 7 in 30 inch rows, with same planter, on Bennington and Cardington silt loam soils. Tile drainage is systematic. 1978 crop was wheat with a clover plow-down mixture seeded. On all plots a blend of 300# 0-0-60 and 200# 0-44-0 was broadcasted in the fall. 225# 14-21-9+2z+11s was applied next to the row. In the no-till plots 200# N was applied as 28%. In the fall chiselled plot 160# N was applied as anhydrous (82%) and 40# N was applied as 28% with a total N-P-K on all plots as follows: 231.5-135-200. No-till plots received 2 qt. Roundup 4EC 6 days prior to planting to eradicate quackgrass. 2 qt. Aatrex 4L and 2.5 qt. Bladex 4L were applied just after planting with the 28%. Spot treatment with 1/2 pt. Banvel D post emerge. Fall chiselled plot #4 had 3.5 pt. Dual 6E and 2 qt. Sutan 6.7E incorporated. Excellent grass and broad-leaf control on all plots except for poor control of fall panicum in the no-till plots. Diazinon seed treater and 14# Furadan 10G banded on plots #1, #2, and #3, while 6# Dyfonate 20G was banded on plot #4. No insect problems. Harvested November 6.

In reduced tillage and no-till, herbicides must do the entire weed control job. Selecting proper herbicides and applying them in uniform rates across the field is essential. A herbicide is only as good as it's application.

1979 TILLAGE COMPARISON CULTURAL & ECONOMIC DATA

Rich Reichert, Rt. 2, Attica, Ohio 44808

PLOT DETAILS

Planted Dekalb XL23 on May 2 in 36 inch rows on both plots. Intended seed drop was 25,000; of which 30,600 plants emerged in the spring field cultivated plot, and 29,950 emerged in the fall plow plot. (Planter dropped more seed than anticipated.) Soil in both plots is Blount silt loam with systematic tile drainage. 1978 crop was soybeans. A blend of 200# 18-46-0 and 300# 0-0-60 was broadcasted in the spring on both plots, as well as 200# 8-32-16 next to the row. 150# N was applied as 28% with a total N-P-K applied as follows: 202-156-212. 2 qt. Lasso 4EC and 2 qt. Atrazine 4L were applied with the 28%. Broadleaf and grass control was excellent in both plots. 13# Furadan 10G was banded at planting. European Corn Borer problem in both plots, treated with 10# Furadan 10G by plane first week of July. Harvest earlier than normal because of this damage, on October 17.

No-till is not the only option when considering benefits of reduced tillage. If done properly, various types of reduced tillage practices can provide time, energy and erosion benefits while still maintaining or improving yields.

1979 TILLAGE COMPARISON CULTURAL & ECONOMIC DATA

Jason Kalb, 6010 Norndron Rd., New Washington, Ohio 44854

PLOT DATA

Planted Pioneer 3518 in two plots on May 8 in 30 inch rows. Treatments to both plots were the same. Intended seed drop was 30,000; of which 29,100 plants emerged in plot #1 and 28,050 emerged in plot #2, in the Bennington, Cardington silt loam soils. No tile drainage present. 1978 crop was corn. 125# 0-0-60 was broadcasted in the spring. 285# (25 gal.) 9-27-3 applied next to the row. 163# N was applied with 55 gal. 28% for a total N-P-K as follows: 187-72-73. 1 pt. Paraquat CL with X-77 spreader at 16 oz./100 gal. 28%, 1.5 qt. Aatrex 4L and 2 qt. Lasso 4EC were applied just after planting with the 28%. Excellent grass and broadleaf control. 13# Furadan 10G banded at planting. No insect problems. Harvested November 8.

This reduced tillage corn plot contained 2000 pounds of previous crop residue covering about 44% of the soil surface at planting time. This residue helped prevent surface compaction and cracking through the growing season without cultivation.

Ross Eckstein, 6521 Lehman Road, Chicago, Illinois, 312-4-854

PLOT DETAILS

Planted Pioneer 3518 in plot #1 and Pioneer 3518 in plot #2 in 30 inch rows. Except for seed depth, all other things were the same. Intended seed drop was 28,000; actual seed drop was 23,600 in plot #1 and 23,600 emerged in plot #1. In the Bennington silt loam and Bennington, Cardington silt loam soils, 100 lb. N was applied as anhydrous ammonia a few days prior to planting. 200 lb. 15-24-24 was applied next to row for a total N-P-K as follows: 100-177-177. 1.5 qt. Aatrex 4L and 3 pt. Dual 6E were applied just after planting. Excellent grass and broadleaf control. No insect problems. Harvested November 7.

When changing to reduced or no-tillage farming, you must be certain that the changes made will work. Checking seed drop, planting depth and seed-soil contact after planting are good ways to begin building the certainty or familiarity with the new practice.

1979 YIELD COMPARISON CULTURAL & ECONOMIC DATA

Don Phenice, 5601 Stevens Rd., New Washington, Ohio 44854

PLOT DETAILS

Planted Pioneer 3780 on May 7 in 30 inch rows with two different planters: plot #1 - Allis Chalmers; plot #2 - Buffalo. Intended seed drop was 30,000; of which 28,000 plants emerged in plot #1, and 27,880 plants emerged in plot #2, in Bennington and Lykens silt loam soils. Tile drainage was systematic. 1978 crop was corn. On both plots a blend of 300# 0-0-60 and 200# 0-44-0 was broadcasted in the fall. 225# of 14-21-9+2z+11s was applied next to the row. 200# was applied as 28%, with a total N-P-K as follows: 231.5-137-200. 1 pt. Paraquat CL with X-77 spreader at 16 oz./100 gal. 28%, 3 pt. Dual 6E and 2 qt. Aatrex 4L were applied on both plots just after planting with the 28%. Spot treatment with 1/2 pt. Banvel D post emerge. Excellent grass and broad-leaf control except for some fall panicum. Diazinon seed treater and 14# Furadan 10G applied on both plots. No insect problems except plot #1 was treated with 4# Sevin 50 WP in June for cutworms. This damage could be seen in final population counts as shown on the previous page. Harvested November 6.

Planting reduced till corn after corn with the Buffalo slot planter. A variety of planters were used to plant demonstration plots. When adjusted properly for field conditions, they all did an excellent job.

Ed and Dick Harer, 7487 Kennedy Rd., Bloemville, Ohio 44818

PLOT DETAILS

Planted Trojan 115A on May 7 in 30 inch rows. Intended seed drop was 26,100; of which 23,500 plants emerged in the Condit silt loam soil. Tile drainage is installed. 1978 crop was soybeans. 300# 6-15-40 was broadcast in the fall. 200# (21 gal.) 9-27-3+2s was applied next to the row. 175# N was applied with 60 gal. 28%, for a total N-P-K as follows: 218-119-12 +5s. 2 qt. Aatrex 4L and 3.3 pt. Dual 6E were applied after planting. Excellent grass and broadleaf control. Heptachlor seed treater used and 14# Furadan 10G was applied in the furrow. No insect problems. Harvested October 26.

Ultimate success of reduced tillage is usually measured in terms of crop yield. Here Project Conservationist Dave Wurm helps Dick and Ed Harer check moisture on their 18 bu/ac corn.

1979 TILLAGE COMPARISON CULTURAL & ECONOMIC DATA

Ed and Dick Harer, 7487 Kennedy Rd., Bloomville, Ohio 44818

PLOT DETAILS

Planted Pioneer 3780 on May 7 in 30 inch rows. Intended seed drop was 29,900; of which 27,500 plants emerged in the Condit Tiro silt loam soils. Tile drainage is systematic but surface drainage is needed. 1978 crop was corn. 300# 6-15-40 was broadcasted in the fall. 240# (21 gal.) 9-27-3+2s was applied next to the rows. 178# N was applied with 60 gal. 28⁰ for a total N-P-K as follows: 218-110-127+5s. 1.5 qt. Aatrex 4L and 1.7 qt. Bladex 4L were applied after planting. Good grass and broadleaf control except for some nutsedge and green foxtail. Heptachlor seed treater used and 14# Furadan 10G was applied in the seed furrow.

Crop residue on the surface through the growing season not only reduces erosion and aids weed control, but also conserves surface soil moisture for following months when moisture demands are high.

1979 YIELDAGE COMPARISON OF FURROW & ECONOMIC DATA

Donald Crum, 9473 New Haven rd., Shelby, TN 38575

PLANT DETAILS

Planted Wayne soybeans on June 7 in 15 inch rows. Planting rate of 200,000 seeds; of which approximately 170,000 plants emerged in the Alexandria, cardinton, caminton silt loam soils. No tile drainage present. 1978 crop was corn. 200-5-16-10 was applied at planting in the row for a total N-P-K as follows: 8-32-20. 1 qt. Paraquat CL with X-77 spreader at 8 oz./100 gal. water, 3 qt. Lasso 4EC, and 3/4 pt. Sencor 4 were applied just after planting using 50 gal. water as carrier. Excellent grass and broadleaf control except for a few common ragweeds. Inoculation used. No insect problems. Harvested November 9.

Harvesting no-till beans after corn. Good weed control and minimal volunteer corn helped this plot yield 49 bu/ac.

PROOF PLANT

Planted Sorghum (*Sorghum bicolor*) in the field at a planting rate of 180,000 plants per hectare. The plants emerged in the Cardigan field in late May. The first insecticide treatment in the field, 1978 crop, was made on July 12 with 200 g/ha of 25% diazinon. Diazinon was applied for a total of 285 g/ha in two applications of 142.5 g/ha. Paraquat (4-wildfire) was applied to the field on August 1 and 14. Senecor 4E were applied with the complete fertilizer just after planting. This is not recommended because the insecticide will reduce the activity of the fungicide, the wetting agents applied to cut existing vegetation, and the herbicide. Stowett herbicide was applied to control weeds of the field. Weed control was fair and grass control poor, with all common and established not controlled. Field triple noctuid seen first in the field on November 13.

All most tillage planter should have a roller to open or fill the seed furrow. The roller should be aligned with the coulters with regard to the lateral alignment. Double row opener or planter should have a roller. An important step in obtaining a planter.

1979 TILLAGE COMPARISON CULTURAL & ECONOMIC DATA

Tom Niese, 7552 Sawyer Rd., Tiro, Ohio 44887

PLOT DETAILS

Planted Callahan 5250 soybeans in three plots on May 16, drilled in 6 inch rows. Planting rate of 205,000 seeds; of which approximately 150,000 plants emerged in the Marengo, Olsted silty clay loam soils and Bennington, Cardington silt loams. Tile drainage is systematic. 1978 crop was soybeans. 300# 7-20-34 was fall broadcasted on all plots. 1 qt. crop oil, 3 pt. Dual 6E and 3/4 pt. Sencor 4L were applied on plot #1, while just 3 pt. Dual 6E and 3/4 pt. Sencor 4L were applied on plots #2 and #3. Excellent grass and broadleaf control in plots #1 and #2. Common ragweed and buttonweed in plot #3. No insect problems. Harvested October 15.

Planting reduced tillage systems is another option open to farmers seeking fuel and time savings. Increased surface roughness with previous crop residue near the surface also helps erosion control.

NO-TILL AND REDUCED TILL HERBICIDE-INSECTICIDE RESULTS

Tables 7, 8, and 9 summarize the herbicide and insecticide treatments used on all no-till and reduced till plots. Overall grass, broadleaf, and insect control was good to excellent in 100% of the no-till corn and soybean plots. In reduced tillage plots only two were ranked poor to fair in any category. Following are specific observations made involving herbicide control:

1. Paraquat CL or Roundup 4EC was used in all no-till plots; Paraquat CL for quick burndown of existing vegetation and Roundup 4EC for a slower burndown, but more effective control on perennials such as quackgrass (Roundup translocates throughout plant). The total cost of the Roundup 4EC applications were included in plot production costs even though future years are benefitted. In three of the reduced till plots a low rate of Paraquat CL was used to insure control of young germinated grasses and broadleaves without extra tillage.

2. Carrier for Roundup 4EC applications was 30 gallons of water, while the carriers for Paraquat CL in corn plots were most often 28% nitrogen ranging from 34 to 71 gallons per acre, or water at 40 to 50 gallons per acre. By using 28% nitrogen an extra trip over the field was saved.

3. Grasses, especially fall panicum, were the main weeds considered before residual herbicide recommendations were made. The previous years herbicide, the possibility of plant injury from herbicide carryover, and next year's planned crop were also considered.

4. 2,4-D Amine and Banvel D were used post emerge in some plots for Canada thistle. This mixture was also used pre-emerge in one alfalfatimothy sod plot on the Fritz farm. Basagran was used in one reduced till soybean plot to help control broadleaves not initially controlled (Green plot).

5. In most cases, residual herbicides were tank mixed with Paraquat CL and applied soon after planting. A separate application of Roundup 4EC was applied before planting in plots where it was used. Residual herbicides were then applied soon after planting.

Following were specific observations made involving insecticide control:

1. Wire worm, seed corn maggot, seed corn beetle - No significant cases of damage from any one of these insects seen in any plots. A planter box treatment was used in all no-till corn plots but one, and in 4 of 9 reduced tillage corn plots. Most treatments contained captan, a fungicide commonly used when planting early to protect the seed from damping-off disease and decay, and an insecticide such as diazinon or lindane to control one or more of the above pests probably under those conditions. One no-till soybean plot received planter box treatment.

2. Rootworms - No rootworm problems were observed in any plots. All corn plots but 3 were treated for rootworms at planting. In the future, cost savings for this treatment may be realized by adhering to crop rotations and by initiating a rigorous pest scouting program.

3. Slugs - No slug problems were encountered.

NO-TILL AND REDUCED TILL HERBICIDE-INSECTICIDE RESULTS

4. Cutworms - Cutworms were observed in a few of the no-till plots but never to any extent that needed treatment. In one reduced tillage plot on the Phenicie farm, spot treatment with Secin 50 WP had to be applied for cutworms.
5. Grasshoppers - No grasshopper problems were encountered.
6. European corn borer - One reduced till plot had enough borers feeding to make treatment economically feasible (Reichert farm). One no-till plot (Hofbert farm) had some borers present, but not to the extent that required treatment.
7. Flea beetles - No problems were encountered. Many of the plots did receive treatment where Furadan 10G was used.
8. Armyworms - No army worm problems were observed in any of the no-till or reduced till corn plots. Again, costs for initial treatment of acreage can be reduced by adherence to cropping rotations, pest management scouting, and other less expensive insecticide controls. Furadan 10G was applied in some plots for armyworm control.
9. There were no insect problems encountered in any of the soybean plots.

Scouting for pest problems is a good way to insure maintenance of the present crop and to learn which pesticides work best. Field checking can help save pesticide costs and make pesticides more effective when needed.

SOIL LOSS CALCULATIONS

For all demonstration plots, soil losses (erosion) were calculated using the Universal Soil Loss Equation. Factors in the equation are rainfall amount and intensity, soil erodibility, slope length, slope steepness and conservation practices (reduced tillage, cross-slope farming, etc.). Rainfall information for the Project area was determined from charts published by the Soil Conservation Service. Soil erodibility data was taken from the same Soil Conservation Service publication, based on predominant soil types in the 5-15 acre plots. Slope length and steepness were measured in the field and amounts of surface residue were estimated shortly after planting. In soil loss calculations all residues were converted to corn residue equivalent; i.e., 500# soybean residue equals approximately 1000# corn residue.

To determine percentage reduction in soil loss as a result of no-till or reduced tillage, calculations were made comparing the reduced tillage practice with conventional fall plow operations for the current crop rotation.

Erosion control is directly and most significantly related to the amount of residue maintained on the soil surface. The two major factors in this calculation are 1) type and amount of residue and 2) the percentage of residue left on the surface by tillage practices. Without at least 1000# corn residue per acre, or 500# soybean, sod or small grain residue on the surface, soil erosion is not reduced. Calculations were made assuming the following amounts of residue produced per acre: 100 bu. corn produces approximately 5600#; 50 bu. soybeans produces approximately 2500#, 45 bu. wheat produces approximately 4500#; and 12-inch clover plowdown mixture produces approximately 1000# residue per acre. The amount of residue left on the surface after 30% winter loss is directly related to the type of tillage tools used, and the depth at which they are used. For example, the amount of residue incorporated below the surface for some different tillage operations are as follows:

<u>Tillage operation</u>	<u>% incorporated</u>
Moldboard plow	100%
Chisel w/twisted shanks (7" deep)	70%
Coultered chisel (6-7" deep)	60%
One-way disk (6-7" deep)	70%
One-way disk (4-5" deep)	50%
Field cultivator w/sweeps (4-5" deep)	30%
Flexible disk (3-4" deep)	25%

SUMMARY - CONCLUSIONS

1. With only short range planning, reduced tillage and no-tillage practices were successfully demonstrated during a cool, wet growing season.
2. Economics of reduced and no-tillage systems appears favorable after one year of observation. Of the 31 reduced and no-tillage plot variations done for both corn and soybean cropping systems, 28 showed positive net returns ranging from \$40 to \$179 per acre and averaging \$97 per acre. Net returns from the other 3 plots ranged from -\$36 to -\$9 per acre, averaging -\$19 per acre. In these plots minor changes in management steps would seemingly have produced positive net returns as well. (See economic data for each plot beginning on page 12). There were too few conventional tillage plots to make accurate comparisons between conventional and reduced tillage performances. However, it was felt that reduced till and no-till tillage systems were at least as profitable as the conventional tillage systems in the area.
3. Erosion reduction with reduced and no-tillage practices can be significant. From calculations done on 19 plots having a variety of crop rotations, 14 showed an estimated soil loss reduction of 50% or more while 7 plots showed reductions of 75% or more. No plots showed an increase in soil loss. This data suggests that on site retention of nutrients, particularly phosphorus, would be markedly greater, as well.
4. Learning proper management steps is the key to successful reduced no-tillage operations. A program to help demonstrate good crop stands having good weed control and comparable or increased yields is the quickest way to gain acceptance of these practices. Adequate stands and weed control in demonstration plots was quite important for practice acceptance within the Honey Creek Project area.

Keeping soil and fertilizers on the land not only increases yields but also decreases costs of cleaning lakes, streams, ditches and harbors.
