KEY WORDS (Continue on coverse side II necessary and identify by block number) Dam Safety National Dam Safety Program Genegantslet Lake Dam Visual Inspection Chenango County Susquehanna River Basin Hydrology, Structural Stability 20. ABSTRACT (Contants an reverse side if necessary and identify by block number) This report provides information and analysis on the physical condition of the dam as on the report date. Information and analysis are based on visual inspective of the dam by the performing organization. Emmination of available documents and a visual inspection of the dam did not reveal conditions which constitute an immediate hazard to human life or property. However, the dam has some deficiencies which need to be evaluated and remedied. FORM DD , TON 7 1473 EDITIONOF I NOV 45 IS OBSOLETE SECURITY CLASSIFICATION OF THIS PAGE (Minon Data Enterent) ···· Ξ. ۰.

Using the Corps of Engineers' Screening Criteria for initial review of spillway adequacy, it has been determined that the dam would be overtopped by all storms exceeding 5% of the Probable Maximum Flood (PMF) inflows. While this dam has withstood overtopping in the past, it cannot be assured that overtopping will not eventually cause the dam to fail. Since failure of the dam would increase the hazard to downstream residents, the spillway capacity is adjudged as seriously inadequate and the dam is assessed as "Unsafe, non emergency".

The classification of "unsafe" applied to a dam because of a seriously inadequate spillway is not meant to connote the same degree of emergency as would be associated with an "unsafe" classification applied for a structural deficiency. It does mean that there appears to be a serious deficiency in spillway capacity and if a severe storm were to occur, overtopping and failure of the dam could take place, significantly increasing the hazard to loss of downstream of the dam.

Inspection of the dam also revealed that there was a seepage problem on this structure. Seepage was exiting on the downstream slope and at the toe in the embankment section at the right end of the dam. There were also several locations where leakage was noted through the laid op stone portion of the dam.

It is recommended that within 3 months of the date of notification of the owner, a hydrologic/hydraulic investigation of the structure should be commenced. Investigation into the seepage problem should also be commenced within 3 months. Mitigating measures deemed necessary as a result of these investigations should be completed within 18 months.

Several other deficiencies were noted on this structure. These should be corrected within 12 months of the date of notification. Among the items which should be corrected are the eroded area on the downstream slope at the sefteend of the dam, gaps between sections of pipe which need to be filled with mortar, displaced stones on the laid up stone portion of the dam, brush and small trees growing on the embankment, an outlet channel from the spillway

PHASE I INSPECTION REPORT NATIONAL DAM SAFETY PROGRAM

APPROVED FOR PUBLIC RELEASE; DISTRIBUTION UNLIMITED

OTIC FILE COPY

NEW YORK DISTRICT CORPS OF ENGINEERS

FEBRUARY, 1981

81 10 20

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I Investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported cordition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through frequent inspections can unsafe conditions be detected and only through continued care and maintenance can these conditions be prevented or corrected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the Spillway Test flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. Because of the magnitude and rarity of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as necessarily posing a highly inadequate condition. The test flood provides a measure of relative spillway capacity and serves as an aide in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

Phase I Inspection Report National Dam Safety Program

Name of Dam:	Genegantslet Lake Dam (I.D. NY 846)
State Located:	New York
County :	Chenango
Watershed:	Susquehanna River Basin
Stream:	Unnamed tributary of Gengegantslet Creek
Date of Inspection:	October 22, 1980

ASSESSMENT

Examination of available documents and a visual inspection of the dam did not reveal conditions which constitute an immediate hazard to human life or property. However, the dam has some deficiencies which need to be evaluated and remedied.

Using the Corps of Engineers' Screening Criteria for initial review of spillway adequacy, it has been determined that the dam would be overtopped by all storms exceeding 5% of the Probable Maximum Flood (PMF) inflows. While this dam has withstood overtopping in the past, it cannot be assured that overtopping will not eventually cause the dam to fail. Since failure of the dam would increase the hazard to downstream residents, the spillway capacity is adjudged as seriously inadequate and the dam is assessed as "unsafe, non emergency".

The classification of "unsafe" applied to a dam because of a seriously inadequate spillway is not meant to connote the same degree of emergency as would be associated with an "unsafe" classification applied for a structural deficiency. It does mean that there appears to be a serious deficiency in spillway capacity and if a severe storm were to occur, overtopping and failure of the dam could take place, significantly increasing the hazard to loss of downstream of the dam.

Inspection of the dam also revealed that there was a seepage problem on this structure. Seepage was exiting on the downstream slope and at the toe in the embankment section at the right end of the dam. There were also several locations where leakage was noted through the laid up stone portion of the dam.

It is recommended that within 3 months of the date of notification of the owner, a hydrologic/hydraulic investigation of the structure should be commenced. Investigation into the seepage problem should also be commenced within 3 months. Mitigating measures deemed necessary as a result of these investigations should be completed within 18 months.

Several other deficiencies were noted on this structure. These should be corrected within 12 months of the date of notification. Among the items which should be corrected are the eroded area on the downstream slope at the sefteend of the dam, gaps between sections of pipe which need to be filled with mortar, displaced stones on the laid up stone portion of the dam, brush and small trees growing on the embankment, an outlet channel from the spillway eneduit shirt word along the treat tog only and to the state of a structure and the state.

OVERVIEW GENEGANTSLET LAKE DAM I.D. No. NY 846

Phase I Inspection Report National Dam Safety Program Genegantslet Lake Dam I.D. No. Ny 846 #94D-3437 Susquehanna River Basin Chenango County, New York

SECTION 1: PROJECT INFORMATION

1.1 GENERAL

a. Authority

The Phase I inspection reported herein was authorized by the Department of the Army, New York District, Corps of Engineers, to fulfill the requirements of the National Dam Inspection Act, Public Law 92-367.

b. Purpose of Inspection

This inspection was conducted to evaluate the existing conditions of the dam, to identify deficiencies and hazardous conditions, to determine if these deficiencies constitute hazards to life and property, and to recommend remedial measures where required.

1.2 DESCRIPTION OF PROJECT

a. Description of Dam

The Genegantslet Lake Dam is an earth fill and laid up stone dam with a drop inlet spillway and a conduit passing through the embankment.

The dam is approximately 300 feet long and about 10 feet high. The upstream slope of the dam is composed of earth fill. The laid up stone is exposed on the center portion of the downstream face. The earth fill extends over the top of the laid up stone, forming the crest along the entire dam. Earth and rock fill form the downstream slope at either end of the structure.

The spillway consists of a 48 inch reinforced concrete pipe flowing into the base of a drop inlet structure. There are wooden stop logs in the center of the structure which are used to control the water level in the lake. When the stop logs are in place, water must flow over them and then to the outlet pipe. If the stop logs are removed, the 48 inch pipe would act as a resevoir drain.

The top of the drop inlet structure is open to permit flow. The crest on the upstream face is 2 feet below the top of the structure providing additional capacity. All of the openings have screens to prevent debris from entering the drop inlet.

There is a 48 inch concrete outlet pipe leading from the base of the drop inlet to a concrete manhole 25 feet downstream. Another 48 inch pipe extends 116 feet from the manhole to a headwall at the outlet.

b. Location

This dam is located in the Town of Mc Donough, off Moon Hill Road on an unnamed tributary of the Genegantslet Creek. The dam is approximately 3/4 mile north of the village of Mc Donough.

Size Classification

The dam is 9.5 feet high and has a storage capacity of 2,000 acre-feet. Therefore, the dam is in the small size category as defined by the "Recommended Guidlines for Safety Inspection of Dams".

Hazard Classification

The dam is classified as "high" hazard due to the presence of one house immediately downstream of the dam and 6 additional houses plus one trailer located near the stream channel in the Village of Mc Donough.

Ownership

The dam is owned by the Genegantslet Lake Association, Inc. The secretary-treasurer of the association is Frank Ulrichs, 127 South Broad Street, Norwich, New York 13815. Mr. Ulrich's telephone number is (607) 334-3789.

Purpose of Dam

The dam is used to maintain the water surface of Genegantslet Lake for recreational purposes.

Design and Construction History

g. Design and construction miscory This dam was constructed around 1900. No information was available concerning the original design or construction of the dam. In 1947, the owner contracted with Les Strong Construction Company of Whitney Point, New York to perform work designed to reduce the leakage through the dam. This same company made further repairs in 1955. The 1955 work included placing shale fill on the upstream slope to again reduce leakage. A 36 inch iron pipe through the dam was sealed as part of this work, since it was considered to be a major source of the leakage.

Major modifications to the structure were made in 1965. At that time, clay fill was placed on the upstream face and the new conduit was installed to provide some control over the lake level. The design engineer for these modifications was Mr. Carl Crandall. P.E, of Ithaca, New York.

Normal Operating Procedures

Stop logs to within about 1/2 foot of the lower crest of the drop inlet maintain the water surface at approximately this elevation from April thru October. In October, three stop logs (2 inch by 12 inch) are removed to lower the water surface during the winter months.

SECTION 2: ENGINERRING DATA

2.1 GEOTECHNICAL DATA

a. Geology

The Genegantslet Lake Dam is located in the Glaciated Allegheny Plateau of physiographic province of New York State. This plateau is underlaid by a great thickness of sedimentary rocks from the Devonian Era which lie almost horizontal. Severe trenching by streams and glacial erosion has carved the upland into a rugged terrain. The Susquehanna Hills rise to elevations of up to 1700 feet between the rolling, relatively narrow valleys. The surficial soils and features of the area are the result of glaciations during the Cenzoic Era, the last of which was the Wisconsin glaciation.

A review of the "Brittle Structures Map of the State of New York" indicated that there are no faults in the immediate vicinity of the dam.

b. Subsurface Investigations

No records of any subsurface investigations performed for this structure were available. The only subsurface information available was from a 1925 inspection report which stated that the foundation of the dam consisted of clay and hardpan.

2.2 DESIGN_RECORDS

No records were available concerning the original design of this structure. An engineer's report and plans for the modifications made to the structure in 1965 were available. This design work was performed by Mr. Carl Crandall, P.E., of Ithaca, New York.

2.3 CONSTRUCTION RECORDS

No records exist for the original construction of this structure. A contract between the owner and the Les Strong Construction Company of Whitney Point, New York was available, and it described the repairs made to the dam in 1947. The same company made additional repairs in 1955. There were several photographs in the files which were taken during this construction. The only records from the 1965 modifications were the plans prepared by Mr. Crandall and photographs taken during construction.

2.4 OPERATION RECORDS

There are no regular operation records maintained for this structure.

2.5 EVALUATION OF DATA

Data available for the preparation of this report was somewhat limited. In addition, several of the dimensions shown on the plans, such as the size of the riser did not agree with the actual dimensions measured during the inspection.

SECTION 3: VISUAL INSPECTION

3.1 FINDINGS

a. General

Visual inspection of the Genegantslet Lake Dam was conducted on October 22, 1980. The weather was overcast and the temperature was in the forties. The water surface at the time of the inspection was 2.5 feet below the top of the drop inlet structure. Water was flowing over the stop logs inside the drop inlet.

b. Dam

Several deficiencies were observed on this structure. The most serious deficiency noted was the seepage exiting both on the downstream slope and at the toe. The most concentrated seepage was in the embankment section between the right abutment and the center of the dam where the laid up stone face is exposed. There was also leakage through the laid up stone portion in several locations.

Another deficiency noted was erosion of embankment material on the downstream slope at the left end of the dam near the headwall for the spillway conduit. This erosion was probably caused by flow over the top of the dam.

Brush and saplings growing on the embankment and some displaced stones on the laid up stone segment were other deficiencies noted on this structure.

c. Spillway

The drop inlet and the outlet conduits were in good condition. Trash racks over all openings on the drop inlet prevented debris from entering the spillway. These trash racks were properly maintained and there was no accumulation of debris around the drop inlet.

The outlet conduits were composed of sections of reinforced concrete pipe which were 4 feet long. Inspection of the pipe revealed that the individual sections were not fit together tightly. Furthermore, only the bottom third of the joints between sections had been mortared. There was no mortar in the remainder of each of the joints. There was some seepage into the pipe through several of the joints. The joints where seepage was observed were approximately midway between the outlet of the pipe and the buried manhole which is downstream of the drop inlet.

The conduit upstream of the drop inlet structure extends into the lake. It was submerged and could not be observed.

d. Reservoir

There was no indication of soil instability in the reservoir area.

e. Downstream Channel

The outlet channel from the spillway conduit ran along the downstream toe of the dam. This fact may have contributed to the erosion problem beyond the head wall. The channel contained riprap but the toe of the dam was not well protected.

3.2 EVALUATION OF OBSERVATIONS

Visual inspection of the dam revealed several deficiencies. The following items were noted

- 1. Seepage both through the embankment section at the right end of the dam and the laid up stone section.
- 2. Erosion of embankment material on the downstream slope at the left end of the dam.
- 3. There were gaps between sections of the outlet pipe. Motar had been placed only in the bottom third of these joints.
- 4. There was some brush and small trees growing on the embankment.
- 5. There were some displaced stones on the laid up stone portion of the dam.
- 6. The outlet channel from the spillway ran along the toe of the dam.

SECTION 4: OPERATION AND MAINTENANCE PROCEDURES

4.1 PROCEDURES

The only operating procedures for this structure involve the removal and replacement of stop logs in the drop inlet structure. Three stop logs each about (2 inch by 12 inch) are removed in October to lower the water surface during the winter months. In April, after the ice has gone out of the pond, the stop logs are replaced. When these stop logs are in place, the normal water level in the pond is ab out 1/2 foot below the crest of the drop inlet structure.

4.2 MAINTENANCE OF DAM

There are no formal maintenance procedures for this structure. Mr. Ulrichs of the Genegantslet Lake Association reported that brush and weeds are cleared annually.

4.3 WARNING SYSTEM IN EFFECT

No apparent warning system for evacuation of downstream residents is present.

4.4 EVALUATION

「日日」のう にんないていている

The operation procedures on this dam are generally satisfactory. The deficiencies noted on the structure are evidence of the need for additional maintenance efforts.

SECTION 5: HYDROLOGIC/HYDRAULIC

5.1 DRAINAGE AREA CHARACTERISTICS

Delineation of the watershed draining into the reservoir pool area was made using the 7 1/2 minute USGS quadrangle sheet for Pitcher, New York. The 5.04 square mile drainage area consists of wooded lands and open fields. Hilltops at the boundary of the drainage area range from elevation 1660 to elevation 1840. Relief within the drainage area is moderate to steep with steeper slopes in the eastern portion.

5.2 ANALYSIS CRITERIA

The analysis of the floodwater retarding capability of this dam was performed using the Crops of Engineers HEC-1 computer program, Dam Safety version. This program uses the Snyder Synthetic Unit hydrograph method and the "Modified Puls" flood routing procedure. The spillway design flood selected for analysis was the Probable Maximum Flood (PMF) in accordance with the recommended guidelines for the U.S. Army Corps of Engineers.

5.3 SPILLWAY CAPACITY

The spillway consists of a drop inlet structure with 48 inch pipes going into and out of it. Wood stop logs in the center of the drop inlet structure provide some control over the level of the lake.

The spillway capacity was calculated assuming that all of the stop logs were in place. The elevation of the stop log crest was thus the same as the upstream riser crest. The crest of the remainder of the riser was two feet higher and was assumed to be equal to the top of dam elevation. The total spillway capacity for a water surface at the top of the dam was 55 cfs.

5.4 RESERVOIR CAPACITY

Normal storage capacity of the reservoir with the water surface at the spillway crest and the top of the dam is an additional 219 acre feet which is equivalent to a direct runoff depth of 0.81 inches over the drainage area.

5.5 FLOODS OF RECORD

There was no data concerning the occurence of the maximum known flood. It was stated in the Engineer's report, prepared for the 1965 modifications, that three feet of water flowed over the dam during a flood in the mid-thirties.

5.6 OVERTOPPING POTENTIAL

Analyses using the PMF and one half the PMF indicates that the dam does not have sufficient spillway capacity. The inflow from the PMF is 11741 cfs and the outflow is 11449 cfs. The dam would be overtopped to a computed depth of 5.91 feet for this storm event. For the peak outflow of one-half the PMF (5612 cfs), the depth of overtopping would be 3.63 feet. All storms exceeding 5% of the PMF will result in the dam being overtopped. It was apparent from the visual inspection that the dam is overtopped frequently.

5.7 EVALUATION

Using the Corps of Engineer's screening criteria for initial review of spillway adequacy, it has been determined that the dam would be overtopped by all storms exceeding 5% of the PMF. While the dam has withstood overtopping in the past, the fact that the structure is composed of earth fill and laid up stone makes overtopping undesireable. The very limited spillway capacity results in frequent overtopping and it cannot be assumed that this will not eventually cause the failure of the dam. Since a failure would increase the hazard to downstream residents over that which would exist just prior to the failure, the spillway capacity is adjudged to be seriously inadequate.

SECTION 6: STRUCTURAL STABILITY

6.1 EVALUATION OF STRUCTURAL STABILITY

a. Visual Observations

Visual observations revealed that there were several deficiencies on this structure which could affect the stability. Seepage through the dam at the right end and in the laid up store portion was the most serious deficiency. Erosion of the embankment material on the downstream slope near the outlet to the spillway conduit was also noted. It appears that this erosion was caused by flow over the top of the dam. The outlet channel from the spillway flows along the toe of the embankment creating a potential stability problem.

b. Stability Evaluation

This structure is composed of earth fill and laid up stone The earth completely covers the laid up stone at both ends of the dam, but in the center, the stone is exposed on the downstream face.

Due to the nature of the composition of this structure, a stability analysis was not considered to be feasible.

SECTION 7: ASSESSMENT/RECOMMENDATIONS

7.1 ASSESSMENT

a. Safety

The Phase 1 inspection of the Genegantslet Lake Dam revealed that the spillway capacity is seriously inadequate and outflows from all storms exceeding 5% of the Probable Maximum Flood would overtop the dam. While the dam has withstood overtopping in the past, this regarded as undesirable. Failure of the dam would increase the hazard to downstream residents. Therefore, this is assessed as unsafe, non-emergency.

In addition to the spillway inadequacy, other deficiencies were noted which affect the safety of the structure. The most serious of these was seepage through the dam exiting along a substantial portion of the downstream toe. There was also some erosion, probably caused by flow over the top of the dam.

b. Adequacy of Information

The information available for the preparation of this report was somewhat limited. Plans for the 1965 modifications were used, but some of the dimensions shown on these plans did not agree with measurements made at the time of the inspection.

c. Need for Additional Investigations

Since the spillway has been assessed as seriously inadequate, additional hydrologic/ hydraulic investigations are required to more accurately determine the site specific characteristics of the watershed. Analysis will then be required to determine how to provide the additional spillway capacity meded.

Investigation into the seepage is also required. A method of either eliminating or controling the seepage should be devised.

d. Urgency

The additional hydrologic and hydraulic investigations which are needed should be commenced within 3 months of the date of notification of the owner. Investigation into the seepage problem should also be commenced within 3 months.

Mitigating measures deemed necessary as a result of the investigation should be completed within 18 months of the date of notification. Other deficiencies should be corrected within 12 months.

7.2 RECOMMENDED MEASURES

a. After the hydrologic/hydraulic investigation has been completed, mitigating measures dealing with the seriously inadequate spillway should be undertaken.

b. After the investigation into the seepage problem has been completed, appropriate remedial actions should be taken.

c. The eroded area on the downstream slope at the left end of the dam should be refilled with compacted embankment material.

d. Gaps between sections of the outlet pipe should be filled with mortar.

e. The outlet channel from the spillway conduit should either be relocated away from the toe of the dam or lined with riprap to better protect the downstream toe.

f. Displaced stones on the laid up stone portion of the dam should be replaced.

g. Brush and small trees growing on the embankment should be cut.

単語目

h. An emergency action plan for the notification of downstream residents should be developed and implemented.
